of the screening tests (6 hours of exercises) in the frames of the compulsory subject Food quality and legislation.
In depth knowledge of the physiology of perception, the cellular mechanisms of perception, about individual sense organs and senses, on perception of colour, flavour, sensory active components, texture, off odours and foreign aroma, as well as on the E-nose, GC-olfactometry, tests with consumers, and methods of data analysis applying tools like MS Excel or SPSS are provided through both, an elective subject Sensory evaluation techniques for BSc (35 hours of lectures, 15 hours of seminars, 20 hours of exercises) and a compulsory subject Sensory analysis for MSc students (25 hours of lectures, 10 hours of seminars, 15 hours of exercises). Examples of software solutions for sensory analysis and data collection are provided to students; although only through the demonstration by the lecturer. Besides a large number of tests that students carry out during practical exercises, they are included also in preparation of samples, sample labelling, preparation of evaluation forms, and realization of sensory evaluation itself. Seminars for MSc students comprise elaboration of the project involving selection of the issue, a food product to evaluate, and adequate sensory method(s), design of evaluation forms, execution of the evaluation process with a sensory panel, data analysis and critically commenting of the results. Students submit written seminar and present their project to audience.
Students of Interdisciplinary doctoral study programme in biosciences at 3rd Bologna level can attend an elective subject Linkage of sensoric and instrumental methods, in which contemporary sensory and instrumental techniques in food processing and quality control are discussed and holistic approach in evaluation of quality is stressed.

Education for end users
Education in the context of seminars is composed from theoretical and practical part, i.e. lectures and practical exercises, usually in proportion 2:3 or 3:4, respectively. The amount of seminar hours varies depending on the requirements of the trainees and level of knowledge comprehended. Seminars of 15 hours or less are intended for those, who anticipate only basics from sensory evaluation, while over 30-hour, 50-hour or even 75-hour seminars are designed for trainees, who wish to be trained and qualified for the sensory evaluation in a specific field. Seminars are organized for differently sized groups, usually with minimally 10 and up to 40 participants. For practical exercises trainees are arranged into groups - panels of 10.
Most of the attendees have only scarce or none prior knowledge from the sensory analysis, therefore lectures comprise general theoretical knowledge from sensory science: definition of sensory analysis, general conditions for sensory analysis, types and training of sensory assessors, physiological basis of perception, and sensory methods - various tests, their applicability, advantages and disadvantages. Practical work – exercises include a) tests for evaluation of sensory sensitivity of the candidates using model systems: identification of four basic tastes, the ability to memorize the intensity of a stimulus, the ability of smelling, and b) different sensory methods used in practice: discrimination tests, scales etc. on model systems and food products. For assessments of the samples mainly paper forms are used, while samples of meat and meat products are evaluated also by using tailored computer programme. The attendees to the seminar receive a compilation of lecture notes, a study material that is more or less extensive, depending on the type and purpose of the education.

RESULTS AND DISCUSSION

Many graduates in Food Science and Nutrition are involved in sensory evaluation also in their professional career. Those working as lecturers in secondary schools and vocational colleges, have introduced chapters from sensory science into school curricula, while food technologist working in the industry apply sensory evaluation in a routine quality control or when modifying an existing or developing a new product. At the later they are often confronted with issues of acceptability or liking of such product among consumers. On the account of good cooperation between the industry and the faculty, many of these questions

may be solved by tests with consumer panels consisting of students, while at the same time the students experience the real life problems and professional challenges.
However in-depth knowledge of sensory evaluation is often needed by professionals from the food industry, therefore we organize different short courses and post-graduate seminars adjusted to users' demands. Sensory courses (seminars) and trainings are also organized for various audiences i.e. beekeepers, school teachers, farmers, consultants and winemakers.
The lectures and exercises are tailored to the purpose and scope of the seminar. Education of sensory assessors of a particular food product, like **honey assessors**, involves also topics from beekeeping technology, honey production and processing, European honey legislation, the rules on honey sensory assessment in Slovenia and presentation of the assortment of honeys produced in Slovenia. Practical exercises comprise, in addition to the aforementioned tests for screening and training of candidates, an extensive training on a given product, in this case, honey. A selection of typical samples is presented to attendees to learn about recognition of sensory properties and about their characteristics (e.g. intensity). Later candidates encounter a variety of samples of particular type to evaluate the intensity of their sensory properties, detect possible defects, and discuss the findings.
It is important for each profile of participants, nature and scope of the seminar that adequate samples are provided for the training and the assessment of the performance of trainees. Candidates have to fulfil two types of conditions to qualify for sensory assessor of a given food group as summarized in Table 1. Conclusion of the seminars is usually associated with a festive award ceremony.

Table 1. Minimum criteria for obtaining a license *Sensory assessor* of a particular food product or group of products.

1. Sensory tests	**2. Assessment of food samples**
- Thresholds recognition test - Recognition of basic tastes test - Intensity memory test - Discrimination test - Ranking test - The minimum number of total points is defined in advance	- Evaluation of sensory properties of a number of samples from the particular food group using defined sensory methods - Repeatability of the assessment results of a trainee - Assessments of a trainee must be placed within the set criteria. - The number of samples is defined in advance.

Trainees, licensed sensory assessors, may participate in sensory panels of sensory contests and assessment at different levels: local, regional and international. However to take part in sensory panels the continuity of work and training is required, as well as license renewal within the prescribed time. The license expires also when the candidate does not participate in sensory evaluation for more than two years. For example **assessors of wine, must and other products from grape and wine** have to attend several sensory evaluations annually and an additional training every two years. The training of this profile of sensory assessors was founded by Wine act (Wine act, 2006) and has been running in Slovenia for 8 years. In this time 574 candidates have been trained. An overview of different profiles of sensory assessors trained at Biotechnical faculty is presented in Table 2.

Table 2. Profiles of sensory assessors, number of candidates and course duration.

Type of sensory assessors or attendees	Number of trained attendees	Course duration (hours)
Assessor of wine, must and other products from grape and wine	574	74
Honey assessor	60	50
Honey inspector	150	27
Beekeeping inspector	43	16
Assessor of meat and meat products	331	20
Official inspectors	10	16
Agricultural advisors	38	9
Teachers – basics course	41	16
– advanced course	12	8
Paper industry	10	8
Food industry – basics course	36	16
– advanced course	21	16

At the Department of Food Science and Technology panels of expert sensory assessors were formed, whose members collaborate with food industry in product developments and quality controls. With their professional work these assessors contribute to the characterization and better recognition of typical Slovenian food products. Moreover, they are involved as lecturer in sensory seminars and as panel members in sensory evaluations of food products for various clients, among other Slovenian consumer association, or at different contests and assessments. In accordance to the requirements for training of sensory assessors the sensitivity and performance of panel members is being tested regularly. Besides, they improve their skills and proficiency by attending international conferences on sensory science and by participating in international sensory panels.

CONCLUSION

The majority of Slovenian food producers nowadays employ internal sensory assessment of products as a part of quality control. Generally, sensory analysis is in Slovenia well recognised among professionals. As it was observed, the quality of food products was improved over the years of continuous education services, and the progress was notable especially in products of artisanal production, e.g. honey. Recently the club of honey assessors, and wine assessors, respectively, was established, that concerns about promotion of Slovenian honey and wine, respectively, with emphasis on sensory characteristics of these products. However the education curriculum needs to be further enriched with topics on consumer science. Moreover, implementation or diffusion pathways of information obtained with sensory analysis to the end users should be clarified. Only so, the importance of continuous training of the assessors will be recognised and understanding of differences between sensory evaluation and hedonic tasting by the general public improved.

ABSTRACT: Food industry invests great effort into attempting to enhance aroma of the food products and often use natural and artificial flavourings. Aroma compounds are released from food during eating. Delivering aroma compound to olfactory and oral cavity (orthonasal and retronasal) is influenced by numerous factors. The aim of this research was to examine the influence of food matrix viscosity on aroma release. The orthonasally and retronasally intensity of four aroma compounds: ethyl butyrate, ethyl caproate, isoamyl acetate, and benzaldehyde which were added in the same amount in the four different food matrixes was sensory analysed by the fifteen trained panellist. The food matrix of different viscosity served as a barrier to the movement of a flavour substance. Food matrixes were represented by aqueous solution of sucrose, starch, oil-water emulsion and yoghurt, all in three levels of viscosity: low, medium, high. Viscosity was measured by MYR rotational viscometer. ANOVA and Principal Component Analysis (PCA) were used to analyse sensory results. It was found that the viscosity of sugar, starch and oil matrixes influence aroma release, while the viscosity of yogurt did not significantly influence on delivering aroma to human sensory receptor. Sucrose enhanced perception of aroma compounds. Transmission of aroma compounds to the oral cavity and olfactory epithelia from food matrixes was hindered.
Key words: *aroma compounds, peception, viscosity, sensory analysis*

INTRODUCTION

Compounds responsible for odours are designated as aroma compounds. Aroma compounds perceived on olfactory epithelium, results in odour character of food. Aroma of most food products consists of complex mixtures, sometimes consisting of several hundred compounds. Those compounds are volatile and the amount of volatile present in food is extremely low. More than 7000 volatile compounds have been identified in food. But of all volatile compounds only a limited number are important for aroma. Those compounds are called aroma active compounds. Intensity of aroma active compounds depends on their concentration and sensory threshold. Contribution of aroma active compounds to overall aroma perception is evaluated on the basis odour active value (OAV). It is ratio of aroma compounds concentrations in food to odour threshold (Leitner and Siegmund, 2009).Thus the presence, contents and composition of volatile substances in food have a substantial influence on its quality.The growth in the identification of aroma chompounds over the past five decades was a direct result of the development of new analytical techniques. Despite the advances in instrumental analysis, human nose is often more sensitive than any instrumental detector (Falcao et al., 2008). For aroma compounds to be perceived by human, they must be released from the food matrix so they can enter the airways of the nose and come into contact with the olfactory receptors. Aroma release from food depend on many factors: physiochemical characteristic aroma compounds themselves and their concentrations (2000; Bult et al., 2002; Plotto et al., 2008) physical state of matrix (Cook et al., 2003; Jaros, 2003; Seuvre at al., 2004) aroma compounds interactions with basic food components (Saint-Eve et al., 2006; Lawrence et al., 2009; Merabtine et al., 2010; Nasri et al., 2011) and the psychophysiology state of human (Grosch, 2000; Djordjevic et al., 2004; Ruijschop et al., 2009). Foods are a complex mixture of water, carbohydrates, lipids, proteins and other organic compounds which can interact with aroma compounds. The nature of these interactions can be chemical binding (irreversible covalent bonds), physicochemical

binding (van der Waals forces, hydrogen bonds, hydrophobic interactions or ionic bonds) or simply, the differing propensities for aroma compounds to be absorbed into different phases of the food. Physical considerations include those where the food matrix physically interferes with aroma a compound reaching sensory receptors, the food matrix serves as a barrier to the movement of an aroma compounds. The barrier may be small such as a food having some viscosity that reduces mixing or the surface area of food in the mouth lowering the possibility of evaporation in oral cavity or in air over food. The barrier may be very large, for very viscous food where aroma compounds remain locked in food matrix.
Therefore, the aim of this work was to sensory evaluate influence of food viscosity on aroma compounds release from different food matrix by trained panel, i.e to investigate influences of food viscosity on aroma delivering to oral cavity and olfactory epithelia.

MATERIAL AND METHODS

Samples and sample preparation

In this study four aroma-active componuds were used (Tab. 1).

Table 1. Basic data of investigated aroma-active compounds

Compound	Producer	Pure%	Treshold	According to author
Ethyl Butyrate (EB)	Acros Organics	99	1 µg/L	Takeoka et al., 1990
Ethyl Caproate (EC)	Acros Organics	99	1 µg/L	Takeoka et al., 1990
Iso-amyl Acetate (IAA)	Fisher Scientific	99.55	2 µg/L	Takeoka et al., 1989
Benzaldehyde(BA)	Panreac Sintesis	99	0.35 µg/L	Buttery et al., 1990

Series of 5 different concentrations of each aroma compounds were prepared for the training of the panellists. The first concentration in series was threshold value and each next was 50% higher than the previous one. Dilution was made with redistilled water. Concentration values were marked from 1 to 5 corresponding to odour active value OAV in order to simplify aroma intensity measure. Concentration of aroma compounds and their OAV are showed in Tab.2.

Table 2. Concentrations of aroma compounds in series (µg/L)

Compound	Odour active value (OAV)				
	1	2	3	4	5
EB and EC	1	1.5	2.25	3.375	5.0625
IAA	2	3	4.5	6.75	10.125
BA	0.35	0.525	0.7875	1.18125	1.771875

Table 3. Levels of viscosity solution measured by MYR viscometer (V1-R)

Food matrix Temp. 20 ^{0}C	Low viscosity (I)		Medium viscosity (II)		High viscosity (III)	
Sugar (sucrose)	Spindle/rpm	mPa s	Spindle/ rpm	mPa s	Spindle/ rpm	mPa s
Oil* (sunflower oil)	R2/100	125	R2/100	157	R2/200	520
Yoghurt	R2/100	99	#	#	R2/200	136
	R2/50	60	R2/200	107	R2/200	700
Starch paste	R3/100	350	R3/100	450	R4/100	680

**Oil matrix was presented just in two modality – low and high viscosity*

Food matrixes were presented with four modalities: sugar, (aqueous solution of sucrose) oil (commercial sunflower oil and emulsion of oil and water 50:50 with lecithin as emulsifier) protein (commercial yoghurt) and carbohydrate (maize starch paste). Each of food matrix was presented in three levels of consistency (adjusted by water) measured by MYR rotational viscometer marked as presented in Tab. 3.
Samples were prepared as follows: 50 millilitres of each food matrix in three levels of viscosity were put in 100 ml cup coded with a random 3-digit number. Cups were closed.

Just before a sensory evaluation in cups were added 5 ml of aroma compounds in concentration which corresponding to OAV-3 (see Tab 2).

Panellists
An established and trained panel of 15 panellists (7 male, 8 female) aged between 20 and 45 years, was used in the study. The panellists had been recruited and selected among 24 volunteers, on the basis of their sensory acuity, in particular their ability to distinguish between concentrations of the same stimulus. The panellists participated in six 1-h trainings and three 30-min evaluation sessions on different days over 6 week. During an initial training session panellists received specific training in the use of threshold concentration of stimuli and rated 5 different concentrations of the same aroma compounds.

Sensory analysis
Intensity of aroma compounds was evaluated orthonasal and retronasal. Panellists were offered a block of samples consisted of 4 series for each food matrix in same concentration (OAV 3 - Tab 2) of each aroma compounds in 3 different food viscosity. That means 4 blocks of food matrix x 3 levels of viscosity x 4 aroma compounds, in total 48 samples for each panellist. The panellists were asked to evaluate perceived aroma intensity firstly orthnasally and then retronasally. After they finished one block of samples they had pause of 10 min and then started with evaluations of other blocks of samples. Perceived aroma compounds intensity was quantified using numerical scale from 1 to 5. Due to easier using, the end points of scale were offered to panellist too where 1 was threshold concentration and 5 was the maximum concentration of tested aroma compounds in redistilled water (see Tab. 2).The panellists were asked to evaluate perceived aroma intensity of samples rated them between end points of scale. To avoid confusion the term ‘‘odour’’ was used to refer to the orthonasal olfactory perception evaluated above the cup and ‘‘aroma’’ to refer to the retronasal olfactory perception.

Data Analysis
Two-way ANOVA and, where necessary, Tukey multiple-comparison tests (α 0.05) were applied to the replicate data (n=15). For the visualizations of all experimental variables Principal Component Analysis (PCA) was performed. The aim of PCA was to determine the differentiations between food matrixes, their viscosity, as well as to distinguish between perceived aroma orhonasally and retronassally. All statistic analyses were performed using the statistical package StatBox 6.7 –Grimmerlow, Paris, France.

RESULTS AND DISCUSSION

Aroma release from the sweet matrix
To determine whether level of viscosity of sucrose solution had influence on odour perception for the 4 aroma compounds two-way ANOVA was performed.The ANOVA showed significant effect of the matrix viscosity ($F_{3.054}$= 3.8488; p=0.023357) and type of aroma compounds ($F_{2.663}$=4.3151; p=0.00592) on perceived intensity of odour. Tukey’s test ($p < 0.05$) showed a significant decrease of odour release with level of sucrose solution viscosity from low to high (Fig 1.A). Sucrose enhances intensity of odour released from sweet matrix for each tested aroma compounds (Fig 1.B). All compounds were scored above 3, what is concentration which corresponds to their OAV in water. Those results are in accordance with Labbe et al., 2007; who have concluded that sucrose enhanced odour and aroma.

Aroma release from the oil matrix
Intensity ratings for perceived odour decreased as a function of oil concentration (Fig. 2.A). Statistical analysis revealed a highly significant effect of the level of emulsion viscosity ($F_{3.932}$ = 12.396, p<0.001). However, there is no difference in perceived odour intensity of 4 tested aroma compounds as reported in Fig. 2.B. The odour intensity of each of four aroma

compounds in oil emulsion was below 3 means lower than theirs intensity in aqueous solution. It is well-known that most of aroma compounds are lipophilic. Therefore, in oil emulsion aroma compounds prefer to reside in the particulate oil phase and its concentrations in the continuous phase is decreased greatly thereby lowering its concentration in air phase. Investigation of Van Rut et al., 2002 showed that eighteen out of the 20 aroma compounds showed a significant change in air/liquid partition coefficient and therefore on odour release above liquid as results of change in emulsifier concentration.

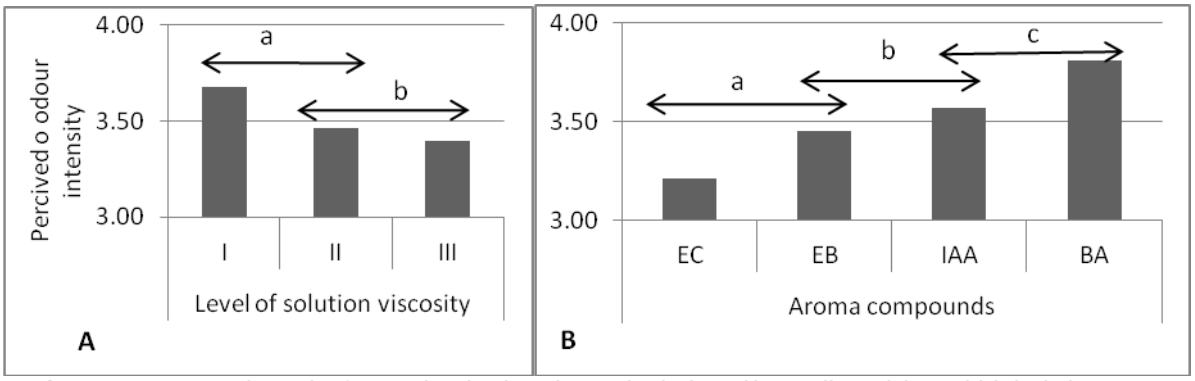

Figure 1.A Mean (n=15) of perceived odour intensity in low *(I),* medium *(II),* and high *(III),* sucrose solution viscosity. **1.B** Mean of perceived odour intensity of the individual aroma compounds *(EC-Ethyl Caproate EB- Ethyl Butyrate IAA- Iso-amyl Acetate, BA- Benzaldehyde)* The different letters indicate subset of significantly different samples obtained from Tukey test ($p \leq 0.05$)

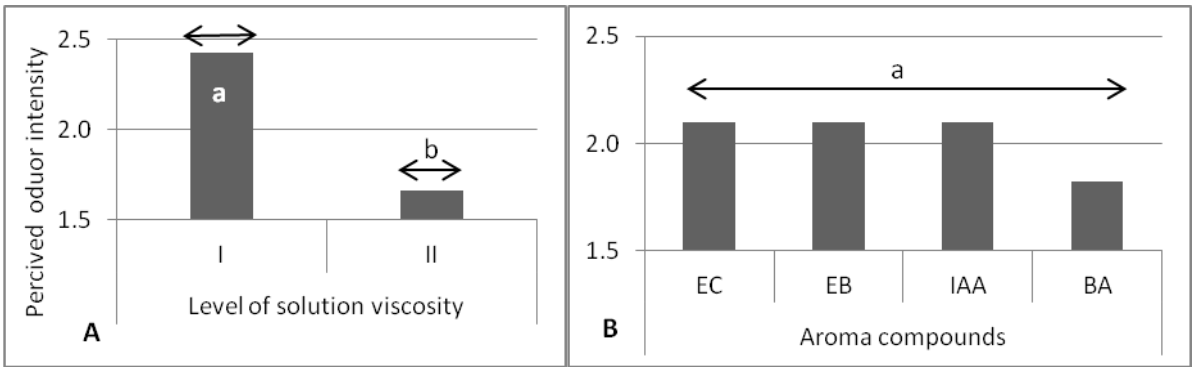

Figure 2.A Mean (n=15) of perceived odour intensity in low *(I),* and high *(III)* oil emulsion viscosity. **2.B** Mean of perceived odour intensity of the individual aroma compounds *(EC-Ethyl Caproate EB- Ethyl Butyrate IAA- Iso-amyl Acetate, BA- Benzaldehyde)* The different letters indicate subset of significantly different samples obtained from Tukey test ($p \leq 0.05$)

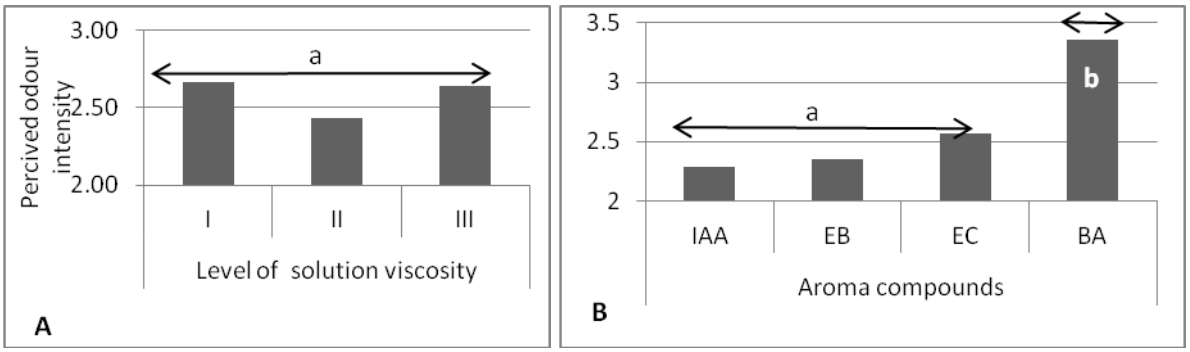

Figure 3.A Mean (n=15) of perceived odour intensity in low *(I),* medium *(II),* and high *(III),*yoghurt mat6rix viscosity. **3.B** Mean of perceived odour intensity of the individual aroma compounds *(EC-Ethyl Caproate EB- Ethyl Butyrate IAA- Iso-amyl Acetate, BA- Benzaldehyde)* The different letters indicate subsets of significantly different samples obtained from Tukey test ($p \leq 0.05$)

Aroma release from yoghurt

Differences in yoghurt viscosity did not influenceon intensity of aroma compound release significantly (Fig. 3.A). Unlike other compounds Benzaldehyde showed significantly higher perceived odour intensity. Odour intensity of Ethyl Caproate, Ethyl Butyrate and Iso-amyl Acetate in yoghurt were lower than 3 means protein as main component of yoghurt entrapment those aroma compounds.

Aroma release from starch matrix

Intensity ratings for perceived odour decreased as a function of viscosity of starch paste (Fig. 4.A). ANOVA revealed a highly significant effect of the level of starch viscosity ($F_{3.054} = 5.193$, $p < 0.001$) and kind of aroma compounds ($F_{2.663} = 4.3151$; $p<0.005$) on perceived intensity of odour. Tukey's test ($p < 0.05$) showed significantly higher perceived odour intensity from low then from medium and high viscous starch paste. Tukey's test ($p < 0.05$) showed significantly higher odour intensity for Benzaldehyd compared to other aroma compounds (Fig.4.B). It could be noticed that starch matrix reduced the release aroma compounds because all of them were assessed below 3 what is their OAV in aqueous solution.

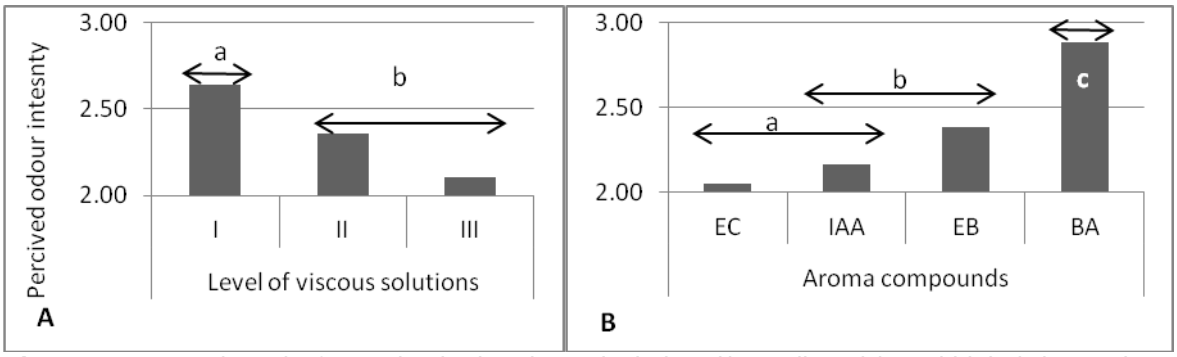

Figure 4.A Mean (n=15) of perceived odour intensity in low *(I),* medium *(II),* and high *(III),* starch paste viscosity.**4. B** Mean of perceived odor intensityof the individual aroma compounds *(EC-Ethyl Caproate EB- Ethyl Butyrate IAA- Iso-amyl Acetate, BA- Benzaldehyde)* The different letters indicate subsets of significantly different samples obtained from Tukey test ($p \leq 0.05$)

PCA analysis

In order to get an overview of the similarities and differences among 22 samples on the basis of food matrix (sugar, oil, starch, yoghurt) levels of matrix viscosity (I, II, III) and way of perceived intensity of aroma compounds (odor, aroma) principal component analysis was performed (Fig 5).

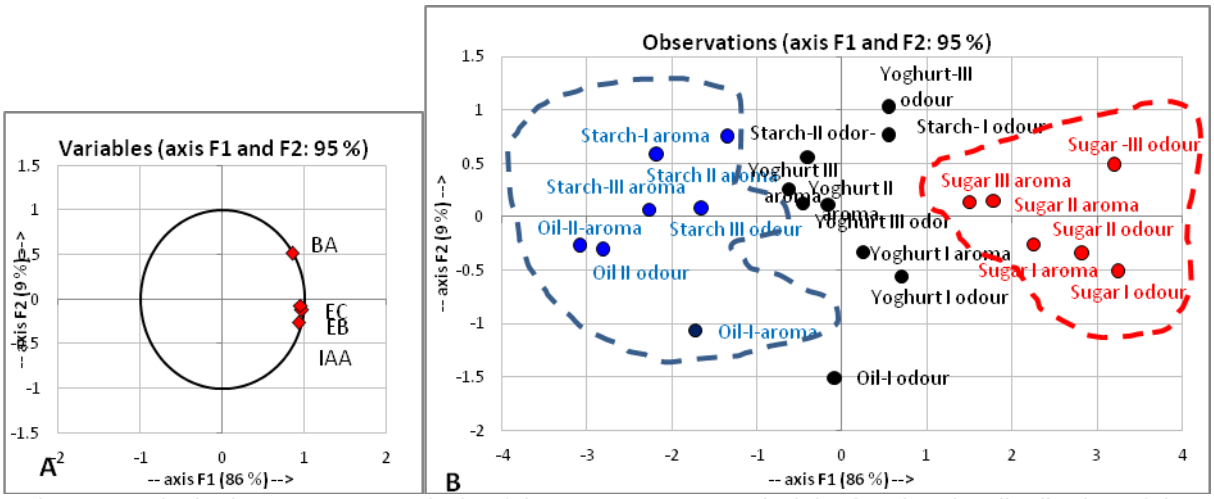

Figure 5. Principal component analysis of the aroma compounds (A), showing the distribution of the samples: I, II, III means three levels of viscosity; (B)

All quantitative data of sensory evaluation of investigated aroma compounds were subjected to PCA analysis in order to find correlations among aroma compounds (loading plots Fig. 5.A). 86% of the total variance was explained by the PC1 and all aroma compounds contribute to the PC1. The sample sites located on the score plot (Fig. 5-B) show clearly the distribution on two clusters. The first one is on the right side of the plot and represent sugar food matrix and all 3 levels of viscosity which contribute to enhancing, specially, odour but also aroma intensity for all aroma compounds. On opposite side located starch and oil matrix which decreased aroma intensity for any level of viscosity. From the plot it could be seen that aroma intensity of all aroma compounds is perceived lower then odour intensity. Several authors (Voirol and Daget, 1986; Pierces and Halper, 1996) who investigated differences between orthonasal and retronasal olfaction concluded that those differences could be explained as a less efficient access of volatiles compounds to the sensory area when they follow the retronasal way.

CONCLUSIONS

It was found that the viscosity of sugar, starch and oil matrixes influence on aroma release while the viscosity of yogurt did not significantly influence on delivering aroma to human sensory receptor. Sucrose enhanced perception of aroma compounds and yoghurt enhanced aroma intensity of benzaldehyde. Transmission of aroma compounds to the oral cavity and olfactory epithelia from oil, starch paste and yoghurt matrixes were hindered. Perceived aroma intensity (retronasal) was less then perceived odour intensity (orthonasal) for all tested aroma compounds.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project “Olfaktorno utvrđivanje intenziteta oslobođenih aromatskih jedinjenja iz različitih matriksa hrane“ (Olfactory Evaluations of Intensity Realised Aroma Compounds from Different Food Matrixes) financed by the Federal Ministry of Education and Science, Bosnia and Herzegovina.

ABSTRACT: The aim of this study was to quantify consumers attitude towards functional products based on cereals and to find the underlying dimensions that can predict respondents' willingness to use these products. For the analysis of consumers attitude were used a multivariate methods MANOVA and discriminant analysis. Roy's-test, Pearson coefficient of contingency (χ), multiple correlation coefficient (R) also applied. When the results in relation to the education level of respondents are observed, it was found that highest difference among respondents was in their attitude regarding health status information whereas the least difference was in their attitude regarding the way of presenting information about functional product based on cereals. The introduction of functional products based on cereals will not automatically be successful without the simultaneous introduction of information that is of use to consumers in making informed choices about purchase and inclusion in their diets.
Key words: *consumers, functional foods, cereals*

INTRODUCTION

Together with the development of consumer awareness and changes their behaviour, the needs for quality products with precisely defined nutritive and other characteristics are increasing. In the last decades consumer demands in the field of food production has changed considerably. Consumers more and more believe that foods contribute directly to their health (Mollet, Rowland, 2002). Consumer benefits from the consumption of so-called "functional" foods are potentially very wide-ranging, and are associated with different advantages to human health and quality of life. The term "functional food" has been linked with various definitions that vary from simple statements to rather more complex ones. Consumer acceptance of the concept of functionalfoods, and a better understanding of its determinants, are widely recognized as key success factors for market orientation, consumer-led product development, and successfully negotiating market opportunities (Ares, Gámbaro, 2007). The assumption that functional products with specific health advantages are likely to deliver population-wide benefits is not now generally accepted.In recent years, cereals have also been investigated regarding their potential use in developing functional foods. Cereals are grown over 73% of the total world harvested area and contribute over 60% of the world food production providing dietary fibre, proteins, energy, minerals, and vitamins required for human health. Most research on functional foods is concentrated to possible health effects, We do not know too much about consumer response to these products (Saher et al., 2004). The addition of vitamins and minerals in cereals, known as food enrichment or fortification, is a common practise in developed countries used to prevent vitamin and mineral deficiency in the diet. The main components used in white flour fortification are thiamine, riboflavin, niacin, folates and iron. The fortification of cereals was technologically available from the point when it was possible to synthesize pure forms of vitamins and minerals which were controllable. It should be noted that food fortification made it possible to find the causative relation between nutrient deficiency and occurrence of degenerative diseases. The main argument that contributes to better sale of functional food is the claim that it is beneficial for health which particularly affects younger generations

seeking for higher quality of life (Cross, Frost, 2009). Increased demands after healthier and more nutritious products is a consequence of more conscious consumers which contributes to constant necessity for new products and increased differentiation of product assortment (Lineman 1999., Deliza et al., 2003).Consumers have been increasingly interested in health effects of food or their components. As an answer to these demands, food industry makes efforts to provide various food products enriched with functional components (Position of the American Dietetic Association: Functional Foods 2009).
Previous studies have shown that:

- Consumers are sceptic towards nutritive and health claims,
- Consumers are not able to clearly distinguish between these claims (although they perceive them as useful),
- Consumers prefer shorter claims rather than complex ones (Verbeke et. al. 2009).

These statements are probably the consequence of lack of motivation and knowledge on basic physiological functions. It is obvious that the particular health benefit is more useful for the consumer than the way it is presented (Van Trijp, Van der Lans, 2007).
However, consumers rarely prefer or dislike a food on the basis of business orscientific terms describing its healthiness or nutritional value (Lähteenmäki, 2003).

MATHERIAL AND METHODS

The research was conducted through randomly distributed survey on the teritory of Novi Sad. The consumers attitude has been tested on a sample with 508 respondents divided to subsamples based on: ages, education and gender.
Ages:

- <18 year-140 respondents,
- 18-30 year-67 respondents,
- 31-50 year-237 respondents,
- >50 year-64 respondents.

Education:

- Primary school-103 respondents,
- High school-338 respondents,
- Faculty-67 respondents.

Gender

- Male
- Female

For the analysis of consumers attitude a multivariate methods MANOVA and discriminant analysis were used. Roy's-test, Pearson coefficient of contingency (χ), multiple correlation coefficient (R) were also applied. The results are further analyzed by estimating the homogenity of subsamples, distance among them and Cluster analysis (Anderson, 1984).

RESULTS AND DISCUSSION

The entire study was conducted in thematic groups, and analyzes the difference between: age, education and gender of respondents in relation with the following units:

- Consumers attitude about their health ,
- Consumers attitude about understanding nutritional and health claim,
- Consumers attitude about purchase of functional products based on cereals,
- Consumers attitude way of information about functional products based on cereals

The higher the discrimination i.e. difference among the subsamples, the more expressive are subsample characteristics. The percent of contribution (%) for each entirety shows how the particular whole defines the characteristics of a subsample in relation to other entirety. It is also given an overview of characteristics with homogeneities of each subsample in relation to the measure of discrimination and degree of ascendingly sorted characteristics. The

contribution of entirety (space) to characteristics and contribution of characterisctics within space are important parameters that define the hierarchy within the spaces and order of the characteristics.

Table 1. The contribution of the entirety to characteristics

Contribution %	Consumers attitude	subsamples
12.088	about their health	education level
12.035	about their health	ages
11.476	way of information	ages
11.094	understanding nutritional and health claim	education level
10.509	purchase of functional products	education level
10.331	understanding nutritional and health claim	ages
9.765	purchase of functional products	ages
7.929	way of information	education level
4.238	purchase of functional products	gender
4.139	about their health	gender
3.738	way of information	gender
2.658	understanding nutritional and health claim	gender

The contribution of total to characteristics of subsamples (%) (Table 1.), showed that the highest difference between respondents was in their statements regarding health information in relation to their education level and age. There were also significant differences between the respondent statements regarding the way of presenting information about functional food in relation to the age group of respondents as well as their statements regarding understanding nutritional and health claims in relation to education level and age of respondents. On the other hand, least differences were observed with respondent attitudes about buying functional food, information on health status, way of presenting information about functional food, understanding claims in relation to the gender of respondents.

Table 2. The contribution of the entirety to characteristics

Contribution %	Consumers attitude	subsamples
28.686	purchase of functional products	gender
28.018	about their health	gender
25.301	way of information	gender
17.996	understanding nutritional and health claim	gender

Analysing the results in relation to the gender of respondents (Table 2.), it was observed that highest difference among respondents was in their attitude regarding buying functional foods whereas the least difference was in their attitude about understanding claims.

Table 3. The contribution of the entirety to characteristics

Contribution %	Consumers attitude	subsamples
27.599	about their health	ages
26.317	way of information	ages
23.691	understanding nutritional and health claim	ages
22.393	purchase of functional products	ages

Analysing the results in relation to the age of respondents (Table 3.) it was observed that highest difference among respondents was in their attitude regarding health status information whereas the least difference was in their attitude about functional product purchase.

Table 4. The contribution of the entirety to characteristics

Contribution %	Consumers attitude	subsamples
29.043	about their health	education level
26.656	understanding nutritional and health claim	education level
25.249	purchase of functional products	education level
19.051	way of information	education level

When the results in relation to the education level of respondents are observed (Table 4.), it was found that highest difference among respondents was in their attitude regarding health status information whereas the least difference was in their attitude regarding the way of presenting information about functional product based on cereals.
There was a clearly distinguished difference among certain education levels of respondents with regards their statements on health status information.

CONCLUSION

The introduction of functional products based on cereals will not automatically be successful without the simultaneous introduction of information that is of use to consumers in making informed choices about purchase and inclusion in their diets. The approach being most widely adopted to inform consumers is that of market segmentation, with origins in market research. Understanding consumers' risk perceptions and concerns associated with processing technologies, emerging scientific innovations and their own health status may enable the development of information strategies that are relevant to wider groups of individuals in the population, and deliver real health benefits to people increasingly suffering from illnesses relating to ageing and over-nutrition. Research has shown that ages and education level can significantly affect to consumers' understanding of nutritional and health claims: The most important factors are: the availability of information, age and education level.

- With increasing consumers age also increasing interest of consumers to read the content on the nutritional and health claim.
- Older consumers better understand information presented on nutritional and helath claim.
- Age of consumer significantly affected their attitude as regard to which information on the claim is the most important.
- Older consumers usually read the labels and possess enough knowledge on the elements of labelling.
- Consumer age affects the consumer's reliance over health claims. More educated consumers consider information presented in nutritional and health claim important for proper choice of product and perceive it as an inherent part of a quality product.
- Consumers with higher level of education know more about what nutritional and health claim should contain.
- More educated consumers more frequently check the title of producer on the label and the nutritional and health claim.

Based on the influences of:gender, age and education level to consumers attitude toward information provided by the nutritional and health claim, it is possible to predict the requirements and models of their behavior.

ABSTRACT: Traditional food products represent a heritage and are the result of accumulated empirical knowledge that is passed through the generations.
Dairy products, including cheeses and kajmak, have a long tradition of production and consumption in Serbia. The two known groups of autochthonous Serbian cheeses are white brined and pasta filata cheeses which are represented in central and south parts of Serbia, respectively. Kajmak is a dairy product with unique composition and sensory properties and with great potential to be recognizable brand of domestic agriculture.
Nowadays, the most of these products are usually produced in households and small craft dairy plants which are poorly organized. Such manufacturing methods of traditional dairy products differ greatly from region to region, yielding products of uneven quality and safety with wide variation in composition and characteristics. All of these are certainly the main reasons why such a delicious dairy products are not recognized as traditional products with protected origin as well as have been left out of the world market and remains only significant on a local level.
This paper discusses the main problems and difficulties of the traditional dairy products manufacture such as organization of primary milk production, quality of raw milk, conditions in the production dairy plants, lack of knowledge etc.
Also, the available and missing resources in traditional dairy products manufacture were considered in order to indicate the possibilities and the main ways for improvement of traditional production and placement on market. The main goals in future should be based on the detailed defining of composition, properties and method of production of selected dairy products, establish better control, better connection between different public and private Institutions, associations and collective actions of producers on market, the education of producers as well as consumers etc.
The increasing of the supply of products with tradition and geographical designation of origin should be an important commitment for rural development as well as overall agriculture in Serbia. All of these can help for better positioning and distribution of valued traditional Serbian dairy products on domestic and world markets.
Key words: *traditional production, cheese, kajmak,*

INTRODUCTION

Traditional food represents a cultural heritage and is the result of accumulated empirical knowledge passed from generation to generation. Production and consumption of different traditional food, including dairy products, has a long tradition in Serbia (Dozet et al., 1996b, Dozet et al., 2006). All types of traditional products differ with unique composition and properties and are associated to the territory of their origin included the production methods, climatic conditions, habits, environmental conditions, etc. However, nowadays, these products are still significant just on a local market and have been left out of the world market.
This article is focused on the short review of the main characteristics of autochthonous Serbian dairy products, including two most popular groups of cheeses and kajmak, as well as present difficulties in the traditional production of these products. Also, considering the resources in the traditional production, possible directions for its improvement and their better positioning on market are discussed.

Traditional Serbian dairy products

The most famous dairy products in Serbia whose production dates back to the past are cheeses and kajmak. Within the group of cheeses the best known are two following types: white brined and pasta filata cheeses. The main characteristics of these dairy products as well as basic steps of production procedure were given below.

White brined cheeses

White Brined cheeses (WBC) are the most important family of cheeses for Serbia and neighboring countries (Mediterranean region). The cheeses of this family are the most widely produced and consumed cheeses in Serbia and represent about 60 % of total cheese consumption (Dozet et al. 2006). There are many different types of Serbian brined cheeses, named according to their production regions as follows: Sjenica, Zlatar, Svrljig, Homolje cheese (Dozet et al., 1996a). These cheeses may be very similar, but they also rather different in respect of the milk type, region of production, manufacturing protocols, composition and sensory properties, etc. Traditionally, they were usually made from cow's, sheep's and goat's milk (Dozet et al., 1996b), but nowadays they are mainly produced from cow's milk. However, all of them have the characteristic of being ripened and stored in brine until their consumption.

Currently, WBC in Serbia are produced by both traditional and industrial methods. Traditionally, white brined cheeses have usually been made from unpasteurized or medium heat-treated milk, without starter cultures and in small dairy plants and households using simple equipment (Dozet et al., 1996a,b). The general procedure of WBC production involve next steps: raw milk heating, addition of $CaCl_2$ and starters at 30– 35^0C if they are used, renneting and coagulation (40-60min.), cutting into 1–3-cm cubes, rest for 10–15 min, moulding into rectangular or cylindrical moulds, draining (usually without or under low pressure), cutting the curd into the final cheese dimensions, salting (in brine or with dry salt), packaging in containers and ripening at 16–18^0C (until pH reaches a value of 4.6) and storage at 4-8^0C. Because of the low pH, the high salt content and the relatively short ripening period, biochemical changes are not extensive during ripening.

The colour of WBC ranges from off-white to yellowish when they are made from cow's milk. They have no rind and gas holes, but the other openings should be present in the cheese mass. The texture of WBC is smooth, soft and crumbly but still sliceable. Their shape varies and depends on the package container. Usually cheese blocks are rectangular or cubic and weigh between 250–1000 g.

Pasta filata cheeses (Kashkaval)

Pasta filata (PF) cheeses are the second most popular cheese group in Serbia and East-Mediterranean countries (Dozet et al., 1996a, Pudja and Milanovic, 2000., Alichanidis et al., 2008). Production and consumption of cheese is associated with the southern part of Serbia, around the city Pirot, and the most famous cheese in this group is Pirotski Kashkaval (Pudja and Milanovic, 2000). Currently, the most of pasta filata cheeses are produced on industrial scale using the modern equipment. However, traditional production of Kashkaval is still present in some rural areas in Serbia.

Traditionally, they are produced from raw sheep's milk but today the most cow milk is used. The manufacture of Kashkaval cheese consists of two independent stages: (i) production of the curd and its acidification (cheddaring) (ii) texturizing of the acidified curd (heating, kneading and stretching in hot water or brine). General production procedure consists of following phases: heat treatment of raw milk until coagulation temperature (31-34^0C), coagulation with rennet, cutting of curd (6–8-mm cubes), left for about 10 min then scalded to 42^0C for 35 min with stirring, collecting of curd mass and forming of cheese blocks. Then, curd blocks left to be acidified (cheddaring process) until pH reaches a value of 5.2 which is the most important step in pasta filata cheese production. Curd acidification to a certain extent is of importance since it results in the characteristic fibre-like structure of the final cheese. The acidified curd is cut into long thin slices and texturised by soaking the cheese mass in a hot water or brine (80-85^0C) using the modern equipment or with intensive manual

labour in industrial and traditional method, respectively. Traditionally, the curd mass is placed into wooden baskets, immersed in hot water and manipulated with a wooden stick until a homogenous compact structure is obtained. The hot curd was then transferred to a table and hand-kneaded like dough, partially salted and moulded in metal or wooden hoops. A small amount of salt is applied 4-5 times to the cheese during the first 2-3 weeks of ripening. Cheese are left to ripen for about 2–3 months 12–15^{0}C/RH 85%) and storage 2–4^{0}C (Pudja and Milanovic, 2000., Kindstedt et al., 2008).
The typical form of Kashkaval cheese is flat, cylindrical, with a smooth, amber-coloured rind. The texture of all Kashkaval-type cheeses is laminar, elastic, very close with visible layers, occasionally with random slots but without gas holes. The National Committee for Standardization in Serbia has defined the National Standard for Kashkaval cheese (Standard SRPS E.C2.010:1997). The Standard takes into account traditional manufacturing practices, as well as modern trends in the industrial production of the cheese. According to the Standard, 'Kashkaval is a semi-hard or hard, pastafilata cheese which is available in two types: Kashkaval (weigh 5-10 kg, diameter 30 cm and 10-13 cm in height) min. 56% dry matter, min. 45% fat in dry matter and min. 8 weeks ripening period) and Kashkaval Krstas (weigh up to 3 kg, min. 54% dry matter, min. 45% fat in dry matter and min. 4 weeks ripening period). Both cheese types can be produced from cows', sheep's, goats' or mixed milk, which may be raw or pasteurized.

Kajmak
Kajmak is a dairy product with unique composition and sensory characteristics. Nowadays, kajmak is usually produced in households and small dairy craft plants by traditional method. In the past, the several attempts have been proposed as a solution for industrializing of kajmak production but unfortunately there still is no significant application of them (Pudja et al., 2008).
Traditional kajmak procedure is based on the surface activity of the top layer of boiled milk. Hot milk is poured into the open shallow vessels where, due to surface activity and evaporation, a kind of initial skin is formed on the top of the milk. After initial skin formation, a gradual process of milk cooling takes place and lasts about 24 h, with a final temperature that ranges from 10 to 15^{0}C. Important factors that control the process of kajmak formation are: milk composition, milk temperature, the humidity and temperature of the surrounding air, and the temperature difference between the milk and air. The kajmak formed on the top of the milk is collected, salted and, layer by layer, placed in appropriate vessels. It may be consumed immediately after manufacture, as a fresh kajmak, or after a maturation period, as a ripened kajmak. Maturation of kajmak usually takes place 15–18^{0}C at least over 15–20 days, but also can be stored in cold conditions (below 8^{0}C) over 3–6 months, and in some cases up to one year (Pudja et al., 2008).
The color of kajmak is mostly influenced by the ripening time, composition of milk fat and milk type. Fresh kajmak has a light color ranging from white to ivory, while ripened product differ with light to dark yellow. The flavor of fresh kajmak is mild, creamy and milky which become more intensive and stronger due to numerous volatile, aromatic compounds formed from proteolytic and lipolytic processes undergone during ripening. The consistency and structure of fresh and mature kajmak vary widely. Fresh kajmak is characterized by a soft, creamy consistency and good spreadability. Mature kajmak has a harder and grainy structure due to its higher total solids level, but also more spreadable structure (Pudja et al., 2008).

Designation of origin and geographical indication
In last 20 years, special attention was given on the protection of origin of different food, including dairy products, which differ with long tradition of production within some specific regions. Traditional Serbian dairy products which are described above are still not recognized as specific products with signs of geographical origin. However, Homolje cheeses, which belong to WBC, are protected with sign of protection geographical origin on a local level and according to domestic Regulations (Radovanovic et al., 1996), but they are still out and without significant recognition on wide dairy products market.

The idea of protecting and preserving diversity of traditional foods, including cheeses, is defined by the Paris Convention back in 1883rd year. The term "*Appelation d'Origine Contrôlée*" (AOC) was first time introduced in this document which identified the value of food in specific region and clearly defined quality and authenticity of such products. In Europe, this concept was widely accepted 1992nd (Regulation EC 2081/92) and current Council Regulation (EC) No 510/2006 is valid. This Regulation defines all terms and different levels of food origin protection. EU Regulation sets out provisions three types of geographical description on agricultural products and foodstuffs from a defined geographical area. A PDO (Protected Designation of Origin) covers the term used to describe foodstuffs which are produced, processed and prepared in a given geographical area using recognized know-how (such as Mozzarella di Bufala Campana, Italy). A PGI indicates a link with the area in at least one of the stages of production, processing or preparation (such as Canestrato di Moliterano, Italy). The link with the area is therefore stronger for PDOs. Traditional speciality guaranteed (TSG) sign emphasizes a product's traditional composition or traditional mode of production (Boerenkaas, Netherland; Mozzarella, Italy) (www.eu.europa.eu).

Currently, about 1320 products (excluding wines and spirits but including beer) were defined with PDO, PGI and TSG marks in the European Register. The main countries in terms of value of PDO/PGI production are Italy (33% of the total), Germany (25%), France (17%) and the United Kingdom (8%). In addition, it is estimated that part of the production of 30% of protected products are exported outside the EU. Cheeses account for third of total PDO/PGI products (~35%) and represent ~8% of total cheese produced in EU (3-4% of world production). The study carried out by the European Commission's shows a constantly rise in exports of these products in last few years (www.eu.europa.eu).

The use of corresponding EU symbols on the labels of specific food products encourage the diversification of agricultural production, protect the product names from misuse and imitation and provides consumers with clear and concise information on their origin. The introduction of these terms also benefits the rural economy, since it boosts farmers' income and maintains the population in less favoured or remote areas.

As it was said above, the good example of improvement production and placement of traditional foods, regarding to cheeses, are Italy, Switzerland and France which differ with very well organized and developed agriculture sector.

In Italy 1 millions of tons of cheeses are produced and more than 450.000 tons are cheeses with designation of origin (www.clal.it). The most of cheeses are consumed on domestic market, but also it is very important export of them which contribute significantly to country economy. Namely, Italy exports almost 270.000 tons of cheese, with a value of 1.4 billions of euro (www.wds2011.com). The export of protected cheeses is within 10 to 28% of total cheese production, with constant rise, depending on the cheese type. Main Italian exported cheeses are Mozzarella and other fresh cheeses (~36%), Grana Padano PDO and Parmigiano Reggiano PDO (~25%), Pecorino Romano PDO, Gorgonzola PDO and Provolone (www.clal.it, www.wds2011.com). Similar data can be analyzed for other countries such as France, Swiss and for the last few years Spain, Portugal etc.

However, it is evident that protection of traditional production of food may have positive influence on overall economy as well as for rural development of country.

The problems and recommendation for improvement of production and placement of traditional dairy products

Traditional production of food, including dairy products, in Serbia is faced with numerous problems and difficulties which result in non adequate positioning of such products on the domestic and world market.

Traditional production of dairy products is strong connected with changes of primary milk production as well as livestock in some regions. Namely, the great migration of population from rural areas has contributed to closing of numerous farms. Currently, in Serbia the production of raw milk (about 65%) is mostly connected with high numbers of small farms, with 1 to 5 cows (Popovic, 2008). This is extremely small if compared with EU-15 where the average herds size is around 40 cows, ranging from 14 cows per holding in Greece to 80 in

the UK (Berkum, 2007). High number of farms, small scale production and shortage of awareness for cooperative action makes this ring in whole dairy chain the weakest. Because of that one of the main measures of agricultural policy should be aimed to education and stimulation of dairy farmers through Extension service to organize cooperatives.

The poorly organized primary production results often in bad quality of raw milk which has a direct impact on dairy products quality and safety. As mentioned above, the most of traditional dairy products are produced in housholds and small scale dairy plants. Currently, about 40% of raw milk market is controlled by 16 middle sized and 180 small sized dairy companies but the actual data about milk amount which is processed in households is still unknown (Popovic, 2008). The often bad hygienic conditions in these type of plants and housholds contribute to substanial safety risks and poor microbiological quality of traditional dairy products. Moreover, the procedure of dairy products manufacture differ greatly from region to region, yielding products of uneven quality with wide variation in composition and characteristics which also prevents the proper positioning of them on the market. Also, it is important to emphasize that until now and regarding to protection of geogrpahical origin the manufacturing protocols of the most autochthonous dairy products are not well defined. Hence, one of the most priority in future is detailed defining of raw milk quality, composition and properties as well as production protocols for typical Serbian dairy products. On that way it is possible to start the serious procedure for the geographical protection of orgin on the local as well as on the EU level.

Traditional dairy products, such as cheeses and kajmak, are usually produced from raw milk without using starter cultures. Specific native microflora has an inportant role in the numerous events during ripening of traditionally made products and forming their specific sensory properties. Hence, due to poor manufacturing conditions, there is uncontrolled growth and activity of endogenous microflora during production and ripening processes, leading to potential safety risks and spoilage of final products. On the other hand, the use of commercial starter cultures as well as introduce of heat treatment, which is common for industrial production, enables improvement of safety aspects, but impairs cheeses specific sensory properies. The autochthonous microflora is claimed to play a major role in determination of cheese specificity. Biodiversity of cheese microflora is very significant because their selection enable obtaining authentic starter cultures for standardization and protection designation of origin for these traditional cheese types. The diversity of microflora within the area of origin has been the subject of study in several Serbian traditional cheeses (Radulovic, 2010, Martinovic et al., 2008). For the improvement of the authentic microflora issue, it is necessary to isolate lactic acid bacteria (LAB) from traditional cheeses and evaluate their technological properties, in order to test their potential application as components of defined starter cultures (Radulovic et al, 2011).

Application of selected microorganisms may help to improve a product safety with remaining the unique and specific sensory properties of autochthonous dairy products. Such kind of traditional cheese standardization is known for well organized country as Switzerland. Cheeses, such as Emmental, Gruyer etc., with PDO sign, are usually produced in numerous small scale family plants from raw milk, sometimes with addition of LAB selected from traditional made cheeses (Saric et al., 2007). However, it is important to emphasize that the main role in selection of LAB, quality control and research activities as welll as supplying producers with unique starters, belong to the biggest scientific Institute. Based on that, it is clear how is important to make strong connections between dairy products producers and scientific institutions. In Serbia, there are several scientific institutions working on autochthonous LAB research, but with the insufficient level of collaboration. One of the priorities should be merging the collections of LAB, isolated from particular cheeses in order to establish the base for supporting and upgrading the production of the autochthonous dairy products. This may also be a meaningful step in efforts to establish the integral concept for the certificates of origin issue for various dairy products.

The specific production procedure of some traditional products such as kajmak also may present the obsticle for better organization and getting the high quality product. Namely, traditionally kajmak production includes numerous steps that represent potential safety risks

for kajmak and the remaining milk such as: (i) the vast surface of the milk layer in contact with the surrounding air; (ii) the long-lasting process of milk cooling with a very long period at a moderate temperature able to stimulate microbiological growth and (iii) the low level of technical support and the transfer of the different products by hand (Pudja et al., 2008). Regarding this, it is necessary to find a solultion for improvement and modifications of some steps in kajmak production which will enable to get product with high quality and safety. The improvement of kajmak production should be based on the shortening of the production time, introducing the constant and defined environmental conditions, the use of selected starters, better processing control, but with keep all characteristics that are typical for traditionally-produced kajmak. In that activities also the scientific institutions may participate significantly.

An important characteristic of traditional production, as well as the majority of the primary production and/or processing, is lack of knowledge and cooperative actions (beetween Institutions and producers). In practice, there are just few associations of dairy farmers and dairy products producers, that don't have any economical or political influence on market or related institutions. In developed countries such are Italy, France and Switzerland the existing of that organisation is key factor for common/joint participation and succes on market. Therefore, it is necessary to establish a better relationship between all relevant actors in the chain, such are scientific institutions, local authorities and traditional products manufacturers. For overcoming this problem, the formation of association on regional and national level is of primary importance, as well as inclusion in international and world associations (such as World wide Traditional Cheese association, established and based in January 2012. in Ragusa, Italy) is very helpful for gaining and exchanging experience.

The absence or malfunctioning of the control and certification procedures is a major problem for all types of quality signs and damages the credibility and further development of the protected products and quality sign labels. In order to establish an effective control system can be recommended actions include technical assistance projects involving an international expertise are required, training and study tours.

The next request which may help to getting quality sign and recognizable lables of Serbian traditional products is harmonization of the existing regulations with EU regulation model. What is more into question is the way the regulations are understood and implemented by the institutional stakeholders.

Institutional networks involved in the protection of geographical indications (GI) of traditional foodstuffs should be enlarged. Currently, so far the responsibilities related to the protection and promotion of GI are mainly concentrated on the Offices for Intellectual Property which leads to an overestimation of the legal aspects and to a poor consideration for practical agricultural and rural development issues, as well as for market issues. The role of the national and local agricultural institutions, local authorities, economic institutions and agencies and research institutes needs to be better defined or re-defined. Increasing awareness of producers/processors on the opportunities which could be offered by the PDO/PGI system is also important and can be achieved through organization of study tours end exchanges with farmers and producers in developed countries (EU, Switzerland), publication of information material and guidelines for farmers, producers and local authorities. However, it can hardly be achieved on a proper way if the legal and institutional framework and the objectives are not clearly defined.

At the end, increasing the visibility of quality sign products on the market and awareness of the consumers is very important from economic impact of any geographical indication protection. Hence, the awareness of the consumers should be achieved through market and consumer surveys, trainings, specialized tours, campaigns, adoption of logos and labeling for some local markets.

CONCLUSION

Serbia has a long tradition of production and consumption of dairy products, especially white brined and pasta filata cheeses and kajmak. However, these products, besides their unique and specific properties, have been left out of the world market and remain significant only on

a local level, due to poor organized and uncontrolled primary production and processing of raw milk, lack of knowledge and cooperation actions between different Institutions and producers etc.
Establishment of conditions for getting sign of protection origin (PDO, PGI, TSG) represents national interest in field of agriculture and rural development in Serbia. As primary assignment, it is necessary to make better organization and connections between all important segments and phases during production of autochthonous dairy products. Improvement of production should be based on the detailed defining manufacturing methods, composition and properties of selected products, establishing better control of all phases during production.
This complex problem requires engagement all national responsible authorities, through promoting, planning and coordinating activity of harmonization of regulations, cooperation actions, education of producers, and sensitizing public awareness on the importance of protecting and valorizing traditional dairy products and developing marketing strategies.
Better positioning of traditional dairy products in Serbia represents an important potential in rural development and domestic agriculture, having a direct effect on development of trade and placement of our traditional dairy products in domestic and foreign markets.

ABSTRACT: The white brined cheeses are the most popular cheeses with the long tradition of production and consumption in Serbia. Modern medical research studies indicate the importance of diet in the maintenance and improvement of health. In this regard, for the last decades, there is rapid growth of food products with dietetic and functional properties, including products with probiotic bacteria, which could be beneficial for human health. Milk products, including cheeses, represent a good base for the development of new products with functional properties, especially those with probiotic bacteria.
The effects of commercial and autochthonous strains of lactic acid bacteria on the composition and proteolysis of white brined cheeses were studied throughout 30 days of ripening. Cheese A was produced with commercial strains (LL 50 A and MY 721, DSM, Netherlands) *Lactococcus lactis* ssp. *lactis*, *Lactococcus lactis* ssp. *cremoris* and probiotics *Lactobacillus acidophilus* and *Bifidobacterium lactis* and cheese B with autochthonous strains *Lactococcus lactis* ssp. *lactis* 563*, Lactococcus lactis* ssp. *cremoris* 565 and potential probiotics *Lactobacillus plantarum* 564. The rate of proteolysis was analyzed by the water and 5% phosphotungstic acid soluble nitrogen fractions, as well as by SDS and UREA PAG electrophoresis. The viability of probiotic strains during cheeses ripening was also determined.
A significant influence of different starter and adjuncts bacteria on the composition was not found. The proteolysis rate was significantly different ($p<0.05$) between cheeses made with different starter cultures, due to different proteolytic activity of bacteria used. The viability of adjunct probiotic bacteria in both cheeses were maintained on the high level during the overall ripening period that are necessary for acquirement of their therapeutic effects.
Cheeses made with autochthonous bacteria showed a higher rate of secondary proteolysis, as well as higher flavour scores, and were more acceptable than cheese made with commercial probiotic bacteria.
Key words: white brined cheeses, lactic acid bacteria, probiotics, proteolysis, sensory properties

INTRODUCTION

Probiotics are “living micro-organisms, which upon ingestion in certain numbers (10^7 cfu/g) exert health benefits beyond inherent basic nutrition”. Foods containing such bacteria fall within the “functional food” category and the market for such products has rapidly grown for last twenty years (Saarela et al., 2000).
Milk products, including cheeses, represent a good base for the development of new products with functional properties, especially those with probiotic bacteria (Ross et al., 2002). The white brined cheeses are the most popular cheeses with the long tradition of production and consumption in Serbia (Dozet et al., 2006). The most of them are still produced in small scale production plant and often are characterized with various composition and properties. However, there is limited knowledge about white brined cheese produced with probiotics. Currently, many different strains and species of lactobacilli and bifidobacteria have been used commercially as probiotics (Ong et al., 2006, Bergamini et al., 2006). However, for last decades numerous researches carry out in direction to find new probiotic strains (KiLiç et al., 2008). Considering the fast growing interest for application of

probiotic strains in dairy products, it could be presumed that it is possible to isolate some strains, from different food, including traditional made cheeses, with potential probiotic ability, among the autochthonous strains (Radulović, 2007, Radulović et al., 2010a, b).
The objective of the present study was to analyse influence of commercial and potential autochthonous probiotic strains isolated and selected from traditional made cheeses on the composition and proteolysis of white brined cheeses.

MATERIAL AND METHODS

Cheese manufacture

The white brined cheeses were made from fresh cow`s milk which was heated at 72^0C/30s, then cooled until 34^0C and 200 mg/l $CaCl_2$ was added. Two different starter cultures were used as follows: cheese A was produced with commercial lactococci (LL50A, DSM, Netherlands) and probiotics *Lactobacillus acidophilus* LAFTI®L10 and *Bifidobacterium lactis* (MY 721, DSM, Netherlands) and cheese B was produced with autochthonous lactic acid bacteria which are consisted of strain *Lactococcus lactis* ssp*. lactis* 563 ($1.7x10^{11}$/ ml),), *Lactococcus lacti*s ssp. *lactis* 565 ($2.5x10^9$/ml) and potential probiotic *Lactobacillus plantarum* 564 ($1.8x10^9$/ml) in ratio 1:1:1 (Collection of Microbiology Laboratory, Faculty of Agriculture, University of Belgrade, Serbia). Then calf rennet (Sacco Clarici, Italiy) was added and the coagulation took place in 45 min. at 32^0C. Once curdling was completed, the coagulum was cut into small pieces (2–5 cm) and stirred three times for 5 min. during 30 min. The cheese mass was carefully transferred from cheese vats into the mold with cheese clothes. After about 1h of draining (without pressing), the pressure was applied (max. 3kg/kg) for 3h. Then, the cheese curds were cut into pieces of 10x10x7cm with knife. The curd blocks were dry salted with 2.4% NaCl. The ripening took place in brine (8%) at 12^0C during 30 days. The cheeses were sampled and analyzed after 1, 7, 15 and 30 days of ripening.

Analytical methods

Cheese samples were analyzed in duplicate for dry matter (DM), fat (MF), total protein (TP) and salt content (NaCl) by standard methods (Carić et al., 1998). The pH of cheese slurry was measured by a pH meter (Consort, Belgium).
Proteolysis was also studied by means of water-soluble nitrogen (WSN) according to the method of (Kuchroo and Fox, 1982), and phosphotungstic acid (5%) soluble nitrogen (PTAN), according to (Stadhousers, 1960), both expressed as a percentage of the total nitrogen matter (WSN/TN and PTAN/TN).
SDS PAG electrophoresis of cheese samples was performed according to Laemmli (1970) method, using a vertical slab unit TV200YK (Consort, Belgium) with 100x200x1mm slabs, Tris-glycine electrode buffer, constant current of 80 mA, a max. voltage of 300V for 4 h, with 4% stacking gel (pH 6.8), and 12% separating gel (pH 8.9). Urea Page was conducted according to Andrews method (1983) using the same equipment.
Data were analysed using STATISTICA 6.0 (StatSoft, USA) data analysis software. LSD test was used to determine differences among cheeses at a 0.05 statistical level.

RESULTS AND DISCUSSION

The composition of the various cheeses during ripening is summarized in Table 1.
The brined cheeses, according to fat in dry matter and moisture in fat free content, belong to full fat and soft cheese category (Table 1). Our results are in agreement with literature data about white brined cheese composition (Macej et al., 2006). Generally, white brined cheeses showed significant variations of composition due to different production method. There were no significant differences ($P>0.05$) in the gross composition of brined cheese made with commercial and autochthonous lactic acid bacteria (Table 1.). Similar studies were reported in previous studied (Ong et al., 2006, KıLıç et al., 2008). Most of the cheese composition parameters did not change significantly ($P>0.05$) during 4 weeks of ripening. However, a

significant increase of dry matter content (P<0.05) after 7 days of ripening was detected, probably due to salt absorption in cheese, as well as water diffusion from cheese into brine. pH values of cheeses were regularly decreased (data not shown) indicated on the good acidogenic ability of autochthonous lactic acid bacteria what is especially important for their use as starter culture in cheese production. Also, the numbers of starter and adjunct probiotic bacteria were maintained on the high level during all investigated time (data not shown). This is especially important for acquirement of probiotic bacteria therapeutic effects (Ross et al., 2002).

Table 1. Composition of white brined cheeses produced with commercial and autochthonous starter cultures during 30 days of ripening

Day of ripening	Cheese	Dry matter (%)	Total Protein (%)	Fat in Dry matter (%)	Moisture in free fat basis (%)
1	A	39.43±0.15a	13.57±0.60a	51.36±1.81a	75.95±0.77a
	B	36.14±0.21b	12.29±0.22b	52.35±2.48a	78.76±1.01a
7	A	42.35±2.28a	14.09±0.26a	52.78±1.52a	74.22±2.30a
	B	46.33±1.55b	16.23±0.24b	54.33±0.97a	71.71±1.50a
15	A	48.35±2.37a	16.73±1.02a	54.81±0.06a	70.25±1.98a
	B	46.42±1.19a	15.82±0.52a	55.30±0.49a	72.08±1.09a
30	A	48.55±2.30a	16.65±0.52a	53.61±1.72a	69.52±2.71a
	B	46.43±0.71a	15.69±0.55a	55.79±2.85a	72.32±0.83a

Results are given as mean ± standard deviation (n = 3); Means in each column with the same letter did not differ significantly (P > 0.05);

The most important biochemical change during ripening of the brined cheeses was the extent of proteolysis which the most influence on the sensory properties of products. The proteolysis parameters of brined cheeses made with commercial and autochthonous starter bacteria were shown in Table 2.

Table 2. Proteolysis paramters of white brined cheeses made with commercial and autochthonous starter cultures during ripening

Day of ripening	Cheese	WSN/TN (%)	PTAN/WSN (%)	PTAN/TN (%)
1	A	3.53±0.22a	8.03±0.32a	0.28±0.01a
	B	4.08±0.09b	11.05±0.46b	0.45±0.01b
7	A	5.39±0.23a	10.92±0.40a	0.70±0.01a
	B	6.14±0.06b	12.76±0.53b	0.79±0.03b
15	A	5.93±0.41a	20.91±0.72a	1.24±0.13a
	B	6.62±0.48b	21.75±0.16b	1.32±0.09b
30	A	6.26±0.21a	20.88±1.05a	1.31±0.09a
	B	6.92±0.30b	22.13±0.66b	1.42±0.06b

WSN/TN – water soluble nitrogen/total nitrogen, PTAN/WSN – nitrogen soluble in phosphotungstic acid/ total nitrogen, PTAN/TN – nitrogen soluble in phosphotungstic acid/total nitrogen, Results are given as mean ± standard deviation (n = 3); Means in each column with the same letter did not differ significantly (P > 0.05);

The content of WSN/TN marked a constant and significantly increases (P<0.05) during all cheese ripening period (Table 2.), but it was the most intense during the first 7 days. The content of WSN/TN was about 7.0% at the end of ripening, which is significantly lower compared to WSN/TN of traditionally made white brined cheese. Abd El Salam (2008) showed that the index of ripening of the most white brined cheeses were within 12–20%. The lower ripening index of experimental cheeses was consequence of short period of ripening. Generally, both cheeses were characterized by a weak proteolysis.

The content of PTAN/TN increased constantly during the ripening period. At the end of the examined period, the content of PTAN/TN was about 1.30% and 1.40% for cheese A and B, respectively. It was significantly lower compared with PTAN/TN of traditionally made cheeses, which is often within 3–5% (Abd El–Salam and Alichanidis, 2008). These results confirm the facts about slower and less distinct proteolysis changes during the ripening of UF cheeses.

Different starter cultures showed significant influence (P>0.05) on the rate of proteolysis determined by WSN/TN and PTAN/RN contents. Autochthonous lactic acid bacteria showed a more intense proteolysis activity probably as result of different proteolytic activity of bacteria used.

Protein profiles of all cheese samples during 30 days are shown in Fig. 1, which indicates no major proteolysis during ripening. As was reported in previous studies (Ong et al., 2006), the β-casein fraction showed only a minor decrease. Intensity of β-casein bands was about the same after storage, showing that neither probiotics nor commercial starters had strong proteolytic activity.

1 – α casein standard, 2 –β casein standard, 3, 4, 5, 6 - cheese A and 7, 8, 9, 10 – cheese B after 1, 7, 15 and 30 days of ripening

CONCLUSIONS

The both white brined cheeses made with commercial and autochthonous starter and adjunct probiotics cultures characterized with very acceptable sensory properties. It can be concluded that autochthonous lactic acid bacteria can use as starter cultures in production of white brined cheese. The application of these bacteria can enable the standardization of traditional made cheeses as well as create a new product with functional properties.

The results also indicate that *Lb. plantarum* 564 is suitable for development of an acceptable probiotic brined cheese. Incorporation of probiotic cultures in cheeses provides potential not only to improve health status and quality of products but also to increase the range of probiotic products as well as improvement of their sensory properties.

ABSTRACT: Traditional and typical agri-food products in the Republic Serbia have an important place in consumption. These products, especially from the Pester region in the South-Western of the Republic of Serbia where the Sjenica cheese is produced, have a good image in the Serbian market.
From the market side there are no difficulties for commercialisation of traditional and typical agri-food products. However, only some of them are protected properly, while for the majority there is no protection of any kind and many of them are at risk to be lost from the market and therefore the agri-food potential would be not valorised.
Evidence from other countries, especially from the EU, showed that Protected Geographical Indications (PGI) could ensure proper valorisation of agri-food potential and improve marketing. The objective of this paper was to analyse how PGI of Sjenica Cheese could allow preserving and valorising of resources of Pester region.
Key words: *geographical indications, Sjenica Cheese, agro-food potential, marketing*

INTRODUCTION

Competition in the market of agricultural and food products is permanently increasing. Manufacturers of Serbia still can sell their products due to special taste and quality that are the result of favourable climatic conditions and the specifics of certain localities.
However, most of the agri-food products to both the domestic and foreign market are sold as "no name" and therefore achieve lower prices than products that are trademarks. For producers of Serbia is important to protected designation of origin so to have added value for their products. Otherwise there is a risk that many authentic Serbian products disappear from the market.
The protection of geographical origin is of high importance for small farmers in particular for small family farms in Serbia. In Serbian agricultural production family farms are the most important entities in the aspect of available capacity and in terms of total production. Private family farms use one part of the production for its own consumption, while the remaining part is sold at the market.
Increasing the competitiveness of commercial family farms is one of the strategic goals of Serbia after changes in 2000. In addition, the Ministry of Agriculture holds the position that agricultural and food products are becoming Serbian brand, and that our country has a large, under-exploited production potential. Supporting small family business is in accordance with the EU CAP.
Designation of origin is viewed as a part of marketing instrument and contributes to increasing of the commercial value of products or services. In addition, it is considered that the products with protected origin achieve higher prices (Babcock and Clemens, 2004). Number of products having geographic indication in the EU increases and there is market growth (EU 2007, Mesić et al, 2010).
Numerous case studies show that food quality insurance and certification schemes, including GI, can contribute significantly to the product value. The benefit is limited not only to the farmers and producers, but the other participants in the value chain like wholesalers and

retailers benefit too. Finally, rural areas and society as a whole would enjoy benefits. It is important to point out that benefits should be distributed equally among the participants in the value chain (Gay, 2007).
Aims of the protection of geographic indications of products are to protect product names from misuse, providing information to consumers about the specific features and origin of products, to encourage diversification of agricultural production and rural stability (Soeiro, 2005.).
Protection of geographic indications is in Republic of Serbia regulated by law. Namely Law on Indications of Geographical Origin (Official Gazette of RS No. 18/2010) and Rule book on the content of the request for registration of geographic origin and content requirements for the recognition of the status of authorized user of designation of origin (Official Gazette of RS, No. 93/2010).
Although, almost all Serbian regions are known for some of the products that have a unique recipe, possibilities of protection of agricultural and food products with geographic designations are in Serbia not sufficiently utilized. In Serbia there are 43 designations of origin and each year on average there are two new applications for protection (The Intellectual Property Office of the Republic of Serbia)
This is due to the fact that there is lack of knowledge, information, organizational and marketing skills, financial resources, institutional support and an effective control system. Moreover, studies of social and economic benefits do not exist.
Therefore, the aim of this research is to examine the possibility to valorise the agri-food potential and improve marketing by protection of the geographic indication in the case of “Sjenica Cheese”.

MATERIAL AND METHODS

For this paper the desk research and field visits and interviews with producers using semi-structured questionnaire were applied. Desk research has been focused on collection and analysis of available data on the area and products, while the interviews with the producers aimed to find their perception of protection of geographical indications. The sample size was 49 systematically most advanced family farms from Pester. The data were processed using descriptive statistics and SWOT analysis.

RESULTS AND DISCUSSION

Pester plateau area has favourable conditions for raising cattle, rather than for agriculture and horticulture. Pester plateau abounds in pastures that are distant from the village and are at a considerable altitude. A clean natural environment, rich meadows and pastures, combined with the traditional mode of production have resulted in superior food products characteristic for this area. Farmers from the area have always been known for producing high quality dairy and meat products.
The sheep grown in Sjenica was selected by modification of domestic sheep breeds most common in Serbia. This breed was adapted to conditions of poor nutrition and care, as well as adapting to the frequent rain and snow. It weights on average 45 kg, making it one of the largest Pramenka breed.
Characteristic grasses and herbs to feed sheeps, along with air and water give a special taste and aroma to food from Pester. Authentic conditions of the area such as geographic features and altitude, climate and microclimate factors in the way of cultivation and animal nutrition could not be found in other regions in Serbia.
Sjenica cheese is a dairy product and belongs to a group of white cheese in brine. This cheese is made from sheep, cow or mixed sheep and cow milk, which is characterized by a specific taste, aroma, flavour, texture, and fullness of flavour. The cheese is kept in wooden barrels in which it never deteriorates, as was the case centuries ago.

One of the basic assumptions of the protection of the geographical origin is the use of bottom-up approach where producers, define procedures and practices and provide the majority consent of all interested parties. To undertake activities producers expect to have benefit of activities of geographic indication protection. The main survey findings are presented in the following table. The possible answer were in the range from 1 - do not agree at all to 5 – agree.

Table 1: Producer opinion regarding geographic indications

		MEAN	SD
A	Increase selling price	2,50	0,50
B	Increase volume of selling	3,45	0,82
C	Reduce black market	3,83	0,75
D	Protect misuse of the name	2,00	0,25
E	Increase the confidence of consumers	4,00	0,63

Source: Survey

The result shows that the producers on average do not expect that protection of geographic indications would cause high valorisation of resources. Typical answer is that they do not know if the protection would bring higher product prices. The standard deviation shows that there are no big differences among producers. As the process needs time and money it is to be expected that producers would not protect their product without external support.
It is interesting that there is no expectation that there would be protection of misuse of the name (average answer 2.00). This finding shows that main issues of protection of geographic indications are related to enforcing state regulations regarding property rights. Interesting point is that producers expect that consumer confidence would increase as well as volume of selling. That means that producers are aware of the potential benefit of geographic indications.
In the following table the results of SWOT analysis are summarised providing the most important element for potential valorisation and marketing improvement.

Table 2: SWOT analysis of the “Sjenica cheese”

Strengths	Weaknesses
- Favourable climatic and environmental conditions - biodiversity, climate, altitude - Long production tradition and unique production methods - Positive consumer perception	- Small scale producers - Product packaging not adjusted for small households - Inappropriate marketing skills - Not standardised production process - No appropriate product labelling - Absence of producers’ associations
Opportunities	**Treats**
- Positive trends regarding demand for regional specific product - Institutions recognise the importance of support for the support of the geographic indications - Funds for supporting the process of protection of geographic indications are available	- Opening the Serbian market for supplies from other countries - Serbian consumers do not necessary prefer domestic product more than imported - Government policy is not predictable and therefore for producers is difficult to create strategic plans

Source: Survey

CONCLUSIONS

Republic of Serbia is known by the wide range of the regional products. However, only some of them are protected. Without protection products are marketed as “no name” products. As a consequence selling prices are lower than for products that already have a specific name.

One possibility to increase valorisation of agri-food products is protection of geographic indication.
This was shown on the case of Sjenica cheese. Results of analysis show that producers understand the concept and advantages. However, it could be concluded from the survey that probably this process is not possible without support from the institutions. Regarding marketing, producers expect that with protection consumer confidence in product would increase. In short, solution for valorisation of potential and improving marketing of geographic indicationss products lies not only by producers, but also on the institutions and other members in the value chain

ACKNOWLEDGEMENTS

This paper is the result of the research financed by the Ministry Education and Science of the Republic of Serbia.
Project number: III46001: "Development and implementation of new and traditional technologies in the production of competitive food products with added value for European and world markets - create wealth with Serbian wealth. The research period of this project is from 2011th to 2014th year.

ABSTRACT: Defined geographic area with their specifity regarding unique plant species and autochthonous breeds – Sjenica and Pirot Pramenka, among traditional cheese-making practice of local community, are prerequisite for protection of denomination of geographic origin of Sjenica cheese and Pirot kachkaval.
Sjenica cheese belongs to the group of soft, white cheeses in brine and it is produced as autochthonous product made of sheep milk, on the territory of Sjenica-Pester Plateau.
Pirot kachkaval is firm cheese of steamed curdle produced from mix of sheep and cow milk (1 : 2 ratio) on the territory of Stara Planina Mountain.
These are geographical areas where production takes place in village households/farms and on mountains in summer cottages (katun, bacija), which is characteristic of craft dairy processing. Specific traits of traditional manufacturing of Sjenica cheese and Pirot kachkaval derive from climatic conditions, characteristic grass associations of the specific mountain region and milk from autochthonous populations (Sjenica and Pirot sheep). In order to maintain the traditional manufacturing technology of these native products and to have organized production, it is necessary to protect the geographical origin of these products.
***Key words**: specificity of geographic area, Sjenica cheese, Pirot kachkaval*

INTRODUCTION

European Community, in its Regulation (EEC) No. 2081/92, has defined the concept of »Protected Denomination of Origins« (PDOs) – denomination of origin, and »Protected geographical Indications« (PGIs) – geographic indication for products whose quality derives from the uniqueness of the geographic area of their origin, including human and natural factors, and which are produced and processed in defined, unique geographic areas (Mijačević et al., 2005).
From this aspect we analyzed the specificity of thge geographic area, its pedological, climatic, floristic characteristics and breed structure in sheep breeding, for the purpose of obtaining of the denomination of the geographic origin for Sjenica cheese and Pirot kachkaval.

MATERIAL AND METHOD

Investigation included survey of the traditional production of Sjenica cheese and Pirot kachkaval, which comprised survey of 12 households/farms on the territory of Sjenica-Pešter Plateau and Stara Planina Mountain, randomly selected. Survey consisted of questions relating to main elements of traditional production of Sjenica cheese and Pirot kachkaval. On Pešter Plateau the following locations were selected: Štavalj, Karajukića bunari, Krstač, Breza, Leskova, and on the territory of Stara Planina mountain, the study was carried out in following villages: Dojkinci, Brlog, Jelovica, Visočka Ržana and Rsovci. Eventually, the following analyses of samples of Sjenica cheese and Pirot kachkaval were carried out:

- Determination of the water content in fat free matter of cheese by using the following calculation: %WFFMC=%H_2O/(100-%MM)x100
- Determination of the milk fat content by method according to Van-Gulik (Carić et al.,2000)
- Calculation of the milk fat content in dry matter (FinDM)
- Determination of pH value by using the pH-meter with combined electrode.

RESULTS AND DISCUSSION

Characteristics of Sjenica – Pešter Plateau and conditions for autochthonous production of Sjenica cheese

Sjenica – Pešter Plateau is located in the south-western part of Raška region and in the north it occupies smaller part of Old Vlah. In the east it borders with Novi Pazar low land and Donji Pešter, in the south with lower Kolašin, and in the west with central Polimlje. It is surrounded with mountain ranges of Golija, Javor, Jadovnik, Ozren, Žilindar, Ninaja and Pometenik. This area represents a unique mountain range, with numerous valleys, ravines, fields, which are located between 1000 and 1350 m above sea level. Pešter is an area with typical carst field and morphological forms which are characteristic of carst: places where rivers sink into earth, lost rivers, waters and caves – so called “pešters“.

This Plateau has continental climate of typical of mountain Plateaus, characterized by long retention of low temperatures between the surrounding mountains, and winters last very long time, because of poorly developed forest strips, with lot of snow and wind, with strong snow storms and great snow drifts. Summers are fresh, short lasting and windy with distinct difference in temperatures between day and night time. Geological foundation consists of gravel, sand and clay, which from the aspect of vegetation structure indicates that meadows and pastures are predominant.

In the area of Sjenica-Pešter Plateau, main branch of economy is agriculture, i.e. livestock production, dairy farming. Mainly sheep (approx. 18000 heads) and cattle (total of 16437 heads, of which 12000 are cows) are reared (Petrović, M. M, 1993). Dominant sheep breed is Sjenica sheep. This is the largest Pramenka, of triple production abilities, it has white colour fleece all over its body except on the face and lower legs. The body is medium-developed, deep with insufficiently expressed widths. Head is of medium length with typical black circles around eyes. Milk performance ranges from 80-130 l in lactation of 180 days. This sheep breed is suitable for rearing in all areas and systems, extensive and intensive, it can be used in production of milk and meat (Petrović, P. M., 2007).

Rearing of livestock is different in winter and summer. In summer, livestock grazes on meadows and pastures which are either state owned or in private ownership. After the vegetation period, from November to May, nutrition of sheep is based on hay from meadows (grass-leguminous mixtures), where high quality cultures are predominant such as Timothy grass, rye grasses, alfalfa, red clover, etc. In addition to hay, during winter, also concentrated feeds are used which livestock farmers prepare them selves by grinding the cereals/grain (barley, oats, wheat) produced on their own field crop surfaces. Structure of plant associations in this area has significant impact on the specific quality of Sjenica cheese. Table 1 presents floristic composition of pastures on location Vrujci, on Sjenica – Pešter Plateau, 1158 m above sea level.

Share of plants belonging to plant family Poaceae – grasses on this location was 48,40%, and shares of leguminous plants and other species were 9,60% and 42,00%, respectively. In case of grasses, the highest share was determined for plants of good and medium quality, from the aspect of livestock nutrition.

Table 1. Floristic composition of pastures on location Vrujci, on Sjenica – Pešter Plateau (Vučković et al., 2004)

Fabaceae,%	Poaceae,%	Other species,%

On defined/determined geographic area of Sjenica – Pešter Plateau, which is specific in regard to climate, phytocenological composition of pastures, sheep population and tradition, the Sjenica cheese is produced. It belongs to the group of soft, white cheeses in brine, and it is autochthonous cheese produced from raw sheep milk. Production takes place in households/on farms and also in the mountains in so called summer cottages (katuns, bačije), which is typical of home production and processing of milk. Since sheep are kept around these summer cottages from May to November, ripening process of Sjenica cheese lasts from 5 to 7 months. Low pH value and long ripening process prevent development of pathogen microorganisms and contribute to safety of this cheese. In Table 2, the chemical composition of Sjenica cheese is presented.

Table 2. Physical-chemical composition of Sjenica cheese

Parameters	**MFFB,%**	**FDM,%**	**pH**
Number of samples	12	12	12
X	73.32	58.42	4.47
SD	2.9	1.74	0.07
CV	4.30	2.30	1.5

Legend: **MFFB** *– water in fat free matter; FDM – fat in dry matter*

Data presented in Table 2 show the average water content in fat free dry matter of cheese (MFFB) of 73,32% %, hence it belongs to the group of soft cheeses, and in regard to content of fat in dry matter (58,42%), it belongs to the group of full fat cheeses (Codex Alimentarius, 2000). Average pH value was 4,47 indicating acid environment which is not suitable for development of pathogen microorganisms. Analyzed cheese samples had adequate sensory characteristics: cheese slices of adequate form, no deformities or damages, and typical white colour. Cheese slice was typical, medium firm, and cross section had moderate number of holes. Odour/smell was also typical, clearly indicating sheep milk, and taste was pleasant and dairy – sour. Since Sjenica cheese is characterized by a distinctive and recognizable

richness of the taste, aroma, odour, this product is in demand and appreciated outside the territory where it is produced.

Characteristics of Stara Planina Mountain and conditions of autochthonous production of Pirot kachkaval

Stara Planina Mountain constitutes far western branches of the Balkan mountain system, stretching from the Black Sea to Vrška čuka, the total length of 530 km. In Serbia, it extends with its slopes from Zaječar to Dimitrovgrad, covering the far eastern part of Serbia. In geological aspect, all formations are represented on this mountain, from Palaeozoic to the most recent formations. In completely defined geographic area/territory of Stara Planina Mountain (Pirot, Dimitrovgrad), in conditions of specific climate, phytocenological composition of pastures, Pirot kachkaval is produced using the milk from Pirot sheep.

Climatological picture of Stara Planina Mountain is very complex and, depending on the altitude, is represents transition between moderate continental and mountain climate. Diverse geological-petrographic, morphological, climatic, hydrographical and other factors have influenced forming of different pedological types of productive soil, with various physical, chemical and biological properties.

The diversity of geographical and ecological/environmental factors of Stara Planina Mountain has caused the specificity of its plant and animal life (Petrović, 1997).

Table 3 shows the presence/share of plant species in pastures of certain localities of Stara Planina Mountain.

Table 3. Presence/share of plant species in pastures of Stara Planina Mountain (Tomić et al., 2003)

Location (a.s.l.)	Fabaceae,% Leguminous plants	Poaceae,% Grasses	Other species,%

In the floristic composition of the pasture, leguminous plants represent the group of plants very important for animal nutrition and increase of production of milk and meat. The following useful leguminous plants determined in studied areas were most represented: Trifolium pratense, Trifolium repens, Trifolium campestre, Trifolium montanum, Lotus corniculatus, Vicia craca, etc., and their share ranged from 0 to 42,40%. Share of grasses ranged from 44,00-82,31%, whereas other plant species where presented in the range from 13,60-36,66%.

As the result of exceptional natural conditions, livestock production has centuries old tradition. In the structure of animal population, due to specific natural and ecological/environmental factors, sheep breeding has the leading position. The most famous products from this unpolluted area are: Pirot kachkaval, Pirot lamb and Pilot kilim (Petrović, P. M, 1993). First »wheels« of Pirot kachkaval set out into World were manufactured on Stara Planina Mountain (Petrović, 2007). Mastery of making kachkaval in this area dates from the time of nomad livestock keepers, so called «Crnovunci« who lived on the pastures of Stara

Planina Mountain from the end of the 19th century until the third decade of the twentieth century. Indigenous production of Pirot kachkaval is the result of many years of developing of the production technology through generations.
The specificity of this autochthonous product (Pirot kachkaval), in addition to climate, soil, botanical composition of pastures and meadows, is under the considerable influence of sheep population, whose milk is used as raw material for manufacturing of said products, as well as rearing conditions (Štimac et al., 2003). In regard to sheep breed structure, predominant breed is Pirot Pramenka. This is an old sheep breed adapted to conditions of Stara planina Mountain and Pirot area, which, in time, and due to improved nutrition and rearing, has realized significant genetic progress. Pirot Pramenka is breed of triple production ability, it has fleece of white colour all over the body, except its face and lower parts of legs. The body is medium-developed, with insufficiently expressed widths and depths. The head is of medium width and length. Hair covering the face is white or grey-spotted. Milk performance is good and it ranges from 70-100 l in lactation of 180 days. (Petrović, P. M., 2007). Quality of sheep milk among other things depends on the climatic conditions, grazing and variations caused by metabolic status of the sheep (Sevi et al., 2004). Also, yield and chemical composition of milk depend on the genotype, lactation stage and health condition of animals (Mioč et al., 2009). Pirot kachkaval is produced from mixture of raw sheep and cow milk (ratio 1: 2). Production takes place in settlements high in the mountains, so called »bačije« according to traditional technology. It is cheese from steamed curdle and technological procedure, in addition to standard stages (curdling, curdle treatment), there are also following stages: ripening and steaming of ripe curdle which takes place at t^0 85-90^{0}C, in duration of several minutes. This heat treatment of curdle prevents the development of undesirable microorganisms. The quality of Pirot kachkaval obtained in this way, expressed in physical-chemical parameters, is presented in Table 4.

Table 4. Physical-chemical characteristics of Pirot kachkaval

Parameters	**MFFB,%**	**FDM,%**	**pH**
Number of samples	12	12	12
X	47.07	48.43	5.46
SD	1.30	1.82	0.03
CV	2.70	3.20	0.50

Recently, number of cheese consumers who demand high quality exclusive products produced in small quantities and by implementation of „traditional“ technology has been increasing. Cheeses produced in this way have richer aroma compared to industrial cheeses produced according to strictly defined technology and in controlled production conditions, therefore the influence of raw material used, micro flora and creativity of the producer are reduced to minimum (Štimac et al., 2003). Therefore, indigenous production of Pirot kachkaval is of great importance for domestic and foreign market. In order to maintain and preserve the traditional technology and have organized production, it is necessary to protect the geographic indication of these products (Jovanović et al., 2004).

CONCLUSION

Determination of the geographic area of the Sjenica-Pešter Plateau and Stara planina Mountain, as well as specificity of these areas due to micro-climatic factors, terrain and geological characteristics, structure of the vegetation and phytocenological composition of the pastures, as well as breed structure and existing tradition in cheese making, are arguments for obtaining of the geographic indication of origin for Sjenica cheese and Pirot kachkaval.

ABSTRACT: Kajmak is a traditional Serbian dairy product which can be classified between cheeses and butter. Initial stage of kajmak production (first 60 min of kajmak formation process) results in surface coagulation of top layer of milk, due to mutual influences of: (1) surface tension driven by protein concentration increase; and (2) water evaporation driven by high milk temperature.
In traditional production, milk temperature is decreased for 30-40°C during the initial phase of kajmak formation. Skin layer, initially formed, incorporates only about 10-15% and 2-3% of total milk fat and proteins, respectively. Numerical simulation of the kajmak formation process indicated the existence of the energy loss, which is mainly caused by the complex processes of simultaneous convective and evaporative cooling of milk.
Creation of the modern procedure for kajmak production faced the request for changes regarding both, mass and energy balance. Analysis of the mass balance of the kajmak production indicates that it is possible to complete the initial phase of kajmak production with significantly reduced amount of milk. Adversely, energy balance analysis indicates that the reduction in the amount of milk at the same time creates a serious energy deficit. Therefore, one of the central issues of modernization of kajmak production is addressed to the adequate balance of mass and energy.
Key words: *kajmak, surface activity, mass and energy balance, convective and evaporative cooling*

INTRODUCTION

Kajmak is traditional Serbian dairy product usually produced in households and small dairy plants. Kajmak, due to its specific properties, can be (clasified) between cheeses and butter. Characteristics of kajmak show great variation *(Dozet et al., 1996; Pudja et al., 2005b)*. This is mostly caused by variation of milk composition during lactation, type of dairy cows diet, as well as by changeable environmental conditions during kajmak production.
Process of kajmak formation can be divided into two phases: (i) hot and (ii) cold phase. During the hot phase the initial kajmak skin is formed, and it represents kajmak's upper layer. This layer is then, in the cold phase, being enriched with milk fat, and thus the lower layer of kajmak is formed *(Pudja et al., 2004)*.
Parameters influencing formation of upper and lower layer are at phase distance and the natures of their driving forces are completely different. In that respect, their characterization and optimization may be carried out separately. Traditional method of manufacture occupies very long time, and contains numerous steps which make up potential safety and quality risks (*Djerovski et al., 2006).* In order to carry out the industrialization of kajmak production it is necessary to standardize all steps of manufacturing process. This ultimately leads to risk-free product with standard high quality.
Fact that initial skin incorporates less than one-third of milk fat of whole kajmak suggests that its formation can be performed with relatively small amounts of milk (*Puđa et al., 2005a*). As a result of high surface tension, surface-active milk components concentrate at milk-air interface *(Kristensen et al., 1997)*. Formation of initial skin is a result of protein coagulation at milk surface on account of enormous rise of their concentration, whilst the greatest extent of dry matter of initial skin is milk fat.

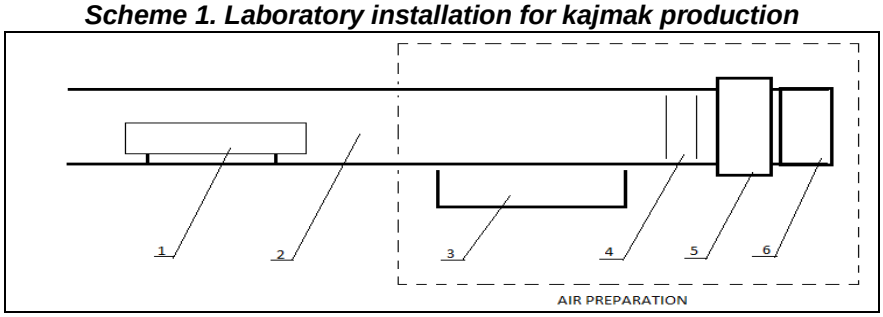
Troughout the formation of kajmak surrounding air remains in contact with milk, and afterward with the initial skin. Temperature and relative humidity are the key factors determining process course and therefore initial skin and kajmak properties (*Pudja et al., 2004*). Function of air is conveying water and energy away from the system. Hence, better defining of mechanism and dynamics of mass and energy conveying during the procces of kajmak formation is one of the central issues of industrialization of kajmak production.
Our objective was to examine mass and energy balance during the formation of initial kajmak skin, by applying different conditions regarding air parameters and amount of used milk.

MATERIAL AND METHODS

Production of initial skin

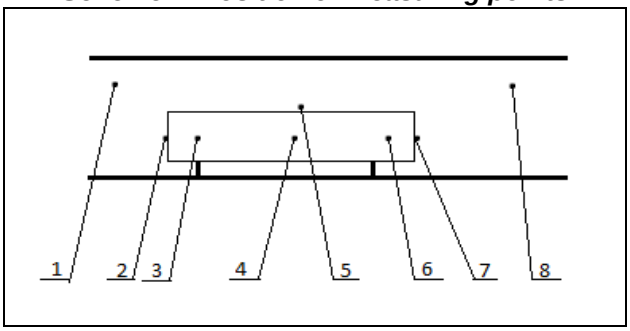
This paper investigates first 60 min of kajmak formation from milk of average composition (4% fat, 3.4% proteins). Raw milk was obtained from Dairy plant „PIK Zemun“, Belgrade. Heat treatment of milk included heating to 95^0C, with detaining holding for 10min at 85^0C and 10min at 95^0C. Following heat treatment, milk was placed under specific conditions and initial skin was being formed. In that purpose, vessels P1 and P2 were used, with indentical base dimensions 0.2x0.43m. Vessel P1(wall height 0.10 m), with milk level of 0.08 m is suitable for simulation of traditional method of kajmak production, while vessel P2 (wall height 0.05 m) with milk level of 0.03 m used suits recommended industrial procedure.
Initial skin formation was examined through experiments A, B and C. Experiment A was conducted using P1, under conditions reflecting those in traditional method of manufacture where milk was subjected to enviromental air. Experiments B and C were conducted in test instalation for kajmak production, with invariable air parameters (30ºC; 70% RH, 0,7 m/s). This instalation consists of 0.2x0.3m tunnel and elements for air preparation (Scheme 1). Experiments B and C were performed in P1 and P2 vessels, respectively. Parameters of inlet and outlet air and milk used were measured at points indicated (Scheme 2). Digital thermometers Peack Tech 5110/5115, Germany, was used to measure temperature of milk and temperature of vessel wall, while air parameters were measured with Kestrel 4000 NK instruments, USA.

Scheme 1. Laboratory installation for kajmak production



1. Vessel; 2. Tunnel; 3. Humidifier; 4. Heater; 5. Cooler; 6. Fan or ventilator

Scheme 2. Position of measuring points



1. T_1, RH_1 – inlet air parameters; 2.,7. T_2, T_7 – vessel wall temperature; 3.,4.,6. T_3, T_4, T_6 – milk temperature; 5. T_5 – temperature of air streaming over milk; 8. T_8, RH_8, V_8 – outlet air parameters.

Milk heat loss, i.e. heat flux caused by evaporation and heat transfer trough vessel walls, was calculated using measured air parameters (*McAdams., 1954; Mills., 1995; Burmeister., 1993; Voronjec and Kozić., 2002.).*

RESULTS AND DISCUSSION

Analysis of mass and energy transfer

During formation of initial skin air flows over the milk surface establishing heat and mass transfer. At interface, milk and air particles have equal temperature, regardless temperatures of steady airflow away from milk and milk at certain depth.

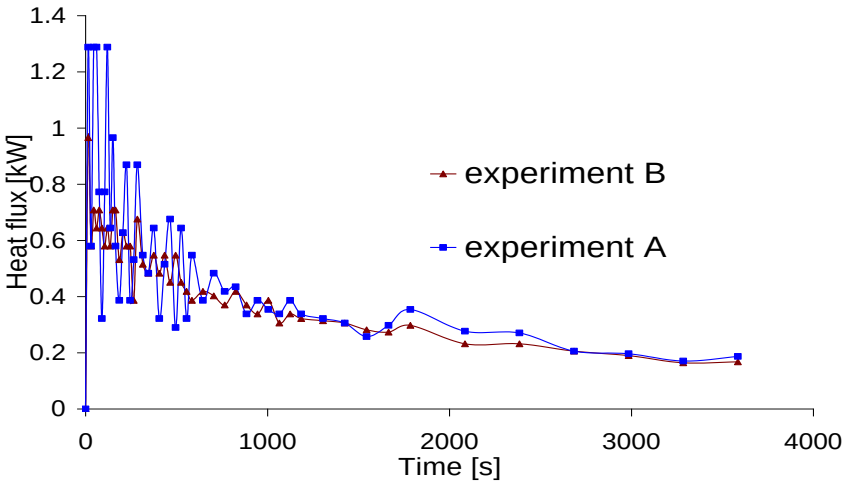
Dalton law states that amount of evaporated water from milk at milk-air interface is equivalent to difference in absolute humidity of interface air and steady flow air. Convective cooling of milk is conditioned by temperature difference of steady flow air and interface air.

At the beginning of process, part of heat flux is transferred to airflow by evaporative milk cooling. Consequently, airflow receives certain amount of vapor and meanwhile airflow temperature is increased owing to convective cooling at interface. Considering the fact that milk vessel is positioned in tunnel where all its sides are in contact with airflow, milk is additionally cooled by heat transfer trough vessel walls. This process of coupled evaporative and convective cooling causes faster milk cooling at interface and in case of small amount of milk resulting in process time decrease.

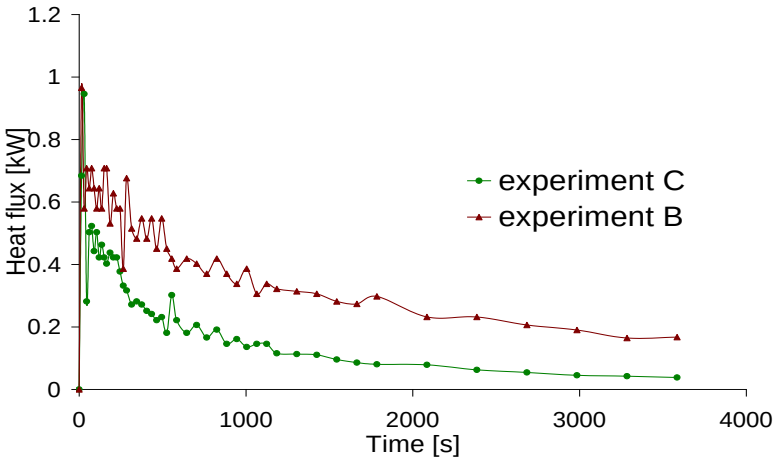
After formation of initial skin, heat flux from milk to air is established in form of heat transfer trough vessel walls and formed initial skin. Heat transfer trough vessel walls is continuous process, but intensity of exchanged heat flux decreases over time due to gradual cooling of milk and decrease of temperature difference between milk and air. In the case of heat transfer trough the initial kajmak skin layer at milk/air interface it can be assumed that convection, both from air and milk side is more dominant than conduction trough the kajmak skin layer. Since the thickness of initial skin in the initial phase is low, this part is negligible, but in later phases, due to accumulation of material it needs to be taken into account when heat balance is analyzed. Water evaporation from milk is present throughout the milk cooling process due to kajmak skin layer porosity and is taking place parallel with heat transfer trough the plate walls and skin layer. Water evaporation into free airflow is continuously present, but amount of vapor decreases over the time as milk temperature and skin porosity reduce.

Mass and energy balance

Data of energy consumption during the first 60 minutes of kajmak production, which was acquired from experiments of traditional kajmak production process with uncontrolled conditions and simulation of innovative procedure of kajmak production in controlled conditions are shown in Figure 1.



a)



b)

Figure 1a. Energy consumption during the initial kajmak skin formation with same amount of milk with uncontrolled (A) and controlled (B) air parameters

Figure 1b. Energy consumption during the initial kajmak skin formation with different amount of milk and constant air parameters

Examining traditional kajmak production gives us that air temperature and relative humidity are dependent of environmental air parameters and room natural ventilation. Calculation of evaporative heat flux in initial stage of traditional kajmak production is impossible due to the fact that vapor at milk/air interface is intercepted and absorbed by large amount of environmental air. This amount of vapor is negligible comparing to the amount of air in the room, thus relative humidity of air in room would not be changed.

Also, the presence of very unstable heat transfer from milk during initial phase of kajmak formation was found. This can be explained with changeable air parameters and local air speed around the vessel in this stage. After the skin is formed, when heat transfer from milk gets generally convective character, energy consumption becomes more stable. Comparing traditional production with simulation of modern kajmak production under the constant environmental conditions (Figure 1a), it can be concluded that energy consumptions in both cases have similar character. Simulation of modern kajmak production is carried out with higher inlet air temperature and with less air compared to amount of air in traditional production. Energy consumption during the kajmak formation in controlled air conditions but with different amount of milk was very similar which can be seen in Figure 3b.

Total heat flux observed in 60 min of milk cooling is very dependent of milk level, i.e. unt of milk used (Table 1). Reduction of milk level from 8 cm to 3 cm resulted in total heat flux decrease of 42%. However, when energy consumption is expressed per kg of milk it can be found that there is a notably higher consumption (5.11 kW/kg) for vessel with lower level of milk (experiment C), comparing to 3.67 kW/kg for vessel with higher level of milk (experiment B). Comparison of experiments A and B, that were performed with identical level of milk, but with different air parameters, demonstrates insignificant difference in energy consumption. This points out that choice of appropriate air parameters can move modern industrial production towards traditional method.

Table 1. Overall heat consumption during the skin layer formation (60 min.)

Experiment	Inlet air temperature [°C]	Inlet air φ [%]	Milk, height of column[m]	Q [kW]
A	15 - 17	43 – 45	0.08	25.15
B	30	70	0.08	22.01
C	30	70	0.03	12.78

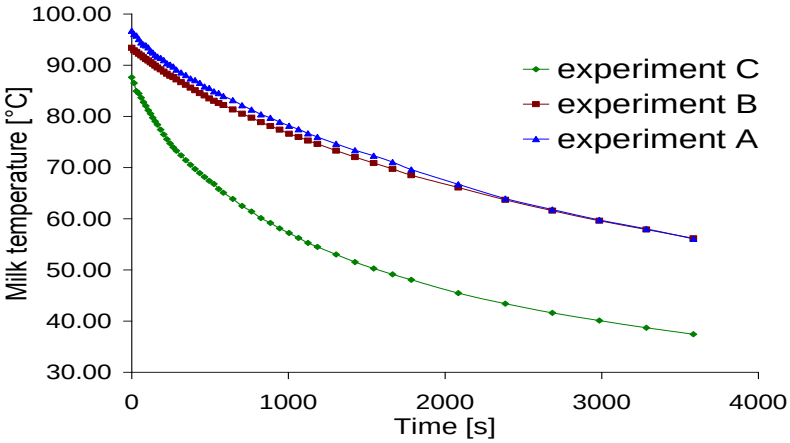


Figure 2.Change of milk temperature during the kajmak skin layer formation (60 min.)

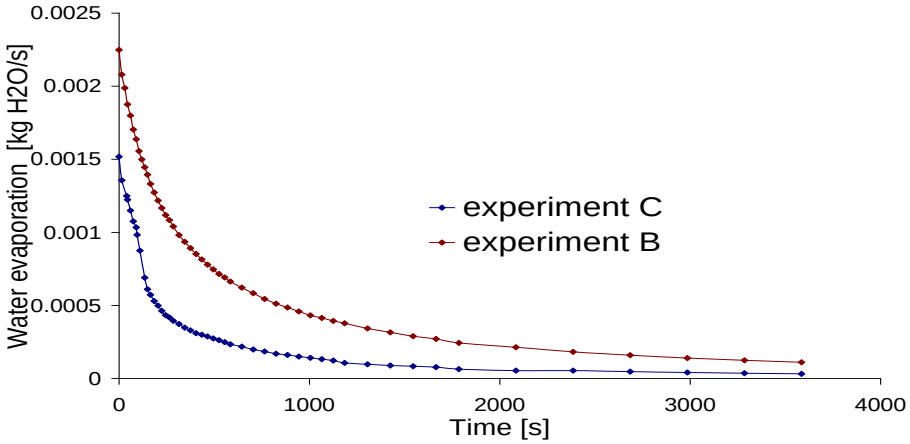

Figure 3. Water loss caused by water evaporation during the skin layer formation (60 min.)

Course of milk temperature change in experiment A is very similar to temperature change in experiment B. Also, milk temperatures in these experiments, are from the moment of establishment of stationary conditions, almost identical.

Formation of the initial kajmak skins in experiments performed with different levels of milk used (B and C) showed that temperature changes were more noticeable in vessel with lower level of milk. This is probably result of faster cooling of lesser amount of milk used (experiment C).

Based on the results showed above, it can be concluded that reducing od milk amount as well as height resulted in energy deficit.

All of this mentioned earlier, leads to conclusion that reducing of milk level results in energy deficit which must be compensated, and thus approach to traditional method of manufacturing.

Comparing traditional production with simulation of modern kajmak production concept under the constant environmental conditions (Figure. 3), it can be concluded that the water evaporation process was very intensive and showed similar character regardless the amount of milk used. In later phase of process, the evaporation was reduced as a result of skin formation and milk cooling process.

Evaporation was stabilized during the final stage of the kajmak skin formation process which was the result of the stable mass transfer through the skin formed.

However, it can be concluded that the amount of water evaporated varied depending on the milk level, i.e. amount of milk used. The loss of water, i.e. amount of 1.51 and 0.57 kg in experiment B and C, respectively, was found despite the same surface and environmental conditions. Difference found in quantity of evaporated water was a consequence of lower heat capacity of milk used.

CONCLUSIONS

Analysis of the mass balance of the kajmak production indicates that it is possible to complete the initial phase of kajmak production with significantly reduced amount of milk.
Similar changes of heat flux during the traditional kajmak production and modern procedure performed with same milk level but different environmental conditions was found.
Lowering the milk level leaded to serioius energy deficit which furthermore contributed to faster cooling of milk and lesser intensity of evaporation. Theese results indicate that it is necessary to compensate mass and energy deficit.

ABSTRACT: The goal of this paper was to determine the proximate composition and sensory characteristics during storage of Sremska sausage produced in a traditional way in the smoking house, from the meat of commercial 7-month-old Swedish Landrace pigs. Sausages were produced in December; the muscle-fat ratio was 75:25, with the addition of 2.2% nitrite curing salt and spices. After filling in pig small intestine, the sausages were hung to dry with the temperature ranging between 10–15^{0}C and relative humidity between 75–90%. They were then occasionally smoked during the first 14 days. Sampling and chemical analyses were carried out on 0, 3rd, 7th, 14th and 21st day of production. Sensory evaluation was performed at the end of the production process (first day) and during storage, on 60th and 120th day. The sausage was characterized by a long ripening period, which is considered typical for the traditional production method. The minimum pH (4.97) was reached on 14th day, then it increased slightly to 5.18 (21st day). The values of acidity and peroxide number of the fat increased at the end of the production process. During the ripening, water content significantly decreased (from 58.13% at beginning to 30.21% at the end), that resulted in large weight loss of 41%, while the proportion of fat, protein and ash significantly increased. At the end, final product had distinctive spicy flavor, dark red color and firm consistency. During storage, overall sensory quality has slightly reduced, but sensory scores were still high for this type of product.
Key words: *Sremska sausage, traditional smoking house, proximate composition, sensory characteristics*

INTRODUCTION

Majority of fermented sausages are produced in Italy, Germany and Spain (Di Cagno et al., 2008), but almost every European country has at least several country specific products belonging to this group (Casaburi et al., 2007). Sremska sausage is typical representative of fermented sausages of small diameter in Serbia, and it is traditionally produced in households or small manufacturing facilities in the region of Vojvodina (North Serbia). In households, traditionally, during winter time, Sremska sausage is produced from pig meat, with the addition of salt and spices. Stuffing obtained in this way is often filled using manual stuffer into pig intestines which are then formed into pairs 20-25 cm long. Sausages are hung on wooden sticks, drained, and transferred to smoking room where they are smoked using so called cold procedure for 6 to 7 days, often even longer. After smoking process, comes drying which usually lasts about 2 weeks (Tojagić, 1996). In said conditions, maturation is finished by the end of the third week, when Sremska sausage acquired all typical sensory and physical-chemical properties. Said composition and production conditions (animals fed in households with various food, smoking of sausages in conventional smoke rooms, air drying) are some of the factors of the specificity of the sausages produced in this manner, and give them advantage in regard to sensory traits, compared to sausages produced in industrial conditions where climate chambers are used (Karan et al., 2009).
Currently, there is a much higher market share for the sausages produced with starter cultures and in controlled climatic conditions than the naturally fermented sausages. However, there is a strong demand for the naturally fermented sausages by consumers. In

this regard, objective of this paper was to determine changes in chemical composition during production and of sensory properties during storage of Sremska sausage produced in traditional smoking house.

MATERIAL AND METHODS

The sausages were produced during December in small processing plant of the Institute for Animal Husbandry (Belgrade, Serbia). In production of sausage meat originating from pigs of Swedish Landrace of average age of 7 months, was used. Main raw materials used for production of Sremska sausage were meat of leg and shoulder and back fat in ratio 75:25. Meat and fat tissue were previously frozen at the temperature -18^{o}C, and then chopped using the cutter machine (Seydelman K60) until granulation of around 8 mm was achieved. Following additives were used: 2.2% nitrite salt, 0.3% sugar (glucose), 0.8% hot ground peppers, 0.5% sweet ground peppers, 0.15% onion (powder) and 0.15% black pepper (ground). Stuffing was filled into pig small intestine, diameter 32 mm. After filling, sausages were hung in the traditional smoke room, without any possibility of temperature and humidity control, where temperature ranged from 10 to 15^{o}C and humidity from 75 to 90%. Sausages were occasionally smoked during first 14 days. Whole process of production lasted 21 days, after which time sausages were vacuum packaged and stored at 4^{o}C. Samples used in our study were taken on 0 (mix before stuffing), 3rd, 7th, 14th and 21st day of production and on 60th and 120th day of storing.

During the production process the following was monitored: weight loss, by measuring 12 individual sausages on a scale (Chyo MK-2000B), accuracy of 0.1 g; pH value, measured using pH-meter with glass electrode Hanna, HI 83141 (Hanna Instruments, USA); the values of acidity and peroxide of the fat were determined, following the Serbian Official Standards SRPS ISO 660 2000 and SRPS ISO 3960 2001, respectively, after extraction of the fat, following the method of Folch et al. (1957); main chemical composition: quantity of water by drying of samples at temperature of 105^{o}C to a constant mass, quantity of fat by method of extraction according to Soxlet (with petrol-ether as solvent), quantity of proteins using method according to Kjeldahl and quantity of mineral matters (ashes) by burning of samples at temperature of 550-600^{o}C to a constant mass (AOAC, 1990).

Sensory analysis of sausages was done by seven semi-trained evaluators at the end of production process (first day) and after 60 and 120 days of storage. For sensory evaluation numeric-descriptive scales with 5 point system were used (from 1-exceptionally unacceptable to 5-exceptionally acceptable). Following meat attributes were determined/scored: appearance, colour, texture, odor and taste.

For statistical analyses of changes in proximate composition during production process the ANOVA procedure of Statistica 7 software (StatSoft, USA) was performed. If the main effect was found significant, Tukey's test was used to evaluate the significance of difference at $p<0.05$.

RESULTS AND DISCUSSION

The drop of pH value in traditional dry sausages is slight and fermentation is long because of low temperatures (Stajić et al., 2011). pH values are result of the influence of multiple factors, the most important are the amount and type of added sugars, type of muscle tissue and composition of stuffing, as well as present microflora (Hiero et al., 1997). Changes in pH values of Sremska sausages during ripening are given in Figure 1. During the first two weeks of ripening, the pH value decreased from 5.88 to about 4.97, possibly due to production of organic acids by microorganisms, basically production of lactic acid (Lücke, 1994). After that, it increased slightly to about 5.18 in the last 7 days of ripening, probably as a consequence of proteolytic changes. These results were in agreement with literature data for similar fermented products (Salgado et al., 2005; Kozačinski et al., 2008; Stajić et al., 2011).

Processing conditions can influence the rate of acid production and also the change of pH value in products (Salgado et al., 2005). In the research of the changes occurring during ripening of Sremska sausage in climate chamber, Živković et al. (2012) stated that the minimum pH value was reached on day seven of the production process, afterwards a slight increase was registered, to reach the value of 5.17 at the end of production process (14th day).

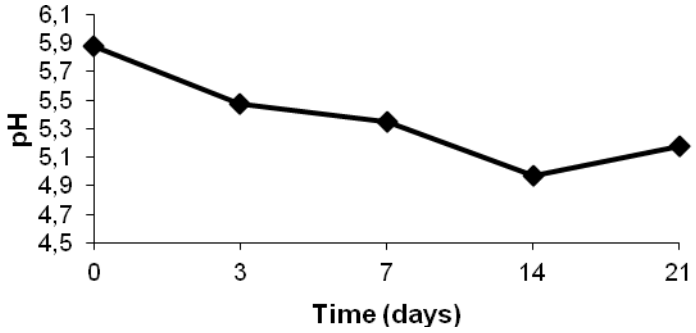

Figure 1. Changes in pH value during production

Dry fermented sausages are characterized by significant water loss during production process, whose intensity depends on the duration of drying, air temperature and humidity (Lücke, 1994). Figure 2. shows the weight loss during production of Sremska sausage. The most intensive loss occurred between day 3 and 7 of production. After one week, the weight loss was 25.25%, and at the end of the production process 44.05% (21st day).

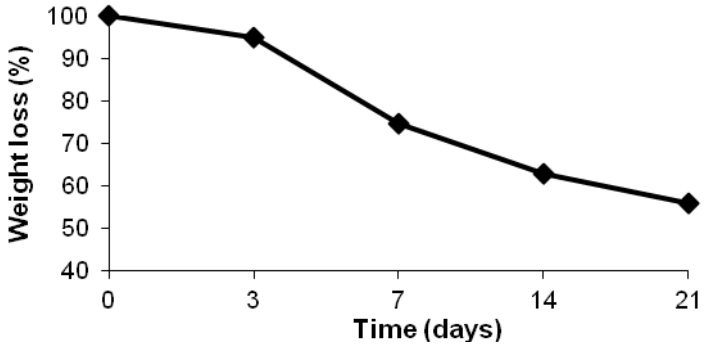

Figure 2. Weight losses of Sremska sausage during production (%)

The acidity of the fat increased during the ripening of Sremska sausage (Fig. 3). The acid number increased slightly in the first seven days of ripening and, afterwards, more rapidly until the end of ripening. Increase of the acid number during ripening of fermented sausages was recorded by other authors, however, our final value at 21st day (8.11 mg KOH/g fat) are much higher than those described by (Roncalés et al., 1991; Salgado et al., 2005).
The intensity with which lipolysis is developed during ripening varies considerably between different varieties of fermented sausages as a function of the different manufacturing procedures and the raw material used (Lois et al., 1987; Domínguez Fernández and Zumalacárregui Rodríguez, 1991). The peroxide number increase constantly during the production process (Fig. 3) and similar results have been reported by Ferrer and Arboix (1986). On the other hand, Nagy et al. (1989) found that the peroxide number of Hungarian Salami decreased in the first 10 days of ripening. The final peroxide number of the fat from Sremska sausage in this trail was 9.08 meq O_2/kg fat, which is in accordance with values stated by Salgado et al. (2005) for *Chorizo de cebolla*, a Spanish traditional sausage.

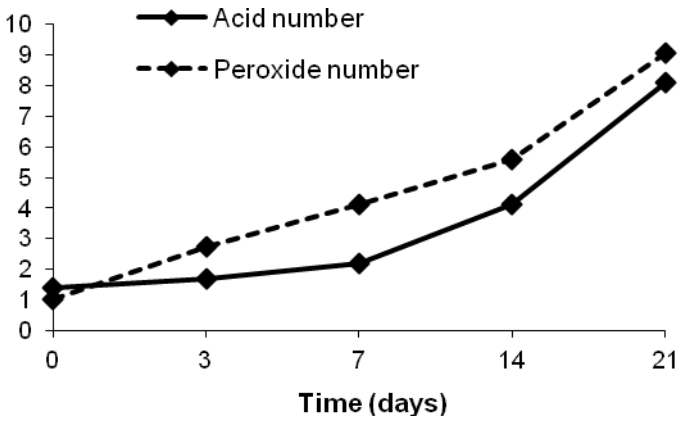

Figure 3. Changes in the fat acid number (mg KOH/g fat) and peroxide number (meq O_2/kg fat) during ripening

Changes of main chemical parameters of Sremska sausage during ripening are characterized by known tendency of increase of dry matter content (Živković et al., .2011). The proximate composition of Sremska sausage during the ripening is shown in Table 1. As a consequence of drying, at the end of ripening, sausages were characterized by a high fat content (36.42%) and low moisture content (30.21%). Ash and protein content also significantly increased during the production process, which is typical for dry fermented products (Kozačinski et al., 2008).

Table 1. Changes in proximate composition (%) of the Sremska sausage during ripening (mean ± standard deviation)

Day	Moisture	Lipid	Protein	Ash
0	58.13 ± 1.81[a]	21.23 ± 0.56[a]	17.73 ± 1.12[a]	2.85 ± 0.10[a]
3rd	56.93 ± 2.43[b]	21.69 ± 1.38[a]	18.37 ± 0.76[a]	3.04 ± 0.06[a]
7th	49.22 ± 1.06[c]	24.50 ± 0.82[b]	21.79 ± 0.93[b]	4.41 ± 0.12[b]

21st	30.21 ± 0.95[e]	36.42 ± 2.09[d]	27.79 ± 1.14[d]	5.67 ± 0.18[c]

[a,b,c,d,e] Mean values in the same column with the different superscripts differ significantly ($p<0.05$)

Sensory characteristics of fermented sausages are related to breakdown products of lipids which, in turn, transform to flavour compounds during ripening and they are influenced by the quality and type of raw material, smoking, fermentation rate and time, and the rate and extent of drying (Berdagué et al., 1993; Johansson et al., 1994). Sensory evaluation of sausages at the end of production process (first day) and after 60 and 120 days of storage are presented in Figure 4. At the end of production process, final product had distinctive spicy flavor, dark red color and firm consistency.

The overall sensory quality of the sausages reduced during storage, especially in sensory scores for texture and smell, but these scores do not indicate that the product is unacceptable and they were still high (greater than 4.1). On the first and the 60th day from the production, the color was evaluated with 4.5 and after 120 days, color was evaluated with 4.3. Less average evaluation for the color was due to changes in the color after cutting (appearance of the grayish color).

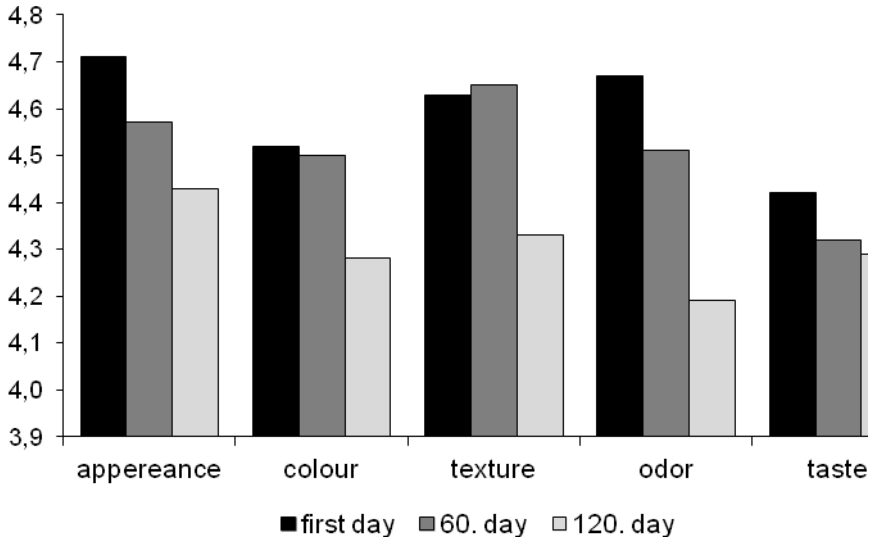

Figure 4. Sensory evaluation of Sremska sausage

CONCLUSIONS

The sausages were characterized by a long ripening period of 21 day, which is considered typical for the production in traditional smoking house. The minimum pH (4.97) was reached on 14th day, then it increased slightly to 5.18 (21st day). The values of acidity and peroxide number of the fat increased during the production process. As a consequence of drying and large weight loss, at the end of ripening, sausages were characterized by a low moisture content and high fat, protein and ash content. At the end, final product had distinctive spicy flavor, dark red color and firm consistency. During storage, overall sensory quality has slightly reduced, but sensory scores were still high for this type of product.

ABSTRACT:“Meat from tiblica” produced in a household and stored in controlled conditions (8°C) was sampled and examined once a month during the period of nine months. Microbial population in meat and chopped back fat during storage consisted of aerobic mesophilic bacteria, lipolytic bacteria, yeasts and molds, coagulase-negative cocci and lactic acid bacteria, without the presence of pathogens. Due to specific production (smoking and baking of meat after brining), the meat contained a lower microbial count in comparison to chopped back fat for 1 to 3 log, despite the lower a_w. Physico–chemical parameters indicate to growth of proteolytic and lipolytic activity of determined microbial groups, but not to spoilage. The grades of sensory traits of the product were rising until the seventh month of storage and even after the last month of storage, the grade was higher in comparison to the first month of storage. The results are in favor of the fact that “meat from tiblica” is a safe product of high quality.
Keywords: *“meat from tiblica”, microflora, safety, quality*

INTRODUCTION

Traditional products are characterized by specific features which are the result of production procedures and the climate conditions. The question of producing safe regional specialties outside the industry and craft, in family farms, catering and rural household is always actual in practice (Kozačinski et al., 2008). “Meat from tiblica” is a traditional product of special value and quality and it is a constituent part of cultural heritage of the area of Međimurje, North Croatia. Quality and health safety of the product depends on many factors – from quality of raw material, through technological process of production, to microbiological and chemical changes during storage.

MATERIAL AND METHODS

“Meat from tiblica” was produced in a household according to the procedure described in Figure 1. The product was stored at 8°C in controlled conditions during the period of nine months, and it was sampled and analyzed once a month.
Aerobic mesophilic bacteria, lactic acid bacteria (LAB), coagulase-negative cocci, *S. aureus*, *E. coli,* yeasts and molds, lipolytic bacteria, sulphite-reducing clostridia, enterococci *Salmonella* spp. and *L. monocytogenes* were isolated and identified in microbiological analyses of the product during storage. Standard culture-based microbiological methods were used for isolation and determination of listed microorganisms, while determination was conducted by the API system (BioMerieux, France).
Physico-chemical analyses included a determination of water activity (a_w meter, Rotronic, Switzerland), pH value (pH meter, WTW, Germany) and ammonia in meat (microdiffusion procedure by Schmidt, Živković, 1986), as well as titratable acidity (EN ISO 660:2009) and peroxide number of chopped back fat. The fatty-acid composition of the product was determined by gas chromatography. Samples were prepared according to the norm HRN EN ISO 5509:2004 and analyzed according to HRN EN ISO 5508:1999. GC analysis was

performed on CP-3800 (Varian, Palo Alto, USA) by split/splitless injector and a flame ionization detector. Capillary column DB 225ms 30m x 0.25mm was used, with 0.25 μm film thickness and a temperature program which was rising from 60°C, 4°C/min until it reached the temperature of 210°C which was maintained for 15 minutes. Helium was used as a carrier gas (mobile phase) at a flow rate of 1mL/min. The injector temperature was 250°C and sample split ratio was 1:30, whereas a flame ionization detector temperature was 250°C. Samples were injected manually (0.1 μL).
Five evaluators participated in the sensory evaluation of "meat from tiblica". Each sensory indicator was evaluated according to a scoring system 1 to 5. Sensory analysis of a finished product was conducted according to a shortened protocol by Cocolin et al. (2005) which included the grade for color, odor and consistency of meat and chopped back fat, as well as the grade for cross-section appearance and taste of meat.

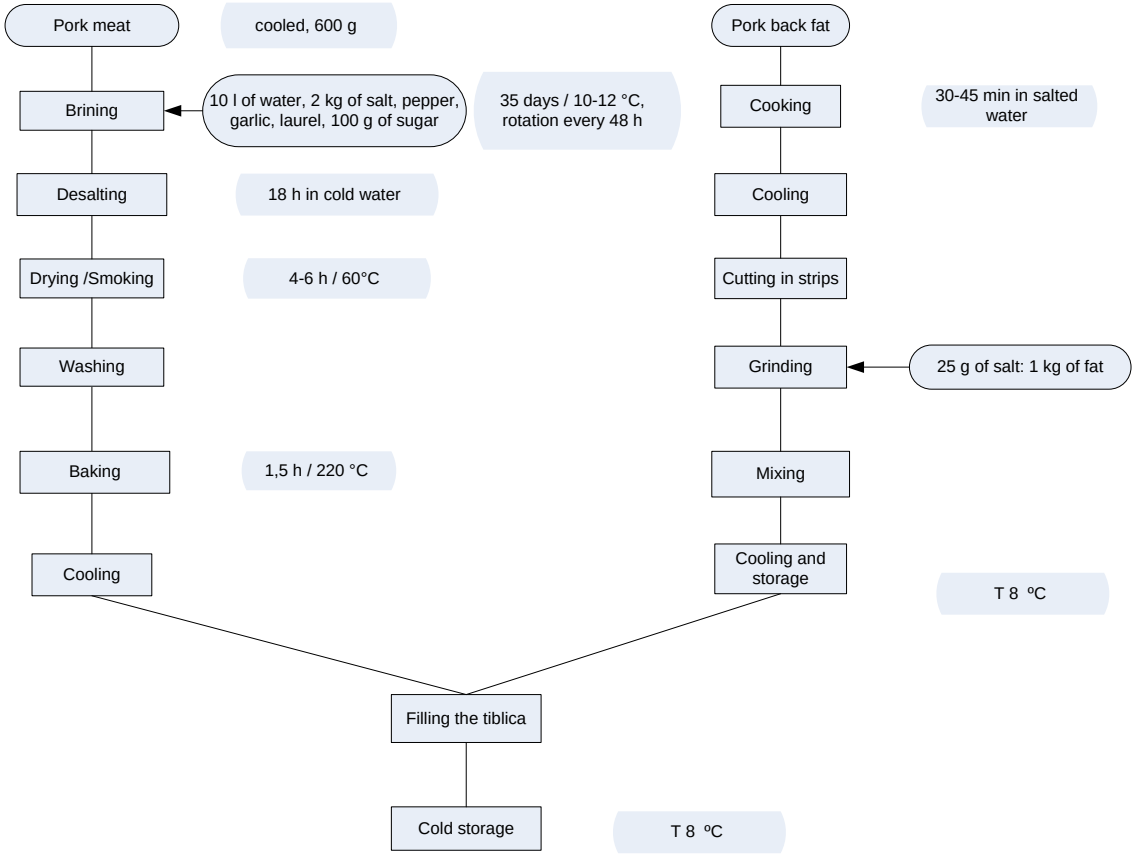

Figure 1. Procedure of "meat from tiblica" production

RESULTS AND DISCUSSION

Results of monitoring of selected microorganisms in "meat from tiblica" are presented in Table 1. Compared to initial number, after 9 months of storage we find slight decrease of coagulase-negative cocci and aerobic mesophilic count (0.4-0.5 logs) and significant increase of lipolitic bacteria and yeast/moulds (1 and 1.3 logs, respectively). After nine months of storage, In product's chopped back fat, the number of yeasts and molds, aerobic mesophilic bacteria, lipolytic bacteria and coagulase-negative cocci were within a narrow range from 5.15 to 5.62 $\log_{10}$ CFU/g. The LAB number was lower during storage in meat (2-3 $\log_{10}$ CFU/g) than in chopped back fat (4-5 $\log_{10}$ CFU/g). It is important to emphasize that LAB were found in the meat after second month of storage even though the meat was baked, so it can be presumed that they were growing up to a certain point in meat too, as a result of an interaction of meat with chopped back fat. Our finding confirms the results of other authors who proved that *Micrococcaceae,* LAB, then yeasts and molds have a significant

part in maturating process of meat products (Samelis et al., 1998, Lücke, 2000, Zdolec, 2007, Zdolec et al., 2007, Martín et al., 2008). LAB were not a dominant population in our product as it is the case in fermentation of sausages, but we can assume that they do affect sensory characteristics of a finished product, along with other factors of maturating and storage.

Bacteria *Salmonella* spp. and *L. monocytogenes,* then enterobacteria, sulphite-reducing clostridia, enterococci, *E. coli* and *S. aureus* were not determined (or they were below the limit of detection) in any sample of meat and chopped back fat during storage of "meat from tiblica", which is important to be emphasized regarding product's safety.

The pH value of meat was decreasing mildly and continuously until the sixth month of storage (0.4 units) and then slightly increased to final value of 6.22 (Table 2.). The similar pH trend was determined in chopped back fat (Table 2.). The a_w results in meat samples show that values remained at the approximately same level during storage, whereas they were growing in chopped back fat, (Table 2.). The ammonia content in the meat was growing continuously during storage (Table 2.). Peroxide number and titratable acidity in chopped back fat were also growing continuously (Table 3.). If we interpreted the results according to Živković (1986), who listed that sensory flawless fat should have titratable acidity lower than 2 and peroxide number lower than 3, the sample would not be considered sensory flawless in the last month of storage because its titratable acidity was 4.11. But, fat and chopped back fat are not equal products; fat is obtained by melting (high temperatures), and chopped back fat by cooking and then mincing back fat tissue.

Total impression	**4.28**	**4.4**	**4.63**	**4.59**	**4.63**	**4.74**	**4.81**	**4.75**	**4.73**

We determined an increase in the concentration of SFA in the product, and a decrease in MUFA and PUFA concentrations during storage (Table 5.). The same trend has been shown by the results of fatty acid composition of different kinds of cooled or frozen meat (Kesava and Kowale, 1993; Lee et al., 1994; Hernandez et al., 1999; Nürnberg et al., 2006; Alvarez et al., 2009; Mahecha et al., 2009; Sučić, 2010). Oleic, palmitic, stearic and linoleic acids were the most frequently presented fatty acids in meat and chopped back fat in our research, which is in accordance with the results of Njari (1986) and Valsta et al. (2005). A favorable PUFA/SFA ratio has also been confirmed (Wood et al., 2003).

The samples in our research were stored in controlled conditions at 8°C. Such storage is in accordance with the recommendation of Renčelj (1997) and Kolakowska et al. (2003) that the appearance of an unpleasant aroma and oxidation can be prevented or slowed down by using dark or non-transparent packaging and cold storage. The samples of the finished product met the requirements for sensory characteristics of "meat from tiblica" listed by Renčelj (1997). The meat got softer and juicier with the duration of the storage, so the grades for sensory characteristics were consequently increasing until the seventh month of storage. Particularly good grades were given to characteristics of odor and taste, then meat consistency. When the storage was completed, the total grade for meat and chopped back fat was 4.74, which is higher for 0.43 than after the first month of storage (Table 4.). A full,

mature (more aromatic) taste achieved and kept by our product until the end of storage, as well as softer meat, can be attributed to interaction, i.e. changes, of muscle and fatty tissue, the same as with Renčelj (1997).

CONCLUSIONS

Characteristcs of „meat from tiblica", especially gustatory quality, depend on the interaction of meat and chopped back fat during storage of product. The product received high grades for sensory characteristics during nine months of storage and met the demands in terms of microbiological quality and safety of meat products. Microbial population consisted of aerobic mesophilic and lipolytic bacteria, yeasts and molds, coagulase-negative cocci, and LAB to a lesser extent, without the presence of pathogens. Physico-chemical changes of product during storage indicate to a growing lipolytic and proteolytic enzyme activity in determined groups of microorganisms and probably tissue enzymes, which possibly contributed to sensorial quality of "meat from tiblica". The product was sustainable during nine months at 8°C.

ABSTRACT: The excessive intake of sodium (Na) has been linked to hypertension and consequently to the increased risk of stroke and premature death from cardiovascular diseases. The reduction of added NaCl in fermented meat products has been proposed in order to decrease the amount of sodium in the diet. The effect of partial replacement of NaCl by KCl and glycine to physicochemical, microbiological and sensory characteristics of homemade Slavonian sausages was analyzed. According to the results, the partial substitution of NaCl by KCl and glycine had no effect on basic composition, pH, a_w, color coordinates and texture of the fermented sausage. The reduction of NaCl slightly increased the number of *Enterobacteriaceae* and *Staphylococcus aureus*, but all samples were still microbiologically safe, according to the EU legislation. According to the sensory scoring test the highest rated sausage was the one containing 1% NaCl, 0.9% KCl and 0.1% glycine, the second rated was the control sausage with 2% NaCl and the third one was the sausage with 1% NaCl and 1% KCl. According to these results, it is possible to achieve the reduction of 50% of NaCl in homemade Slavonian sausages by replacing it with KCl (substitution level between 30 and 50%), and glycine (substitution level between 10 and 20%) while still maintaining traditionally desirable sensory properties.
Key words: *homemade Slavonian sausage, lowering level of NaCl, partially replacing NaCl, the effect on physicochemical, microbiological and sensory characteristics*

INTRODUCTION

Reduction of NaCl content became important measure in improvement of health, because eexcessive intake of sodium (Na) has been linked to hypertension and consequently to the increased risk of stroke and premature death from cardiovascular diseases. The main source of sodium (Na) in the diet is sodium chloride (NaCl) (Ruusunen & Puolanne, 2005). Meat and meat products contribute 20.5% to the sodium intake in Ireland, 20.8% to the sodium intake in UK, and 21.0% to the sodium intake in USA (Desmond, 2006). Salt (sodium chloride, NaCl) is an essential ingredient in dry fermented sausages, and therefore they are one of the biggest sources of dietary NaCl from meat products (3.3 – 4.8 g/100g final product). NaCl in these products contributes to water-holding capacity, fat binding, color, flavor and texture. Salt also plays an important role in ensuring the microbial stability of dry fermented sausages (Gelabert, Gou, Guerrero, & Arnau, 2003; Zanardi, Ghidini, Conter, & Ianieri, 2010). In October 2003 the FSA announced a “salt model” in order for the UK food industry to reduce the amount of salt in food products. In August 2005 the FSA proposed new target (g/100 g) which was supposed to be achieved by 2010 suggesting a maximum of 1.4 g of salt/550 mg of sodium for sausages (Desmond, 2006; Food Standard Agency [FSA], 2006).
Apart from lowering the level of salt added to the products, there are currently three major approaches to reduce the salt content in processed foods: the use of salt substitutes (KCl,

phosphates, potassium lactate, glycine, calcium ascorbate, calcium chloride); the use of flavor enhancers and masking agents; the optimization of the physical form of salt (Desmond, 2006). Most authors studied the effect of partial replacement of sodium chloride by KCl, potassium lactate (K-lactate), glycine, calcium ascorbate, calcium chloride (Gou, Guerrero, Gelabert, & Arnau, 1996; Gimeno, Astiasaran, & Bello, 1998; Gimeno, Astiasaran, & Bello, 1999; Gimeno, Astiasarán, & Bello, 2001; Ibanez et al., 1995; Gelabert et al., 2003; Guardia, Guerrero, Gelabert, Gou, & Arnau, 2006; Guardia, Guerrero, Gelabert, Gou, & Arnau, 2008). A salt substitution level of 40% by KCl (Gelabert et al., 2003; Askar, Elsamahy, Shehata, & Tawfik, 1993; Gou et al., 1996), and of 30% with K-lactate and 20% with glycine affects unfavorable flavor and textural changes (Gelabert et al., 2003). Microbial stability of sausages produced by partial substitution of NaCl by KCl, K-lactate and glycine was slightly reduced (Gelabert et al., 2003).

There is no accurate data on sodium intake from meat products in Croatia and no research article on reducing salt in the Croatian autochthonous meat products has been published yet. Therefore, the aim of this research was to explore possibility of partially replacing NaCl with KCl and glycine in the homemade Slavonian sausages, in accordance to microbiological, physicochemical and sensory characteristics and consumer's preference.

MATERIALS AND METHODS

Sausage preparation

A homemade Slavonian sausage is a type of smoked, fermented and dried-ripened sausage produced in Slavonia (Eastern region of Croatia), made from pig meat of 12 months old crossbreed between Swedish Landrace and Large White, raised on the family farm and slaughtered in a commercial slaughterhouse. Pig carcasses were transported to a small scale facility in Eastern Croatia where the sausages were produced.

The meat from the third quality parts of the pig such as pork belly and *cca.* 20% of the second quality parts, such as pork shoulder, was cut into stripes 30 cm long, 10 cm wide and 3 cm thick and placed in a freezer until the temperature of the meat reaches -2 to -5 °C. The meat is than grinded through a grinding plate with holes of 7 mm in diameter. Six different batches of homemade Slavonian sausages, (control batch with traditional formulation - 2.0% of NaCl) and five batches with the partial substitution of NaCl by KCl and glycine (Table 1) were manufactured. All six batches (5 sausage samples of each batch) were made with a standard formulation for homemade Slavonian sausage: raw pork of third and second quality (96.8%), garlic (0.2%), red hot paprika powder (0.4%) and sweat paprika powder (0.6%) with variable NaCl, KCl and glycine content (Table 1).

Table 1 Percentage of reduction and molar substitution of NaCl by KCl and glycine

	Control sample	$SB_{50;50}$	$SB_{60;40}$	$SB_{70;30}$	$SB_{50;40;10}$	$SB_{50;30;20}$
NaCl	100	50	60	70	50	50
KCl	-	50	40	30	40	30
Glycine	-	-	-	-	10	20

Control sample: 20 g NaCl/kg product.
SB – sausage batch

The mix was stuffed into natural casing (pig's thin intestine (lat. *intestinum tenue*)) and the resulting sausages were smoked with dry hard wood every second day for two weeks. The temperature and relative humidity at this stage were about 18 to 20 ºC and 70 to 90% respectively. After smoking, the

Slavonian homemade sausages were left for the ripening process in a dark room with the temperature from about 14 to 17 ºC and relative humidity 70 to 80% for 45 days. The sausages were made in a non-industrial environment, characterized by a small-scale batch production with a limited degree of mechanization, using traditional techniques and strongly defined by the climate and region of origin. Once collected, the samples were placed in a

portable cooler and transported to the laboratory within one hour, and then stored in a refrigerator (below 4°C) up to maximum 24 h before analysis.

Physicochemical parameters

Before physicochemical analysis sausage samples were tripartite and, after removing the outer casing from each sausage, the edible part was ground until a homogenous mass was obtained.

The FoodScan Meat Analyser was used to determine moisture, total protein, total fat and collagen according to the Association of Official Analytical Chemists method (AOAC, 2007. 04.)

pH values were determined in a homogenate of the sample with distilled water (1:10, p/v) using pH/Ion 510 – Bench pH/Ion/mV Meter (Eutech Instruments Pte Ltd/ Oakton Instruments, USA), according to the ISO 2917:1999 Method (ISO, 1999) and pH/Ion 510 Instruction Manual.

Salt content (sodium chloride (NaCl)) was determined according to the ISO 1841:1970 Method (ISO, 1970).

Water activity (a_w) was determined using a Rotronic Hygrolab 3 (Rotronic AG, Bassersdorf, Switzerland) at room temperature (20 ± 2 ºC).

Five sausage sample of each batch were analyzed. Three determinations for each parameter were measured in each sample. Results shown in the Table 3 are the means of the five sausage samples.

Determination of color

Samples for instrumental color measurement were cut in 1 cm thick slices after removing the outer casing. Color measurements (L*, a*, and b* values) were taken using a Hunter-Lab Mini ScanXE (A60-1010-615 Model Colorimeter, Hunter-Lab, Reston, VA, USA). The instrument was standardized each time with a white and black ceramic plate (L_0 = 93.01, a_0 = -1.11, and b_0 = 1.30). The Hunter L*, a*, and b* values respectively correspond the lightness, greenness (-a*) or redness (+a*), and blueness (-b*) or yellowness (+b*). The color measurements were performed on homemade Slavonian sausage at room temperature (20 ± 2 ºC). Five sausage sample of each batch were analyzed. The color of each sample was measured ten times. Results shown in the Table 4 are the means of the five sausage samples.

Texture profile analysis

A Universal TA-XT2i texture analyzer was used to conduct texture profile analysis (Bourne, 1978). Samples for texture analysis (TPA) were cut in 1×1×1 cm cubic samples after removing the outer casing. Five sausage sample of each batch were analyzed. Ten cubic samples 1×1×1 cm of each sausage sample were compressed twice to 60% of their original height with a compression platen of 75 mm in diameter. Textural analyses were performed at ambient temperature. Force-time deformation curves were recorded at a crosshead speed of 5 mm/s and recording speed also 5 mm/s. Hardness, springiness, cohesiveness, gumminess and chewiness were evaluated. These parameters were obtained using the Texture Expert for Windows (version 1.0) Stable Micro Systems. Results shown in the Table 5 are the means of the five sausage samples.

Sensory analysis

Scoring test

A group of 5 selected and trained sensory panelists (ASTM, 1981; ISO 8586-1, 1993 and ISO 8586-2, 1994) evaluated the sensory characteristics of the sausages studied. Appearance, texture, taste, color and odor were assessed using the scoring test in which samples were given scores from 1 (very poor) to 5 (excellent). The overall sensory quality takes into account all factors of sensory quality that need to be evaluated by sensory panelists, was calculated according to the following formula: overall sensory quality = (appearance × 2) + (texture × 6) + (taste × 8) + (color × 2) + (odor × 2). This formula is based

on the relative importance of the different sensory characteristics which were calculated according to the opinion of 5 experts asked to assess, in an organized open discussion, those different sensory characteristics for this specific experiment.

Microbiological analysis

Microbiological analyses were performed on the 5 samples of each type of sausage. Classical microbiological methods were used for isolation and identification of the microbial population. *Salmonella* was analyzed by Method ISO 6579 (ISO, 2003a); *Enterobacteriaceae* by Method ISO 5552 (ISO, 1997); *Staphylococcus aureus* by Method ISO 6888-1 (ISO 1999); *Sulphite-reducing Clostridia* by Method 15213 (ISO, 2003b) and *Listeria monocytogenes* by Method ISO 11290-1/A1 (ISO, 2004).

Data analysis

Differences among the average values of the same physicochemical, color and texture parameters between sausage batches with different NaCl content were analyzed through the analysis of variance (ANOVA). Differences between scores for sensory parameters between sausage batches were also analyzed through the analysis of variance (ANOVA) and Fisher's least significant difference test (LSD), with significance defined at $P<0.05$. For determination which sausage samples differ one from another according to mean score values for every sensory parameter and overall sensory quality, Friedman's nonparametric ANOVA was used. Moisture content, fat content, protein content, collagen content, NaCl content, pH, $a_{w,}$ color parameters, textural parameters and sensory characteristics were subjected to correlation analysis (multivariate method) to determine the possible statistical relationships between them. Statistical analysis was carried out Statistica ver. 7.0 StatSoft Inc. Tulsa, OK. USA.

RESULTS AND DISCUSSION

Table 2 shows basic composition, pH and a_w of 6 different batches of homemade Slavonian sausage and raw meat used for sausages preparation. All sausage mixtures were prepared from the same raw meat mixture and the only difference between batch formulations was the NaCl, KCl and glycine content. Initial values of pH, a_w and moisture content were very similar for all batches (almost the same as in raw meat).

Table 2 Basic composition, pH, a_w and microbiology of 6 different batches of homemade Slavonian sausage and raw meat

Parameter	Control sample	$SB_{50;50}$	$SB_{60;40}$	$SB_{70;30}$	$SB_{50;40;10}$	$SB_{50;30;20}$	Raw meat
Moisture (%)	32.23^{a}	31.05^{b}	28.85^{d}	28.48^{d}	29.50^{c}	28.76^{d}	72.97
Protein (%)	31.79^{e}	33.24^{c}	33.87^{b}	32.91^{d}	33.97^{b}	37.17^{a}	21.59
Fat (%)	26.18^{e}	27.12^{d}	27.45^{c}	28.93^{b}	29.10^{a}	28.96^{b}	4.96
Collagen (%)	4.32^{bc}	4.84^{abc}	4.90^{abc}	3.94^{c}	5.06^{ab}	5.41^{a}	1.31
NaCl (%)	3.86^{a}	1.94^{d}	2.01^{c}	2.68^{b}	1.89^{e}	1.95^{d}	0.11
a_w	0.89^{a}	0.88^{a}	0.86^{c}	0.85^{d}	0.87^{b}	0.86^{c}	1.00
pH	5.29^{a}	5.24^{b}	5.15^{d}	5.18^{c}	5.25^{b}	5.17^{cd}	5.48
Staphylococcus aureus (log_{10} CFU/g)	-	1.70*	2.00*	2.00*	2.00*	2.00*	2.17*
Enterobacteriaceae (log_{10} CFU/g)	-	1.60*	1.30*	1.30*	1.48*	1.00**	2.90**

^{a,b,c,d,e} Within a row, least squares means with different superscripts differ significantly ($p<0.05$)

*Value appears in one of the 5 samples analyzed for each sausage batch;

** Value appears in two of the 5 samples analyzed for each sausage batch

Although all batches followed the same drying process, the highest moisture content and pH value were observed in the control sausage batch (sausage with the highest NaCl content).

Except that, no clear effect (no statistically significant correlation between tested parameters and NaCl content) was found in the basic composition, pH and a_w, which could be the consequence of the reduction and partial replacement of NaCl. There is a statistically significant positive correlation between protein and glycine content (0.90), moisture content and a_w (0.94), moisture content and pH (0.86), pH and a_w (0.81) which are expected and statistically significant negative correlation between fat and moisture content (-0.83).
Table 3 shows the results of instrumental color measurement of 6 different batches of homemade Slavonian sausage. The control sausage batch shows the highest L* (lightness) value. That is in contrast to the findings reported by Zanardi et al. (2010) and Gimeno et al. (1999), but they used a mixture of NaCl, KCl and $CaCl_2$, and particularly $CaCl_2$ could be the possible reason for the product with higher L* values. There is also a positive significant correlation between moisture content, and L* value (0.95) which isn't in agreement with Pérez-Alvarez, Fernández-López, Sayas-Barberá, and Cartagena-Graciá (1998). There is no statistically significant correlation between color coordinates and NaCl content, indicating that salt reduction or partial replacement with KCl and glycine doesn't affect sausage color.

Table 3 Instrumental color measurement of 6 different batches of homemade Slavonian sausage

Color characteristics	Control sample	$SB_{50;50}$	$SB_{60;40}$	$SB_{70;30}$	$SB_{50;40;10}$	$SB_{50;30;20}$
L*	32.61^{a}	31.62^{ab}	30.32^{c}	30.37^{c}	30.44^{bc}	30.79^{bc}

b*	14.01^{b}	14.68^{ab}	13.93^{b}	14.90^{ab}	14.05^{b}	15.59^{a}

^{a,b,c} Within a row, least squares means with different superscripts d

Textural properties are given in Table 4. Control sausage showed the lowest value of hardness and gumminess and the highest value of springiness, but otherwise, no other clear effect was found in the texture as a consequence of NaCl reduction. Sausage batches with higher moisture content and a_w are less hard (negative significant correlation between moisture content and hardness (-0.82) and a_w and hardness (-0.91)). Sausage batches with higher pH are more springy (positive significant correlation between pH and springiness (-0.98) (Tables 2, 4).

Table 4 Texture profile analysis (TPA) of 6 different batches of homemade Slavonian sausage

Parameter	Control sample	$SB_{50;50}$	$SB_{60;40}$	$SB_{70;30}$	$SB_{50;40;10}$	$SB_{50;30;20}$
Hardness (g)	2889.65^{d}	3049.80^{cd}	4554.38^{ab}	4830.71^{a}	4092.65^{b}	3458.13^{c}

^{a,b,c,d} Within a row, least squares means with different superscripts differ significantly ($p<0.05$)

Table 5 shows sensory scores for appearance, texture, taste, color and odor of 6 different batches of homemade Slavonian sausage, which were given by 5 trained sensory panelists using a scoring test. Scores indicate that there is no significant difference between samples in texture, taste, color and odor, while a small but significant difference in appearance was observed (Fisher's LSD test). The overall sensory quality was calculated according to the following formula: overall sensory quality = (appearance × 2) + (texture × 6) + (taste × 8) + (color × 2) + (odor × 2), taking into account the relative importance of the different sensory characteristics. The sausage with 1% NaCl, 0.9% KCl and 0.1% glycine was highly scored for overall sensory quality. The second rated was the control sausage with 2% NaCl and the third rated was the sausage with 1% NaCl and 1% KCl, but there was no statistically significant difference between sausage batches in overall sensory quality scores (according

to Friedman's test results). That indicates that partial replacement of NaCl with KCl and mixture of KCl and glycine weren't perceived by the sensory panel.

Table 5 Results from sensory scoring test of 6 different batches of homemade Slavonian sausage

Sensory characteristics	Control sample	$SB_{50;50}$	$SB_{60;40}$	$SB_{70;30}$	$SB_{50;40;10}$	$SB_{50;30;20}$
Appearance	3.4^{ab}	3.4^{ab}	2.6^{b}	3.4^{ab}	3.6^{a}	3.0^{ab}
Texture	4.0^{a}	4.0^{a}	3.8^{a}	3.6^{a}	4.0^{a}	4.0^{a}
Taste	3.6^{a}	3.6^{a}	3.8^{a}	3.4^{a}	3.8^{a}	3.6^{a}
Color	4.2^{a}	4.2^{a}	4.0^{a}	4.0^{a}	4.0^{a}	4.2^{a}
Odor	3.8^{a}	3.8^{a}	3.4^{a}	3.4^{a}	4.4^{a}	3.8^{a}
Overall quality (Friedman's test)	76.4^{a}	75.6^{a}	74.4^{a}	70.4^{a}	78.4^{a}	74.4^{a}

^{a,ab,b} Within a row, least squares means and ranking sums with different superscripts differ significantly ($p<0.05$)

In relation to sensory analysis, there is a significant negative correlation between instrumental measured hardness and sensory score for texture (-0.83). Significant positive correlation was found between the moisture content and the sensory scores for color (0.94) and L* value and sensory scores for color (0.92). Significant negative correlation was found between fat content and sensory score for color (-0.83), which indicate that less hard sausages with higher moisture content and lightness and lower fat content would be perceived as sausages of highest quality.
Microbiological quality as well as safety, as a consequence of the NaCl reduction, was not affected according to the currently valid Croatian legislation adjusted to Commission regulation (EC) No 2073/2005 (R 2073, 2005) and (EC) No 1441/2007 (R 1441, 2007). But, in sausage batches with partially replaced salt content, in one of 5 samples analyzed for each sausage batch, slightly elevated, but below legislative limits, counts of *Staphylococcus aureus* and *Enterobacteriaceae* were detected, probably as a result of salt reduction. There is also a significant negative correlation between the total count of *Enterobacteriaceae* and NaCl content (-0.88) as well as with the total count of *Staphylococcus aureus* and NaCl content (-0.88).

CONCLUSION

Partial replacement of NaCl with KCl (30-50%) and glycine (10-20%) has no negative effect on physicochemical properties and microbiological safety of homemade Slavonian sausages. According to the sensory scoring test the highest rated sausage was the one containing 1% NaCl, 0.9% KCl and 0.1% glycine, the second-rated was the control sausage with 2% NaCl and the third-rated was the sausage with 1% NaCl and 1% KCl, but there were no statistically significant difference between sausage batches.
According to these results, it is possible to achieve the reduction of 50% of NaCl in homemade Slavonian sausages by replacing it with KCl (substitution level between 30 and 50%), and glycine (substitution level between 10 and 20%) in order to maintain traditionally desirable sensory properties

ABSTRACT: With the aim of preserving the quality of traditional fermented sausages and provision of continuity in production, a task of this work is to determine the quality of "užička" sausages, which is traditional Serbian product. This paper presents the results of sensory evaluation of traditional "užička" sausage and the results color and texture instrumental measurement, at the end of the production process.
Sausages were made from I category (50%) and II category (20%) beef, II category (20%) pork meat, fatty tissue (10%), nitrite curing salt (2.50%), sucrose (0.33%) and spices (1.25%). mixture was stuffed in bovine small intestines. Sausages were smoked in traditional smokehouses - smoking, fermentation, ripening and drying lasted 21 days. Sausages were made in three replicates.
Sensory properties of sausages (color, cut surface, coherence, tenderness) were evaluated using quantitative descriptive test (scale of intensity, of 1 to 10) at the end of production. Color and texture of "uzicka" sausage instrumentally ("Chromameter CR-400" and "INSTRON model 4301"), were analyzed, aiming to define the total quality.
Results of sensory avaluation showed that the most desired properties had sausages from a third fermentation, produced in the January, when climatic conditions were optimal for the production), and the results of instrumental measurements of color and texture are in agreement with the results of sensory evaluation.
Key words: *"Užička" sausage, sensory analysis, colour and texture instrumental analysis*

INTRODUCTION

Dry fermented sausages have always been appreciated and demanded by consumers for its quality – recently, they also became the subject of growing interest in research area. Available literature provides information about the authentic ways of fermented sausages production with special emphasis on microclimate conditions. Also, detailed microbiological, physico-chemical, sensory and other research are conducted in this area (Ambrosiadis et al., 2004; Morretti et al., 2004; Cocolin et al., 2005; Gasparik-Reichardt et al., 2005; Turubatović et al., 2004; Vesković-Moračanin, 2009). Flavour and other properties of traditionally fermented sausages are influenced by the selection and quality of basic raw material, metabolic activity of the present epiphytic microflora, physical and chemical changes due to drying, smoking, enzymatic breakdown of proteins and fats, external factors (temperature, relative humidity and air circulation), duration of ripening and other (Mendoza, 2001).
„Užička" (domestic) sausage and „kulen" are the most popular national representatives of this group of sausages.Traditional (household) production of these sausages takes place in colder periods of the year (November - January). Pork is the basic component, obtained from animals (often „Mangulica" breed) slaugtered on the same day of manufacture. Used meat is of high quality (mostly, shoulder, sometimes leg). In the cases when meat of lower quality is used (higher content of fat and connective tissue), it has to be grinded. Sometimes, beef can

be also added. Other ingredients are common salt, sweet or hot grinded paprika and garlic. Sausages are smoke for several days in traditional smokehouses (twice a day) and are air-dried to the end of the winter (Tojagić, 1996).
Such way of production was the only viable option in the past regarding food preservation since no other means were available at the time. Sausages had high nutritional value and desirable aroma of well riped meat and together with the flavour from added spices, this type of product was tastier than common dried meat. The specific raw material composition and production conditions (natural and diverse animal feeding, smoking in traditional smokehouses, air drying) were some of the factors that contributed to the overall taste and specific sensory properties compared to industrially produced fermented sausages. National market today offers dry fermented sausages with similar sensory properties, but, unfortunatelly, overemphasized acidic flavour, often unacceptable for the consumers (Radetić, 1997; Petrohilou i Rantsios, 2005).
In order to preserve the quality of traditionally fermented sausages and to provide consistency in production process, we set the task to investigate sensory properties of „Užička“ sausage manufactured in traditional manner and to determine colour and firmness of the sausages using instrumental analysis.

MATERIALS AND METHODS

„Užička“ sausage was manufactured in traditional way in craft plant Brković Nikola on Zlatibor.
„Užička“ sausage was produced from beef of category I (50%) and II (20%), II category (20%) pork meat, firm fatty tissue (30%), nitrite pickle salt (2,50%), sacharose (0,33%) and spices (1,25%) (sweet and hot grinded paprika, black pepper and garlic). Frozen fatty tissue pieces were added to the cutter, followed by chilled meat, previously grinded up to 20mm granulation, while nitrite salt, sacharose and spices were added last. After the homogenisation and granulation of ∅ 8mm, mixture was stuffed into bovine small intestine ∅ 37-40 mm. Mixture temperature was -3°C. Sausages were hand shaped in the form of a horseshoe.
After the stuffing, sausages were left to drain and were kept in low humidity air in order for their surface to dry thus preparing for the smoking process. Sausages were smoked in traditional smokehouses using beech wood. Smoking, fermentation, ripening and drying lasted 21 days. „Užička“ sausage was produced in three intervals: November (the first fermentation - IF), December (the second fermentation – IIF) and January (the third fermentation – IIIF).
Using quantitative - descriptive test (Baltić, 1992; SRPS 6658, 2002), with grading scale from one to ten (1-unacceptable, 10-optimum), at the end of each fermentation, sensory properties of sausages were asessed (colour, surface cut, consistency – connection degree of meat and fatty tissue, fatty tissue quality, tenderness, and overall impression). Five persons panel was assembled in order to investigate sensory properties. Pannelists were previously tested for detection and recognition of various tastes (SRPS 3972, 2002) and odours (SRPS 5496, 2002).
Colour was determined according to CIE *L*, a*, b** system (*L** = light intensity, *a** = share of red, *b** = share of yellow) using Chromameter CR-400 (Minolta Co. Ltd.). Colour of cut surface was measured on three fresh cuts, three repetative measures taken at each surface.
Tenderness and firmness were determined on Instron 4301 instrument, by measuring cutting force and penetration force. Cutting force was determined using Warner-Bratzler contact acessory (force 0.25 kN, speed 100 mm/min). The samples were prepared by cutting 8 one-inch cylinders from each sausage using the mold. Penetration force was measured by five-pole needle (force 0.25 kN, speed 100 mm/min, sample thickness 10 mm). Samples were prepared by cutting the sausage with circular meat knife into 10 mm thick cylinders.
The results were statistically processed by calculating mean ($\overline{X}$) and standard devistion (Sd) for each sensory property. Coefficient of variation (Cv) was also calculated as relative

measure of dispersion showing the differences between multiple measurements. Statistical calculations were carried out using Microsoft Excell.

RESULTS AND DISCUSSION

Table 1 shows the results of sensory evaluation of "Užička“ sausage
"Užička“ sausage from first fermentation (IF) was manufactured in November, when the micro-climatic conditions of the smoking and drying were favorable, so the sausages from the first fermentation were evaluated with high grades for the properties studied and ranged from 8.3 to 9.00. Also, sausage from third fermentation (IIIF), produced in January, evaluated high grades for the properties studied which ranged from 8.00 to 9.00.
„Užička“ sausage from the second fermentation (IIF), produced in late December, were rated slightly lower scores, which ranged from 7.00 to 7.70.
It can be concluded that the climate conditions were favourable for sensory properties of fermented sausages. The most favourable conditions for manufacturing traditionally fermented sausages are in the period of the year with low temperatures and high relative humidity (Radetić, 1997).
The grades for color were the highest (8.50) in sausages produced in January (IIIF). Overall impression was also the highest in this group (8.90) comparing to sausages from IIF (8.80) and IF (7.50). Significant differences were observed in evaluation.
The results of sensory evaluation of “Užička“ sausage from IIIF were in accordance with the results obtained by the group of authors for similar product (Saičić et al., 2006; Vesković-Moračanin and Obradović, 2009). Morretti et al. (2004) evaluated sensory properties of traditional sausage from Sicily produced from meat of autochtonous pigs (Nero Siciliano), where ripening of one group was carried out in traditional way (Sicilian taverna), while the ripening of the second group was conducted in industrial conditions.
The authors concluded that the ripening of sausages in controlled conditions can be done during the entire year, while in traditional production, ripening cannot take place in summer time due to high temperatures.

Table 1. Results of sensory evaluation of „uzicka“ sausage at the end of production process

	I Fermentation			II Fermentation			III Fermentation		
Sensory properties	$\bar{X}$	Sd	Cv %	$\bar{X}$	Sd	Cv %	$\bar{X}$	Sd	Cv %
Colour	8,40	0,50	5,95	7,60	0,50	6,58	8,50	0,50	5,88
Surface of cut	8,30	0,45	5,39	7,40	0,42	5,65	8,70	0,27	3,15
Coherence	8,80	0,45	5,08	7,30	0,45	6,13	8,60	0,50	5,81

Tenderness	8,90	0,42	4,70	7,10	0,22	3,15	8,20	0,50	6,10
Overall impression	8,80	0,27	3,11	7,50	0,50	6,67	8,90	0,42	4,70

$\bar{X}$ – mean
Sd – standard deviation
Cv– coefficient of variation

Table 2 shows the results of colour instrumental determination of "Užička“.
The results of cut surface colour show that sausage produced in November (IIF) were slightly lighter (L*-value) compared to sausages produced in December (IF) and January (IIIF),

however the differences were not statistically significant. The highest share of red was recorded in sausages from IIIF. Share of yellow (b*) had lower scores in sausages from IIF.

Table 2. The results of instrumental determination of cut surface colour of „Uzicka“ sausage at the end of production process in CIE L*a*b* sistem

	Light intensity *L**	Sd	Cv	Share of red *a**	Sd	Cv	Share of yellow *b**	Sd	Cv
I Fermentacion	45,36	3,57	7,87	15,52	1,64	10,6	7,34	0,81	11,04
II Fermentacion	43,82	4,16	9,49	17,83	1,58	8,86	7,22	0,62	8,59
III Fermentacion	35,26	2,37	6,72	19,27	0,93	4,83	7,88	1,11	14,09

$\overline{X}$ – mean
Sd – standard deviation
Cv– coefficient of variation

Table 3 shows the results of determination of firmness and tenderness of „Užička“ sausage from all three fermentations by measuring penetration force and cutting force using INSTRON 4301 instrument.

Table 3. Parameters of firmness and tenderness of „uzicka“ sausage at the end of production process

	Penetration force, (N)	Sd	Cv	Cutting force, (N)	Sd	Cv
I Fermentacion	23,55	3,57	15,2	44,37	5,62	12,7
II Fermentacion	18,88	1,96	10,4	39,64	1,78	4,49
III Fermentacion	12,49	1,67	13,4	24,84	2,91	11,7

$\overline{X}$ – mean
Sd – standard deviation
Cv– coefficient of variation

The highest penetration force (measure of firmness) was recorded in samples of „Užička“ sausage produced in November (IF), compared to sausages produced in December (IIF) and January (IIIF). However, higher cutting force was measured in sausages from IF and IIF compared to sausages from IIIF. The reasons for such results are to be found in different climate conditions. At the same time, higher meat content in fermented sausages results in higher firmness. This is corroborated by other authors (Vuković et al, 2009).
The impression is that the assessors overall process of ripening and drying of the sausage, in a third fermentation, should last for another ten days, so that the properties of the products tested in this fermentation, probably, got to a point higher ratings.

CONCLUSIONS

"Uzicka" sausages produced in November (first fermentation-IF) and produced in January (third fermentation-IIIF) had a very desirable sensory attributes, while the sausages produced in December (the second fermentation-IIF) were evaluated with slightly lower grades. Overall impression of "Uzicka" sausages from third fermentation (8.90) and first fermentation (8.80), had better assessment of overall impression than from second fermentation (7.50).
The results of instrumental determination of colour and firmness of „Užička“ sausage samples were in agreement with the results of sensory evaluation.
The investigated properties were better in sausages produced in January comparing to the ones produced in December and November.

On the basis of the obtained results it can be concluded that the best sensory properties of fermented sausages can be achieved when production is carried out in late winter which is the common period for traditional production of „Užička“ sausage.

ACKGNOWLEDGEMENT

The results are part of Integrated and Interdisciplinary Research Project No. III 46009, “Improvement and development of hygienic and technological procedures in producing food animal origin in order to obtain high-quality and safe products competitive on world markets” funded by the Ministry of Education and Science Republic of Serbia

ABSTRACT: In order to contribute to the knowledge about the proteolysis in *Petrovská klobása* the composition of water-soluble (pH 7.4) protein extracts of this traditional dry-fermented sausage was regularly examined as ripening progressed (120 days). Instead of widely utilized, classical SDS-PAGE, the Lab-on-a-Chip (LoaC), fast and reliable electrophoresis based method, was used to follow up the hydrolysis of sarcoplasmic proteins during the ripening. Water activity (aw), pH evolution and an increase of non-protein nitrogen (NPN) fraction were also followed up. Obtained results showed that *Petrovská klobása,* traditionally produced under low ambient temperature, undergoes slow processes of natural fermentation, drying and ripening. The pH decreased slowly from 5.67 (day 0) to 5.30 (day 60) ($P < 0.05$), what had an adverse effect on drying and proteolysis intensity. The aw gradually decreased from initial value of 0.95 to 0.86 ($P < 0.05$), while the NPN fraction increased up to day 90 (1.05 g/100g dm) and then stabilized further on. Throughout ripening slow degradation of sarcoplasmic proteins took place, resulting in disappearance of a few protein bands (≈16, 44 and 93 kDa) during second month of ripening.
Key words: *Petrovská klobása, sarcoplasmic proteins, hydrolysis, Lab-on-a-Chip electrophoresis*

INTRODUCTION

Traditional food products, which are linked with a place or region of origin, are closely connected to the culture and the identity of the local population. They carry a strong symbolic value important for the preservation of cultural identity, and are often perceived as higher quality. Consequently, an increased interest in traditional foods in Europe has been noticed in resent years (Pieniak et al., 2009), and the list of food products registered as PDO (Protected Designation of Origin) and PGI (Protected Geographical Indication) is continuously growing (http://ec.europa.eu/agriculture/quality/door/list.html). This applies also to dry-fermented sausages, which physical and sensorial characteristics are highly dependent on distinct cultural and social backgrounds of the populations, as well as on the environmental/climatic conditions in region of production. A large variety of these products (predominantly from France, Spain, Italy, Portugal, Greece and Slovakia), present on the European market, have been thoroughly characterized (Talon et al., 2008; Roseiro et al., 2008, 2010; Lücke and Vogeley, 2012).
On the other hand, the existing scientific information about Serbian dry-fermented sausages is still scarce, being important to improve the knowledge concerning the physicochemical and biochemical changes during production period. One of these sausages is *Petrovská klobasá*, traditional dry-fermented meat product which is a part of Slovaks' heritage, who inhabited northern part of Serbia (Vojvodina) in the second half of 18th century. Nowadays, *Petrovská klobasá* is produced in traditional manner, during winter (low ambient temperature) and without the use of additives and microbial starters. Drying and ripening process lasts about 4 months. Due to its specific flavor, aromatic and spicy-hot taste, dark red color and hard consistency *Petrovská klobása* is highly appreciated by consumers and it has been registered as PDO (Protected Designation of Origin) under Serbian law (Ikonić et al., 2010, 2012; Petrović et al., 2007; Tasić et al., 2012).

The proteolysis of sarcoplasmic and myofibrillar proteins is very important biochemical phenomena occurring during the ripening of fermented meat products. This phenomena is determined by enzymes originated both from muscle and microbial proteolytic system. It results in yield of several compounds, including polypeptides, peptides, amino acids, aldehydes, organic acids and amines, which participate in both flavour/taste and texture development (Dalmış and Soyer, 2008; Hughes et al., 2002; Roseiro et al., 2008; Spaziani et al., 2009). The changes undergone by the sarcoplasmic and myofibrillar proteins in fermented sausages during ripening have been widely studied using sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE). However, this electrophoretic method is time-consuming and consists of a number of necessary manual steps. On the contrary, microfluidic or Lab-on-a-Chip (LoaC) technology is a miniaturized electrophoresis based technique for fast, reliable and automated analysis of proteins on a chip. (Goetz et al., 2004; Soriano et al., 2003; Torbica et al, 2010).
In order to improve the knowledge concerning the proteolysis in *Petrovská klobása*, the present study reports the results for hydroliysis of sarcoplasmic proteins, obtained using LoaC electrophoresis. The samples were analysed at different times during drying and ripening up to 120 days, after the stuffing operation. Water activity (aw), pH and non-protein nitrogen (NPN) content were also followed up.

MATERIAL AND METHODS

Sausage preparation

Petrovská klobása dry fermented sausages were manufactured in traditional manner using hot-boned lean pork (80%) and pig fat (20%). After mincing the meat and the fat to a size of about 10 mm, raw materials were mixed with seasonings (red hot paprika powder - 2.5%, salt - 1.8%, raw garlic paste - 0.2%, caraway - 0.2% and sucrose - 0.1%). The seasoned batter was immediately stuffed in collagen casings (55 mm in diameter) and raw sausages were entirely processed in traditional smoking/drying room during 120 days.
Samples included seasoned batter prior to stuffing (0) and three randomly selected sausages at each sampling period (days 2, 4, 6, 9, 15, 30, 60, 90 and 120). Determinations of aw, pH and NPN were carried out at these sampling times, and the rest of the sausages were stored at -20 °C pending further analysis. Analyses for all samples were carried out in duplicate.

Water activity, pH and NPN

Water activity (aw) of samples was determined using Testo 650 measuring instrument with a pressure-tight precision humidity probe (Testo AG, USA). The pH was measured using the portable pH meter (Consort T651, Turnhout, Belgium) equipped with an insertion glass combination electrode (Mettler Toledo Greifensee, Switzerland). Dry matter (dm) was determined by drying the samples at 103 ± 2 °C to constant weight (ISO 1442:1997).
In order to determine non-protein nitrogen (NPN) 10 g of sausage were homogenized with 20 mL of 10% (w/v) trichloroacetic acid (TCA) for 1 minute at 13,500 rpm using an T18 Basic Ultra Turrax (IKA-Werke GmbH & Co. KG). The homogenate was left at +4 °C for 2 h, filtered and NPN was determined from 10 mL of filtrate by the Kjeldahl method (ISO 937:1978). The NPN fraction content was expressed as g/100 g dm of sample.

Extraction and LoaC electrophoresis of sarcoplasmic proteins

Sarcoplasmic protein extracts were prepared according to the method of Toldrá et al. (1993). Four grams of sausage were homogenized with 40 mL of 0.03 M potassium phosphate buffer (pH 7.4) for 2 min using an Ultra Turrax at 13,500 rpm. The homogenate was centrifuged for 20 min at 10,000g at 4 °C. The supernatant contained the sarcoplasmic proteins. The protein concentrations of sarcoplasmic protein extracts were determined by method of Lowry et al. (1951), using bovine serum albumin as standard protein, and adjusted with deionised water to give a final concentration of 4 mg/mL.
The chip-based separations were carried out as described by Torbica et al. (2010), using Agilent 2100 bioanalyzer (Agilent Technologies, Santa Clara, CA) in combination with the

Protein 230 Plus LabChip Kit and the dedicated 2100 expert software. The chips were prepared according to Agilent Protein 230 Kit Guide (assay protocol). The complete analysis of 10 protein samples, including sizing and quantification, takes 25 minutes (including the start-up phase of the instrument).

Statistical analysis

One way (ANOVA), Post-hoc (Duncan test) was performed using the software package Statistica 9.1 for Windows, Stat Soft, Tulsa, Oklahoma, USA. Differences were considered significant at $P < 0.05$.

RESULTS AND DISCUSSION

The results of aw, pH and NPN fraction content are presented in Table 1. During the processing of *Petrovská klobása* considerable drying occurred. The aw gradually decreased from initial value of 0.95 to 0.86 ($P < 0.05$). The drying pattern was determined by the influence ambient conditions in traditional smoking/drying room (low air temperature and high relative humidity) which caused slow dehydration of sausage. Likewise, the low environmental temperature adversely affected the growth and activity of the indigenous lactic acid bacteria (LAB) and consequently the intensity of fermentation, as it was previously found in French traditional dry sausages (Rason et al. 2007). Thus, Danilović et al. (2011) reported the highest number of LAB, about 10^7 CFU/g, only after 15 days of ripening in *Petrovská klobása,* made in the same time and from the same raw meat/fat mixture. Obviously, the low growth rate of LAB is consistent with pH profile (Table 1). The fermentation period was prolonged and the pH reached its lowest value (5.30) after 60 days of production, when it started gradual increase due to degradation of proteins, as it was proposed in previously published work of Spaziani et al. (2009). Furthermore, relatively high pH additionally influenced lower intensity of drying since the isoelectric point (pI) of myofibrillar proteins is reached after two months of ripening. At pI the water holding capacity of myofibrillar proteins is the lowest and it can be easily exudated from the muscle fibers and evaporated (Huff-Lonergan, 2002).

Table 1. Changes in aw, pH and NPN fraction content (expressed as g/100 g dm) during the ripening of *Petrovská klobása.*

Ripening time (day)	0	2	4	6	9	15	30	60	90	120
aw	0.952^{b}	0.949^{ab}	0.946^{ab}	0.940^{abc}	0.939^{abc}	0.935^{ac}	0.927^{c}	0.902^{f}	0.887^{e}	0.860^{d}
pH	5.67^{g}	5.63^{f}	5.60^{e}	5.56^{ae}	5.53^{a}	5.48^{cd}	5.47^{c}	5.30^{b}	5.33^{b}	5.52^{ad}
NPN	0.66^{b}	0.69^{ab}	0.70^{a}	0.70^{a}	0.79^{d}	0.82^{e}	0.85^{f}	0.90^{g}	1.05^{c}	1.04^{c}

$^{a-g}$ Means within the same row with different superscript letters are different ($P < 0.05$).
NPN – non-protein nitrogen

The NPN increased progressively up to 90 days of ripening and then stabilised further on. Several authors have reported that proteolysis during the ripening of fermented sausages is followed by an increase in NPN concentration (Candogan et al., 2009; Dalmış and Soyer, 2008; Toldrá, 2002).

Proteolysis of sarcoplasmic proteins

The electrophoretic profiles of sarcoplasmic proteins extracted from *Petrovská klobása* during the ripening are shown in Fig. 1.

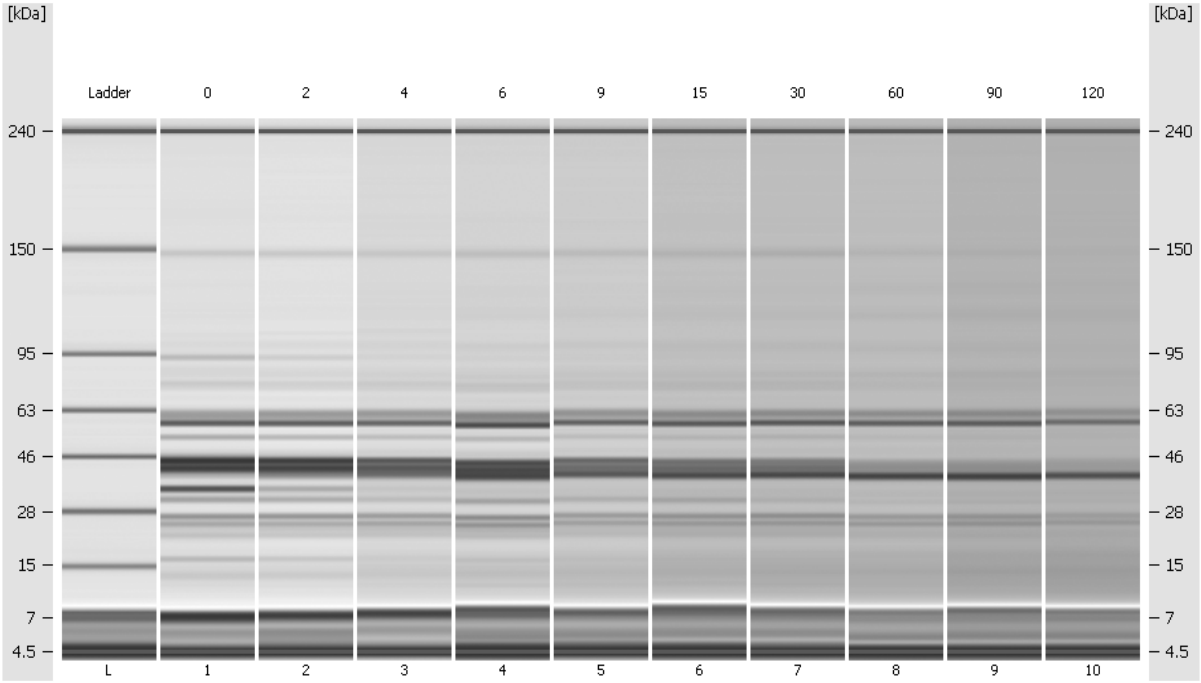

Figure 1. Gel image of electrophoretically separated sarcoplasmic proteins during the ripening of *Petrovská klobása* (lanes 1-10). Lane L (Ladder), molecular weight standards ranging from 4.5 to 240 kDa

The sarcoplasmic proteins, ranging in molecular weight from ≈14 kDa to ≈148 kDa, were already extracted from the seasoned butter (before stuffing) (Table 2). During the ripening period polypeptides with molecular weights of ≈14, 23, 25, 58 and 62 showed a relevant increase, while six new protein bands were detected after 2 (≈40, 99 kDa), 6 (≈115 kDa) and 15 (≈15, 18, 129 kDa) days. Furthermore, the intensity of ≈40 kDa band progressively increased throughout ripening, and after 120 days it was the most common polypeptide in sarcoplasmic proteins extract. This result is in accordance with finding of Martín-Sánchez et al. (2011). Formation and increase of some low molecular weight bands (<20 kDa) has been reported by a number of authors (Dalmış & Soyer, 2008; Hughes et al., 2002; Martín-Sánchez et al., 2011; Spaziani et al., 2009).

Throughout ripening period slow degradation of sarcoplasmic proteins took place. Hence, polypeptides with molecular weights of ≈32, 42 and 53 lost about 50% of their initial concentration only after one month of processing, while protein bands at ≈16, 44 and 93 kDa completely disappeared in next 30 days. On the contrary, the intensity of the protein band with molecular weight ≈35 kDa decreased markedly after only 2 days. Others (Casaburi et al., 2007; Dalmış and Soyer, 2008; Martín-Sánchez et al., 2011; Spaziani et al., 2009) evaluating the proteolysis in fermented sausages found similar low-intensity degradation of sarcoplasmic proteins in products without starter culture as a result of weak activity of endogenous proteases.

In the case of *Petrovská klobása,* the activity of these enzymes was probably negatively affected by relatively high pH (Table 1) and low processing temperature as it was previously reported by other authors (Casaburi et al., 2007; Roseiro et al., 2008). Moreover, dominant lactic acid bacteria strains isolated from this sausage (*Lactobacillus sakei, Leuconostoc mesenteroides and Pediococcus pentosaceus*) showed variable or no proteolytic activity during the ripening (Danilović et al., 2011), confirming a minor role of bacterial proteinases in proteolysis process (Toldrá, 2002).

CONCLUSIONS

The findings of this study show that *Petrovská klobása,* traditionally produced under low ambient temperature, undergoes slow processes of natural fermentation, drying and ripening. The pH drop was slight, adversely affecting drying and proteolysis intensity. Consequently, slow degradation of sarcoplasmic proteins took place, resulting in notable decrease and disappearance of a few protein bands after 30 days of ripening.

ACKNOWLEDGEMENTS

The authors wish to express their sincere gratitude to the Ministry of Education and Science of the Republic of Serbia for its financial support (Project: TR 31032).

ABSTRACT: In this paper, good manufacturing practice (GMP) during *Petrovská klobása* production, throughout three seasons and for the total of 13 batches (A1, A2, B1, B2, B3, B4 – first; C1, C2, C3 – second; D1, D2, E1, E2 – third season), was estimated based on tyramine, histamine, phenylethylamine, vasoactive and total biogenic amines content. Analyses were performed by HPLC-DAD on Eclipse XDB-C18 column. Chromatographic separation of dansyl chloride derivatizated amines was completed in 8 min.
Histamine, as the most important amine from the food safety point of view, was not detected in any analyzed sample. Total content of biogenic amines ranged from 77.8 to 174 mg/kg in the first, from 456 to 744 mg/kg in the second and from 144 to 217 mg/kg in the third production season. Tyramine was not detected in A1 batch, while in others its content ranged from 6.90 (B1) to 160 mg/kg (C3).
For C batches content of phenylethylamin, as well as the sum of vasoactive biogenic amines was found to be higher than values considered as upper limits (30 mg/kg; 200 mg/kg, respectively) for indication of GMP. According to obtained results good manufacturing practice was applied during production of *Petrovská klobása* in the first and third season, while in the second season that was not the case.
Key words: *Biogenic amines, Traditional fermented sausage (Petrovská klobása), Good manufacturing practice*

INTRODUCTION

Petrovská klobása is traditional fermented sausage which has been produced for over 250 years in the area nearby town of Bački Petrovac in the Autonomous Province of Vojvodina, Republic of Serbia. It is produced exclusively from pork meat and fat, red hot paprika powder, salt, crushed garlic, caraway and sugar and is characterized by specific hot taste, aromatic and spicy flavour, dark red color and hard consistency (Petrović et al., 2007; Ikonić et al., 2010; Tasić et al., 2010).
Traditional fermented sausages are characterized by handmade manufacturing usually in small-scale units, following spontaneous fermentation by their particular in-house flora (Talon et al., 2007). In contrary to industrial production, traditional products are manufactured with traditional technologies generally without adding starter cultures and the process of drying and ripening is carried out in rooms with less temperature, relative humidity and air velocity control (Roseiro et al., 2010; Lebert et al., 2007b; Parente et al., 2001). This process favours the growth of autochthonous microflora, originated from the raw materials or environment, which influences the flavour, texture, nutritional qualities, safety, and other characteristics of this type of sausage. (Moretti et al., 2004; Latorre-Moratalla et al, 2008; Lebert et al., 2007a). Also, type of microflora that develops during fermentation, drying and ripening is closely related to the diversity in formulation as well as technological conditions applied during these processes (Latorre-Moratalla et al, 2008; Suzzi & Gardini, 2003). Small producers of traditional products may encounter technical and financial difficulties to comply with official food safety regulations established for industrial processes, such as the hazard analysis and critical control point (HACCP) plan (Latorre-Moratalla et al, 2008, Lu et al., 2010).

The ripening of fermented sausages offers favourable conditions for biogenic amines production due to activity of present and developed microflora, acidification and the proteolysis that increases the amounts of free amino acids available for decarboxylation (Halász et al., 1994; Santos et al., 1996; Shalaby, 1996; Suzzi & Gardini, 2003; Latorre-Moratalla et al, 2008; Latorre-Moratalla et al, 2010).
Biogenic amines are associated with several health disturbances: hypertensive crises, headache, nausea, vasoactivity, and allergic reactions due to its toxicity (Hernández-Jover et al., 1996; Vidal-Carou et al., 1990). Also, they are of concern in relation to food spoilage or ripening stage (Önal, 2007; Roserio et al., 2006; Bover-Cid et al., 2001; Hernández-Jover et al., 1997). The level of biogenic amines in meat and meat products has been used as a quality index of unwanted microbial activity (Lu et al., 2010), as well as for a good manufacturing practice evaluation (Latorre-Moratalla et al, 2008; Eerola et al., 1998; Santos et al., 1996; Shalaby, 1996). Thus, interest in biogenic amines content lies in safety and quality issues (Latorre-Moratalla et al, 2008).
Total biogenic amines content in food considered as dangerous is 1000 mg/kg according to Santos et al., (1996). Shalaby (1996) suggested levels of few amines as parameters for the evaluation of good manufacturing practices (GMP): tyramine 100-800 mg/kg, histamine 50-100 mg/kg, phenylethylamine <30.0 mg/kg, while Eerola et al. (1998) proposed that sum of vasoactive biogenic amines (tyramine, histamine, tryptamine, phenylethyamine) as a possible indicator of hygienic conditions and GMP in the sausage production, which should not exceed 200 mg/kg. Development of appropriate manufacturing technologies to obtain sausages free or nearly free from biogenic amines is one of the current targets of the meat sector, including the traditional manufacturers (Latorre-Moratalla et al., 2010).
The aim of this study was to determine the content of total biogenic amines, content of tyramin, histamine, phenylethylamine and sum of vasoactive biogenic amines as possible indicators of good manufacturing practice (GMP).

MATERIAL AND METHODS

Sausage preparation

All sausage mixtures were made of lean pork meat and fat 80:20, 2.50% red hot paprika powder, 1.80% salt, 0.20% crushed garlic, 0.20% caraway and 0.15% sugar in traditional manner. Pork meat and fat were grounded to a 10 mm particle size and all ingredients were mixed approximately 10 min using traditional technique. Afterward, the mixtures were stuffed in natural or collagen casings and raw sausages were entirely processed in traditional smoking/drying room or, alternatively, in an industrial ripening room (B3 and B4) (Table 1).

Table1. Raw material, casings, processing conditions and the end of drying for examined batches

Batches	Raw material	Casings	Processing conditions		End of drying (day)
			Smoking	Drying	
A1	hot deboned meat (2h *post mortem*)	natural	traditional	traditional room	90.
A2		collagen			
B1	cold meat (24h *post mortem*)	natural			
B2		collagen			
B3		natural	industrial	industrial ripening chamber	45.
B4		collagen			
C1	cold meat (24h *post mortem*)	natural	industrial	industrial ripening chamber	60.
C2		collagen			
C3		collagen			
D1	cold meat (24h *post mortem*	collagen	traditional	traditional room	90.
D2					
E1			industrial	industrial ripening chamber	60.
E2					

Traditionally processed sausages were smoked using cool procedure for 10 days with pauses, while sausages processed in industrial conditions were smoked for 6 h (12 30 min), during 3 days.
According to Serbian legislation (Serbian Regulations, 2004) moisture content for dry fermented sausages has to be less than 35.0%. Sausages dried in traditional room needed 90 days to reach required moisture content, while sausages dried in industrial ripening chamber reached this value after 45 or 60 days, what determined the sampling of the sausages.
At the end of drying period samples were homogenized and stored at -20 °C until analyzed.

Biogenic amines analysis
Tryptamine, phenylethylamine, putrescine, cadaverine, histamine, serotonin, tyramin, spermidine and spermine were determined as their dansyl derivatives following the high-performance liquid chromatography. Sample preparation and extraction were done according to Eerola et al., 1993. HPLC analysis was performed by using a liquid chromatography (Agilent 1200 series), equipped with a diode array detector (DAD), Chemstation Software (Agilent Technologies), a binary pump, an online vacuum degasser, an auto sampler and a thermostated column compartment, on an Agilent, Eclipse XDB-C18, 1.8 µm, 4.6 x 50 mm column. Solvent gradient was performed by varying the proportion of solvent A (acetonitrile) to solvent B (water) as follows: initial 50% B; linear gradient to 10% B in 7.6 min, 10% B to 10 minutes; linear gradient to 50% B in 2 min. System was equilibrated 3 minutes before next analysis. Flow rate was 1.5 mL/min., column temperature was 40 °C and 5 µL of sample was injected. The spectra were acquired in the range 190-400 nm (Tasić et al., 2012).
Detection limits of the amines were determined to be 0.1 µg/g for putrescine and spermidine, 0167 µg/g for cadaverine and tyramin, 0.25 µg/g for tryptamine, phenylethylamine and histamine and 0.5 µg/g for serotonin and spermine.

Statistical analysis
One way (ANOVA), Post-hoc (Duncan test) was performed using the software package Statistica 9.1 for Windows, Stat Soft, Tulsa, Oklahoma, USA. Differences were considered significant at $P < 0.05$.

RESULTS AND DISCUSSION

The contents of biogenic amines in traditional dry fermented sausage *Petrovská klobása* during three production seasons, referred to fresh matter, are presented in Table 2.
Limit of 1000 mg/kg for total biogenic amines content considered by Santos (1996) was not exceeded at the end of drying period in any analyzed sample. The content of total biogenic amines was significantly higher ($P < 0.05$) in the sausages produced in the second season, averagely ranging from 542 to 684 mg/kg, comparing with first and third seasons, but still lower than proposed limit. Shalaby (1996) suggested levels of few amines as parameters for the evaluation of good manufacturing practice: tyramine 100-800 mg/kg, histamine 50.0 - 100 mg/kg, phenylethylamine < 30 mg/kg. Average contents of tyramine did not exceed the recommended values in all analyzed groups, and were in a range from ND to 17.3 mg/kg; from 100 to 160 mg/kg and from 25.4 to 80.3 mg/kg for first, second and third season respectively. Histamine was not detected in any of the investigated sausage groups. Unlike tyramine and histamine, some groups of sausages had greater average content of phenylethylamine than recommended values. So, in groups A1 and A2, made in the first season from hot deboned meat (cca 3 h *post mortem*), the average content of this amine were 51.6 mg/kg and 33.2 mg/kg, respectively. This finding may be one of the reasons why *Petrovská klobása* should be, in the future, made exclusively from cold meat (24 h post mortem). Furthermore, in all investigated groups of sausages made in the second season phenylethylamine content was higher than the proposed 30 mg/kg (C1 30.4 mg/kg; C2 60.2 mg/kg, C3 42.4 mg/kg). Phenylethylamine was not detected in sausages made in third production season. The limit of 200 mg/kg for the sum of vasoactive biogenic amines was

proposed by Eorola et al., (1998) as an indicative criterion for good hygienic conditions and good manufacturing practice. This limit was not exceeded in any sample at the end of drying in the first and third season. On the other hand, average content of the sum of vasoactive biogenic amines in the second season exceeded this limit and were in the range 248-458 mg/kg.

Table 2. Biogenic amines content in traditional dry fermented sausage *Petrovská klobása* as possible indicators of good manufacturing practice

Batch	**Santos (1996)**	**Shalaby (1996)**			**Eorola et al. (1998)**
	total	tyramine	histamine	phenylethylamine	sum of vasoactive
	< 1000 (mg/kg)	100-800 (mg/kg)	50-100 (mg/kg)	< 30.0 (mg/kg)	< 200 (mg/kg)
A1	113[b]	ND	ND	51.6	66.4
A2	164[d]	17.3	ND	33.2	103
B1	174[d,e]	6.90	ND	28.6	73.6
B2	163[d]	16.8	ND	29.4	121
B3	77.8[a]	7.34	ND	ND	36.1
B4	86.5[a]	14.8	ND	11.8	52.8
C1	585[h]	146	ND	30.4	452
C2	542[g]	100	ND	60.2	330
C3	684[i]	160	ND	42.4	248
D1	140[c]	29,7	ND	ND	70,0
D2	151[d]	25,4	ND	ND	63,7
E1	217[f]	80,3	ND	ND	126
E2	181[e]	38,5	ND	ND	90,2

In the same column, different letters means that values are significantly different ($P < 0.05$) Results are expressed as means
ND e not detected.

Based on the obtained results, it can be ascertain that in the first and in the third season there were no deviations from good manufacturing practice in *Petrovská klobása* production. Further on, in the second season there was deviation from good manufacturing practice, although in all investigated sausage groups total content of biogenic amines was below the recommended values (<1000 mg / kg).
During drying and ripening of *Petrovská klobása* differences in biogenic amines type and content were found between groups. These differences could be explained by development of different microflora as well as different time of drying and ripening and with complex interactions of many factors, among which raw materials (hot deboned meat or cold meat), type of casings, appropriate drying model and their interactions certainly take an important role.

CONCLUSIONS

The results obtained in this study indicated no evidence of deviations from good manufacturing practice in Petrovská *klobása* production in the first and in the third seasons, while in the second season such deviation was observed.

ACKNOWLEDGEMENTS

The authors wish to express their sincere gratitude to the Ministry of Education and Science of the Republic of Serbia for its financial support (Project: TR 31032).

ABSTRACT: Olive tree is one of the most important plants related to the economical interest in Albania. Eventually it is one of the study objects, which constitutes a cultivation area of more than 40 000 ha. Studies with focus the olive tree mainly have been of statistical profile comprising, (yield, area of plantation and their exploitation) and botanical (morphological determinations of olive cultivars). Recently has been growing interest on the analytical studies of chemical compositions.
One of the main olive autochthonous cultivars used as a Table olive is the *Kokermadh Berati* cultivated in the region with same name. It contributes by 20% of the total fund of the ~6 million olive trees. This study has analyzed samples from the crop year 2010-2011. It evaluated the oil content, fatty acid profiles, total phenol content and antioxidant activity. GC analysis of fatty acids revealed that the oleic acid content resulted in 76.26%. The content of palmitic acid is relatively low, 10.41%). The level of linoleic acid is considered relatively low (6.92%). The content of the stearic acid resulted 2.20%, while the linolenic acid resulted 0.67%. The Saturated Fatty Acids (SFA) group resulted in 12.92%, the Monounsaturated Unsaturated Fatty Acid (MUFA) content to 79.53% and the Poly Unsaturated Fatty Acid (PUFA) 7.59%. The nutritional value of n-6/n-3 show very interesting values by 10.31. The Total Phenol Content (TPC) expressed as Gallic Acid Equivalency (GAE) resulted 226.97 ±1.40 mg GAE/kg Olive Oil.
Key words: *Kokermadh Berati, Table Olive, Fatty Acid, Total Polyphenol Content*

INTRODUCTION

Cultivation of olive tree in Albania is mainly concentrated in the Western part of the country across the Adriatic and Ionian seas. A number of archeological evidences give indication of the olive cultivation since ancient times (Kafazi and Muço, 1984; Thomaj and Panajoti, 2003). Production capacity varies in 70 000 ton olives, 10000-11000 ton olive oil. The area of planted olive trees is approx. 41000 ha, or 6.3% of the arable land (MBUMK, 2009). This area is distributed in 90 000 farms (MBUMK, 2009). Incomes from this sector vary to 28 million Euros (FAOSTAT, 2011). According to FAOSTAT, Albania is ranked 20th in olive and olive commodities in the world (FAOSTAT, 2011). From the above mentioned data can deduct that the quantity of Table Olive is calculated to 14000 ton (IOOC, 2010).
Scientific studies have concluded that exist 22 autochthonous olive cultivars (Thomaj and Panajoti, 2005).The olive groves are situated mainly in hilly and mountainous lands. A continuous selection throughout the centuries has created that actual structure of olive cultivars. Olive cultivars in Albania are classified in two groups based on the plantation area and their importance: principal and secondary olive cultivars. Principal cultivars are dominant in considerable areas in many regions, while secondary cultivars are not dominant in their region but are localized in some groves. There are six main regions of olive groves that originate since antiquity: *Kalinjoti* (Vlora), *Kokërrmadh Berati* (Berati), *Mixan* (Elbasani), *Ulliri Bardhë Tirana* (Tirana), *Krypsi Krujës* (Kruja), *Kallmet* (Lezha) (Frezzoti, 1930; Kafazi, 1980; Ismaili and Celoaliaj, 1995; Thomai and Panajoti, 2004).
Kokërrmadh Berati (Berati) is a cultivar that is used as Table Olive, and is named according to the name of region. It is a self sterile cultivar, and mainly cultivated in Districts of Berati, Fieri and Lushnja. The fruit' weight varies 6-9 g. The stone weight varies to 0.7 g, and the

flash ray varies to 89.3 %. It is characterized from an average and periodic productivity. The oil content varies 18-21%. The oil quality is good. It is considered of moderate consistency to the cold weather. It is classified as the best autochthon table olive cultivar in Albania.

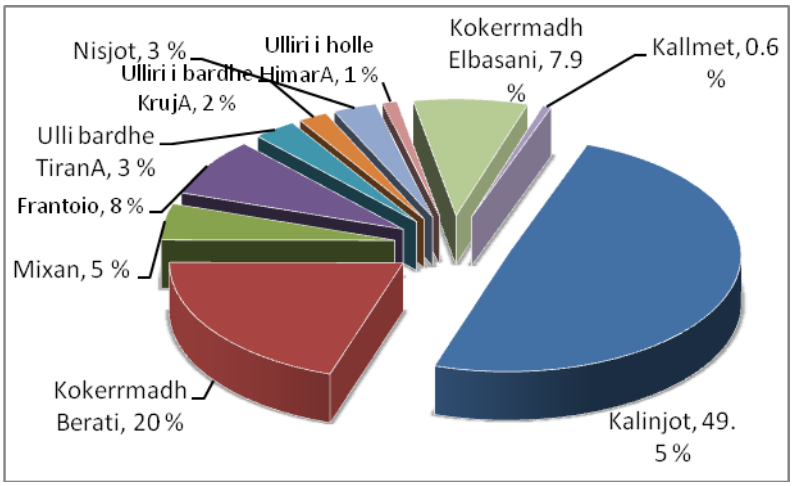

Figure 3: Structure of olive cultivars in Albania

The Berati region owns 6702 ha of olive plantations. The Kokermadh Berati contributes by 90% of overall trees.

Fatty acid profile characterization is used to give a differentiation between olive cultivars as well as to evaluate the nutritional aspects of this product (Boskou, 2006; Mannina *et al.,* 2003).

This study has analyzed the Fatty Acid Profile, Total Phenolic Content for the *Kokermadh Berati* olive cultivar. It is the first study on that cultivars and it has interest for scientific community to make present this cultivar, which is very important in national level, which counts for above 1.2 million planted trees (MBUMK, 2009).

MATERIAL AND METHODS

Olive samples and extraction

Samples of Kokermadh Berati were harvested at the same time (November 2010) from the Berati region. The harvested olive fruits were according to the appropriate maturity index suggested for olive oil extraction period. Oil extraction was carried out using extraction conditions similar to those used at industrial scale, using a SPREM Oliva Press (Italy) in the laboratory. The oil was separated by decanting, transferred into dark glass bottles and stored in the darkness at 4°C until further analysis.

Analytical methods

Fatty acid methyl esters (FAME) were prepared through direct acidic transesterification, as originally proposed originally by Lepage and Roy (1984) and later modified by Carvalho and Malcata (2005), using pentadecanoic acid as Internal Standard. The assay of FAME was carried out with a HP-6890 Gas chromatograph, equipped with a Flame Ionization Detector (GC-FID). Calculations were performed according to AOCS Official Method Ce 1b-89 (Fyrestone, 1994). Identification of fatty acids was undertaken with pure standards (Sigma-Aldrich, Supelco), based on the comparison of retention times. Fatty acids were calculated as the percentage of the total fatty acids. Each sample was analyzed in triplicate.

Total Polyphenolic content (TPC) was measured by a colorimetric method proposed by Kalantzakis et al. (2006). Briefly, samples were dissolved in n-hexane (Sigma, Germany) and extracted with a methanol/water mixture (60:40, vol vol^{-1}). The insoluble fraction (non-polar) in methanol/water fraction was removed, whereas the polar fraction was used, as it was, for further analysis. The absorbance of mixture was measured in UV-VIS Mini-1240

Spectrophotometer (Shimadzu) at 725 nm. Results were expressed as Gallic acid equivalent (mg kg^{-1} olive oil), calculated from the following calibration curve, determined by linear regression, where [GA] is the concentration of Gallic acid, expressed as mg kg^{-1} olive oil: A_{725}= 3.015 [GA] + 0.005 (r^2=0.999). Each sample was measured in triplicate.

Statistical analysis

The complete data was evaluated by randomized block design, with three replicates from fatty acid analysis and duplicates for TPC values. Results were displayed as mean values and standard error (n=3). Significance of the differences among the values was determined by Analysis of Variance using One-way ANOVA test, with a level of significance at $P<0.05$.

RESULTS AND DISCUSSION

Fatty acid composition

The major fatty acids present were: oleic (C18:1), palmitic (16:0), linoleic (C18:2) and stearic acid (C18:0), (Table 1). Results revealed that the fatty acid content falls in the average percentage intervals described by IOOC (2011). Palmitic acid resulted in 10.41%, Stearic acid 2.10 %. The content of Linoleic acid resulted in 76.26%.The content of linolenic acid (LA) varied from 6.92%.

Results showed that there was a similarity among Kokermadh Berati and other Albanian studied cultivars (Topi *et al*., 2011) and other cultivars from Italy and Greece (Aparicio and Luna, 2002; Motilva *et al.,* 2000; Bouaziz, Chamkha, Sayadi, 2004). Comparison of FA profile of Kokermadh Berati with FA profiles of cultivars from Southern coast of Mediterranean sea, showed the same trend where FA profile present high content of polyunsaturated fatty acids (Pinelli *et al*., 2003; Haddada *et al.*, 2008).

n-6/n-3 ratio

Olive oil is an important source of healthy lipids. The proposed ratio **n-6/n-3** = 4, respectively between unsaturated acid with two and three double bound, gives an indication on the quality of the lipid source regarding to nutrional aspects (DGA, 2010). The *Kokërrmadh Berati* presents a ratio **n-6/n-3** of 10.31.

Table 1: Fatty acid composition, SFA, MUFA, PUFA (in % FAME) and n-6/n-3 ratio

Formula	Average±Stdev
16:0	10.41±0.12
16:1(n-9)	0.13±0.04
16:1(n-7)	0.61±0.07
17:0	0.00±0.00
17:1 (n-7)	0.00±0.00
18:0	2.10±0.10

MUFAs/SFAs	6.16
MUFAs/PUFAs	10.48

Analysis of Saturated and Unsaturated Fatty Acids groups

Analyzing the fatty acid profiles based on their family, as saturated (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) fatty acids can be used to distinguish cultivars among each others. Regarding to SFA, this cultivars show good profile, a low content of Saturated Fatty acids. The MUFA value resulted high (79.53%) while the PUFA content very low, 7.59%.

Polyphenol content

Total Polyphenol Content (TPC) for *Kokërrmadh Berati* cultivar resulted 125.6± 6.09 mg kg^{-1} GA (olive oil). Result show major differences compared to other native cultivars (Topi *et al.,* 2011), which may be correlated to the cultivar itself, rather than to agriculture practices or other factors. The comparison of TPC content with other Italian cultivars, reveal that this cultivar shows similarity with cultivars from the Toscana Region, Italy; and Dalmatian Coast, Croatia (Pinelli et al., 2003).

CONCLUSIONS

Analysis of virgin olive oil from native cultivars of Albania is rather important, not only regarding to the scientific interest in characterizing native plants from a specific region, as well as to identify the origin of the virgin olive oils in the market. Study of the chemical composition of the Table olive Kokermadh Berati is important not only to the scientific collection data, but also related to the nutritional aspect. The results of this study are a contribution to the characterization of the Albanian monovarietal olive oils, which should be completed with more samples obtained from different crop seasons.

ABSTRACT: Preservation of foods by fermentation is a widely practiced and ancient technology. Lactic acid bacteria because of their unique metabolic characteristics are involved in many fermentation processes of milk, meats, cereals and vegetables. The fermentation of white cabbage into sauerkraut traditionally proceeds in the presence of salt. White cabbage, cultivar Futoški has protected geographical origin according to domestic legislations because of its specific physical and sensory characteristics, as native as well as sauerkraut. The objective of this study was to follow the dynamics of biofermentation parameters for white cabbage, cultivar Futoški and hybrid Bravo. These two varieties were spontaneous fermented traditionally with addition of salt in concentrations of 2%. Fermentation process was conducted under anaerobic conditions at temperature of 18^{o}C. Organic acids and pH were determinate in defined time intervals during fermentation process. Cabbage heads were also sensorially evaluated in native form before the beginning of fermentation as well as sauerkraut. Sensory evaluation was performed by 4 trained panelists in four measurements. Experiment showed that white cabbage, cultivar Futoški has more acceptable sensory characteristics and faster achievement of completion of fermentation of cabbage tissue.
Key words: *cabbage, sauerkraut, fermentation, sensory, salt*

INTRODUCTION

Increasing consumer demands for healthful foods have fostered the development of an active functional foods market. Numerous vegetable foods are already associated with health promotion and disease prevention. One group of vegetables that has been widely regarded for their antioxidant and anticarcinogenic properties are Brassica vegetables, including all cabbage-like vegetables (Chyou et al.,1990; Higdon et al., 2007). One of the most important commercial products obtained from Brassica vegetables is sauerkraut, which results from the lactic acid fermentation of shredded and salted white cabbage. It has usually been prepared by spontaneous fermentation caused by the lactic acid bacteria (LAB) present on cabbage leaves (Leuconostoc mesenteroides and Lactobacillus plantarum, predominantly) in a correct succession (Holzapfel et al., 2003). This process represents a cheap cabbage preservation method, and also consumers appreciate traditionally fermented products for their outstanding gastronomic qualities (Penas et al., 2010). In Serbia and Vojvodina Futog is well known region where the quality cabbage is cultivated. White cabbage, as raw material has been used like grouser for salads and thermally treated meals during most of the year. During the winter cabbage carried out the biofermentation process and had been storaged like so cold „sauerkraut“ (Niketić-Aleksić G,1988). Traditional foods are an expression of culture, history and lifestyle and generally possess health qualities, since tradition rarely favors foods which are not palatable and healthy. White cabbage, cultivar Futoški has got certificate as product with geographic origin according domestic legislation (Mastilović et al., 2008). White cabbage, cultivar Futoški is traditional population in Futog district, it has some speciphic morphological characteristics like loose heads, specific oval head and thin elastic leaves as

well as slightly expressed nervature of leaves compared to hybrid Bravo F1. Salt addition is a critical factor during cabbage fermentation, because the microbial growth and sensory properties of the final product are affected by the amount of salt used. The salt content in sauerkraut usually ranges between 0.6 and 2% NaCl, but it can even exceed 2%. Pederson and Albury (1969) defined the optimum conditions for fermentation of cabbage into sauerkraut to be uniform salting of the shredded cabbage with 2.0% to 2.25% salt, tightly packing the salted cabbage into the fermentation vessel, covering the vessel to exclude air from the cabbage, and fermenting at a temperature of 18 ◦C(Johanningsmeier et al., 2007). The aim of this work was to compare two varieties during fermentation of whole cabbage heads under optimal conditions for the spontaneous fermentation.

MATERIAL AND METHODS

White cabbage, cultivar Futoški and hybrid Bravo F1 were purchased from producers from Futog, Serbia and fermented in plastic barrels. Cleaned cabbage heads were closely placed in the barrels. Brine with dissolved NaCl was added into the barrels with cabbage heads. Overall content of added salt was 2% calculated on the weight of cabbage and brine. Fermentation process was carried out at 18^{o}C. Cabbage heads were pressed tightly and covered to prevent air from entering the cabbage mixture and CO2 from escaping from the mixture. Cabbage samples were taken from the barrel during time intervals of 20, 40, 50 and 75 days of fermentation.

The pH of the cabbage juice was measured by using a pH-meter (ExStick^{TM}, Extech Instruments, U.S.A) during fermentation. A pH meter was calibrated with pH 4 and pH 7 buffers and used for brine pH determinations. Temperature of the brine and room temperature were measured on daily basis. Total acidity, given as total lactic acid, was measured by titration using 0.1 N NaOH with phenolphthalein as indicator. Volatile acidity expressed as acetic acid was also determined. All chemical analyses were carried out in duplicate.

Fresh cabbage before fermentation process and after fermentation was sensory evaluated in order to characterize white cabbage, cultivar Futoški in relation with hybrid Bravo F1.

The four panelists were trained to evaluate fresh cabbage and sauerkraut using category scale. Fresh cabbage head shape was scored like appropriate (score 1) inappropriate (score 0) according characteristic shape of white cabbage, cultivar Futoški. Color of leaves, nervature of the leaves, leaf thickness, elasticity of the leaves, density of cabbage heads, sweetness were scored at scale of 0=not detectable to 15,5 very strong.

Fermented cabbage heads of cultivar Futoški and Hybrid Bravo F1 were also sensorial evaluated using scoring 1-5, where number 1 refers to not acceptable and number 5 to excellent taste and quality. Several commercial sauerkraut samples were evaluated by the panel during training for the purpose of selecting one that exhibited flavor attributes suitable for use as a reference. Panel was evaluated the color and uniformity of color of the pickled cabbage heads and color on the cross section, also hardness of the heads, elasticity of the leaves, presence of mucus, firmness. Odor was evaluated by intensity and note of odor. Flavour was evaluated like intensity of saltiness, sourness and note of flavour.

RESULTS AND DISCUSSION

Fig. 1 shows the decrease of pH value of white cabbage, cultivar Futoški i Hybrid Bravo brine during fermentation. Futoški cabbage achieved pH lower than 3.5 after 8 days of fermentation process, while the hybrid Bravo under same conditions achieved pH 3.5 after 11 days. Some authors cited more rapid decrease of pH in treatments with more added salt (Wiander et al., 2011).

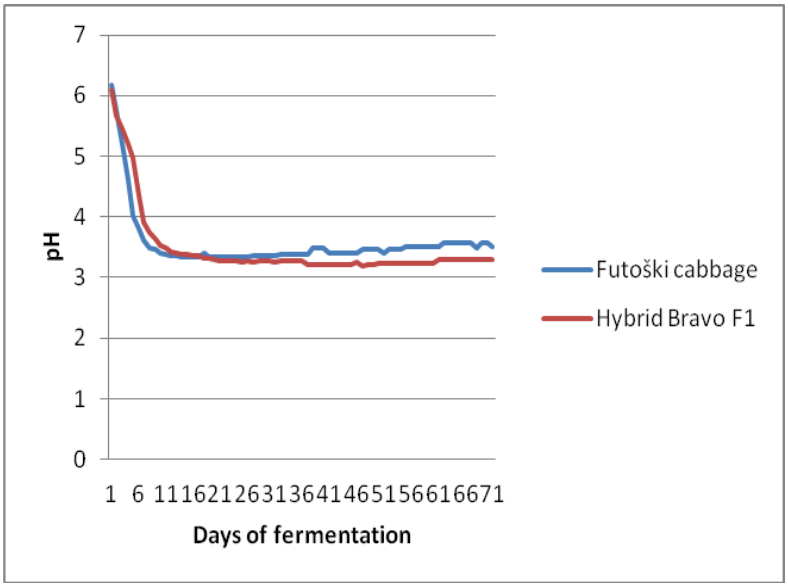

Figure 1. Decrease of pH value during fermentation process of cabbage

On Fig. 1 is shown sensorial evaluation of fresh cabbage heads of two variaties, white cabbage cultivar Futoški and Hybrid Bravo. Futoški cabbage has lighter color of the leaves, thinner leaves, milder nervature of the leaves, better elasticity of leaves. There is no significant difference between sweetness and wetness of theese two variaties.
Sensorial evalution of cabbages which were taken after 20 and 40 days of fermentation determinated that white cabbage cultivar Futoški after 20 days of fermentation achieved that diffusion of salt and brine into the cabbage tissue covered more than 90% of cabbage leaves surface. On the other hand Hybrid Bravo achived same level of diffusion only after 40 days of fermentation. This could be explained because Futoški cabbage has more loose heads and leaves are not packed so tightly as is the case with hybrid cabbage heads.

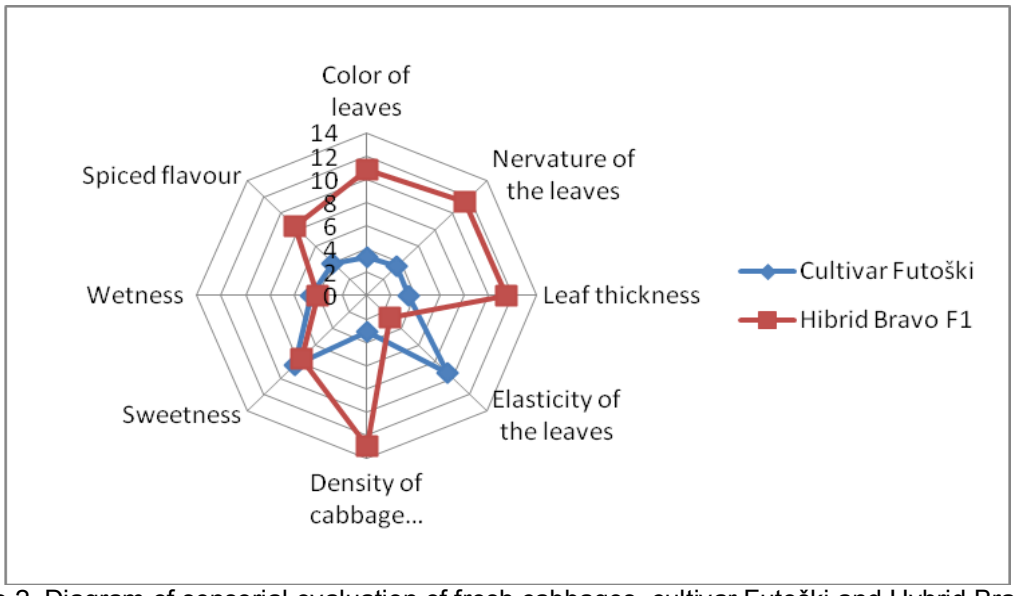

Figure 2. Diagram of sensorial evaluation of fresh cabbages, cultivar Futoški and Hybrid Bravo F1

Table 1. shows total acids content and volatile acids content produced during fermentation. Overall acidity in white cabbage, cultivar Futoški is slightly lower than the hybrid Bravo F1, but it is in the expected range according Trail et al.,1996, Pravilnik, 1979.

Table 1. Chemical characteristics of white cabbage, cultivar Futoški and hybrid Bravo F1 during fermentation

	Days of fermentation	pH	Total acids content expressed as lactic acid (%)	Volatile acids content expressed as acetic acid (%)
White cabbage, cultivar Futoški	20	3,3	1,09	0,056
	40	3,27	1,12	0,063
	50	3,28	1,13	0,065
	75	3,34	1,21	0,067
Hybrid Bravo F1	20	3,56	1,29	0,067
	40	3,21	1,36	0,075
	50	3,18	1,39	0,075
	75	3,29	1,44	0,078

Figure 2. shows diagram of sensorial evaluation of pickled cabbage heads cultivar Futoški and Hybrid Bravo F1.

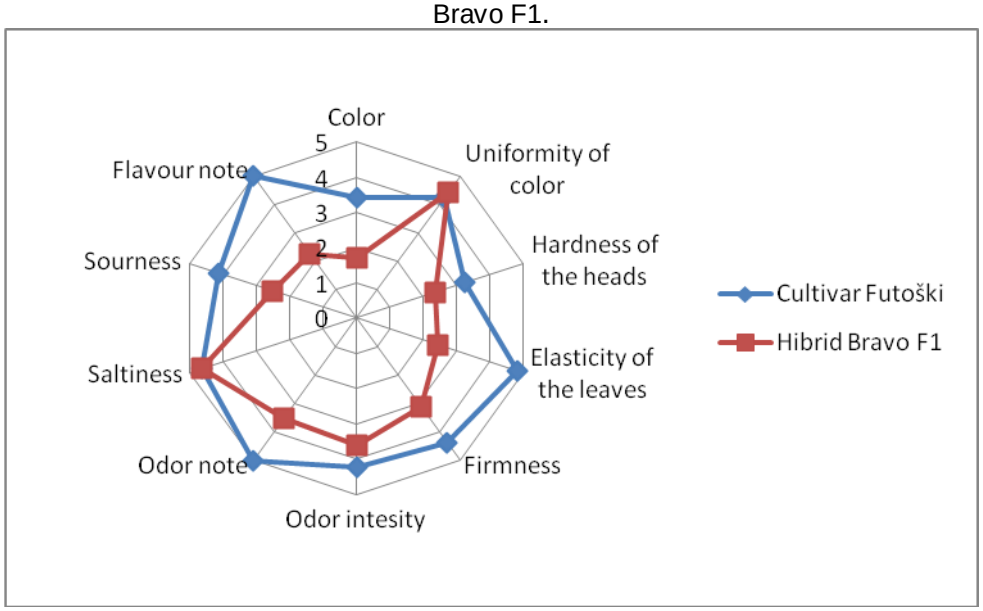

Figure 2. Diagram of sensorial evaluation of pickled cabbages, cultivar Futoški and Hybrid Bravo F1

CONCLUSIONS

Comparation of two varieties, white cabbage, cultivar Futoški and hybrid Bravo in native form and as fermented cabbage shows that white cabbage, cultivar Futoški has specific, more acceptable sensorial characteristics for fermentation. Fermentation process was developed faster in the case of Futoški cabbage, decrease of pH value was more rapid and diffusion of salted brine was more effective than in the hybrid cabbage heads. Chemical analysis shows that fermentation process was conducted in the desired direction. Slightly lower overall acidity proving mild odor and flavour in fermented Futoški cabbage what is important for the consumers who find it pleasant and acceptable.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project III 046001 financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT: The aim of this study was to characterise the most typical flour mixture bread (wheat flour and rye flour) produced in the Portuguese region of Viseu and evaluate if there are relevant differences between the samples tested. Nine samples from local producers were analysed considering the morphology, physicochemical (density, alveolus percentage, texture, colour and water activity) and sensorial properties. The form and dimensions of all breads were determined, as well as proximate composition and total salt content.
The forms of the breads were different, some round and others long. Nutritionally this type of bread turned out to be a food with high nutritional value, high percentage of ash (2.8-4.9%) and low values of fat, with a high range of salt content (0.4-1.4%). The physical properties were quite different between samples, although some of them are not perceptible by the consumer. This was the case of bread density whose results were 0.25-0.56 and the sensorial panel, constituted by a panel of 40 untrained tasters aged 7 to 63 years, did not find any difference. The traditional breads presented overall appreciation between 4.8 and 6.8, related with different colour and elasticity parameters.
Key words: *bread, density, texture, colour, salt, sensorial analysis*

INTRODUCTION

Bread is a food with an ancient history that assumes in diet a great cultural, social and religious importance. Bread is part of daily life for many people, starting right at breakfast, and is regarded as the basis of feed and the first source of energy (Vaz, 2004). The main ingredients of bread are flour, water, salt and yeast, of which the flour is assumed as the mass structural component, and therefore the key ingredient to obtain the bread. Water is also an essential ingredient in the formation of the mass. The salt helps in controlling fermentation, contributing to the fortification of the gluten in the flour, being decisive in the hydration of the masses, acting also as a flavour enhancer turning the bread crumb whiter (Leon and Rosell, 2007). The yeast carries out alcoholic fermentation, i.e. converts the fermentable sugars present in the mass into ethanol and carbon dioxide, which is the gas responsible for the growth of bread. Bread quality is highly dependent on the cereals most commonly used, for being considered the nobler, is wheat (*Triticum*, and more specifically *Triticum sativum*).
The advantages of a diet rich in vegetables and fibre are known since ancient times. However, only from the twentieth century there was a real concern about the low level of fibre intake in most diets. Wheat flour is an excellent source of fibre, particularly insoluble fibre (Leon and Rosell, 2007). Also the rye flour has high fibre content, especially dietary fibre, thus having positive effects on digestion and decreasing the risk of coronary heart disease, hypercholesterolemia, obesity and diabetes (Leon and Rosell, 2007). According to Pathlrana and Shahidi (2007), wheat is also a major source of antioxidants, in many cases greater than most fruits and vegetables. Among the antioxidants found in wheat highlights some phenolic acids such as ferulic, phytic or selenium acids, flavonoids, among others. As with most of the vitamins and minerals, also antioxidants are present in wheat in the bran and germ, and thus their content is reduced during the grinding process for obtaining flour (Pathlrana and Shahidi, 2007).

Addition of small amounts of rye flour to products made with wheat flour promotes the water absorption and prolongs the shelf life of the product, since it reduces the amount of amylose and amylopectin available to suffer retrogradation. As the artisan baking process is extended to industrial scale, the use of flour enhancing agents has been applied, because of the need to improve the process characteristics and shelf life of the products obtained. For decades, the enzymes were added to flour in bread production in order to improve its volume, flavour, aroma, structure of the crust and crumb, tenderness and shelf life (Nunes, 2008).
In Portugal they are known more than 100 varieties of bread. The raw material used (corn, wheat or rye) is very much dependent on the region and the weather. Various types of bread are obtained, according to cereals used (corn, wheat, rye, mixtures, whole flours), as well as the manufacturing process and type of fermentation (Almeida et al., 2008).

MATERIAL AND METHODS

Samples

In order to obtain a significant sampling, seven types of regional bread were collected in the district of Viseu, Portugal, and for each type three samples were taken triplicate. Each type of bread was accompanied by an identification form, having all the characteristics of raw materials and manufacturing process.

Chemical analyses

Several experimental determinations of chemical properties were done: moisture content, water activity, ash content, crude fat, crude fiber content, protein content, using the official methods of AOAC (2000). Determination of Chloride was done by the Mohr Method and the determination of carbohydrates was accessed by difference.

Physical analyses

In this study we performed several experimental determinations of physical nature such as size, color, density, alveolar characterization and cellular texture. To analyze the dimensions and volume of the loaves were measured the thickness, width and length. For calculating the volume the form was approximated to an ellipsoid. To determine the density were carefully cut pieces of bread in the form of parallelepipeds. From each sample were taken 15 cubes with 1 cm edge, which later were weighed on a precision scale.
In this study, the color parameters were evaluated using a colorimeter chroma meter (Minolta, Japan) expressing the results in the CIELab system coordinates: L* which is the brightness and varies between 0 (black) to 100 (white), the a* ranges from -60 (green) to +60 (red) and b* ranging between -60 (blue) to +60 (yellow). It was also determined cylindrical color coordinates: value, shade or hue (hº) and saturation (C):

$$Value = \frac{L^*}{10} \quad (1)$$

$$H^{\circ} = \tan^{-1}\left(\frac{b^*}{a^*}\right) \quad ; \quad \text{if } a^*>0 \text{ and } b^*>0 \quad (2)$$

$$C = \sqrt{a^{*2} + b^{*2}} \quad (3)$$

To do the alveolar characterization image analysis was used, using the program "Image J", developed by Wayne Rasband at the National Institute of Mental Health United States of America. From each sample, 5 fresh slices were prepared with a thickness of 10 mm (pattern cutting). For the analysis of texture properties was used a texturometer TA-XT2 from "Stable Microsystems." The analyses were performed immediately after manufacture, and for that were cut out seven slices (10 mm) per sample, removing a cube per slice (crumb) 30 mm edge.

Sensorial analyses

Sensory analysis was performed in a laboratory prepared for that purpose, on the day of delivery of the samples by a panel of 40 untrained tasters, aged between 7 and 63 years, who were asked to rate the following attributes: crumb colour, crust colour, aroma (bread, firewood and fermented), taste (bread, wood or fermentation), elasticity, density, and finally the overall appreciation. In this test the taster expressed the intensity of each attribute through a scale where verbal Hedonic expressions are translated into numeric valuesin order to allow statistical analysis. The scale of values varied from 0 (less intense) to 10 (more intense).

RESULTS AND DISCUSSION

Tables 1. to 5. show the results of the different determinations made to all the bread samples analysed in terms of medium values, standard deviations and analysis of variance. Samples that have the same letter show no significant differences in the parameter analysed, for p> 0.05. Thus, the greater the number of letters of classification, the greater the ability to discriminate between samples.

Chemical properties

From Table 1. it is visible that the values of moisture are not much different among the samples analysed. The sample from *Flor de Cabanas* showed the highest value, although this result is not from the formulation itself, but perhaps because this sample has a high fiber content, and the presence of fibres contributes to a greater absorption of water (Cauvain and Young, 2006). On the other hand, the sample from *Viso* showed the lowest value for moisture percentage. Regarding the water activity of the bread samples, and although the values were not so different from each other, the truth is that statistically there are some differences to be noticed.

In relation to the ash content, the samples from *Oliveira & Alves*, *Panifil*, *Pedregal* and *Flor de Cabanas*, showed very similar values (from 3.86 to 3.96), not statistically different as the analysis of variance confirmed. The sample showing a higher percentage of ashes is the sample from *Pazurara*, being this value statistically different from all the others, and this could be explained by the fact that this sample has in its constitution flour 130, with high power extraction.

Table 1. Chemical composition of the bread samples analysed.

Sample	Moisture (%)	Ash (%)	Fat (%)	Fiber (%)	Protein (%)	Salt (%)	Carbo-hydrates (%)	Aw
F. Car.	47.42±0.14^{b}	3.80±0.01^{c}	0.51±0.11^{b}	0.06±0.01^{e}	14.59±0.25^{c}	0.40±0.02^{e}	81.1±0.30^{b}	0.96±0.77^{b}

Pazurara	35.27±0.20^{e}	4.90±0.03^{a}	0.26±0.02^{c}	0.05±0.01^{e}	10.23±0.35^{e}	1.06±0.03^{c}	84.7±0.29^{e}	0.94±0.64^{ac}
Ol.&Alves	37.21±0.26^{d}	3.96±0.02^{d}	0.31±0.02^{bc}	0.55±0.01^{b}	11.25±0.24^{d}	1.47±0.03^{a}	84.8±0.22^{d}	0.94±0.58^{cd}
Panifil	36.70±0.28^{d}	3.94±0.01^{d}	0.37±0.09^{bc}	0.18±0.01^{c}	12.90±0.21^{a}	0.93±0.04^{f}	82.8±0.25^{d}	0.95±0.57^{ab}
Viso	28.08±0.14^{c}	2.76±0.01^{b}	0.37±0.08^{bc}	0.29±0.02^{d}	8.92±0.19^{b}	0.74±0.02^{d}	88.0±0.17^{c}	0.93±0.42^{d}
Pedregal	35.69±0.16^{e}	3.88±0.01^{d}	1.19±0.09^{a}	0.89±0.01^{a}	10.52±0.21^{de}	1.14±0.03^{b}	84.4±0.23^{e}	0.94±0.33^{cd}

Results are given as mean ± standard deviation (n = 3). Samples in the same column with the same letter are not statistically different for p>0.05.

In terms of fat content, the samples from *Flor de Cabanas*, *Oliveira & Alves*, *Panifil* and *Viso*, showed values statistically similar to each other. On the other hand, the sample from *Pedregal* contrasts with the others, showing a much higher value, which might be explained by the addition of any kind of lipidic ingredient, although this information was not provided by the manufacturer.

The levels found for cellulose are similar in the samples from *Flor de Carregal* and *Pazurara* as well as between in those from *Flor de Cabanas* and *Viso*. The sample showing the

highest fibre content is the sample from *Pedregal*, perhaps because in its constitution has two types of flour with high power extraction, wheat 130 and rye 150, as stated in the ingredients form.
The amounts of protein in the different samples analysed are in general different from each other, except for samples from *Flor de Cabanas* and *Flor de Carregal*, which have higher protein contents.
The results in Table. 4 also show that the salt contents in the samples analysed are quite different, with sample from *Oliveira & Alves* presenting the higher chloride percentage. Considering the information on the identification form for that bread, according to which the salt content should be lower, this fact may be due to the addition of a higher quantity of salt than that established in the formulation.
Regarding the contents of carbohydrates, the results among the samples do not differ significantly. Even though, the sample from *Viso* stands as the one with the higher value, which can be explained by its lower values in terms of ash and protein contents.

Physical properties
According to the values shown in Table 2. in terms of the colour coordinates for the crust, it was found that the parameters L and Value do not differ significantly. These parameters indicate that the samples were quite dark (with values standing near the middle of the scale). Regarding the parameter a in the samples *Flor de Carregal*, *Pazurara* and *Viso*, the values were similar to each other, as well as in the samples from *Flor de Cabanas* and *Panifil*. These values indicate the predominance of the red colour over green. With relation to the parameters b, hue (cylindrical coordinates colour) and c (saturation or chroma), no significant differences were seen between the samples. Furthermore, and since the values of b are highly positive, the colour yellow is dominant over blue, as expected. The results for the crumbs are quite similar, although showing a lighter colour and less intense brown.

Results are given as mean ± standard deviation (n = 30). Samples in the same column with the same letter are not statistically different for p>0.05.

The larger sample (Table 3.) was the *Panifil*, which is distinguishable from the others, perhaps because it has a higher content of salt and proteins, thus inducing a good fermentation. As to the crumbs density, the sample from Flor de Cabanas is highlighted as the denser, while all others are statistically identical. As to the alveolar characterization, the

sample from *Viso* revealed a greater total area, a higher alveolar percentage as well as a bigger alveolus average size.

Table 3. Physical properties of the bread samples analyzed.

Sample	Whole bread volume (cm^3)	Crumbs density (g/cm^3)	Slice alveolar characterization			
			Area ($pixel^2$)	Nº Alveolus	% Alveolar	Size ($pixel^2$)

Pazurara	737.23±5.76^{b}	0.38±0.05^{b}	721473.8±124114.1^{c}	107.2±15.4^{b}	10.4±1.8^{b}	6839.6±1383.8^{b}
Ol.&Alves	474.89±8.99^{e}	0.25±0.03^{e}	1319942.8±412921.5^{bc}	231.8±50.6^{bc}	25.1±8.1^{c}	5660.2±925.0^{b}
Panifil	878.16±6.87^{a}	0.31±0.04^{d}	1178604.8±417663.8^{bc}	186.4±63.7^{bc}	14.2±5.1^{bc}	6567.0±1911.5^{b}
Viso	632.64±7.73^{d}	0.25±0.02^{e}	3559231.2±525330.7^{a}	229.2±24.8^{bc}	45.3±5.6^{a}	15753.2±3299.5^{a}
Pedregal	548.49±8.87^{f}	0.32±0.05^{cd}	1500673.4±4078623.0^{bc}	274.0±48.7^{ac}	24.3±5.5^{c}	5451.2±874.5^{b}

Results are given as mean ± standard deviation (n = 3 for volume, n = 15 for density, n = 5 for alveolar characterization). Samples in the same column with the same letter are not statistically different for p>0.05.

By analyzing the results of textural properties in Table 4., it was found that in general the samples are very similar. The parameters chewiness and hardness in the sample from *Flor de Cabanas* are higher, which might be explained by the higher density as previously reported. In terms of cohesiveness and elasticity, it was the sample from *Panifil* that showed the highest values.

Table 4. Textural properties of the bread samples analyzed.

Sample	Hardness (N)	Elasticity (%)	Cohesiveness (dimensionless)	Chewiness (N)
F. Car.	5.52±1.53^{b}	88.92±2.72^{c}	0.60±0.05^{a}	2.91±0.67^{b}

Pedregal	2.42±0.82^{c}	96.14±1.63^{d}	0.78±0.02^{bc}	1.79±0.50^{c}

Results are given as mean ± standard deviation (n = 7). Samples in the same column with the same letter are not statistically different for p>0.05.

Sensorial properties

According to what is described in Table 5., it was found that the different samples were equally perceived by the tasters in relation to the following attributes: bread aroma, wood aroma and ferment aroma, as well as in terms of density, wood flavour and ferment flavour. Regarding the sensory parameters: crust colour, crumb colour, elasticity and ferment flavour, the perceptions were also very similar. As regards the overall assessment, the samples were also perceived in a similar way, highlighting however the sample from *Flor de Cabanas*.

CONCLUSIONS

The results from this work showed that the breads were different in shape and size, as well as density or alveolar characterization. Nutritionally this type of bread turned out to be a good food with high percentage of minerals and low values of fat. However, the salt content varied quite a lot among samples. The physical properties were quite different between samples, although some of them were not perceptible by the panel members. This happened, for example with density, whose results varied a lot and the sensorial panel was not able to differentiate the samples. The traditional breads presented a global appreciation between 4.8 and 6.8, related with different colour and elasticity parameters.

ABSTRACT: Plum brandy is traditional Serbian alcoholic beverage, made by distillation of fermented plum variety *Prunus domestica.* Distillate is colorless and has characteristic fruit aroma, which originates from the component of the inner layer of the plum skin. According to the Serbian tradition, plum brandy is sometimes mixed with different medicinal herbs, and these products are treated as forms of herbal medicine. Medicinal herbs are rich source of polyphenols and other valuable compounds, which can contribute to the functional properties of brandies. These products are usually produced from a large number of herbs and spices, which, also, change the aroma complex and contribute to the color. In this study, it was investigated the effects of two herbal compositions which were consisted of 44 plants with different ratio of aromatic and bitter herbs on sensory characteristics and antioxidant capacity of herbal brandies. Sensory assessment of samples was performed by using modified Buxbaum model of positive ranking. The total phenolic content of samples was determined according to the Folin-Ciocalteu spectrophotometric method. The antioxidant capacity (ATC) was tested by using two methods: 1,1-diphenyl-2-picrylhydrazyl (DPPH) and ferric reducing ability of plasma (FRAP). The total sensory quality of samples was 17.85 and 17.95, which were very good scores. The total phenolic content of samples was 145.56 and 130 mg/L gallic acid equivalents, while the antioxidant capacity was 0.69 and 0.61 mM Trolox according to DPPH assay, and 2.08 and 1.75 FRAP units according to FRAP method. The obtained results suggested that higher content of the bitter herb significantly influenced the antioxidant capacity and not significantly affected the sensory profile of special brandy. Based on sensory assessments, the sensory properties of these special brandies were completely acceptable for the assessors.
Key words: *herb brandy, sensory characteristics, antioxidant capacity*

INTRODUCTION

Official Gazette of the Republic of Serbia for regulation of spirits appoints that herb brandy has to be made from distillate or mixture of distillate of agricultural origin and macerate and/or distillate of macerate of aromatic plants (parts or whole plant). The ethanol content of basic distillate must have at least 37.5 % (v/v) (Pravilnik o kategorijama, kvalitetu i deklarisanje rakije i drugih alkoholnih pića, 2010).

Herb brandies are produced in many Mediterranean countries and in a number of Balkan countries, such as Serbia, Macedonia, Bulgaria, Greece and Croatia. The distillate for production herb brandy is usually made from various fermented fruits depending on the production's tradition and the region of origin. The most used distillate for production Serbian herb brandy is made by double distillation of fermented plum, variety *Prunus domestica.* Distillate is colorless and has characteristic fruit aroma, which originates from the component of the inner layer of the plum skin (Popović et al., 2008).

Serbia has a century old tradition of collecting and using aromatic and medical herb. The wisdom of using medicinal herb to promote good health and treatment various diseases have been saved to present days. According to this heritage, distillate is mixed with different medicinal herbs, and these products are still treated as forms of folk medicine. The beverage is usually produced from a large number of herbs and spices, which also change the aroma complex and contribute to the color.

In production of beverage with herb aroma, the most frequently used method for extraction the aromatic and active phytochemical compounds from plants is maceration in the ethanol/ water solution. This process has benefits compared to other separation techniques. Processing on low temperature does not provoke denaturation of herb components and preserves the health properties of beverage (Tonutti and Liddle, 2010). Herbs are rich source of bioactive components like different polyphenols, phytoalexins, alkoids, cumarins, diterpenes, lignans, organic acids, organic oils, volatile oils, etc (Saroya, 2011). Medicinal herb can have many health benefits for consumers including antioxidant activity, digestive stimulation action, anti-inflammatory, antimicrobial, hypolipidemic, antimutagenic effects and anticancerogenic potential (Wojdylo et al., 2007). In the last decade the antioxidant characteristics of beverages have become very important for its quality (Gorjanović et al., 2010).
The functional and sensory characteristics of food and beverage depend of the concentration, combination and chemical composition of various herbs. The variation and diversity of chemical composition of plants depends on various effects, such as the anatomical part of plant, the location and time of harvesting, the storage condition and many others. To produce the beverage with standard chemical composition and quality, the use of herbal extracted is the best solution.
In this study, it was investigated the effects of two herbal composition on sensory characteristics and antioxidant capacity of herb brandies. Both compositions were produced with 44 different plants but with different ratio of bitter herbs.

MATERIAL AND METHOD

The plum brandy was obtained from local homemade manufacture from the region of Kruševac and herbs from local health food store. Air-dried plant or its parts were cut into small pieces and added in 45 % v/v alcohol medium (plum brandy). The extraction of plants (two plant composition with different concentrations of bitter herbs) was carried out in glass bottles which were placed on shaker in dark place at room temperature for period of 10 days. The mixture was filtered through 70 g/m^3 filter paper.
In study it was analysed two different herb brandies with various ratios of bitter herbs. Herb brandies contain the flowing extracts of 44 plants (39 herbs (aromatic and bitter), four dried fruits and wood's bark): sweet odorata (*Asperula odorata*), peppermint (*Mentha piperita* L.), mountain germander (*Teucrium montanum* L.), wall germander (*Teurium chamaedrys*), hibiscus (*Hawaiian hibiscus*), stinging nettle (*Utrica dioica* L.), common sage (Salvia officinalis L.), pot marigold or english marigold (*Calendula officinalis* L.), camomile (*Matricaria chamomilla* L.), mellisa (*Melissa officinalis* L.), sweet flag (*Acorus calamus*), wild thyme or creeping thyme (*Thymus serpyllum* L.), horehound (*Marrubium vulgare*), hawthorn (*Crataegus oxyacantha* L.), elder or elderberry (*Sambucus nigra* L.), common gypsy weed or herbal speedwell (*Veronica officinalis*), common yarrow (*Achillea millefolium* L.), sweet marjoram (*Origanum majorana* L.), coltsfoot (*Tussilago farfara* L.), grand wormwood (*Artemisia absinthium* L.), cypress spurge (*Euphorbia cyparissias* L.), horsetail (*Equisetum arvense* L.), common juniper (*Juniperus communis* L.), herb hyssop (Hyssopus *officinalis*), rosemary (*Rosmarinus officinalis* L.), gentiane (*Gentiane lutea*), blueberry (*Vaccinium mytillus*), european mistletoe or common mistletoe (*Viscum album* L.), shepherd's purse (*Capsella bursa pastoris* L.), linnean herbarium (*Paris quadrifolia* L.), centaury (*Erythraea centaurium* Pers.), fennel (*Foeniculum vulgare* Mill.), elecampane or horse-heal (*Inula helenium*), common chicory (*Cichorium intybus*), anise (*Pimpinella anisum* L.), ribwort plantain (*Plantago lanceolata*), vanilla (*Vanilla planifolia*), cinnamon (*Cinnamomum* div.), eugenia (*Eugenia caryophyllata* L.), common fig (*Ficus carica* L.), grape (*Vitis vinifera* L.), plum (*Prunus domestica* L.), apple (*Pirus malus* L), oak wood (*Quercus* sp.).
The total phenolic content (TPC) of herb brandies samples were determined according to the Folin-Ciocalteu spectrophotometric method described by Singleton and Rossi (1965). The total antioxidant capacity was evaluated using DPPH (Kaneda et al., 1995) and FRAP methods (Benzie and Strain, 1996).

Sensory characteristics of the brandies enriched with aromatic and bitter herbs were determined using modified Buxbaum model of positive ranking (Tešević et al., 2005). The common quality parameters were evaluated: clearness – parameter which contributes to the overall visual liking of drink which depend on the purity and hue of color (max 1 points); color - visual impression created as a result of irritation of the retina of the eye with light rays of different wavelengths (max 1 points); distinction – parameter which clearly defines specific and distinctive characteristic synonymous for certain categories of strong alcoholic beverages (max 2 points); odor - a sensory attribute resulting from stimulation of the olfactory receptors in the nasal cavity by certain volatile substances (max 6 points); taste - a sensory attribute resulting from stimulation of the gustatory receptors in the oral cavity by certain soluble substances (max 10 points) (Nikićević, 2005). In this evaluation a brandy sample may have a maximal score of 20 points. Sensory tests were carried out using a panel of five qualified assessors (experts). Sample were served and assessed at professional testing room (air temperature 20 °C, adequate daylight, peace and quietness).
The experimental data were subjected to an analysis of variance (ANOVA), while Tuckey's test was calculated to detect difference ($p \leq 0.01$) between the mean values. Statistical analyses were performed with the statistical program MS Excel (Microsoft Office 2007 Professional).

RESULTS AND DISCUSSION

The first goal of this study was to examine the effect of two various concentrations of bitter herbs on sensory and antioxidant characteristics of herb brandies. The TPC and antioxidant potential were presented in Table 1. The results of ANOVA showed that the various concentration of bitter herbs very significantly influence on the TPC and antioxidant characteristic (ATC) of these herb brandies ($p < 0.01$). Based on these results, the adding the herb in spirit significantly influence on the TPC and increase the ATC of plum distillate. The concentration of herbs is also important factor for the TPC and ATC, the higher amount of herb increase ATC and improves the healthy properties.

Table 1. TPC and antioxidant capacity of herb brandies

sample	TPC (mg/L GAE)	FRAP (mmol TE)	DPPH (mmol TE)
P	5.10 ± 0.25^{A}	0.12 ± 0.02^{A}	0.050 ± 0.002^{A}
HB1	145.56 ± 0.00^{B}	1.75 ± 0.03^{B}	0.610 ± 0.010^{B}
HB2	130.00 ± 2.56^{C}	2.08 ± 0.03^{C}	0.691 ± 0.015^{C}

Each value is the mean ± standard deviation of three replicate experiments.
Within each column the different letters mean that differences were very significant according to Tuckey's HSD test at $\alpha \leq 0.001$

a. Total phenol content, expressed as milligram of gallic acid equivalents per liter of brandy.
b. Total antioxidant capacity expressed as mmol of Trolox equivalent.

P - plum brandy; **HB1 -** herb brandy with higher content of bitter herb; **HB2** - herb brandy with lower content of bitter herb.

The sensory scores of evaluated herb brandy samples were 17.85 and 17.95, which were a very good score and higher value than sensory score for basic alcohol medium (15.8). The herbal components significantly affected on the sensory characteristics of plum distillate, and gave the specific herb aroma to the samples. The sample HB1 had more insensitive bitter taste then HB2, due to higher amounts of bitter herbs. The sensory assessors evaluated both samples with very similar value; therefore higher bitterness was acceptable for the assessors. The color of herb brandy samples had characteristic green tones, which originate from herb components and change the color of otherwise colorless distillate.

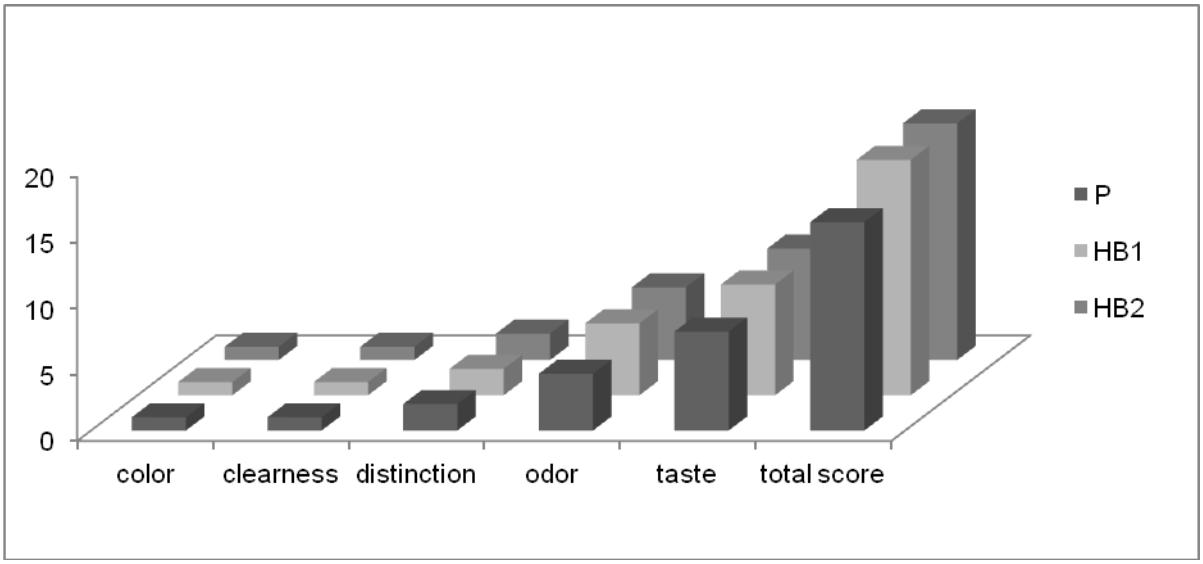

Figure1. Sensory characteristics of herb brandies

CONCLUSIONS

The present study showed that the higher quantity of bitter herbs in the plant mixture of samples significantly affect on the TPC and ATC. The sensory characteristics of herb brandy samples were changed, but not significantly affect on the total sensory scores. The both bitterness intensity of the samples was acceptable for the assessors. Based on these results, it was demonstrated that extracting the higher amount of bitter herb increased the ATC, and did not significant effect on the sensory score. The used herb improves the sensory characteristics and improved healthy properties of the spirits. According to these results, the sensory properties of special brandies were completely acceptable for the assessors.

ABSTRACT: The aim of this study was to examine the possibility to predict concentrations of ethanol, fructose, glucose and total acidity in wine Prošek using specific wavelength.
Wines Prošek were produced using two grape varieties (Plavac mali and Pošip). Physical-chemical measurements (relative density, real alcohol, total extract, reducing sugars, pH, total acidity, volatile acidity, ash, free sulphur dioxide, total sulphur dioxide) were conducted for wine samples. The absorbance of wines Prošek was measured using defined wavelengths with the instrument NIR-128-1.7-USB/6.25/50 µm with scan range 904-1699 nm.
Calibration equations were developed from NIR data using partial least squares (PLS) regression with internal cross validation. Using PLS regression, very good calibration statistics (R^2 > 0.80) were obtained for the prediction of total alcohol, fructose, glucose and acidity for the red wine Prošek produced from grape variety Plavac mali regardless which yeast was used in the production. The same efficiency was detected for the white wine Prošek produced from the grape variety Pošip only in predicting content of alcohol and acidity. From the stacking data of the experiment and gained from the models can be concluded that near infrared spectroscopy could be used as rapid alternative method for the prediction of the concentration of alcohol and acidity for Prošek wines regardless the grape variety and in prediction of concentration of fructose and glucose just for Prošek wines produced from grape variety Plavac mali regardless the yeast used in the wine production.
Key words: *NIRs, wine Prošek, prediction*

INTRODUCTION

Growing interest in the safety and traceability of food and beverages is a challenge for the development of methods for proving and detection. Methods that require pre-treatments of the sample also must include highly-skilled personnel what is the main reason why fast and non-destructive methods are more and more in use (Alishahi et al., 2011). Among them, near infrared spectroscopy has proven to be a successful analytical method for analysis of a variety of food products (Nicolaï et al., 2007; Reid et al., 2005; Sirisomboon et al., 2007). NIR region (750 – 2500 nm) is very useful spectral fingerprint of food samples in which vibration and overtone combinations of basic bonds (O–H, C–H and N–H) are the main recordable phenomena (Williams et al., 2001). In the food industry, NIR measurements are used in measurement (Hernández Gómez et al., 2006; Liu et al., 2010) evaluation of quality (Sirisomboon et al, 2007), quality prediction (Cayuela et al., 2010), and differentiation of samples (Reid et al, 2005) and prediction (Ozaki et al., 2007). Previous studies have shown that some oenological parameters for red wine can be predicted using of near infrared spectroscopy (NIRs). Wine is an important component in Mediterranean dietary tradition and is considered as an important health benefactor since it is rich with antioxidant compounds. The antioxidant capacity of wine (related with phenolic compounds) depends on the grape variety, vineyard location, cultivation system, climate, soil type, vine cultivation practices, harvesting time, production process and ageing (Shahidi and Naczk, 1995) and grape maturity (Le Moigne et al., 2008). The consumer is relating wine quality with the name and

origin, expecting uniformity what is often not easy for the producer regarding different factors influencing the harvest (precipitation, number of sunny days, temperatures, etc.).
This paper discusses the ability of NIRS in prediction of concentrations of ethanol, fructose, glucose and total acidity in wine Prošek using specific wavelength. The inter-relationships between chemical properties and sensorial evaluation can provide reliable results (Williams et al., 1988; Bueno et al., 2010) that could be used in the production and market positioning of the wine (Parpinello et al., 2009; Charters & Pettigrew, 2007).

MATERIAL AND METHODS

Wine production

Dessert wines "Prošek", were produced by semi scaled fermentation from dried grapes of cv. Pošip and *Plavac mali* in the harvest of 2008. Grapes were dried in the glasshouse for 5 days and 18 days, respectively. Dried grapes were crushed, destemmed and sulphited with potassium metabisulphite (15 g/hL). After 4 hours of skin contact at 15 °C, the Pošip must was racked into a 25-litre glass container. Alcoholic fermentation was done with selected yeast Fermol Cryoaromae (*Saccharomyces cerevisiae var. uvarum*, 30 g/hL, AEB s.p.a., Brescia, Italy). Alcoholic fermentations for Plavac mali cv. were done using comercial yeasts (Lalvin EC 1118, *Saccharomyces cerevisiae var. bayanus*, 40 g/hL, Danstar ferment, Switzerland; and Fermol Cryoaromae, *Saccharomyces cerevisiae var. uvarum*, 30 g/hL, AEB s.p.a., Brescia, Italy) and with native yeasts. Maceration for cv. Plavac mali took 5 days and the pomace was punched down twice daily, after which it was pressed on the hydraulic press (pressure <2 bar). The must was put in 10-litre glass vials, where the alcoholic fermentation continued. Temperature during fermentation was between 22 and 24 °C. The first racking was done 29 days, and the second 184 days (6 months) after the beginning of fermentation. After the second racking, Prošek was bottled. All experiments were performed in duplicate.

NIR analysis

NIR spectra of Prošek wine samples were collected in the range of 904–1699 nm using a Control Development, Inc., NIR-128-1.7-USB/6.25/50 µm, with installed Control Development software Spec32. NIR spectroscopy is based on the electromagnetic absorption at the near-infrared region but the spectral analysis has to be assisted with various chemometric techniques (Ding & Xu, 1999; Alishahi et al., 2010).

Application of NIR to fermentation process - wine

NIR has been applied to the measurement of the concentrations of some constituents in wine. Previous studies have measured concentration of ethanol, fructose, and tartaric acid in white and red wines using NIR, based on optical density (transmittance) of wine samples in the wavelength region of 800 – 2400 nm. Six wavelengths were found to be most characteristic for ethanol, fructose and tartaric acid: 1072, 1450, 1696, 1816, 2150 and 2232 nm. Applied NIR instrument collected data in the range of 904 – 1699 nm, and for the prediction were used 3 specific wavelengths of the absorbance spectrum (1072, 1450, 1696 nm) in prediction of ethanol, fructose, glucose and total acidity in wine Prošek. Data were analysed using program *Statistica v. 8*.

RESULTS AND DISCUSSION

Wine Prošek were produced using two grape varieties (Plavac mali and Pošip). Physical-chemical measurements (relative density, real alcohol, total extract, reducing sugars, pH, total acidity, volatile acidity, ash, free sulphur dioxide, total sulphur dioxide) were conducted for wine samples.

Table 1. Average values for basic oenological parameters of dessert wine Prošek, from Pošip and Plavac mali cv., vintage 2008

Physical-chemical parameters	Grape varieties			
	Plavac mali			Pošip
	EC 1118	Cryoaromae	Native	Cryoaromae
Relative density (20/20ºC)	27.8	25.5	26.3	27.0
Real alcohol (vol %)	14.3	13.4	13.7	10.5
Total extract (g/L)	254.5	261.3	259.5	334.2
Reducing sugars (g/L)	215.2	206.6	214.5	280.7
pH	3.8	3.7	3.8	3.9
Total acidity (g/L)	7.7	7.9	6.8	7.4
Volatile acidity (g/L)	1.6	1.9	1.5	1.9
Ash (g/L)	3.8	3.9	3.8	5.2
Free sulphur dioxide (mg/L)	3	4	2	11
Total sulphur dioxide (mg/L)	37	36.5	36.5	125.5
Glucose (g/L)	69	81	84	210
Fructose (g/L)	180	137	145	166

Table 1 presents results of oenological parameters of wines produced from different grape varieties, with different yeasts. Using NIR process analyser, each spectrum of different wine Prošek from cv. Pošip and Plavac mali was recorded. Each sample was recorded in triplicate and the mean value was calculated. In figure 1 are presented means of NIR spectrums (absorbance).

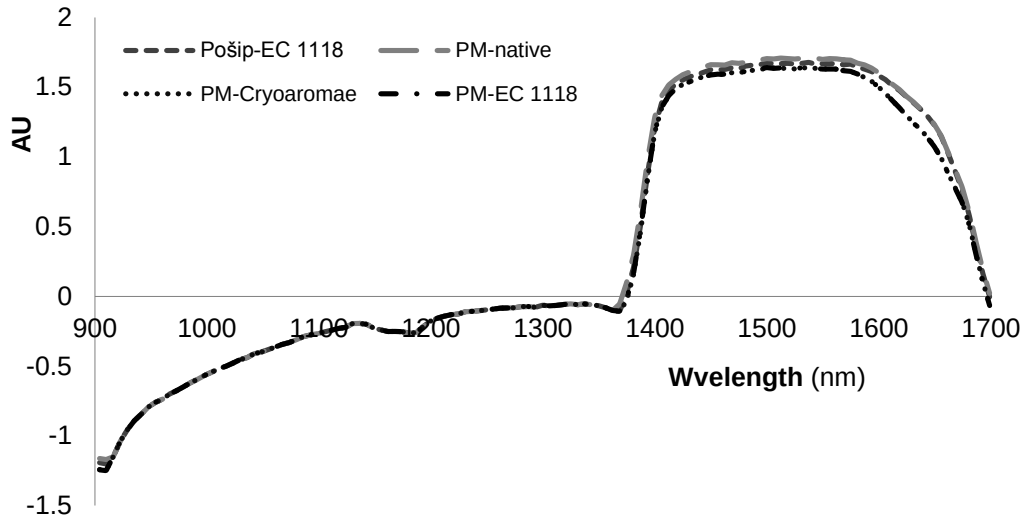

Figure 1. Absorbance spectra for wine Prošek produced from different grape (Plavac mali (PM), and Pošip)

Analysing presented spectres, it seems that all records are very similar, regardless of the grape used in the wine production, with an exception in the range 1400-1700 nm, where the curves show slight differences. Presented results are in accordance with the study conducted by Cozzolino et al. (2004). The range of the used NIR instrument is significantly narrower then the instruments usually used (with a range from 400 nm to 2500 nm), but to ensure the data differentiation between the samples that represent all stage in the wine production, for the further analysis is necessary to use some chemometric techniques. To predict expected concentration of ethanol, acidity, and glucose and fructose in white and red Prošek wines using NIR wavelengths: 1072, 1450 and 1696, but based on absorbance values although

Ozaki and co-workers (2007) have indicated 6 different wavelengths the restriction of the NIR instrument with the range of 904 – 1699 nm was the reason of reducing the number of NIR wavelengths on just 3. The linear model was used with the following form:

$$y_i = a_i \cdot AU_{i,1072} + b_i \cdot AU_{i,1450} + c_i \cdot AU_{i,1696} + d_i \quad \text{where } i = 1,..,4 \qquad [1]$$

i=1 ⇒ concentration of ethanol; *i=2* ⇒ concentration of acidity; *i=3* ⇒ concentration of glucose; *i=4* ⇒ concentration of fructose; *a,b,c d* ⇒ constants that differ regarding the *i*;
AU ⇒ absorbance unit for specific wavelengths given in the subscript.

In figures 2 and 3 is presented the agreement between the experimental data and values of the concentration of the equation 1. Following results indicated high correlation with the chosen wavelength what implies the possibility to predict the chosen concentrations of ethanol (*i=1*), acidity (*i=2*), (glucose (*i=3*), fructose (*i=4*).

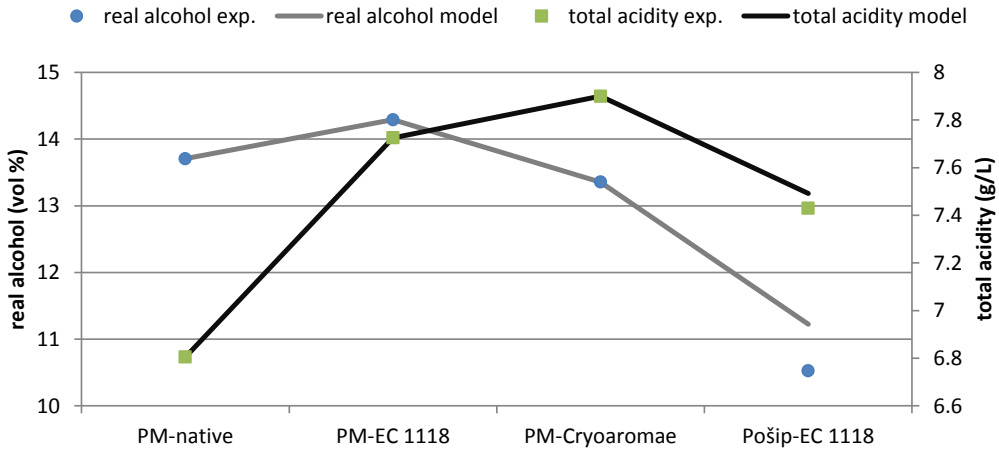

Figure 2. The agreement of experimental data and values gained with the model for real alcohol and total acidity

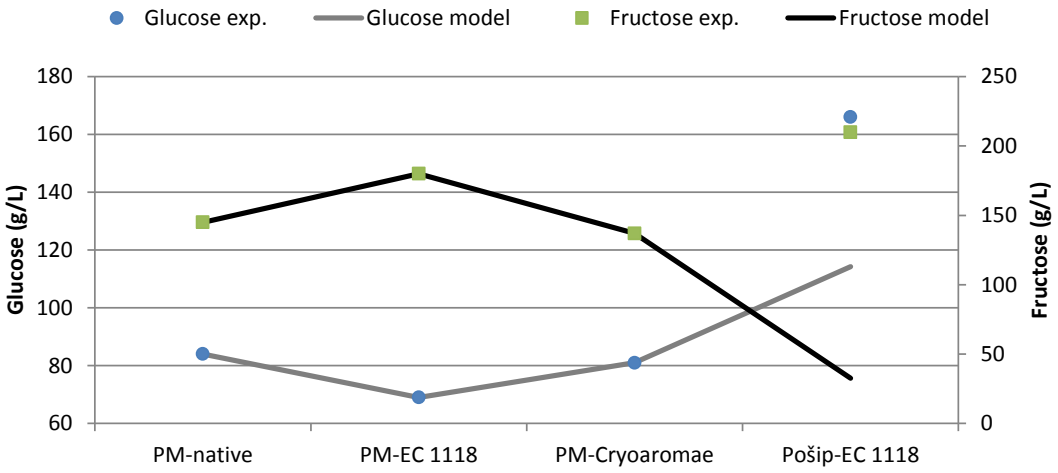

Figure 3. The agreement of experimental data and values gained with the model for glucose and fructose

In summary, this work annotated the advisability of use of NIR for on-line monitoring of product quality and selection (Alishahi et al., 2010; Nicolaï et al., 2007). It has also demonstrated the potential of NIR spectroscopy for prediction of chosen concentrations that are characteristic of quality of the wine Prošek what gives now the NIR spectroscopy also the

quantitative characterisation beside the qualitative characterisation of an observed product (Müller and Steinhart, 2007).

CONCLUSIONS

Near infrared spectroscopy showed promise as a rapid, non-destructive method in prediction of oenological parameters as concentration of ethanol, acidity, glucose and fructose for the desert wine Prošek. But the prediction of concentration of oenological characteristics using just 3 wavelengths (1072, 1450 and 1696) was more effective for red wine Prošek (produced prom cv. Plavac mali) than for the white wine Prošek (produced from cv. Pošip). This paper has presented that NIR spectrums and their specific wavelengths can be a useful tool for quality control. NIR can be used qualitatively to detect, to identify, and to qualify which grape was used in the wine production as well as the quantity of chosen oenological parameters of wine Prošek.

ACKNOWLEDGEMENTS

ABSTRACT: The Republic of Serbia is known as a producer of wide range honey varieties. The Vlasina plateau in the south part of Serbia covers the area of 12740.90 ha. According to the Regulation of the Government of the Republic of Serbia ("Official Gazette of RS", no. 30/06) Vlasina area is protected as a landscape of outstanding features and categorized as a natural resource of great importance for the Republic.
The diversity and specificity of biotopes Vlasina areas have caused a high diversity of flora, vegetation, fauna and ecosystems that are characterized by high degree of origins and authenticity of natural features. The area is habitat for a number of natural rarities, as well as natural phenomena. Beekeepers in the area mainly deal with stationed beekeeping in beekeeping directly at Vlasina plateau.
The aim of this paper was to find out whether producers of Vlasina honey are familiar with geographical indications (GIs) and to determine their perception and attitudes about these indications. The article presents the results of a research that shows that only a small part of producers are familiar with GIs. This group believes that GIs would have positive effect on honey competitiveness and especially on marketing, increasing sales prices and reduce a black market. The results suggest that there is a need of better information regarding GIs.
Key words: *GIs, Vlasina honey, marketing*

INTRODUCTION

Vlasina is the plateau in the Republic of Serbia with good natural conditions and moderate continental climate as well as richness of flora which provides excellent conditions for the bee-keeping and honey production. Honey is healthy product and one of the few products that can be consumed without any human processing (Ványi et al. 2011).
According to official data annual honey production in Serbia is approximately 4500 tonnes (Statistical Yearbook of the Republic of Serbia). This indicates that total value of honey production doesn`t has significant contribution to the Gross Domestic Product in Serbia but other benefits play more important role. At the present time bee-keeping is most commonly family business and one of the additional activities which can provide alternative income (Ostojić et al. 2011).
In order to improve marketing of their own products and achieve recognition on the market, domestic producers of agricultural products are increasingly interested for protection of geographical indication of products (Mesić et al. 2010).
Geographical indications as a marketing tool contribute to commercial value of products or services and increase the potential of selling with higher prices. With transmission of cultural tradition of the region and the specifics of the area in food production it can be create a unique product identity (Babcock and Clemens, 2004).
Primary objective of protection of geographical indications is to prevent the possibility of unfair competition. In the Republic of Serbia there are some products that are perceived by consumers as very specific for a certain region. In the Institute for Protection of intellectual property till now is protected a total of 58 products, of which 43 products are with domestic origin.

Encouraging the production of protected autochthonous products and their promotion could significantly contribute to the rural economy through the increase of income of farmers who are engaged in the production of these products. The procedure of protection takes time and financial resources and it is important that producers recognize the importance of protecting their products and the benefits arising from such protection.
The aim of this research is to examine attitudes of honey producers towards geographical indications.

MATERIAL AND METHODS

In this research a structured survey was conducted designed for bee-keepers in the area of Vlasina plateau in order to understand their attitudes towards GI. Sampling was carried out using a simple random sample through a survey, as an instrument of data collection. The research was conducted in 2011.
The survey included 86 honey producers who are bee-keepers on Vlasina plateau. Data were collected on age and gender, the size of production, the sales of honey, share of income from honey production in total income, if they are familiar with geographical indications and their opinion about possibility of conducting one for Vlasina honey. The data were analysed using descriptive statistics.

RESULTS AND DISCUSSION

This research included 88% men and 12% of women respondents. More than 60% of respondents aged over 50 years which indicates unfavourable age structure. Most of the respondents have finished high school (47.2%), but the number of interviewed with higher education is slightly lower (45.8%).
Total annual production and sale of honey is showed in table 1.

Table 1: Total annual production and sale of honey

	Mean	Mode
Produced (kg)	989	500
Sold (kg)	644	400
Price (RSD)	360	400

On average every bee-keeper produces about one tone of honey per year, of which approximately 70% is sell on the market and remaining part is home consumption. It is important to underline that most bee-keepers produces only 500 kg honey per year. These provide us information that producers on Vlasina are small scaled.
The share of income from honey in total income by the most survey producers is medium (51%). Only 22 % stated that honey production has large or very large share in their income, which leads to the conclusion that this group consists of commercial honey producers. About quarter of producers stated that they have very low (8%) or low (19%) income from honey production (Table 1). The relative importance of income provides useful information regarding attitudes towards GIs.

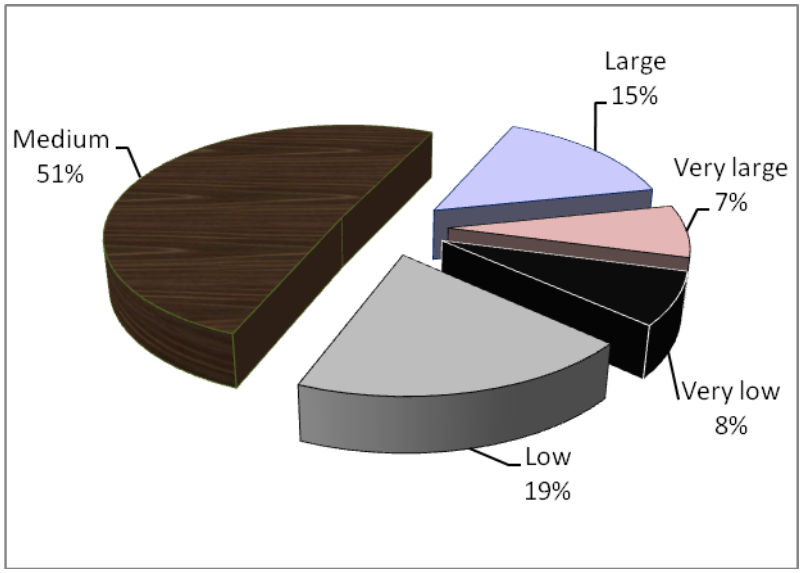

Figure 1. The share of income from honey in total income

Regarding possibility of protection of GI only 15% think that is very promising idea and 34% that is promising idea, and the remaining part of 51% has opinion that is not promising or bad idea (Table 2). This results show us that producers from Vlasina honey are divided into two equally groups, pro and contra GIs. This is probably results of the fact that process of geographical protection cause cost and producers are not sure of the benefit. In addition producers are not sure how protection of GIs would protect from unfair competition.

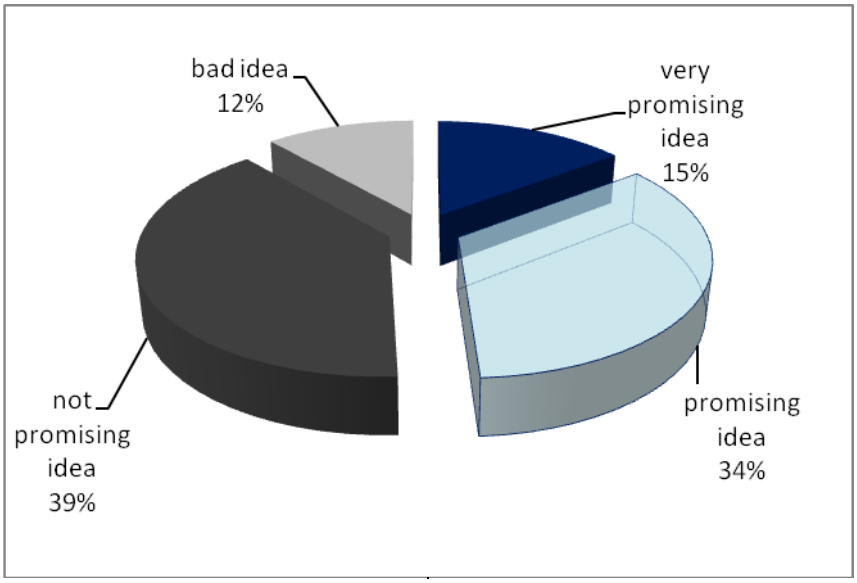

Figure 2. Attitudes towards possibility of geographical indications

CONCLUSIONS

The Vlasina plateau has high diversity of flora and fauna and specific ecosystem. The area is habitat for a number of natural species, as well as natural phenomena. The area is known by producing of high quality honey. Bee-keepers in the area mainly deal with stationed beekeeping in beekeeping directly at Vlasina plateau. As a rule bee-keepers are small in size and honey production is addition activity. Producers are aware of the importance of GI, but only a half of them think that protection of GI is a good idea. This is probably because of the relative high cost of protection and insecurity regarding further benefit of this activity. In this

case the incentive from institution could contribute to the development of positive attitudes towards GIs.

ABSTRACT: Foodborne illnesses - especially those caused by microbial hazards - have major public health consequences worldwide. In order to ensure continuous improvement in the health of population related to foodborne hazards, government is responsible for creating the Food Safety Policy. On international level, large efforts have been made to develop certain tools to link specific food safety requirements with its effect on public health. Risk analysis framework, laid down by the Codex Alimentarius during the past two decades, linked food safety and public health through risk assessment. Based on the formal approach to risk analysis, Appropriate Level of Protection, Food Safety Objective, Performance Objective, Performance Criterion and Microbiological Criterion are concepts evolved for purpose of risk management. However, the use of these relatively new concepts in Microbiological Risk Analysis is still quite limited and inconsistent.
Key words: *Microbiological Risk Analysis, Food Safety Objective*

INTRODUCTION

Foodborne illnesses are a real and formidable problem worldwide, causing great human suffering and significant economic losses. In industrialized countries, it is estimated that up to one third of the population are affected by foodborne diseases each year (Kaferstein *et* Abdussalam, 1999; Schlundt *et al*., 2004). Therefore, food safety is a fundamental public health concern and achieving a safe food supply poses major challenges for international and national food safety officials. An array of biological, chemical and physical hazards pose risks to human health and obstacles to international trade in foods. It is generally accepted that biological hazards - primarily microbiological, such as *Salmonella*, thermophilic *Campylobacter*, *Yersinia enterocolitica*, verotoxigenic *Escherichia coli* and *Listeria monocytogenes* - represent the highest foodborne risk for human health nowadays (Pointon *et al*., 2006; EFSA/ECDC, 2012). To protect and improve health of population, these risks need to be assessed, managed and communicated through the process of Microbiological Risk Analysis. In order to start this process, the government is responsible for creating the Food Safety Policy. To link specific food safety requirements with their effects on public health, certain tools have been developed during the last two decades (Figure 1). These tools are briefly described in this paper.

MICROBIOLOGICAL RISK ANALYSIS

Risk analysis, i.e. Microbiological Risk Analysis in the context of this paper, is a systematic, disciplined approach for making food safety decisions. It is a powerful tool for carrying out science-based analysis and for reaching sound, consistent solutions to food safety problems related to microbiological hazards. This process enables authorities to identify the various points of control along the food chain at which measures could be applied, to weigh up the costs and benefits of these different options and to determine the most effective one(s).
Microbiological Risk Analysis comprises three components: risk management, risk assessment and risk communication. Risk assessment is a scientifically based process consisting of the following steps: a) hazard identification; b) hazard characterization; c)

exposure assessment; and d) risk characterization. Risk management is the process of weighing policy alternatives in the light of the results of risk assessment and, if required, selecting and implementing appropriate control options (prevention, elimination, or reduction of hazards and/or minimization of risks), including regulatory measures. Risk communication is the interactive exchange of information and opinions concerning risk and risk management among risk assessors, risk managers, consumers and other interested parties (CAC, 1999).

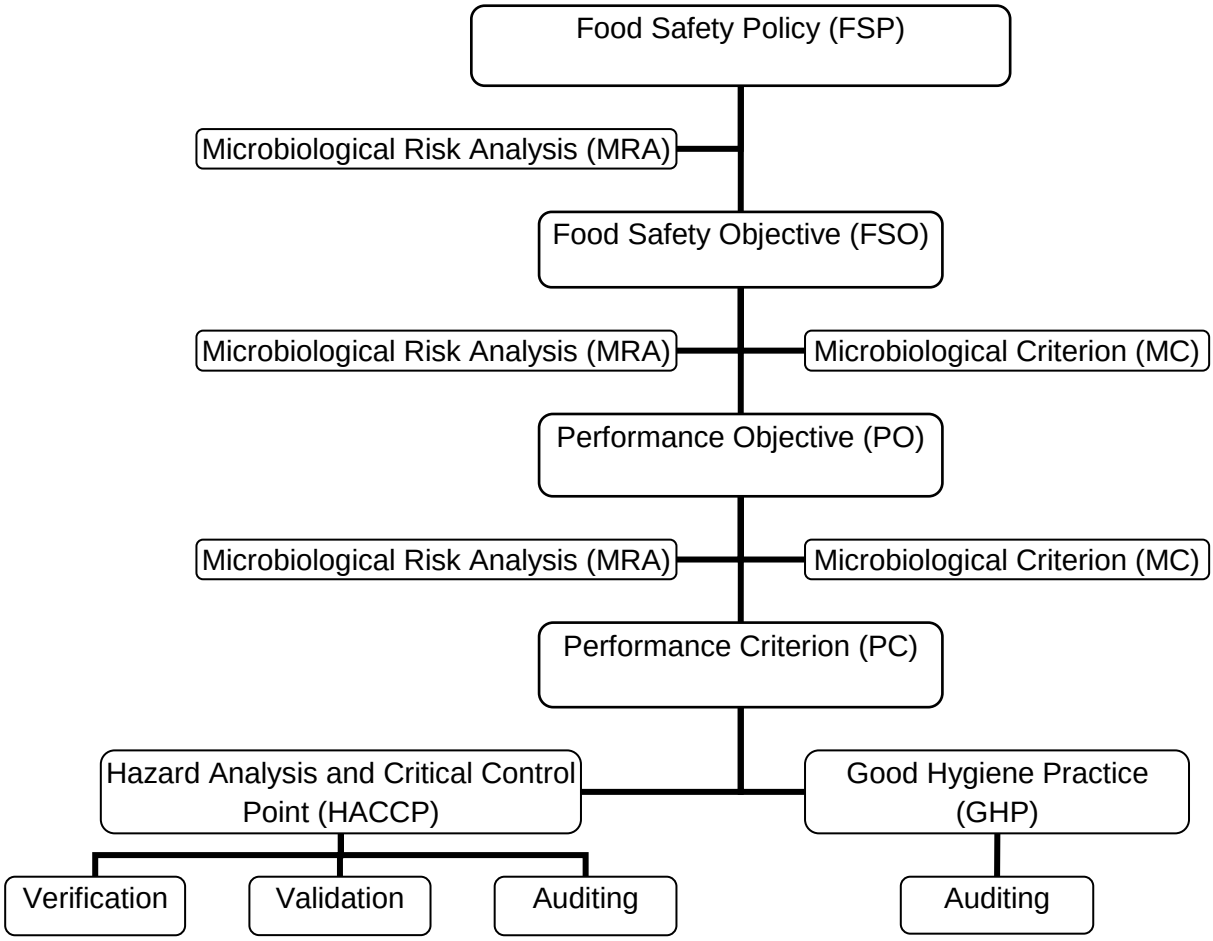

Figure 1. Food Safety Objective concept

APPROPRIATE LEVEL OF PROTECTION

Appropriate Level of Protection (ALOP) is defined by the World Trade Organization as the level of protection deemed appropriate by the member (country) establishing a sanitary or phytosanitary measure to protect human, animal and plant life or health within its territory (WTO, 1994). ALOP can be directly derived from risk assessment results and represents current public health status related to food safety, but can be changed during time (e.g. use of new technologies can change level of some food contaminant in the food chain). Instead of trying to eliminate all hazards from the food chain (i.e. final step of the food chain), ALOP represents the opinion that public health is improved by setting a goal and then determining the frequency and/or level of hazard in food that is compatible with that goal (Zwietering 2005).

Sometimes, ALOP has also been called "acceptable level of risk" (FAO/WHO, 2004); this term is similar to the expression "tolerable level of risk" preferred by the International Commission on Microbiological Specifications for Foods (ICMSF), because it recognizes that risks related to the consumption of food are seldom accepted, but at best tolerated. ALOP can be expressed at different levels. The most common level is total population of one

country, but sometimes it is better to express it on smaller, more specific population (e.g. if only small part of a population consumes certain type of food). ALOP can be general or specific; an example of general is incidence of some foodborne disease (e.g. salmonellosis) in population, and an example of specific is incidence of foodborne disease related to specific food (e.g. salmonellosis attributed to pork).
While ALOP represents current public health status related to food safety, "public health goals" are made to encourage further and future actions to improve public health by decreasing level of foodborne diseases. The concept of public health goals is recently introduced and still not formally defined by Codex Alimentarius. For that reason the difference between public health goals and ALOP is still not clear enough and sometimes these two terms overlap. Public health goals are usually set by the government or authorities of the country responsible for public health. An example of this concept is the target set by the UK Food Standards Agency in year 2001: the reduction of foodborne diseases by 20% by year 2006 (FSA, 2001), which was almost accomplished (Bell, 2006).

FOOD SAFETY OBJECTIVE

To be of use, the ALOP need to be translated into measurable objectives for the food industry. The concept of the Food Safety Objective (FSO) was developed to link the ALOP to food safety systems used in food manufacturing, and to link risk management with its effect on public health (Figure 2) (ICMSF, 2002; Gorris, 2005). Food Safety Objective is defined as the maximum frequency and/or concentration of a hazard in a food at the time of consumption that provides or contributes to the Appropriate Level of Protection (CAC, 2001), i.e. it is related to the point of the food chain when the hazard level can no longer change (ICMSF, 2002). This definition has been considered feasible for some ready-to-eat (RTE) food products with such intrinsic/extrinsic characteristics that restrain the growth of pathogens (Gorris, 2005; Walls *et* Buchanan, 2005; Zwietering, 2005), but not realistic for products that had undergone some treatment (e.g. cooking) at consumer level prior to consumption (Nauta *et* Havelaar, 2008). Also, the current definition relating to the moment of consumption has not been considered compatible with risk assessment methods and results and the value of an FSO derived from a Quantitative Microbiological Risk Assessment (QMRA) model has also been considered questionable (Havelaar *et al*., 2004).
Food Safety Objectives, defined as a part of the risk management process, should be used to govern Hazard Analysis and Critical Control Point (HACCP) system as an outcome definition (Schlundt 1999). Whenever possible, FSOs should be quantitatively expressed and subjected to verification. An example of an FSO is the level of *Listeria monocytogenes* in RTE foods that must not exceed 100 cfu/g at the time the food is consumed or the amount of staphylococcal enterotoxin in cheese that must not exceed 1μg/100g. However, this does not mean that FSOs must be verifiable through microbiological testing. For example, an FSO for low acid canned foods might be established in terms of the probability of a viable spore of *Clostridium botulinum* being present as being less than 0.000000000001 per can. It would be impossible to verify this by end-product testing, but it would be verifiable by measurement of time/temperature protocols that are based on a Performance Criterion (FAO/WHO, 2006).

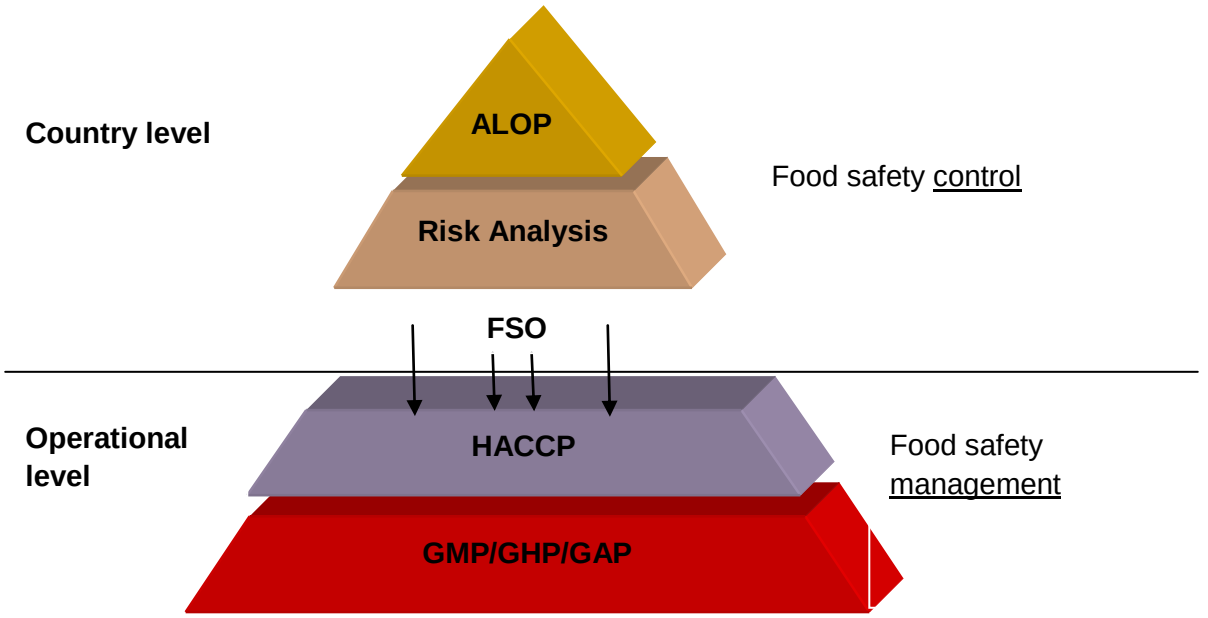

Figure 2. FSO as a link between food safety control on a country level and food safety management on an operational level (Gorris, 2005)

PERFORMANCE OBJECTIVE

As well as for an FSO, the original purpose of a Performance Objective (PO) was to translate an ALOP into levels of hazards in food chain that can be communicated and managed by the food industry. Performance Objective is defined as the maximum frequency and/or concentration of a hazard in a food at a specified step in the food chain before the time of consumption that provides or contributes to an FSO or ALOP, as applicable (WTO, 1994). In contrast to an FSO, a PO can be utilised at points of the food chain where control and verification are possible (FAO/WHO, 2006), and FSO is the value that should lead to the development of PO values earlier in the food chain (Gorris 2005). Also, in QMRA, FSO can be considered as the last PO - before application of the dose response model (Nauta *et* Havelaar, 2008). A PO may be established by the government or an individual food production company may establish its own POs.
Quantitative relationship between an FSO and a PO is different in different situations. When it comes to food that is heat-treated immediately before the consumption, an FSO is more stringent than a PO. For example, the FSO for *Salmonella* in heat treated chicken meat can be "absence in serving at the point of consumption". Since it is likely that a certain number of broiler chickens will be infected with this pathogen and that certain proportion of the broiler carcasses will be contaminated consequentially, it is possible to set up a following PO: maximum of 15% carcasses contaminated with *Salmonella* at the end of chilling process. In subsequent stages of the food chain, with appropriate heat treatment and Good Hygiene Practice (GHP), a given FSO can be achieved. On the other hand, regarding ready-to-eat food, an FSO and a PO may represent the same value or even a PO can be stricter than an FSO - for example, in the case of RTE foods with a relatively long prescribed shelf life, which support growth of *Listeria monocytogenes*.

PERFORMANCE CRITERION

Performance Criterion (PC) has been defined as the effect in frequency and/or concentration of a hazard in a food that must be achieved by the application of one or more control measures to provide or contribute to a PO or to an FSO (CAC, 2008). An example of a PC is a 6D reduction of *Salmonella* spp. when cooking ground beef (Cole, 2004). A Performance

Criterion specifying the frequency and/or concentration of a pathogen is identical to the "acceptable level" to be achieved at a Critical Control Point (CCP) in the context of HACCP.
Process Criterion (PrC) is defined as the physical process control parameter (e.g. time, temperature) at a specified step that can be applied to achieve a Performance Objective or Performance Criterion (CAC, 2005). For example, the control parameters for milk pasteurization in the USA are 71.7°C for 15 sec. This combination of temperature and time will assure at least 6 log reduction of *Listeria monocytogenes* and destruction of *Coxiella burnetii*, as well as other non-spore forming pathogens that are known to occur in raw milk (ICMSF, 1996; Cole, 2004). Process criteria are identical to critical limits on CCPs in a HACCP plans (CAC, 1997b). Performance and process criteria belong to the risk management measures that are to be applied on the operational level (e.g. food producing company) in order to carry out functional risk-based food safety management.

MICROBIOLOGICAL CRITERION

Microbiological Criterion (MC) is a criterion defining the acceptability of a product or a food lot, based on the absence or presence, or number of microorganisms including parasites, and/or quantity of their toxins/metabolites, per unit(s) of mass, volume, area or lot. In contrast to FSOs and POs which only represent limits, an MC consists of several aspects: a) the microorganisms of concern have to be stated, b) a qualitative or quantitative analytical method validated and chosen to give a sufficiently reliable estimate, c) critical limits based on data appropriate to the food, and d) a sampling plan including the sampling procedure and decision criteria for a lot (CAC, 1997a). The authorities can use these criteria to define and check the compliance of food production with the microbiological requirements, and food business operators can use them for verification and validation purposes. An MC may be set by a competent authority or industry and then implemented as a food safety measure using GHP or HACCP approaches (FAO/WHO, 2002). MCs are not derived from risk analysis but rather from management systems controlling foodborne hazards during food processing, determining the acceptability of specific production lots of food (ICMSF 2002).
In the EU legislation (EC, 2005; EC, 2007) an MC concerning the acceptability of food products on the market is termed Food Safety Criterion (FSC), while Process Hygiene Criterion (PHC) provide guidance on and is indicator of the acceptable functioning of HACCP-based food safety system. An example of an FSC is *Salmonella* absence in 25 grams of each of 5 samples of minced meat and meat preparations made from poultry meat intended to be eaten cooked, during their shelf-life of these products placed on the market. An example of a PHC is a presence of *Salmonella* in a maximum of seven of 50 tested neck skin samples derived from 10 consecutive sampling sessions of poultry carcasses after chilling.

CONCLUSION

Food Safety Objective concept is a powerful tool in risk management process which assists governments in achieving health goals throughout the food chain. It requires an integrated approach of risk assessment, risk management and risk communication. This concept is not only useful for protection/improvement of public health with respect to foodborne illnesses - it is a necessary part of modern, longitudinal and integrated food safety system. However, the use of this concept is still limited and inconsistent.

ABSTRACT: Rapeseed/canola (*Brassica napus L.)* is one of the most important edible oilseed crops in the world, as well as a major potential of bio-diesel production in Europe. High oil content is one of the most important characteristics of this crop. Rapeseed meal, which is a by-product of oil extraction, is a highly rich raw material and contains up to 50% protein on dry basis. Plant proteins are largely used in the food and feed industry, and rapeseed proteins are regarded as potential ingredients that may be used as a food and feed additives.
In this paper the quality of rapeseed meal obtained during the biodiesel production was assessed and its use as a nutrient in domestic animals was discussed.
Key words: *rapeseed, by-products, biodisel*

INTRODUCTION

Rapeseed/canola (*Brassica napus L.)* is one of the most important edible oilseed crops in the world, as well as a major potential of biodiesel production in Europe. High oil content is one of the most important characteristics of this crop. Canola seeds contain approximately 38-45% oil and 17-26% proteins. Oil belongs to a group of semi-drying oil with iodine value 95-120. It is used in nutrition and for technical purposes. Technical oil is used in the industry of soap, paint, textile, leather, in printing and as an additive to lubricants. After extraction of oil remains the meal/cake which is used as animal feed. Rapeseed can be used as animal feed in green condition. In the green mass of oilseed rape there is more digestible protein than in corn, sunflower, winter wheat and rye, oats, sudangrass, but also more than in alfalfa. In relation to the mass of green alfalfa, rapeseed contains nearly two times less crude fiber (Marinkovic et al., 2009).
Development of mobile systems has been based on the use of fossile fuel to a great extent. The changes in fuel prices imposed needs for fast discovery of an alternative energy sources. Biodiesel is an adequate solution because it is compatible with fossile fuels, based on restorable raw material and ecologically more acceptable than fossile fuels. The techology of biodiesel production consists of processes of oil expression and reesterification. Meals and cakes – the sources of protein in feed - are obtained as important second products in biodiesel production. Interest with rapeseed press cake as the by-product of the rapeseed oil industry has been increasing along with its potential of being a renewable raw material.
Plant proteins are largely used in the food and feed industry, and rapeseed/canola proteins are regarded as potential ingredients that may be used as food and feed additives. Canola meal, which is a product of canola oil extraction, is a highly rich raw material. The major protein constituents of canola meal are napin and cruciferin, which are storage proteins, and oleosin, which is a structural protein associated with the oil fraction (Uppstroom, 1995). The amino acid composition of canola meal is well balanced and can be used for human nutrition (Aider and Barbana, 2011). Some properties of canola proteins were comparable to those of casein and better than those of other plant proteins, such as soybean, pea and wheat (Ghodsvali et al., 2005). Soy contains more lysine than the rapeseed, and rapeseed seeds contain more sulfur amino acides (Aherne and Kennelly, 1985). The use of canola protein is

limited by the presence of some undesirable compounds, such as glucosinolates, sinapine, phytases and phenols, which are responsible for the toxic, antinutritional and undesirable capacity of canola proteins (Aider and Barbana, 2011). Also, canola meal contains approximately 20% (w/w) carbohydrates, including soluble sugars (Lacki and Duvnjak, 1998). Fibres including cellulose, pentosans and lignin from cell walls, are mainly present in the hulls of canola. High fibre contents in animal feeds decrease its digestibility, thus decreasing the value of the feed (Mailer et al., 2008). However, sinapine remains at levels sufficiently high to cause problems, particularly in poultry feed. Its presence in the diet of brown egg laying hens at levels exceeding 1 g/kg leads to a fishy odour in the eggs (Butler et al.,1982).
Some authors suggest that the palatability of rapeseed products is a limiting factor for their use in complete feed mixutres (Bell et al., 1988). Bitter taste is the result of the presence sinapine in concentration 1 to 1.5% (Straková et al., 2008). Sinapine is a choline ester of sinapic acid which is important in plants for the biosynthesis of lignin and flavonoids (Mailer et al., 2008). Canola breeding programs have succesfully reduced glucosinolates content to trace amounts. New varieties of rapeseed are labeled "00" and for them the name "Canola" is introduced. “Canola” varieties contain less than 1% erucic acid (maximum 2%) and lesser than 20 μmol g^{-1} glucozinolates (maximum 30 μmol g^{-1}).
One of the most important factors determining the composition of oil cakes as feedstuff is the processing method. As for most other oilseeds, pretreatment includes: crushing, cooking and, in rare cases, dehulling. Dehulling of rapeseed aims at the removal of the major part of the fibre and pigments, which otherwise would lower the feeding value of the meal/cake (Ohlson, 1992). As by-product of biodiesel cake is processed in one of the three ways: expression, extraction and expression-extraction combination. The most used proceedings for fat acids methyl ester, i.e. biodiesel synthesis, is the process of transesterification (cold discontinuous and continuous proceedings) (Furman et al., 2005).
The gradual increase in the world’s animal production implicates the need for ingredients to provide protein in diets. Canola meal, which is the product of canola oil extraction, is a highly rich raw materia, and as a second product in biodiesel production is a good energy source. Taking into consideration EU directives that it is necessary to substitute fossil diesel with 0.75% of biofuel per year, the possibility to use the by-products of this industry calls for attention. In this paper the quality of rapeseed cake obtained during the biodiesel production was assesed and its use in animal nutrition was discussed.

MATERIAL AND METHODS

Materials

Testing the quality of oil cake, obtained during the biodiesel production for animal nutrition, was carried out on 11 samples: 4 samples of rapeseed variety, type “Banaćanka”, 4 samples of rapeseed, type “Kata”, and 2 samples of rapeseed, type “Slavica”. Baseline characteristics of the investigated canola seeds are given in Table 1.

Table 1. Characteristics of the tested canola seeds

	Variety		
Property	„Banaćanka“	„Kata“	„Slavica“
Oil content (%)	46	46	44-51
Erucic acid content (%)	< 1.0	< 1.0	< 1.0
Glucozinolate content (mmol/g seed)	< 20	< 20	< 20
1000 grain weight (g)	4.2	4.0	4.3

Processing method

Drainage of non-shelled seeds was performed on a continual press "EKS BIO", the capacity 50 kg/h. The press consists of two parts: a screw conveyor and a basket. The role of the screw conveyor is to ensure the intake of seeds and to push them into the basket. Thus it increases the pressure and enables that the squeezed oil drains through the holes in the basket. At the end of the screw conveyor the cake comes out through a ring opening. The

drainage of oil was carried out at different conveyor speeds and by using different diameters between the end of the screw conveyor and the ring opening. The variations in these parameters were carried out in order to obtain the optimal ratio of the squeezed oil and to achieve optimal effect of the presses. After squeezing the obtained second product (cake) was analyzed as a possible feed for animal nutrition.

Chemical anlaysis

Determination of fat, crude fiber, ash and moisture in the samples was performed by standard methods, while the protein was analyzed by measuring total nitrogen by total combustion (according to Dumas), as the standard method (AOAC 990.03) on the instrument „Elementar, Rapid N cube“. The contents of nutrients was expressed in percentages. The results were statistically analyzed. Depending on the results a conclusion will be given for the following steps in research of the byproducts of biodiesel production.

RESULTS AND DISCUSSION

The values of basic nutrients are presented in Table 2. The obtained results suggest that by-products of biodisel production can be used as feedstuffs for domestic animals.

Table 2. Chemical composition and % of expressed oil of investigated rapeseed cakes

Hybrid type	Sample No	% of expressed oil	*Investigated parameter* (%)				
			Crude protein	*Crude fiber*	*Crude fat*	*Crude ash*	*Moisture*
Banaćanka	1	20	23.17	11.69	30.66	5.23	6.12
	2	30	25.26	12.62	21.56	5.90	6.83
	3	35	26.99	13.69	15.92	6.39	6.62

$\bar{X} \pm Sd$		n.a.	25.28±1.59	12.95±0.99	n.a.	5.82±0.48	6.49±0.30
Kata	5	14	27.32	10.53	29.11	4.42	6.28
	6	35	33.79	12.35	11.77	5.46	7.00
	7	20	28.59	10.52	24.56	4.60	6.76
	8	25	31.21	11.62	18.79	4.89	6.52
	9	30	31.55	11.36	18.38	4.99	6.68
$\bar{X} \pm Sd$		n.a.	30.49±2.56	11.28±0.78	n.a.	4.87±0.40	6.65±0.27
Slavica	10	27	31.17	12.55	14.42	5.72	6.04
	11	23	28.71	9.16	19.34	5.39	6.56
$\bar{X} \pm Sd$		n.a.	29.94±1.74	10.86±2.40	n.a.	5.56±0.23	6.30±0.37

N.A. not statistically analyzed

The levels of investigated components in rapeseed cakes varied as follows: crude proteins - 23.17 - 33.79%, crude fibre 10.52 – 13.80, moisture 6.04 – 7.00, crude ash 4.42 – 5.90 and crude fat 11.77 – 30.66%. The products obtained by applied procedure have high oil content. The total oil content (expressed+crude fat in meal) in seed of canola for the examined varieties ranged as follows: „Banaćanka“ - 46.70 – 51.56%; „Kata“ - 41.42 – 42.34% and „Slavica“ - 37.42 – 46.34%. The obtained results are in accordance with other relevant investigations (Marinković et al., 2009; Straková et al., 2008; Mailer et al., 2008; Uppstrom, 1995 ; Karaosmanoğlu et al., 1996;).

Oils are important dietary ingredients in animal production owing to their high energy value. Futhermore, the fatty acid (FA) pattern of the dietary lipids is reflected in the fatty acid profile of animal products (Jørgensen et al., 2000). Public health concerns are driving research into modifyng the fatty acid profiles of milk and meat, particularly toward less saturated medium chain and more long-chain polyunsaturated fatty acids. The main source of unsaturated lipids are oilseed lipids, among which is the rapeseed used in animal nutrition. Rapeseed oil has moderate levels of 18:2 (n-6) FA and 18:3 (n-3) FA, in ratio of 2:1, and an abundance of 18:1 (n-9) FA. The ratio of 18:2 (n-6)/18:3 (n-3) in rapessed oil makes it of benefit to human and animal health (Gordon Bell et al., 2001).

Crude protein and crude fibre content variance are related to the applied procedure of oil extraction from rapeseed. Comparing to sunflower cake (Table 3) produced in a similar way, rapeseed cake in average has high protein content and low crude fibre content, what makes it a desirable raw material for feed production.

Table 3. Chemical composition and % of squeezed oil of sunflower cakes (Živkov-Baloš et al., 2011)

Hybrid type	*Investigated parameter* (%) $\bar{X} \pm Sd$			
	Crude protein	*Crude fiber*	*Crude ash*	*Moisture*
"Nicholas"	28.13±2.78	15.74±1.12	5.89±0.55	6.57±0.44
"Oliva"	24.46±4.49	17.71±3.02	5.11±0.87	6.44±0.75
"Somborac"	21.88±2.17	18.07±2.26	4.88±0.67	6.14±0.49

CONCLUSION

Considering the fact that biodiesel is made of restorable raw material (plant oils), and that there are some insignificant differences in the energy potential of the fuel, it is quite obvious that biodiesel is the right solution for future. Biodiesel has great advantages in ecological sense. Therefore, in the forthcoming years the exploitation capacity of its by-products should be evaluated as relatively inexpensive protein and energy sources for animal diets. The following factors need to be considered to ensure maximum benefit from rapeseed:

- the efficacy of oil production procces needs to be enhanced;
- pelleting (temperature) helps to increase nutrient utilization;
- enzyme supplement has a positive effect on the nutrient utilization;
- efforts by plant breeding programs focused on rapeseed with improved sinapine, glucosinolates and fibre.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR 031071 "Research on pharmacological characteristics of antimicrobial agents, introduction of new technological solutions and alternative prophylactic methods with the purpose to improve control of infectious animal disease" financed by the Ministry of Education and Science, the Republic of Serbia.

ABSTRACT: Successful maize cropping in rein-fed conditions depends mainly on meteorological factors and in lesser extent on substrate (soil). The trial with 5 maize hybrids was set up during period of 2005-2010 on alluvium and hydromorphous black soil with aim to examine productive traits and silage quality from the energetic point of view. Biomass yield, stover and cob mass were measured, as well as total energy of biomass, as calculated parameter. Nutritive units, total energy and metabolic energy were determined from the silage.
Positive correlation was observed between yield parameters and precipitation amount. In most of seasons, biomass yield, stover and cob mass, total energy of biomass and silage were higher on hydromorphous black soil, compared to alluvium, while the nutritive units and metabolic energy were lower on the same soil during unfavorable seasons. Achieved results indicated that unfavorable meteorological factors could be partly reduced by cropping on heavier soils, such hydromorphous black soil is. In contrast to yield parameters, energy status of produced maize and silage biomass are in lesser extent dependable on meteorological conditions and soil type, and what is more important biomass total energy increases with unevenness of growing conditions. Such situation gives advantage to lower yield crop as a source for energy production (bio-fuels), while high yielding crop have better potential for conversion as a feedstuff.
Key words: *maize biomass, silage, energy status*

INTRODUCTION

Rain-fed cropping is still the most abundant maize cropping practice in many regions. From that point of view, meteorological conditions and soil condition has important position in biomass yielding. Studies of Iqbal et al. (2003) showed that cropping on clayey soil could increase fresh plant mass by better water using efficiency. On the other hand, successful cropping on light soils includes higher fertilization rates and irrigation (Sileshi et al., 2010).
Other than precipitation sums, which mainly affects maize biomass production, temperature factor has large role, too. Growth and development of whole organisms show a temperature response, because of the integrated effects of temperature on the physiological processes involved. Understanding maize growth in response to temperature has led to the concept of “growing degree days” (GDD) (Bonhomme et al. 1994). The GDD approach provides a unit for maize growth estimation in response to variable environmental conditions.
Maize growth and yielding includes capturing of the solar energy, which is 2 to 8 times higher under intensive modern management systems than in hand or animal powered systems (Pimentel, 1984). Produced biomass is main source of feed production and in recent time for energy production. Currently, the dominant source of biomass based liquid transportation fuels is ethanol from maize (Field et al., 2008). Increased production of biomass for energy has the potential to partly replace use of fossil fuels, but it potentially endangers conservation areas, water resources and decreases food security. On the other hand, energy production from the removed agro-residues could give sustainable solution, since the average energy output for food was always greater than that for fuel (Gelfand et al., 2010). The climate, geography and management of land are all factors in the calculation of the amount of

biomass able to be removed sustainably. Sites with steep slope, dry climates, and/or highly erodible soils produce much less and in some cases no removable organic matter. The low nutrients content of corn cobs reduce the amount of nutrients removed with cobs at harvest which later must be replaced to maintain optimal soil nutrient levels (Zych, 2008).
The aim of the study was to compare the influence of meteorological conditions and two soil types during six experimental years on maize yield components, as well as energy status of produced biomass and silage.

MATERIAL AND METHODS

The trial was set up in the PKB Corporation in Padinska Skela (44° 59' 52'' N, 20° 22' 18'' E, 67–69 m altitude) with five maize hybrids, Staniša, Dukat, Srećko, Rubin and Dijamant (FAO 300-600). The crops were established on alluvium (as a model of sandy, light soil) and hydromorphous black soil (as a model of clayey, heavy soil) under rain-fed conditions. The experiment was set up in a random block system on a total area of 216 ha in three replications with an elementary plot of 6 ha. The sowing was performed during April and first decade of May, depending on the meteorological conditions. The plants were cultivated at densities of 68,000-74,000 plants ha^{-1}. The maize harvesting for silage preparation was performed when the dry matter was 34–36%, depending on the meteorological conditions, i.e., during August-September. The cob and stover mass, as a yield parameters of 30 maize plants per replication were determined just before crop harvesting.
The harvested material was transported to pit silos where it was inoculated with Sil-ALL (Alltech, UK) at 1 g t^{-1} plant material and compressed properly. Again, the pit was covered with a plastic sheet and compressed with straw bales (weight 250 kg) for 75 days, when silage samples were collected (three samples per silo pit, at middle and the two ends).
The nutritive units (NU), based on silage composition, analyzed by "Standard accredited methods" (Official Gazette – Službeni list SFRJ 1987; AOAC 1990) were determined as Scandinavian feed unit (SFU), based on methods of Obračević (1990) and van der Honing and Alderman (1988), also the total (TE) and metabolic energies (ME) of silage were determined by method of Obračević (1990). Total energy (TE) of maize biomass was calculated based on thermodynamic data of biomass conversion, proposed by Domalski et al., (1986).
The growth degree days (GDD) were calculated by the formula proposed by Cross and Zuber (1972):

$$GDD = (T_{max} + T_{min})/2 - T_{base}$$

where T_{max} is the maximum daily temperature and was set equal to 30 °C when the temperatures exceeded this level, T_{min} is minimum daily temperature and was set equal to 10 °C when the temperature fall below this value, and T_{base} was taken as 10 °C for maize (Cross and Zuber 1972).
The experimental data of biomass yield, stover and cob mass and nutritive units were statistically processed by analysis of the variance (ANOVA) by the LSD-test (5%), while the GDD, total energy of silage and maize biomass, as well as metabolic energy of silage were presented with standard deviation (SD). Correlation between GDD, sum of precipitation and biomass yield, stover mass, cob mass, nutritive units TE of biomass and silage and ME were presented with significance level P = 0.05.

Meteorological conditions

Meteorological conditions during present period of 2005-2010 emphasized 2007 and 2008 as dry years, with lowest precipitation sum (Figure 1), almost double in relation to other years. Additional impact in 2007 was obtained in highest GDD, particularly caused by high temperatures present during vegetation. From that point of view 2007 was characterized as a unfavorable season.

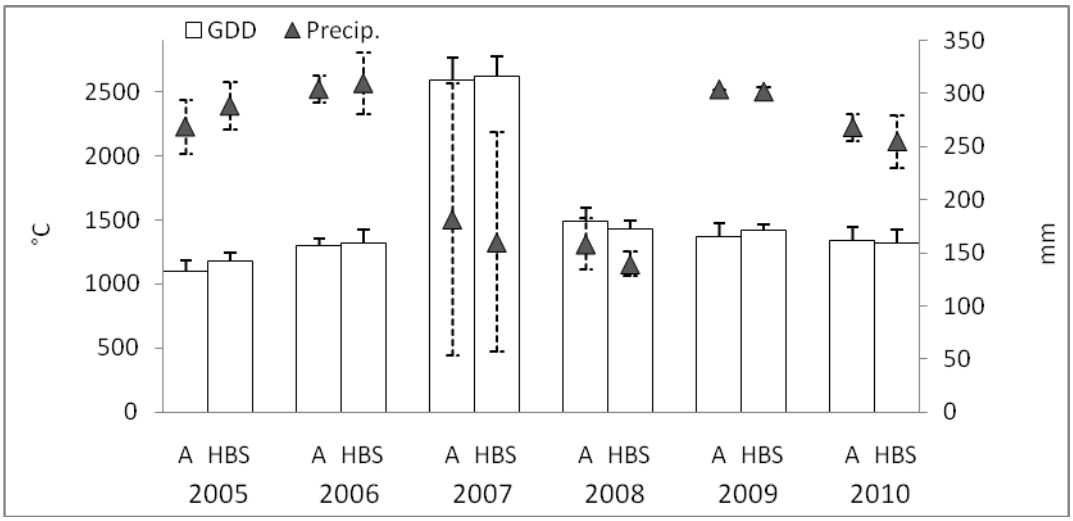

Figure 1. GDD-s and precipitation sum during vegetation period of 2005-2010

RESULTS AND DISCUSSION

The results of biomass yield, stover and cob biomass and nutritive units of produced silage (table 1) had higher, but insignificant average values on hydromorphous black soil. On the other hand, seasonal influences, present in alterations of meteorological factors (Figure 1) emphasized 2005, 2009 and 2010 as years with significantly higher values of produced maize biomass, as well as stover and cob biomass (table 1).

Table 1. Biomass yield, stover and cob mass and nutritive units of silage produced on alluvium (A) and hydromorphous black soil (HBS) during period 2005-2010

	Biomass yield			Stover mass			Cob mass			Nutr. units		
Year	A	HBS	Aver.	A	HBS	Aver.	A	HBS	Aver.	A	HBS	Aver.
2005	42.1	45.4	43.8	2070	2596	2333	389.9	392.8	391.4	0.33	0.36	0.35
2006	32.3	35.6	34.0	1221	1337	1279	326.4	367.1	346.8	0.37	0.36	0.36
2007	29.4	34.5	31.9	1257	1328	1292	294.4	362.9	328.6	0.37	0.33	0.35
2008	31.6	34.7	33.2	979	1084	1031	337.2	370.0	353.6	0.40	0.39	0.39
2009	42.0	44.6	43.3	1271	1458	1364	469.9	493.4	481.7	0.38	0.43	0.40
2010	42.9	42.9	42.9	1727	1881	1804	418.6	404.2	411.4	0.33	0.37	0.35
Aver	36.7	39.6		1421	1614		372.7	398.4		0.36	0.37	
LSD	Soil	Year	Int.	Soil	Year	Int.	Soil	Year	Int.	Soil	Year	Int.
0.05*	6.3	3.7	3.5	562	363	357	65.6	44.1	41.5	0.05	0.43	0.04

**Least significant difference, P = 0.05 (n = 3)*

Positive influence of hydromorphous black soil on a production of maize biomass was particularly underlined during 2005 on stover production and during 2009 and 2010 on cob production. Seasonal influences also had the greater impact on alterations of nutritive units in silage, opposite to soil influence, underlining 2008 and 2009 as seasons with higher nutritive units, in significant.

Energy status of produced maize biomass and silage is giving advantage to silage, according to silage/biomass TE ratio, which is varying from 1.68 (obtained on alluvium in 2007) to 1.98 (obtained on hydromorphous black soil in 2005, Figure 2). Fluctuations in energy of produced maize biomass and silage were minor between examined soil types (< 1% in average), indicating slightly higher values of silage TE and ME on hydromorphous black soil, as well as the lover values of biomass TE (6%, in average) on the same soil, compared to alluvium. Main influence, which induced increase in energy of produced biomass and silage, came from seasonal influence, with highest values of silage TE in 2008 and silage ME in 2005 and 2007, on average, while the highest values of biomass TE was obtained in 2007 and 2010, in average. The higher values of ME and TE of silage and biomass were obtained in years with

relative extreme conditions (Figure 1): high GDD (2007) and low sum of precipitation (2007 and 2008), meaning that favorable meteorological conditions for biomass yielding don't support its quality on energy basis. According to results of Haigh (1995), the highest ME values were obtained during dry and warm seasons, while the lowest values were noticed during wet and cool seasons. Moreover, no correlation was obtained between biomass yield and ME (Millner et al., 2005), indicating that factors which affect yield and its components doesn't affect energy of produced biomass, i.e. silage.

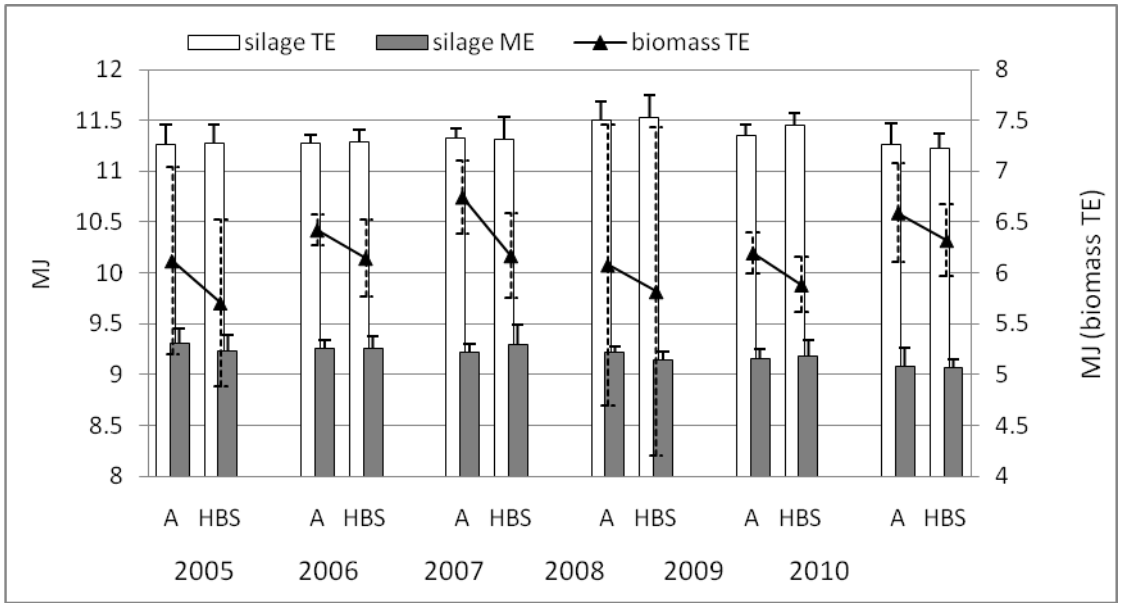

Figure 2. Total energy (TE) of silage and maize biomass and metabolic energy (ME) of silage produced on alluvium (A) and hydromorphous black soil (HBS) during period 2005-2010*; Results are given as mean ± standard deviation (n = 3)*

The variations of meteorological conditions, present in precipitation sum and GDD indicated significantly high impact of both factors on biomass yield (table 2): GDD expressed negative influence, while precipitation sum expressed positive influence. The significant negative correlation of GDD and yield parameters (biomass, stover and cob mass) signifies that the extended vegetation period or high temperatures could induce biomass losses (Herrmann et al. 2005). Precipitations affected stover and cob biomass in higher extent, while GDD was more important for alterations of cob mass. Obtained results confirm model purposed by Wolf and van Diepen (1994), which provided higher biomass yields for hybrids of shorter vegetation and northern parts of Europe (lower GDD-s) including limits in water supply. Opposite to negative correlation between GDD and yield parameters, positive correlation between GDD and biomass TE was observed, similarly to results of Haigh (1995). On the other hand high precipitation induced decrease of silage TE.

Table 2. Correlation coefficients between GDD, precipitation sum and biomass yield, stover mass, cob biomass, nutritive units total energy of silage and biomass and metabolic energy

	Biomass yield	Stover mass	Cob mass	Nutr. Units	silage TE	silage ME	biomass TE
GDD	-0.57*	-0.38*	-0.44*	-0.15	0.07	0.27	0.41*
Precip.	0.60*	0.43*	0.52*	0.00	-0.53*	0.02	-0.01

**Least significant difference, P = 0.05*

CONCLUSIONS

Concluding on based achieved results, meteorological factors presumably affect maize yield components and biomass yielding. Unfavourable climatic changes, present in increased temperature and lower precipitation level could be partly reduced by growing on heavier, clayey soils, such hydromorphous black soil is. In contrast to yield parameters, energy status of produced maize and silage biomass is in lesser extent dependable on meteorological conditions and soil type and that is more important biomass TE is increases with unevenness of growing conditions. Such situation gives advantage to lower yield crop as a source for energy production (bio-fuels), while high yielding crop has better potential for conversion as a feedstuff.

ABSTRACT: Production and circulation of alimentary products are one of the most important activities, and food is an important category of consumer's goods. It can be said that the risks related to the food chain are present in our lives on daily basis. Therefore, health regularity is the first and unconditional request to meet every alimentary product. Healthy safe food is important and from aspect of lowering costs of population healthy treatment, whose diseases are arising from unsafe food usage. It is expected that, by introducing the safety management system of food and by food market regulation, these costs will decrease in the near future. The aim of implementation of the Standards is that, at the global level, these set of common rules will harmonize requirements for safety food management, for all of the jobs in the food chain.
System ISO 22000 sets requirements for the safety management system of food, determining necessary hygienic conditions for the production of correct and healthy safe food. By implementing standards for the safety management system of food chain, it is acting preventable, and identification of production process problems is doing. By this means enterprises get more efficient and more cost-effective protection from unwanted consequences.
Key words: *food, quality, ISO Standards 22000, satisfaction, cost-effectiveness*

INTRODUCTION

Food products are bought and spent for their biochemical values, necessary for the development, maintenance, and daily activities. Its basic function is to satisfy biological needs of human organism. Food consumption is continuous, because of that purchase of food may not be delayed. Having in mind the importance of food in the life of men, it is quite natural that there is a continued need to provide, not only sufficient quantities, but above all, sufficient quantities of totally safe food. In the process of food offering participate individual producers and companies from the field of agricultural production, industrial processing, trade, and all of they can influence to the security of products.
Health problems related to food and the diet show the tendency of growth (Henry Bolton et. al, 2008). Frequency of showing analysis of infectious disease caused by microrganisms in the world has shown that the irregular poisoning is most often a result of treatment in the course of food preparation (Egan et. al, 2007).
Food accuracy depends on processes, which are applied in the primary production of agricultural products, their industrial processing, packaging and manipulation. Food contamination sources may be auxiliary raw materials, packaging, package material, a tool for maintaining hygiene and disinfection, as well as herbicides and pesticides.
Also, foul products can occur and during its non-responsive storage, as well as during the direct use in the household (Milovanović, 2011). For these reasons, as the consequence of different forms of contamination, health and/or safety of consumers may be affected.
Because of occurrence of food crisis in Europe, the quality and food safety have become a significant topic. Food Industry, as one of the most sensitive areas with aspect to the microbiological contamination, deserves particular attention. For these reasons, must be introduced in practice new skills in the management of safety of food „from fields to the table".
It is needful to master the field of food safety through good practice at the different levels of production, distribution and consumption. Parameters that enter in a chain of supply food, as

the new resources, new processes and technology, as a new ways of representation, are the key factors for the construction of a new dimension in the area of food security, which must be managed.
In an effort to ensure food integrity and to increase security of users, legal obligations in all developed countries obliges, and development programs of food producers predict, planned introduction of the system of management.
Given to the fact that Serbia has all of the conditions for the production and export of high-quality and safe food, it is necessary to intensify in the food industry implementation and development of the management system production process of food as goods.

CRITERIONS FOR QUALITY DEFINITON

The role in establishing a system of quality management is very important. It is an important at:

- Determining access to the establishment of quality system
- Proving lines of arguments for the development and improvement of quality systems and
- During the realization of it.

In order to be accepted system of management of quality, primarily should be applied a strategic decision-making. On design and implementation of specific type of quality management, affect different needs, defined goals, provided product or provided services, all activities, as well as the size and structure of the organization. For this reason it is almost impossible to expect community in the structure of quality management.
Main aspects for development of quality management denote next phases:

- Inspection - sorting according to quality ,
- Quality control - planning control ,
- Quality assurance - identifying consumer needs and
- Other activities whose basis is a management of quality - improving effectiveness makes business development

Keeping in mind all bigger complexity of business and environment, the success of organization may result from the use and maintenance of quality management system which is designed so that permanently improves performance of system, process, staff and products, gathering needs of all interested parties,
Standard includes eight quality management principles which should be respected in process of guiding organizations, in order to improve performance.

- The guidance provided to all users,
- Management ,
- Full involvement of staff,
- The systematic approach to management,
- The continued improvement,
- Decision making based on data analysis and information received,
- The mutually beneficial relations and
- Access to the process.

Once established quality management system, must continuously improve its effectiveness (just with responsible management personnel and management of resources). In order to transform input elements and manage its processes, system must define and provide human resource, infrastructure and the working environment.
Also, the products realization, as well as and the process of measurement, analysis and improvement, effects the quality management system effectiveness.

QUALUTY SYSTEM

The International Organization for Standardization (ISO), which is a sort of network of national institutes (162 countries) for standardization, one member from each state, with the centre of co-ordination in Geneva, is the largest world organization, which is involved with the development and issuance of international standards.
ISO standards are the technical standards that ensure technology compatibility box in the entire world. They are designed to be important and useful in the world. Standard ISO 9000 refers to quality management. This means that the organization must:

- Meet the quality requirements of customers,
- Respect legal regulations,
- constantly improving satisfaction of customers and
- Continuously improving performance.

General requirements of ISO 9000 standards are related to the obligation of organization that must establish, to document, implement and maintain system of quality management and to constantly improve its effectiveness and efficiency.
Two significant changes in the new standard ISO 9001 are related to:

- Inclusion of environment of organizations in designing and developing system of quality management in the organization and
- Request that staffs that performs tasks, which affect the compliance with the requirements, must be competent in terms of education, training, knowledge and experience.

Considering the numerous opportunities for food contamination, and above all consequences to the health and safety of people, it can be presumed that the concept of risk analysis and critical control points (HACCP), which is defined by *Codex Alimentarius* for identification, evaluation and control, System of signalization of significant importance for food safety, helps producers to produce healthy food.
The core of the HACCP concept of management system is contained in constant effort that through concrete planned activities, anticipate and define all phases or situation in the entire production cycle that could lead to danger of human health or to endanger safety of consumers.
The concept of HACCP is very significant, because it allows monitoring all production phase, so based on production documentation at any time it can be determined an executor of certain technological grips, which means that it can determine and direct responsibility for security products (figure 1).

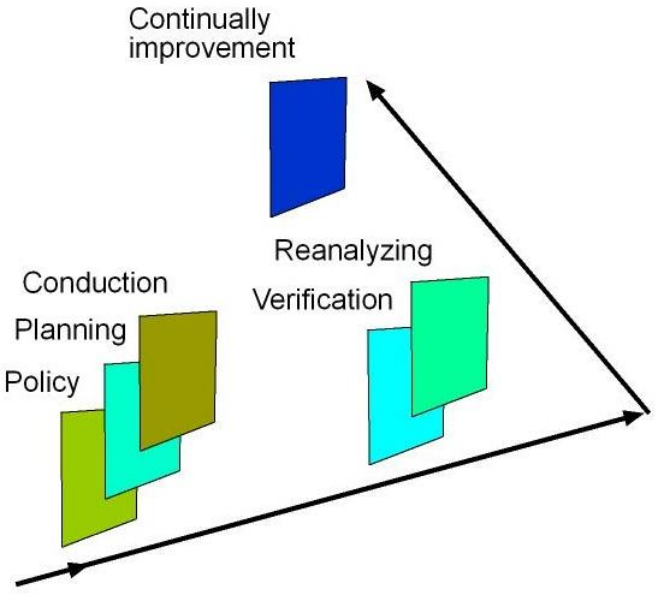

Figure 1. Model of responsibility

HACCP system of governance is not only a necessary condition for the production and export products, but is responsible and for a safe sale. A growing number trade chains operating in Serbia require from the manufacturer to its technological processes adapted with HACCP concept.
Health system guarantees to consumer a safe food, which, also positively influence the competitiveness of products and producers. Therefore, respect for and implementation of mentioned system is what will be required and in the European Union, as well as and on the BRIK market.

UINFLUENCE THAT HAVE MARKETING IN INTEGRATED SYSTEM OF CONTROL

Marketing of healthy and safe food contribute facilitation of natural conditions for the development of healthy agricultural production and processing, encourages implementation of the healthy food consumers and affect the development of the market of healthy food.
By means of marketing campaign should insist on nutrition and low caloric values of food, on its healthy component. Also, it must be emphasized the use of healthy technologies in the production, processing and retail.
In the process of transformation, producers do not need to apply technological procedures which enhance organoleptic characteristics of processing material using synthetic preparations. Quality of healthy food must be sustainable, and health-safety value preserved in processing process.
The role of marketing can be seen from the point of support the development of new technological procedures of preservation, storage and transport of sensitive health food. Marketing participate in finding adequate financial support for the development of new technologies and consequently new products of modern design and contents.
Also, the task of marketing is, that with the help of educational institutions, participate in professional development of all participants in the development, production, placement and quality control of healthy food.
In the terms of stepped-up competition in national, as well as and on the world market, companies are fighting for retention of leadership position, or for conquering new markets. One of the ways that the company battles with problems globalisation is the use logistics in order to provide an advantage in relation to competitors.
The basic logistics task as business functions is the optimization of flow of materials, information and services from entering the system to exiting from it. In order to achieve set task, logistics must use, a complicated mathematical-statistical procedure, support for an integrated information system and high-quality and professional management.
The International Organization for standardization has developed a ISO 28000:2007 specification for the Safety management system in the chain of supply. This standard requires from organization to determine whether adequate security measures are applied and to identify the legal requirements that must be align with it. If some security needs are identified, organization must implement mechanisms and processes which meet the needs.
Risk in the chain of supply is an event that may damage the organization, destroy equipment or goods, or prevent production and delivery.
Standard ISO 28000:2007 asks from companies to:

- Defines the risks that were discovered in the chain of supply through plan security,
- Create report on vulnerabilities of chain of supply in order to define safety scenario,
- Identify critical points and
- Develop a training program.

By introducing the standards ISO 28000, organization sends a clear signal to partners and clients that is a serious participant in the chain of supply, who took concrete steps in order to ensure the flow of material to be safe and effective.

CONCLUSIONS

In basis of the concept of integrated system of control is standard ISO 22000:2005. Standard is a combination of HACCP system and elements of standard ISO 9001:2000 for quality management system. Significant features of the process are its cover of complete alimentary chain.
The core of standard is following elements:

- The interactive communication,
- The system access,
- The following program and
- Principles of HACCP system.

Producers can overcome risks of technological process, and in that way guarantee food safety with their successful functioning. Significant place in the structure of system concept belongs to risk analysis, which provides a high level of protection of human health and life.
The risk analysis includes three interconnected elements:

- The risk assessment,
- The risk management and
- Transfer of information about risk.

In the part in which defines pollutants from living environment and on-farm, risk assessment and risk management implement ecologist and veterinarians.
Significant aspects in primary production may be:

- Implementation of general principles of food hygiene and control,
- Program of permanent supervision of animal health situation and
- Evaluation procedures of different risk and internal validation in accordance with HACCP system.

Obtained information is important, because on the basis of their assessment is carried out a certain technological procedures. These information, also become a part documentation which is base for the health card, which tracks each product.
Also, an important part of the concept is risk analysis and critical control point related to technological processes. Presented area includes the following:

- The determination of control points according to the production process,
- Definition of optimal values and
- Control.

Therefore, completion of the system is a management of safety in food production, which means constantly process monitoring, from entering raw materials, handling, production, distribution and consumption of the final products, and functional through analysis and control of biological, chemical and physical hazards.

ABSTRACT: One of the phenomenons that marked twentieth century is rapid technology progress. This process did not avoid food production and processing. Thanks to rapid development of technology, there has been a development of conventional food production, as well as appearance of genetically modified food. As a consequence of this trend, as well as the concern among some part of human population for their health, we had the return to natural food production in the form of the development of organic food production. One of the characteristics of organic food market in the European Union is the constant growth of demand for this product group, and insufficient quantities of organic products available in this market. These information led to the conclusion that organic food represents an opportunity for less developed countries, i.e. that countries like Serbia can manufacture and sale these products on the market with the highest purchasing power in the world - the European Union market. In this paper the characteristics of demand for organic foods in the European Union where presented, then it was explained in detail why are these products export chance of Serbia, as well as reasons why is the export of organic food from Serbia to the EU very low at the time being. At the end some recommendations that could help Serbia to increase export of organic product to EU countries were proposed.
Key words: *organic products, supply of organic products, supply for organic products in EU*

INTRODUCTION

The technological revolution that started in the twentieth and resumed in the twenty - first century did not pass the food products market. Bearing in mind the constant population growth on one side and limited amount of the arable land on the other, mankind found a new challenge - how to provide food for this ever increasing world population. In order to solve this problem new technologies in food production have been developed and their goal was to achieve increased yield per hectare (Sudarevic 1999). That was the reason why people started using large number of chemical substances throughout the twentieth century, such as pesticides and fertilizers in order to improve efficiency of food production. The research went one step further and made the production of genetically modified food possible. This type of production includes changing of the genetic make up of an organism in order to increase its useful properties such as weight, size or resistance to various diseases.

This trend has twofold consequences. The first consequence of it is the fact that the yield of agricultural crops over the past hundred years or so has increased several times. For example, according to the *CIMMYT* - International Maize and Wheat Improvement Center (2011), crop production increased three times on the same amount of land over the period 1951 to 1991. In that way possible food shortages around the world have been avoided. The second consequence is related to health challenges in the production of conventional and genetically modified food. Even though, because of the methodological requirements, it is extremely hard to prove that both conventional and genetically modified food can be harmful to human health. Today a growing number of consumers believe that the food produced in this way can have adverse consequences.

There is a new methodology of food production as a response to the problems we stated – it is called organic farming. There are several definitions of organic food. According to Allen and Albala (2007) Organic food represents food produced using methods which don't include

modern synthetic pesticides, chemical fertilizers, and which don't include genetically modified food, the food produced without the use of radiation, industrial solvents or chemical food additives. According to International Federation of Organic Agriculture Movements (2011) organic farming is a food production system that sustains the health of soils, ecosystems and people. It relies on ecological processes, biodiversity and cycles adapted to local conditions, rather than the use of inputs with adverse effects Organic Agriculture combines tradition, innovation and science to benefit the shared environment and promote fair relationships and a good quality of life for all involved. We can conclude from these two observations that this type of production is based on the natural way of producing food without addition of any artificial substances and by respecting the principles of health, ecology and equity concerns.
Starting with the stated problems perceived by consumers when it comes to consumption of conventionally produced agricultural products, demand for organic agricultural products is on the rise in market-income countries, especially in most EU member states.
On the other hand, there is not enough unpolluted soil suitable for this type of production so we can conclude that the possibilities of producing organic agricultural products are limited. The only possible solution to meet consumers needs on given markets, at the moment (and in the near future) would be the import of organic products. Organic food market in the European Union is one of the rare markets where demand consistently exceeds supply which makes it extremely attractive to bidders from different countries. Hence the optimism that one of the opportunities for the development of Serbian economy lies in the right investment in both production and export of organic food.
The purpose of this study is to explore the prospects of the export of organic products from Serbia to the markets of developed countries, primarily the European Union.

MACURRENT STATE OF DEMAND FOR ORGANIC FOOD IN THE EU

When someone should describe an ideal market in which he/she wishes to perform, that person would almost certainly state the two such market characteristics: the fact that demand exceeds supply and that market is poised for continued stable and predictable growth (Kotler 2011). Organic food market is one of the few in which the demand for products exceeds supply and in which we have a constant stable growth over the years (European Commission, 2011). According to the EU report about the organic sector, organic food market for the EU-15 countries (members which joined the Union before 2004) in 2006/2007 amounted to EUR 14.4 billion. Up to 80% of that amount (around EUR 11.5 billion) goes to four largest consumers - Germany, United Kingdom, France and Italy. When it comes to relative amounts, the consumption was highest in Austria (around 5%), followed by Germany, Denmark and Luxembourg (3.7% /3.8%). What we can notice from the report is the significantly lower demand for organic products in the EU -12 countries (countries which joined the EU in 2004, together with Bulgaria and Romania). In these countries demand for these sort of products is less than 0.2%, while only in Czech Republic (0.5%) it is higher than the total demand for food products.
Another interesting trend is the significant growth of organic food in the EU over the last ten years. According to the same report there has been a growth of demand for organic food of 18.1% in France for the period 2005 to 2009, 14.0% in Germany for the period 2000-2008, 8.7% in Italy for the period 2001-2009, and 11.9% in United Kingdom for the period 2000-2008. It is interesting that the economic crises caused a drop in demand for organic food only in the UK, while it recorded a growth in Germany, France and Italy.
The report also reveals the fact that the demand for organic food exceeds supply. As a result of this trend we can come to the conclusion that the majority of member states will be forced to import organic food in order to solve this problem. It is expected that a trade between members and non-members of EU in the field of organic food will record a significant increase in the future thus solving the problem of lacking these types of products.
In addition to this report we can find the research in organic food conducted by Richter and Padel (Organic Eprints, 2011). The results of their research are presented in the chart 4. Results are related to the European countries in 2005.

Table 1. Demand for organic food in Europe for 2005 (Organic Eprints, 2011)

Country	Organic market in billions of euros	Market growth percentages compared to 2004	Consumption per capita in euros (€)	Market share of organic food compared to conventional food
Germany	3.9	11%	47	around 3%
Italy	2.4	-----	42	-----
Great Britain	2.33	30%	39	-----
France	2.2	-----	37	-----
Denmark	0.307	10%	57	-----
Austria	0.450	12%	56	around 3%
Holland	0.419	1.4	25	-----
Spain	0.300	-----	7	-----
Switzerland	0.763	-1%	103	around 4.5%
Norway	0.041	-----	10.2	-----
Czech Republic	0.012	30%	1.14	-----

Research by Richter and Padel confirms analysis of the European Union that the organic food market is relatively large with tendency of growth. Market of the four largest countries in the European Union for 2005 exceeds 10 million euros. The biggest market in Europe is Germany with 3.9 billion euros, followed by Italy, France and United Kingdom with over 2 billion euros each. What is interesting is that the United Kingdom achieved highest rate of market growth for the period 2004-2005, with over 30% which might explain the decline in demand for organic foods during the crisis. Switzerland has the highest consumption of organic food per capita by far, it amounts to 103 euros which is more than twice the one of Denmark and Austria, the countries with highest consumption of organic food per capita within the European Union. This data shows that Switzerland, although the market outside the European Union, should not be neglected.

ORGANIC FOOD IN SERBIA

In the remainder of this paper, we stated the main advantages of production and export of organic food from Serbia, followed by the current status of organic food production in Serbia, and finally the factors that negatively affect the current balance of exports from Serbia to European Union.

Organic food as an export opportunity for Serbia

There are several important reasons why organic food represents great opportunity for the development of Serbian economy. They are reflected in cheap labor, large amount of arable land, proximity to the markets of the European Union, and high demand for organic products.

Cheap labor. The way of production and processing of organic food are the reason why this type of production is considered to be labor-intensive industry, that is to say, in order to obtain the same amount of output for the production of organic food it is necessary to employ more labor than conventional food production. This is considered to be one of the primary reasons why organic food is more expensive than conventional food. Since the average salary in Serbia is several times lower than the average salary in certain European countries (according to the Bureau of Statistics average net wage salary in Serbia currently amounts to over RSD 38000 (around EUR 380) (Statistical Office of the Republic of Serbia, 2011), we can say that the production of organic food is far more profitable in Serbia than in EU countries. The unemployment rates are among the highest in Europe (around 22%), so we can conclude that the production of organic food could be great opportunity to launch Serbian economy and reduce unemployment.

A Large Amount of Arable Land - One of the main characteristics of Serbia are large areas of arable and fertile land. The soil fertility makes it possible to produce large amounts of food

without the addition of synthetic inputs such as fertilizers and pesticides. On the other hand, the soil diversity makes it possible to grow various types of crops. This is very important because it is necessary to round up the production process in order for organic production to take place, it is not enough to produce only one crop (Figure 1).

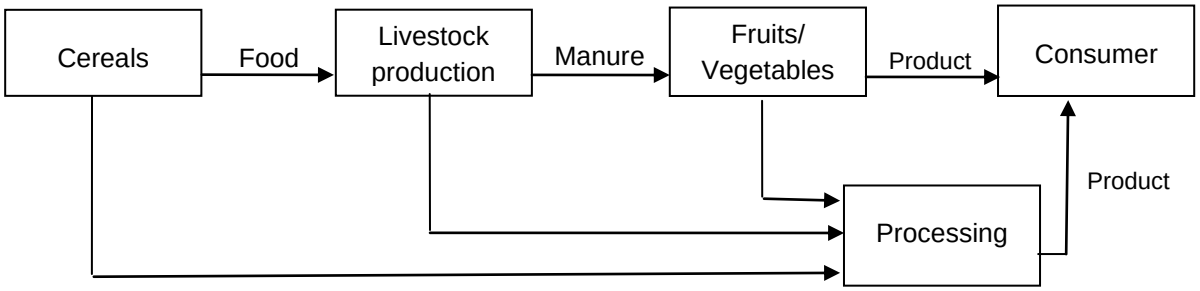

Figure 1. Possible alternatives to organic food production

So for example, after grains have been processed they can be used for direct sale at the market (flour, cornflakes, *etc*.) or they can be used as an ingredient in animal feed. The benefits of livestock production in an organic way may be multiply beneficial: after meat have been processed it can be marketed, it is possible to produce milk and milk products, eggs as well, which can be placed on the final consumers market. Manure can also be used for fertilizing fields in order to get higher yields from organic fruits, vegetables and grains. Organic fruits and vegetables can be sold directly on the market, but can be processed as well (juice, jam, salad in a jar, *etc*.), and then can be placed on the market. Organic food makes sense only if all listed manufacturing segments are covered, which can best be seen on the example of Austria, which achieves the best results in the production of organic food in Europe. In addition, the land in Serbia is still largely preserved for organic production (Sudarevic et all 2011) because of poor use of pesticides and fertilizers due to farmer's low purchasing power, which is not common in most EU countries.

Proximity to EU markets - Another advantage for Serbia could be the fact that it is close to many EU markets, primarily Austria, Italy, Germany and even France, so the transportation costs wouldn't be high and there would be more time to sell the goods, especially if we take into consideration the short-term duration of most food products. The duty-free agreement between Serbia and European Union allows export with no additional export taxes.

High Demand for Organic Products - As it was stated in the previous part of the study, demand for this group of products goes beyond the production possibility, and is poised for continued growth, so we can assume that this trend will continue. We can therefore conclude that the organic food market is a very attractive market.
After defining the factors that are contributing to the development of organic food in Serbia we are going to describe the current state of this agricultural sector in Serbia.

The Limiting Factors
Given the chances that organic food production carries, but a small area of land in Serbia on which this type of production is being used right now as well, it is necessary to define the specific reasons for modest production level of organic food in Serbia. The authors made a list of the limiting factors affecting the level of production of organic food in Serbia by reviewing the literature and by interviewing the experts in the field of organic production.

High Capital Costs - One of the characteristics of the organic production is the fact that it is necessary to have higher initial investment compared to conventional production. This investment can later be compensated by higher prices for the organic products. In Serbia, the problem lies in the fact that capital is very expensive, often several times more expensive compared to the countries of the European Union, which makes the manufacturing process

more expensive as well. Also, banks in Serbia require a high degree of collateral, often in the form of mortgages and / or guarantors, so only few people in Serbia decide to enter into any risky venture because miscalculation may lead to loss of home.
Many estates in Serbia are very small and it often happens that the land of the farmers is located in several locations, which further complicates the manufacturing process (Gulan, B., 2011).
If one considers that organic farming to be labor-intensive, fragmentation of arable land in several locations that each household has, can be a serious problem. On the other hand, many farmers produce the same crops over the years, and even generations back, in more or less the same way, possibly with some technological advances, and that is why they are not willing to experiment with new varieties and new production methods.

Lack of training - Although organic farming is nothing new for the experts, this type of production represents the great unknown. What needs to be done to increase the volume of organic production is a general education of the producers on both the benefits and characteristics of organic farming. It is realistic to expect that the rapprochement between scientific research institutions and manufacturers will lead to increased production of organic products in Serbia. One way of solving this problem might be the employment of a large number of unemployed agronomists who would receive salary from the state which would result in the farmers education. Of course, education about organic food must be a priority in the education of Serbian farmers.

Lack of Variety - According to some authors (Curić J., Ceranić S., 2010) another big problem is a lack of suitable varieties for organic production. This type of production requires the return of some forgotten varieties which posses far better characteristics for this type of production, in relation to available, "modern" varieties. The trouble is that it is very difficult to get those varieties in Serbia due to low demand for these sorts among the existing manufacturers. The development of this market is sure to find a motive for the production and import of some varieties that are missing.

Low Demand for Organic Products in Serbia. Demand for organic products in Serbia is low and we can say that this market is still in its infancy. It is extremely hard to find organic food and the price is far higher than the price of conventional food, especially if take into consideration prices in European Union. Logical development of any company is to become a stable company in the domestic market and then continue to grow its global market performance.
Modest demand for organic food in Serbia can be one of the reasons why there has not been a large enough company that could successfully perform in the EU market. The solution to this problem could be the association of producers and sellers of organic food in Serbia which would educate the citizens of Serbia and generate the primary demand for organic products. Something like this would enable them to increase sales, and to build a cooperation as well, and in that way welcome the joint appearance on third markets .
In regards to the specific data it is very difficult to find the exact data from secondary sources on the demand for organic products in the Serbia. In this study, as a source of data was used a study *"Status and prospects of consumption of organic products"* (Center for Organic Production Selenča, 2011). The advantage of this study is that it was done in 2010, so the data can be considered relevant, while the main disadvantage is the small number of respondents, only 200 of them. The study was conducted exclusively in Novi Sad which can be another drawback, however, taking into account that it is the urban population that is primarily interested in organic food in Serbia, this research can be a solid indicator of demand for the domestic organic market. The survey (Center for Organic Production Selenča, 2011) showed that 89% of respondents is familiar with the concept of organic food. On the other hand, 14% of respondents regularly buy organic products, while 38% of respondents sometimes or rarely purchase organic foods. 48% of respondents do not buy organic products at all. As the main motive for buying organic food (Center for Organic

Production Selenča 2011) are cited health reasons (50% of respondents), then the quality of food (32% of respondents), environmental care is the third most important reason for buying these types of products (15% of respondents), and 3% of respondents did not state the reason for purchasing organic food.

Lack of Security in the Marketing of Organic Agricultural Products - The leading producers of organic agricultural products are, as a rule, the earlier highly successful farmers of conventional agricultural products. It only indicates that the success in this type of agriculture requires systematic, hard work and willingness to learn. Despite all of this, often the biggest problem for transition to this type of production (or the existence) is the possibility of exporting products at prices that are reasonable given the increased costs and reduced yields. Therefore, as a necessary condition appears the requirement that organic farmers provide the appropriate conditions of purchase by the cooperative association, or under contract with the already proven organizers of production for export to international markets.

CONCLUSIONS

Conclusion of the complete study could fit in one sentence - taking into account the characteristics of the organic food market in the European Union and the characteristics of Serbia regarding the production - possibility when it comes to this type of products, export of organic food from Serbia to the European Union would have to be much higher.
The question arises, what to do next? What is necessary to do in order to improve the situation? There are two groups of subjects that can facilitate the process in the positive direction: producers and the state. The first thing that manufacturers should do is to form the association in order to approach the EU market together, but also to generate a common deterrent demand for organic products in Serbia. As far as joint appearance is concerned, the chronic problem of Serbian farmers to meet the demands of distributors in the EU markets is already known (but not in terms of quality but in terms of quantity instead). It often happens that foreign traders find a quality product in Serbia, but later realize that manufacturers not nearly meet their needs. This problem could be solved by manufacturers association, but also by focusing only on certain varieties that would have the best pass and/or which would wear the highest return on invested resources. Association would make it possible to generate greater demand for the organic products in Serbia.
The state can help the manufacturers with both financial and non financial measures. As regards the financial measures, providing strong subsidies for production of certain crops or animals under organic production can positively influence farmers to adopt this form of food production. In cooperation with commercial banks, it is possible to offer more favorable loans where the state would be taking on given cost (interest) or accepting at least a part of the risk if the loans are not returned. These activities would lead to a spillover of risks from the manufacturer to the state which might have beneficial effects on the increase of the organic production. Another direction would certainly be the education of agricultural holdings on the use and characteristics of organic food production. This could be done by linking scientific research institutions and the farms together. On the other hand, creating certain institutions that would help sales of organic food would certainly help both existing and potential producers of these types of products. Also, import of certain varieties that are suitable for organic production and which cannot be found on domestic market would be much easier if certain ministries participated in the enterprise. The state made the first step in hiring agronomists and in providing subsidies to the producers of organic food, but the question is whether this is enough in order to significantly increase production and export of this type of products.

ABSTRACT: The purpose of this paper is to present the implementation of the HACCP system, as a system which ensures the product safety, in the field of honey production of the Primorje-Gorski Kotar County agricultural cooperative which engages in production of its own honey. The implementation of the HACCP system in honey production is presented through the process steps, the risk analysis, and the using of methodology for the detection of critical control points (CCPs) and control measures, which resulted in the HACCP plan design. The flowchart presents 24 process steps, 4 of which demand the control measures to be carried out to secure the food safety. During the implementation of the HACCP system, all the elements of prerequisite programs for good production and hygienic practice were taken into consideration. In the Republic of Croatia, honey and other bee products satisfy quantitative and qualitative domestic market.
Key words: *honey; HACCP; food safety*

INTRODUCTION

Gradual change of orientation of agricultural policies towards sustainable and integrated agricultural development through concepts and instruments of multifunctional development at the same time presents a chance for the development of beekeeping in the Republic of Croatia. Thus the purpose of this paper is to present the implementation of the HACCP system, as a system which ensures the product safety, in the field of honey production of the Primorje-Gorski Kotar County agricultural cooperative which engages in production of its own honey. The activity of the cooperative is based on the production of their own honey, buying off honey, honey production and honey products, and the sale of these products. This includes the production of catering packaging of honey or packaging of honey in plastic containers of 20 grams and glass jars of 25 grams. The capacity of honey processing amounts to a maximum of 10 tons per year.
The implementation of the HACCP system was preceded by the establishment of the HACCP team (members, duties of members, duties of employees), fulfillment of prerequisites of the program of good hygienic and good manufacturing practices (cleaning and disinfection, hygiene, training, equipment maintenance, requirements for visitors, etc.), making the product description (composition, characteristics, packaging, packing, storage conditions, transport, and shelf life), defining the process of traceability, product withdrawal and recall, as well as customer complaints (MPRRR, 2007).

MATERIAL AND METHODS

The implementation of the HACCP system in honey production – in jars and catering packaging - is presented through the process steps, the risk analysis, and the using of methodology for the detection of critical control points (CCPs) and control measures, which resulted in the HACCP plan design.
Process steps show the steps (phases) in the honey production in glass containers and catering packaging.

A HACCP study was made. It comprised a description of the physical, chemical and biological hazards in the materials' receipt, manufacturing, packaging, storing, transporting and selling honey and honey products, which represents risk analysis.
The methodology used for the application of the detection of critical control points (CCPs) is – "Decision Tree" – Figure 1, as well as the application of the methodology for the implementation of control measures.

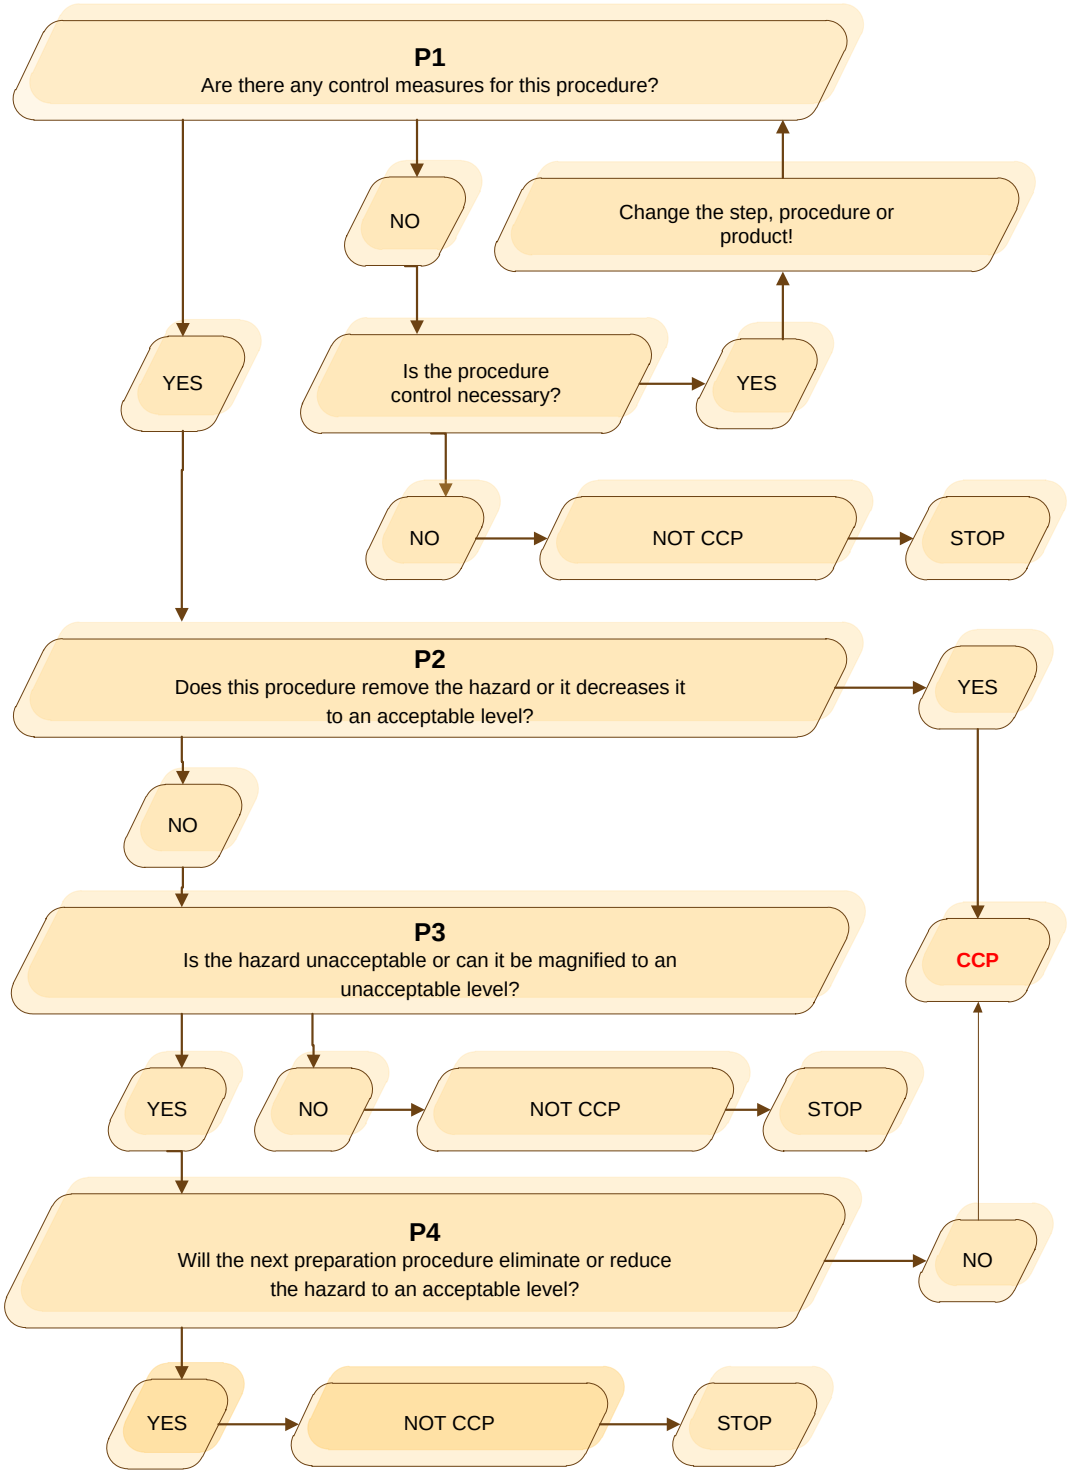

Figure 1. Decision Tree

RESULTS AND DISCUSSION

The flowchart presents 24 process steps, 4 of which demand the control measures to be carried out to secure the food safety (Figure 2).

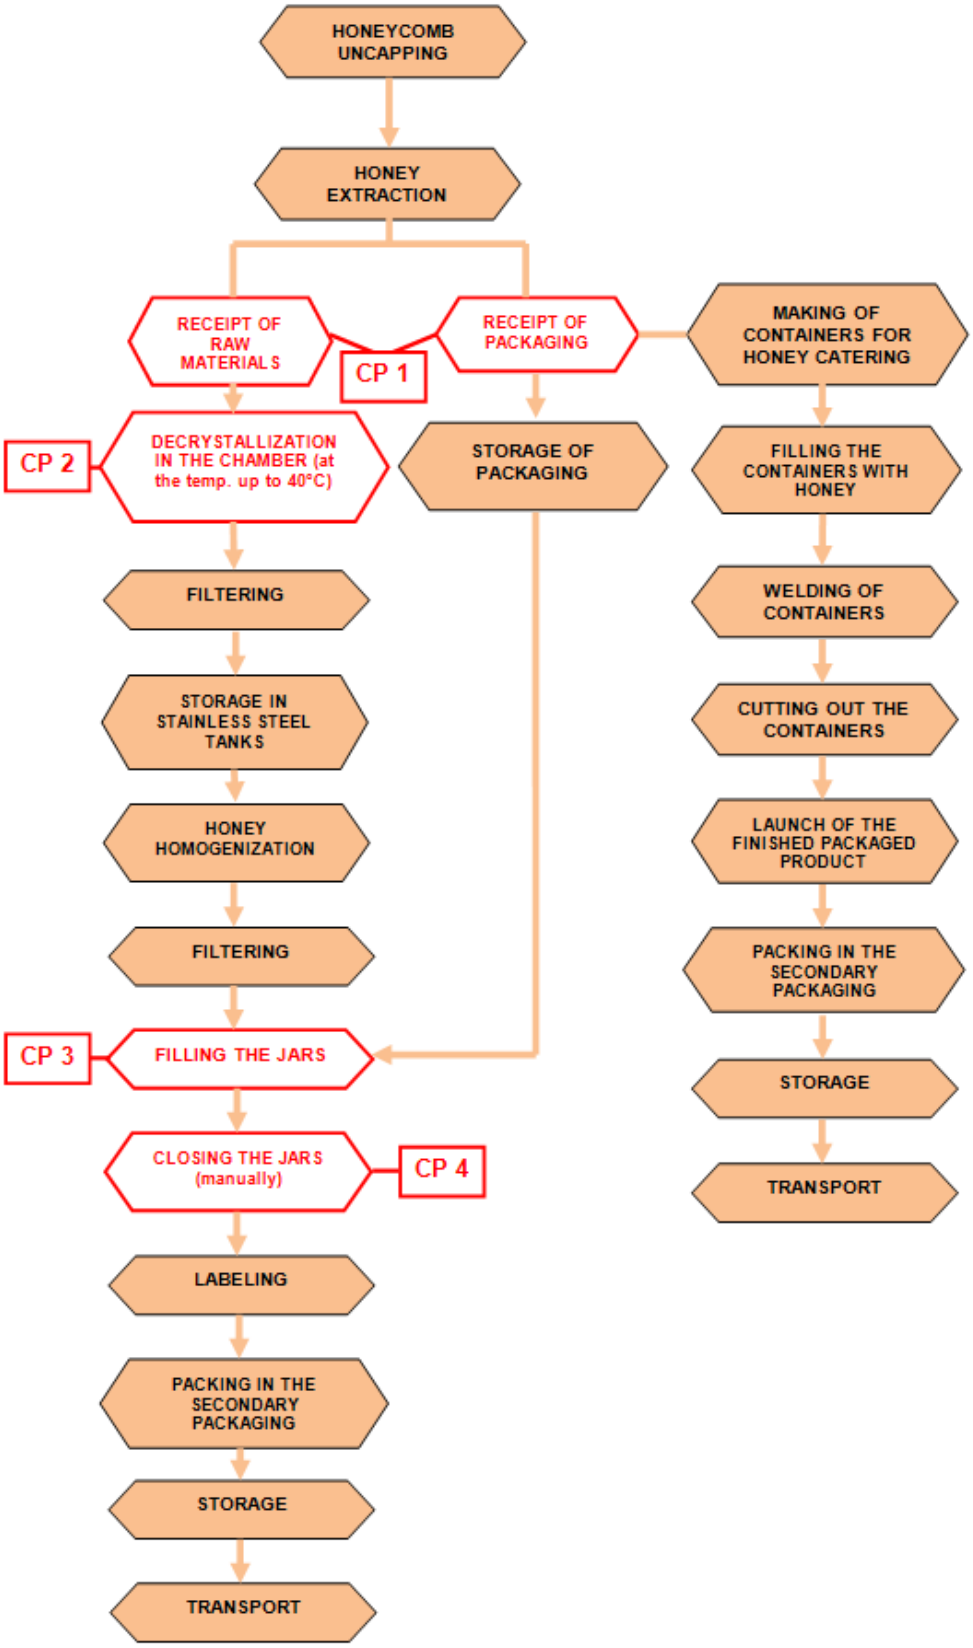

Figure 2. Flowchart

The methodology presented used for the determination of CCP-s and control measures takes into consideration the probability of risks and the amount of danger. The HACCP plan presents the type and description of indentified risk, critical limits, corrective measures and the way of implementing monitoring through procedures, frequency and responsibility, for only 4 process steps, which present the implementation of the control measures: raw materials receipt, packaging receipt, jar filling and jar closing (Tables 1-3).

Tables 1-3. HACCP plan

PROCEDURE IN THE PROCESS	POTENTIAL RISK	P1	P2	P3	P4	CP/CCP	CONTROL MEASURE
3 and 4 RECEIPT OF RAW MATERIALS / PACKAGING	**PH:**	**YES**	**NO**	**NO**		**CP 1**	- safety of raw materials/packaging - possibility of removing contamination by later procedures - employee training for the receipt of raw materials/packaging
	Presence of physical contamination due to damage and unclean packaging.						
	CH:	**YES**	**NO**	**YES**	**YES**	**CP 1**	- safety of raw materials – analytical reports for raw materials - safety of packaging – analytical reports and/or certificates for the purpose of packaging in food industry - employee training for the receipt of raw materials/packaging
	Presence of toxins, chemical substances from the environment, food additives and residues of pesticides.						
	B/M:	**YES**	**NO**	**YES**	**YES**	**CP 1**	- safety of raw materials – analytical reports for raw materials - safety of packaging – analytical reports and/or certificates for the purpose of packaging in food industry - employee training for the receipt of raw materials/packaging
	Presence of microorganisms (moulds, bacteria, and viruses) and spores.						

PROCEDURE IN THE PROCESS	POTENTIAL RISK	P1	P2	P3	P4	CP/CCP	CONTROL MEASURE
9 JAR FILLING	**PH:**	NO	NO			low risk	- GPP (employee training, preventive equipment maintenance) - GHP (SSOP, personal hygiene, employee training)
	Contamination by physical damage (equipment, hands of employees, place).						
	CH:	YES	NO	YES	YES	low risk	- GPP (employee training) - GHP (SSOP, employee training) - quality guarantee of the packaging supplier - supporting documents (analytical reports)
	Contamination by cleaners and disinfection. Contamination by chemical substances from the packaging.						
	B/M:	YES	NO	YES	YES	low risk	**-** GPP (employee training) - GHP (SSOP, employees' hygiene, employee training) - quality guarantee of the packaging supplier
	Contamination by microorganisms from the place, hands of employees, equipment, and packaging.						

PROCEDURE IN THE PROCESS	POTENTIAL RISK	P1	P2	P3	P4	CP/CCP	CONTROL MEASURE
10 JAR CLOSING (manually)	**PH:**	YES	NO	NO		**CP 2**	- GPP (employee training) - GHP (SSOP, employee training)
	Physical contamination due to irregular procedure of jar closing.						
	CH:	YES	NO	YES	YES	**CP 2**	- GPP (employee training), - GHP (SSOP, employee training) - quality guarantee of the packaging supplier - supporting documents (analytical reports) - visual control of closing
	Contamination by cleaners and disinfection. Contamination by chemical substances from the packaging. **Chemical contamination due to irregular procedure of jar closing**.						
	B/M:	YES	NO	YES	YES	**CP 2**	**-** GPP (employee training), - GHP (SSOP, employee training), - visual control of jar closing
	Contamination by microorganisms due to irregular procedure of jar closing. **Contamination by spores of microorganisms due to irregular procedure of jar closing.** **Growth of microorganisms due to irregular procedure of jar closing.** **Germination of spores due to irregular procedure of jar closing**.						

CONCLUSIONS

During the implementation of the HACCP system, all the elements of prerequisite programs for good production and hygienic practice were taken into consideration.
Honey, because of its intrinsic characteristics, especially the sugar content, represents a rewarding type of food when it comes to ensuring safety.
The HACCP plan defines 4 process steps in the honey production in jars and catering packaging which demand implementation of control measures for ensuring the product safety. These are as follows: raw materials receipt, packaging receipt, jar filling and jar closing. In the Republic of Croatia, honey and other bee products satisfy quantitative and qualitative domestic market.

ABSTRACT: Bosnia and Herzegovina (BiH) is a small country whose agricultural production in the current moment of dominant globalization cannot be competitive in terms of quantity, nor from the point of application of new technologies in agricultural production. Perhaps the best opportunity for the agricultural sector of BiH lies in the revitalization of traditional production technologies whose application leads to very high quality products and level of recognition in a broader context. Typical agri-food products diversify rural economy, contributing to the reduction in unemployment of rural population and provide greater employment opportunities for vulnerable rural populations. These products provide a developmental perspective to small farms to better valorize their potential. Valorization of local, traditional agri-food products is a complex process that involves a large number of stakeholders, who have to adjust their goals and values. There are number of agri-food products in BiH that can be characterized as typical products. Among the three products international organization Slow Food recognized as typical in BiH, this paper analyses *grah (bean) poljak* from Petrovo polje - the municipality of Trebinje, which has the Ark of Taste status. Based on data collected from producers in the field, it is found that the profitability of production of *grah poljak* as a typical product, is much higher (profit of EUR 8,917 per ha) compared to conventional cultivation of beans (profit of EUR 3,329 per ha). Therefore, production of *grah poljak* is more than profitable and main barrier to this production may be some other elements of the entire production cycle. This primarily refers to the sale and complete implementation of other marketing elements (distribution and promotion).
Key words: *typical agricultural products, diversification, rural economy, grah poljak*

INTRODUCTION

Rural development policy in Europe has been recognized as a means of preserving the natural and traditional values, which helps preserve national and cultural identities of individual countries. Local, traditional or typical agricultural products and rural development are already significant and representative binomial in many EU countries which have a demonstrable potential in these sectors (Brunori, 2006). Development of legislation and implementation of EU policies on rural development and qualification of production have made that specifics of agricultural and food products become prominent. On the one hand, these specifics are reflected in diversification of rural economy and on the other hand they are significant source of additional revenue for producers and they make the local territory recognizable.

Typical agricultural product can be defined as a product characterized by unique quality attributes that reflect a specifics of certain territorial environment (Brunori and Pacciani, 2006). Characteristics and quality of products are therefore impossible to reproduce in other places, or outside a particular territorial and economic environment. It is a product obtained by implementation of traditional production methods, using specific local resources that provide specific and identifiable quality characteristics and in its title bears the name of the locality from which it comes from (Marescoti, 2006). The specific quality of a product may result from pedological-climatic ambient or from the specifics of manufacturing processes.

Typical agricultural product is the result of collective and localized historical process, accumulated knowledge and skills that are based on a combination of territorial resources, both physical and anthropological. (Pacciani et al., 2001, Brunori, 2007). These products represent a cultural and historical heritage of an area. Since the integrated rural development is based not only on intensive agricultural production, but much more on the revitalization of forgotten and extensive production methods, this creates a new perspective for almost forgotten products to become generators of development in rural areas – one of them is *grah poljak* from Trebinje. In order to revitalize the village, one of the best methods is to preserve and revalorize traditional products of high value.

Bosnia and Herzegovina is a small country whose agricultural production in the current moment of dominant globalization cannot be competitive in terms of quantity, nor from the point of application of new technologies in agricultural production (Samardžić, 2009). Perhaps the best opportunity for the agricultural sector of BiH lies in the revitalization of traditional production technologies whose application leads to very high quality products and level of recognition in a broader context. (Bajramović and Samardžić, 2011). There are numerous products in BiH who are identified as potential typical agri-food products (Bajramović, 2010, Čustović et al., 2009). However, the very existence of resources possessing awareness has no value without its valorization. It is long and arduous process that leads to sustainability of the stakeholders involved in the valorization of resources.

By definition, in terms of dynamic liberalization of international markets, small farms are exposed to high business risk, and their survival as an economic unit is seriously impaired. In this situation, small farms are finding out development strategies that would help them to overcome their core limitation, deficient physical capital. Activation of other resources: knowledge, skills, labor, social capital and so on, is the only development alternative for this widespread socio-economic group (Bogdanov, 2007). Small farms are in a constant pursuit of finding nontraditional ways to increase the added value of their products in order to stay in the race with major manufacturers[1]. One of the competitive factors of small farms is the experienced labor force, which can hardly be copied and major manufacturers cannot easily incorporate it into their production technology and market distribution. The experience, skills and specific knowledge in the production process and product handling are what small farms have as an advantage compared to large farms, and it is closely associated with typical features of products. These factors contribute to greater personalization of products, opening the door to create a development strategy for small farms.

BiH is characterized by a rich ecosystem and biodiversity, which enables the production of various agricultural products. A mixture of cultures and historical heritage of the peoples, who live in this region, is condition of presence of a large number of specific food products, with original manufacturing technology and finishing / processing (Ramić, 2011). The aim of this paper is to take *grah poljak,* certified as a typical BiH agricultural product (Slow Food Ark of Taste status) as an example of the way how to obtain the status of typical BiH agricultural product and achieved level of protection and valorization, and to recognize the economic characteristics of its production compared to the conventional method, all in light of much-needed diversification of BiH rural economy.

MATERIAL AND METHODS

This study used number of recognized scientific and professional methods of which two stand out: the analysis (review) of the relevant literature and learning from good practice (case study). First method is used because issue of typical agricultural products in BiH and diversification of rural economy in general is not elaborated enough and the second one

[1] Additional knowledge and skills of the workforce is capital evaluated relatively low by farms in BiH compared to other resources and they have insufficient knowledge how to mobilize them to generate external revenues. Most commonly seen manifestation of specific knowledge and skills, is women's art to prepare fruit and milk in a traditional manner, knowledge of handicrafts, etc.

because learning from good practice is generally accepted method to understand and introduce new forms of economic activity using the positive experiences of others in the best way. Finally, in economic analysis we used the usual method of comparison and accrual calculations, while the more important economic indicators were calculated based on generally accepted patterns.

RESULTS AND DISCUSSION

Grah poljak (Lathyrus sativus L.) along with Cheese in a sack and Požegača plum Slatko are the only three BiH products that are recognized as typical farm products by Slow Food, the umbrella organization for eco-gastronomic activities. Each product had its own distinctive way of recognizing and recognition, and about the way of *grah poljak* we can briefly say the following: in the past *grah poljak* was very present in the Trebinje region and it has nurtured many generations. Production of *grah poljak* started to phase-out slowly in nineteen sixties, when it was pushed back by more economical and more yielding varieties. A new story of *grah poljak* begins in 2005, when Italian organization UCODEP (today OXFAM Italia) comes in the Trebinje area to investigate the potential typical and traditional products from the region of Herzegovina, as part of the "Taste of Herzegovina" project. Together with the representatives of local community they explored the municipality of Trebinje and in the village of Zgonjevo located in Petrovo polje, story about *grah poljak* is found. Seeing that this product could be interesting as a potential typical product, the search for *grah poljak* has started. The whole village found just a few kilos. At first glance, this bean shows its specificity. It is irregular in shape, like the crushed stone, about 1 cm in size, similar to the color of colorful sea sand and it comes in many shades.

Photo 1. Grains of *Grah poljak*

Supported by UCODEP, *grah poljak* was presented at the fair of typical and traditional products in Turin (Italy) in 2006, under Slow Food sponsorship. It was promoted as a potential typical product from municipality Trebinje area. After being judged favorably at the fair, NGO „Centar za razvoj Hercegovine“ gathered people, potential *grah poljak* producers, and financially supported by Trebinje municipality, „Petrovo Polje“ agricultural cooperative was established. From that moment begins a different story for *grah poljak*. Until today (2011) major stakeholders in preserving this characteristic product and reproduction of its seed material until regular production were Trebinje municipality, cooperative „Petrovo polje“, UCODEP and NGO „Centar za razvoj Hercegovine". From initial few kilos in 2005, after implementing many activities and working in the field, production of seeds was significantly increased, so as a result in 2009, there was amount of 4.5 tons available for spring seeding. Today, at cooperative "Petrovo polje", there are about 50 producers of *grah poljak* who have produced about 25 tons with an average yield of 1,100 kg/ha, in strictly controlled conditions of production.

Promotional activities and valorization of *grah poljak* as a typical product from area of Trebinje municipality helped toward this product become one of the few typical products in BiH with Slow Food Ark of Taste status. Namely, based upon activities on valorization and promotion, participating at fairs of typical and traditional products such as Terra Madre in

Turin (Italy), confirmation for quality and organized work given by representatives of Slow Food after the monitoring of the Trebinje area and discussions with all major stakeholders, Slow Food has accepted the request of the producers of *grah poljak* to form Convivium (Community of "slow" food lovers and producers in a particular area) on 28.5.2009, which represents an important step in the ultimate protection and valorization of the product on the global level. Chemical analysis has been carried *grah poljak* in March 2010 at the Institute of Turin Chamber of Commerce, showed remarkable chemical composition. Among other things, 100 grams of *grah poljak* contains 26.23% of protein.

Based on data collected from producers in the field on expended materials and hours of operations in the labor and machine operation (and their prices) in the production of *grah poljak* and conventional beans, economic analysis was done at the level of production on a surface of 1 ha (Table 1). The goal of such analysis is the comparison of two ways of production and economic justification in general for the production of typical product of *grah poljak* compared to conventional production. Business success is figured out on the basis of the calculated revenues and expenses of production and identified indicators of productivity, economic efficiency and profitability of production.

Table 1. Comparative review of revenues and expenses in conventional bean production and production of typical agricultural product *grah poljak* (Surface 1 ha, in EUR)

Description	Unit	Bean Conventional production			Grah poljak Typical agricultural product		
		Quantity	Price	Amount	Quantity	Price	Amount

D) Cost of production (EUR/kg)				**0.71**			**2.80**

***Source**: Own calculations; **Note**: Calculations were performed in BAM (convertible mark) and then converted into Euro (exchange rate: 1 EUR = 1.95583 BAM)*

A review of Table 1 shows that both productions are profitable, but profitability of production of *grah poljak* as a typical product (profit of EUR 8,917 per ha) was significantly higher compared to conventional production of beans as a vegetable crop (profit EUR 3,329 per ha). This major difference is primarily the result of considerably higher revenues expected in the production of *grah poljak* due to the expected high sales price (EUR 10.23 per kg). This high cost is possible due to the uniqueness and rarity of the product and it has been proven in the field. When it comes to production costs, they were significantly higher in the

production of *grah poljak* (EUR 3,354 per ha) compared to conventional cultivation of beans (EUR 1,784 per ha). This difference arises for two reasons: much higher cost of seed for *grah poljak* production (EUR 10.23 per kg) compared to conventional cultivation (seed beans EUR 3.32 per kg) and significantly higher cost of human labor, which are generally more expensive compared to work of machinery.

Table 2. Comparative review of the economic indicators of business success in the conventional production of beans and typical product *grah poljak* (Surface 1 ha)

Indicator	Beans Conventional production	Grah poljak Tipycal agricultural product
Elements of business success		
Production (kg)	2,500	1,200
Total revenues (EUR)	5,113	12,271
Total costs (EUR)	1,784	3,354
Cost of human labor (EUR)	51	1,442
Profit (EUR)	3,329	8,917
Indicators:		
Productivity		
1. Revenues/Cost of human labor	100	8.51
2. Yield/Cost of human labor	49	0.83
Economic efficiency		
3. Total Revenues/Total costs	2.87	3.66
Profitability		
4. Profit/Total cost*100 (%)	186.53	265.85
5. Profit/Total revenues*100 (%)	65.1	72.67

***Source**: Own calculations*

Table 2 gives a comparative overview of the economic indicators of business success in the conventional production of beans and production of typical product *grah poljak* (Surface 1 ha). Indicators of labor productivity are much higher (of better values) for the conventional production of beans compared to the *grah poljak*. Conventional production of beans with 1 EUR expenses for labor generates 100 EUR of revenues or the value of 1 EUR spent on labor generates the production of 49 kg of beans. In production of typical product *grah poljak* these values are much lower, so the value of 1 EUR expended for labor generates 8.51 EUR of revenues or the value of 1 EUR expended for labor yields 0.83 kg of beans. Other identified economic indicators of success are much more favorable (higher) in the production of typical product - *grah poljak*. The economic efficiency (the ratio between total revenue and total costs) is 3.66 and is significantly higher than in conventional production, where the amount of revenues is 2.87 times the amount of total costs. Finally, analyzing indicators of profitability, *grah poljak* production is profitable: EUR 100 of the production costs generates EUR 266 of profit or EUR 100 of generated revenues makes EUR 73 of profit. These figures are lower when it comes to conventional production of beans, where EUR 100 of the production costs generates EUR 187 of profit or EUR 100 of generated revenues makes EUR 65 of profit.

Previous comparative economic analysis indicates undoubted profitability and economic efficiency of production of *grah poljak* and achieving better economic performance compared to conventional cultivation. Production of *grah poljak* is more than profitable and main barrier to this production may be some other elements of the entire production cycle. This primarily refers to the sale and complete implementation of other marketing elements (distribution and promotion).

CONCLUSIONS

Typical agricultural and food products diversify the rural economy, contributing to the reduction of unemployment of rural population and provide greater employment opportunities for vulnerable categories of the rural population - women and youth. Typical agricultural and food products provide a developmental perspective to small farms to better valorize their potential. BiH agriculture is characterized by small sized farms. Limited resource farms work in mode of semi-natural production and they are characterized by small, unstable and insufficiently diversified surplus of products. These farms are insufficiently competitive, in terms of liberalization of domestic market many of them will not survive. These farms must find a (new) strategy for their survival and development, which includes diversification of revenues and activities, products and services of higher added value, including the typical products. In BiH there are number of agricultural and food products that can be characterized as typical products. Among the three products Slow Food recognized as typical in BiH, this paper analyses *grah poljak* from Petrovo polje - the municipality of Trebinje, which has the Ark of Taste status. Valorization and protection of such products is not only an act of legal recognition, nor the economic development of the product. Product protection is an extremely interesting model of development as it provides a range of development opportunities to the region from which product comes such as giving the new socio-cultural values to traditional and forgotten knowledge and skills, then the more measurable economic indicators such as increased employment, higher revenues and improved access to markets. Based on data collected from producers in the field, it is found that the profitability of production of *grah poljak* as a typical product, is much higher (profit of EUR 8,917 per ha) compared to conventional cultivation of beans (profit of EUR 3,329 per ha). Therefore, production of *grah poljak* is more than profitable and main barrier to this production may be some other elements of the entire production cycle. This primarily refers to the sale and complete implementation of other marketing elements (distribution and promotion).

ABSTRACT: With advancing growth and maturity, forage cells insert a non-carbohydrate material, known as lignin, into the primary and secondary walls. Lignin can be thought of as the primary skeleton of the plant cell. It is important from a nutritional perspective because it is a non-digestible substance and its presence will inhibit the availability of the cellulose and hemicellulose portions of the forage. The experiment was designed as three factorial trials by randomized block system in three replicates. Three stages of growth of red clover (T*rifolium Pratense* L.) *cv* K-27 and K-39 were examined in the second and third cut. Three methods- acid detergent lignin (ADL), permanganate lignin (Per L) and klason lignin (KL) for determining lignin concentration of red clover were compared. Each of these methods gave different lignin values for the same type of forage sample. For all samples KL (Klason Lignin) values were higher ($P< 0.01$) than ADL (Acid Detergent Lignin) and Per L (Permanganate lignin) values. The KL residue concentrations were on the order of 1.60 to 2.20 times greater than the ADL and Per L residues. All three methods reflected maturity trends, although the magnitude of the change was different.
Key words: *red clover, klason lignin, permanganate lignin, cut, cultivar*

INTRODUCTION

Forages play an important role in providing nutrients for ruminants. The efficiency with which the potential energy of forages is utilized depends upon the type and maturity of the forage. Red clover (*Trifolium pratense* L.) is an important forage legume widely cultivated in most temperate regions around the world. In Serbia, red clover is one of the most important leguminous plants grown for forage production. Its success is based on the following characteristics: high seeding vigor, rapid growth, tolerance to acid and humid conditions, nitrogen fixing ability and high nutritive value for ruminants (Leto et al., 2004). The nutritive value of red clover decreases during plant development (Wilman and Altimimi, 1984). The increased content of cell wall constituents, especially lignin, is mainly responsible for this decrease.

Lignin plays a vital role in plant growth and development by improving water conduction through xylem tracheary elements, enhancing the strength of fibrous tissues, and limiting the spread of pathogens in plant tissues (Boerjan et al., 2003). Lignin restricts the degradation of structural polysaccharides by hydrolytic enzymes, thereby limiting the bioconversion of forages and fibrous crops into animal products or into liquid fuels and other industrial products. Lignified dietary fiber also plays an important role in maintaining gastrointestinal function and health in humans (Ferguson et al., 2001).

The various methods of lignin determination often give quite different estimates of lignin concentration (Fukushima and Hatfield, 2001, Fukushima and Hatfield, 2004). One major class of methods for lignin determination utilizes strong mineral acids to hydrolyze the other cell-wall components, leaving lignin as a residue to be measured gravimetrically. The other major class of methods employs oxidizing agents to remove the lignin selectively. In the second class of methods, lignin is estimated either by loss in mass of the sample or through a photometric assay for lignin oxidation products. The acid detergent lignin (ADL) procedure

of Van Soest et al. (1991) is the most commonly employed by animal scientists and agronomists for analysis of forages. There are both hydrolytic (H_2SO_4) and oxidative ($KMnO_4$) versions of the ADL method, the sulfuric acid variant of ADL is the most popular.
Our objective of this study was to compare the accuracy of the acid detergent lignin, permanganate lignin and klason lignin methods for measuring lignin concentration in red clover by employing an independent analytical method.

MATERIAL AND METHODS

The experiment was designed as three factorial trials, by randomized block system in three replicates. Three stages of growth of red clover (*Trifolium pratense* L.) *cv* K-27 and K-39 were examined in the second and third cut. Samples were hand cut with scissors at 5 cm height. The first stage was cut after 22 days of vegetation, at full boot stage, another one after 29 days of vegetation (around 40% flowering), and a third one in full flowering after 36 days of vegetation. Dry matter was determined by drying out samples at 65° C and grinding and sieving them to 1 mm particle size.
The acid detergent lignin (ADL) was determined as the lignin insoluble in 72% (w/w) sulfuric acid, applying the method of Van Soest and Robertson (1980). Briefly, ADL was isolated by filling the crucible containing the ADF with 12 M sulfuric acid and allowing it to drain from the crucible. Additional acid was added periodically over the 3 h room-temperature hydrolysis. The acid insoluble residue was collected by filtration and extensively washed with hot water. A final acetone rinse was used prior to drying the sample overnight at 100^o C. The ADL content was determined as the difference in weight of the residue before and after ashing at 450^o C.
The permanganate lignin (Per L) was determined as the residue remaining after oxidation with potassium permanganate by the method of Van Soest and Wine (1968). Briefly, Per L was isolated by filling the crucible containing the ADF with saturated potassium permanganate and buffer solution, 2:1, v/v. Additional this solution was added periodically over the 90 min. at 20-25^{o}C. After that, by filling crucible not more than half-full with demineralizing solution. The insoluble residue was collected by filtration and extensively washed with 80 % ethanol and acetone. The Per L content was determined as the difference in weight of the residue before and after ashing at 450^{o}C.
The Klason lignin (KL) was determined as the residue remaining after total hydrolysis of the cell wall polysaccharides by the method of Theander and Westerlund (1986). In brief, 0.1 g of samples were treated with α- amylase (Sigma, A 3403) and amyloglucosidase to remove starch, and solubilized wall polymers were recovered by precipitation in 80% (v/v) ethanol. Starch-free, alcohol-insoluble residues were solubilized in 1.5 ml of 12 M sulfuric acid at 30^o C for 60 min. The samples were than diluted with 43.5 ml of water to 0.4 M sulfuric acid prior to secondary hydrolysis in an autoclave (120^o C) for 60 min. The nonhydrolysed residue was collected by filtration through a coarse-porosity Gooch crucible, extensively washed with hot water and dried overnight at 100^o C. KL was determined as the difference in weight of the residue before and after ashing at 450^o C for 6 h.
Data were processed by the analysis of variance in a randomized block design. Effects were considered different based on significant ($P<0.01$) F-ratio. The significance of differences between arithmetic means was tested by LSD test.

RESULTS AND DISCUSSION

As forages mature there is generally a decline in digestibility of the fiber fraction that is associated with an increase in lignin. People have tried to use lignin concentration as a means of predicting cell wall and whole plant digestibility. One of the problems when trying to compare published data from a range of plants is that the type of lignin assay method used may vary.

The concentration of acid detergent lignin of red clover harvested at three different development stages in the second and third cut are presented in Table 1. All three main effects (cut, stage of growth and cultivar) were significant (P< 0.01) in these trials.
The cut x stage of growth interaction was also significant (P< 0.01). The results of this investigation indicated that ADL content was increased with advancing maturity in both cuts, and the mean values were from 38.50 to 57.17 g kg^{-1} of DM in the second and from 26.36 to 52.60 g kg^{-1} of DM in the third cut. The higher content of ADL was found in the second cut than in the third at all three stages of growth.
The cut x cultivar interaction was significant (P< 0.01), and there is evidence for both cuts that K-27 had considerably lower ADL content. In the second cut K-39 contained more ADL than K-27 by 4%, and in the third cut by 12.8%.
K-39 contained more ADL than K-27 at all sampling dates (P< 0.01). Mean values obtained in the present investigation were from 31.49 to 51.68 g kg^{-1} of DM in K-27, and from 33.37 to 58.09 g kg^{-1} of DM in K-39.
With growth and development of K-27 in the second cut ADL concentration increased after the first stage of growth by 19%, and after the second stage of growth by 23.5%. In the third cut, ADL content in this cultivar of red clover was from 24.77 to 47.16 g kg^{-1} of DM (P< 0.01). The content of ADL in K-39 was higher than in K-27 at all stages of plant development, except at the second development stage in the third cut.

A_1 – second cut, A_2 – third cut; B_1 – first stage, B_2 – second stage, B_3 – third stage of growth; C_1 – cv K-27, C_2 – cv K-39. Different letters denote significantly different means (P< 0.01)

The another method of determining lignin content - permanganate lignin resulted in different amounts of residue, with Per L values were consistently higher than ADL values for all forage samples (Table 2). Lignin content in red clover differed significantly between cuts, stages of growth and cultivars (P< 0.01).
Permanganate lignin is based upon the ability to oxidize the lignin from a plant cell wall without affecting the cell wall carbohydrates. This method was developed originally for woody species in which the cell wall carbohydrate is predominately cellulose. In forages the cell wall contains significant amounts of other polysaccharides that are quite susceptible to oxidation by permanganate. For non-woody species this procedure tends to give much more variable results depending upon the cell wall make-up (Fukushima and Hatfield, 2002).
During maturation Per L increased from 47.43 to 77.70 g kg^{-1} of DM in the second cut, and from 34.35 to 71.32 g kg^{-1} of DM in the third cut. The highest increasing of Per L in red clover was after the first development stage in the second cut, and after the second development stage in the third cut. The cut x stage of growth interaction was significant (P< 0.01).
Cut x cultivar interaction was nonsignificant for concentration of permanganate lignin (Table 2).
There was an interaction (P< 0.01) between stage of growth and cultivar of red clover. Concentration of Per L increased with plant maturation from 42.93 to 72.24 g kg^{-1} of DM in K-27, and from 38.84 to 76.79 g kg^{-1} of DM in K-39. Despite the content of ADL in investigated

cultivars of red clover, K-27 contained more Per L than K-39 at all sampling dates, except at the third stage of development.
Concentration of permanganate lignin also increased as the plant matured in both investigated cultivars of red clover. In the second cut, K-27 contained higher concentration of Per L than K- 39 at the second and third development stages, whereas, values at the first stage of development were similar. In the third cut, K-27 contained higher concentration of Per L than K-39 at the first and second development stages, whereas much higher content of Per L was recorded in K-39 at the third stage of plant development.

Klason lignin is one of the oldest procedure and is frequently used for forage samples. The ADL procedure is basically the same except for the hot acid detergent treatment to insure the removal of protein and non-cellulosic polysaccharides before acid solubilization of cellulose (Fukushima and Hatfield, 2002).
Overall, as red clover matured, klason lignin increased (P< 0.01), with differences between cuts, stages of growth and cultivars.
The differences between stages of growth were less in the second cut than in the third cut (P< 0.01). The mean values were from 75.67 to 103.21 g kg^{-1} of DM in the second cut, and from 52.89 to 92.42 g kg^{-1} of DM in the third cut. Cut x cultivar interaction was also nonsignificant for concentration of klason lignin (Table 3). The two cultivars of red clover contained different amounts of klason lignin, with K-27 had consistently higher (P< 0.01) content than K-39.

In agreement with results of previous research (Jung *et al*., 1997) klason lignin concentrations were higher than corresponding ADL and Per L measurements for all samples in the present study**.**

It is generally considered that the major limitation of the KL method for forage samples is the inclusion of protein in the insoluble residue, resulting in artificially high lignin values (Van Soest *et al*., 1991). Cetyl trimethyl ammonium bromide (CTAB) is included in the acid detergent solution specifically for protein removal in the ADL method (Fukushima *et al*., 1991) whereas the KL method does not contain a protein removal step. Hatfield and Fukushima (2005) found large discrepancies between KL and ADL residues, particularly for grass forages. Their results indicated that ADL treatment of samples solubilized some of the lignin. This solubilization appeared to be extensive in grass samples. They concluded that major differences between concentrations of KL-generated residues and ADL residues were due to the loss of lignin as a result of ADL treatment rather than a large incorporation of proteins into the KL residue.
An advantage of the KL procedure is that it can be easily adapted to cell-wall hydrolysis schemes to obtain values for total carbohydrates, total uronic acid, and neutral sugar composition of forage samples, as well as estimating lignin content. The question remains, however, as to how accurately it estimates forage lignin content.
The present investigation has revealed that Klason lignin residues in red clover, especially at late stages of maturity, are very high. Lignin measured as the weight loss upon oxidation with permanganate was smaller than determined with sulfuric acid, agreeing with Hatfield *et al*. (1994.) The same authors reported that ADL values were 76% of those determined by the Per L method.

CONCLUSIONS

On the basis of the findings of this research, it is concluded that:
The Klason lignin method yielded greater estimates of lignin concentration in forages than did the sulfuric acid version of the acid detergent lignin and permanganate lignin method. A small part of this difference can be attributed to nitrogenous compound. The difference between KL and ADL values were of too great a magnitude to be accounted for simply as residual protein condensed in the residues.
The mean values of lignin content were greater in the second cut than in the third cut for all three methods.
The lignin content increased from first to third development stage in the second and the third cut in both investigated cultivars of red clover.
In both cuts, *cv* K-27 had lower ADL content than *cv* K-39 at all three stages of maturity.
cv K-27 had higher Per L and KL content than *cv* K-39 in the second cut.

ABSTRACT: The aim of this study was to investigate the impact of different level of fat in diets on body dimensions and weight gain of carp fry. Fish diets contained 38% protein and 8, 12 or 16% of fat. The experiment was carried out in triplicates, (3 tanks per treatment, 9 tanks in total) for 90 days at the Laboratory for Fish Nutrition, at the University of Belgrade, Faculty of Agriculture. Every tank has a usable volume of 120 gallons of water and water flow of 0.34 $Lmin^{-1}$. After adjusting fish to laboratory conditions, every tank was stocked with 29 fish, average weight 15.4 g.
Based on data of body length and height of fish, obtained in 30-to daily intervals, statistical analysis showed that there were differences among fish from different treatments. Fish fed diets with 8% fat achieved 46.8% higher weight gain than fish fed with food containing 12% fat and 65.4% higher weight gain than fish fed with feed containing 16% fat. Additionally, fish fed with less fat in diet had a more elongated body form and less pronounced body height as well as lower values for fish condition. Based on obtained results, it can be concluded that the diet with lower level of fat is justifiable to use, both from an economic and consumer perspective.
Key words: *carp fry, fat level, growth rate*

INTRODUCTION

The most commonly used fish feed in semi-intensive carp production are cereals. They contain a high percentage of carbohydrates and due to this is a primary source of energy for cultured fish (Sargent et al., 2002). When using grains as supplemental feed, the amount consumed per kilogram of growth rate usually ranges from 3.15 to 3.77, but is usually much more. This kind of feed in semi-intensive carp production results in increased body fat. Supplementary maize diet leads to carp body fat of about 13.26%. Body fat of fish fed supplementary wheat decreases down to approximately 11.22%, while the best results are attained by using triticale diet, producing only about 9.72% body fat (Vacha et al., 2007).
Fat in feed contribute to the better utilization of proteins from the meal, preventing its use as a source of energy (Skalli et al, 2004). Within certain limits, increasing levels of lipids in the diet, results in improved feed efficiency (Watanabe et al., 1979, Johnsen et al., 1993, Peres et al., 1999), providing biologically useful energy and thus sparing proteins. However, fish are able to utilize lipids in food to some extent, above which it may cause reduced growth, lowered food consumption (Ellis and Reigh, 1991) and formation of body fat. When feeding carp with a higher content of fat in diet, the final product is of poor quality, since the its level significantly affects the texture and consistency of fish meat (Huda, 2009).
In recent years, in order to boost production and improve meat quality of carp in South East Europe (Serbia, Bosnia, Romania, Bulgaria), cereals are more or less replaced by concentrated feed. By using supplementary concentrated feed better production results, higher feed efficiency and improved quality of end product, fish meat, are attained (Markovic, 2010). Concentrated feeds generally meet the nutritional needs of fish in terms of proteins, amino acids, vitamins and minerals, especially in periods of natural food deficiency. Nevertheless, the use of concentrated feed implies the necessity of larger financial resources for their purchase.

There is a variety of concentrated feed on the market composed from components of different origin, and various levels of protein and fat. In order to achieve maximum profitability in production, due to high cost of individual components (Aas et al., 2009), and achieve better production characteristics, it is important to know the nutritional needs of fish. By determining the nutritional requirements for fish, optimal production results are achieved with minimum investment.

The fat content of supplemental feed, except having direct effect on weight gain and utilization of feed has a relatively high impact on the characteristics of body dimensions: fork length and body weight (Kocour et al., 2007). Considering the market demand and consumer behavior, especially in Eastern European countries, which favor individuals of greater body size, the objective of this study was to investigate the effect of fat levels in concentrated feed on the weight gain and body dimensions of carp fry.

MATERIALS AND METHODS

The experiment was carried out at the Laboratory of Fish Nutrition, University of Belgrade, Faculty of Agriculture for 90 days. Three different types of concentrated feed were used (Table 1) with the same content of total proteins of 38% and 8, 12 and 16% of fat (Table 2), with 3 repetitions.

Table 1. Ingredients of experimental diets (%)

[3]P/E	19.6	18.6	17.8

1Nitrogen-Free Extract (NFE), g = 100 – proteins (g) – fat (g) – ash (g) – cellulose (g)
*[2]Row energy = protein (g) * 23,6 + fat (g) * 39,5 + NFE (g) *17,3*
[3]P/E = Protein-energy ratio (g proteins $(kJ)^{-1}$ row energy

The experiment was performed in 9 tanks with usable volume of 120 gallons of water and continuous flow of dechlorinated tap water of 0.34 $Lmin^{-1}$. After adjusting fish to laboratory conditions, every tank was stocked with 29 fish, average weight 15.4 g. Fish were fed daily using automatic belt feeders (AGK Kronawitter GmbH) 3% of their body mass. Water

temperature, oxygen concentration and oxygen saturation were recorded at 10 min intervals using OxiGuard system.
In 30-day intervals body weight was measured using a digital balance a digital balance Radwag THB - 600, (accuracy 0.01 g). Fork length and height were measured using the ichthyometer.
Following equations were used for calculating:

Body weight gain: $BWG\ (\%) = (Wt - Wo) / Wo \times 100$,
Wt – final body weight (g) and Wo – initial body weight

Condition factor: $CF = (W / L3) \times 100$,
W - body weight (g) and L – fork length (cm).

Length to height ratio of: $CB = L / H$
L - fork length (cm) and H - total fish height (cm).

Data were examined by one-way analysis of variance with feed as the factor and two-way analysis of variance with factors feed and period. Differences between treatments were tested using the Tukey test.

RESULTS AND DISCUSSION

At the beginning of the experiment, fish had homogenous body dimensions (CV<30%). Average fish body dimensions had no statistically significant differences ($p>0.05$). During the experiment, no significant differences were found for water temperature ($p=0.805$) and oxygen saturation ($p=0.275$). Due to this, it can be presumed that all the differences obtained during the experiment where the effect of different diets.
After the 90 - day experiment, weight gain ranged from 213.9% in fish that received the feed with 16% fat, to 352.2% in fish from the treatment with 8% fat in the diet. Fish fed with 8% fat, achieved 46.8% and 65.4% higher weight gain than fish from the other two treatments. Statistically significant differences were found in the weight gain of fish between treatments with 8% and 12% and 16% fat in the diet ($p <0.001$). Similar results are recorded by Yilmaz et al. (2005), who achieved better results in weight gain of carp fry by applying lower fat diet. By using mixtures with 7% fat, they attained 40% higher weight gain than when using the mixture containing 11% fat, and by 52.1% using 15.4% fat in the mixture. However, research by Manjappa et al. (2002) show that the increase of fat content in the diet has a positive effect on the weight gain up to some extent. Further increase will lead to lower weight gain. However, they pointed out that fish fed feed containing 11.4% fat, achieved 30.6% better weight gain than fish fed with 6.8% fat and 9.4% higher final weight than carp fry fed diet with 9.1% fat. Further increase of fat in the diet from 11.4% to 13% led to a decrease of weight gain by 14% in the four-month study.
Condition factor ranged on average from 1.72 for fish from the treatment with 8% fat in the mixture to over 1.75 for fish in treatment with 12% fat and 1.77 for fish fed with 16% fat. Tukey-HSD test confirmed that the obtained values of condition factor were significantly different between fish fed with 8 and 12% fat ($p = 0.021$), and between fish receiving 8 and 16% fat in the diet ($p = 0.001$). Similar results were obtained by Skoric et al. (2012) for condition factor in carp from the semi-intensive production system, but with no statistically significant difference.
The average fork length was significantly different between the three treatments ($p <0.001$), while the average height differed in fish from treatment with 8% body fat compared to fish with 12% ($p = 0.003$) and fish fed 16% fat ($p =0.001$) in the diet. Conversely, no statistically significant difference was found in the length to height ratio of fish from different treatments.

CONCLUSIONS

Based on the results, it can be concluded that it is more reasonable, both from economic and consumer perspective, to use lower level of fat (around 8%) in feed for carp. As the final goal, fish produced except larger final weight, have a slightly elongated body form and much better meat quality.

THE IMPORTANCE OF THE TRANSITION PERIOD TO ORGANIC MILK PRODUCTION

ABSTRACT: Organic farming primarily aims to produce food with high nutritive value, to maintain or increase soil fertility, prevent and combat soil erosion, biodiversity conservation and to protect natural resources from pollution. In order to base organic production it is necessary to provide the spatial isolation of land parcels and farms of the possible sources of pollution (pesticides, waste water, pollen of genetically modified crops), the plot of land on which the content of harmful substances does not exceed the prescribed maximum level, and proper irrigation water quality (first and second category) and air.
There are many studies that show the health benefits of organic milk compared to milk from conventional production. Organic milk has higher content of polyunsaturated fatty acids and omega-3 fatty acids, more vitamin A, C and α-tocopherol, it does not contain residues of antibiotics, pesticides or other chemicals. Organic milk is healthier because the cows are kept free (in the barn and in the discharge) and they are long time on pasture and without stress.
Although Serbia has an interest for organic milk production, for the health and economic reasons, there is still no market certified milk or other dairy products.
In order to make transition to organic production it must happen through a transition period or the period of conversion to switch from conventional to organic farming. Methods of organic farming in livestock production have to be applicable from the beginning of the conversion period, which begins after the conclusion of the contract on the exercise of control in organic production between the manufacturer and the authorized control organization.
The paper presents a method of organic milk production in period of conversion on a farm in Futog Agricultural High School, where special attention is paid to the following procedures: agro-ecological conditions, the number of animals per hectare, race, diet and posture, health and reproduction of animals, and parallel production (conventional and organic farms at the same farm), cadastral parcel numbers, history of land, fertilization, seed sourcing, analysis of water, controlling weeds, pests and diseases and the effect of biological protection and record-keeping. Detailed implementation of measures of organic plant and livestock production on farms in the period of conversion, which are consistent with the Law on organic farming and regulations on professional standards, are make to avoid the mistakes in next year and ensure the transition to organic milk production.
Key words*: transition period, conversion period, farm, organic milk*

INTRODUCTION

Worldwide demand for organic products is growing rapidly from year to year, particularly in Europe (Popović Vranješ et al. 2011) and also the number of farms switching from conventional to organic production. Most European countries recognize organic farming as a sustainable, eco-friendly production that does not pollute the environment and people as consumers of these products. Philosophy of organic food production is based on and reflects several principles, such as: biodiversity, ecological balance, sustainability, natural soil fertilization and natural pest management. Organic agriculture is possible on the entire farm, part of farm or family farms (Eco-farms) with compatible crop and livestock production, energy balanced, and environmentally and horticulturally developed space.
Procedure of involving producers in organic production is initiated by the manufacturer who submits application to authorized control organization. Based on the application, the

manufacturer and the authorized control organization shall conclude a contract on the performance of control and certification. The transitional period is a time that is necessary to establish a system of farm management, build soil fertility and its biological activity, develop sustainable agro ecosystem and reduces the use of chemicals or their residues produced by using conventional methods of agriculture. Depending on the results of the required chemical analyzes (including the control of land use in the previous three years and production program for the transitional period), transitional period lasting 2 to 3 years will be defined.
In order to establish patterns of organic milk production, it must meet precisely defined conditions, such as isolation of land parcels, livestock farms and processing facilities from potential sources of pollution, water quality, coordinated development of crop and livestock production and the ability of producers for the organic agriculture with the obligation of constant knowledge innovation. The organic production is needed to ensure that the breeding of animals provide organic fertilizer, without which there is no organic production, i.e, the sustainability of land (Lazarević, 2008). Dairy cattle must have access to pasture for at least 120 days a year. All animals must have access to pasture, whenever weather conditions permits, since the land on which pastures are based should not apply manure or composted manure, which is not entirely biological decomposed (www.albertamilk.com). All animals older than 6 months must have access to pasture. Antibiotics, preparations based on synthetic organisms and GMO products are not allowed in food preparation or during the treatment of animals. The use of antibiotics is permitted, except, only in special situations, where its use must be documented, and it is allowed to use up to two times a year. Dairy animals that require more than 2 treatments per year must undergo 12 month conversion period, and those with chronic problems need to be extracted from the herd. Organic milk compared to conventional, has a better fatty acid composition and contains more polyunsaturated fatty acids and omega-3-fatty acids (Ellis et al., 2006; Baltušnikiene et al., 2008; Prandin et al., 2009).

MATERIAL AND METHODS

The aim of this paper was the research concentrated on creating conditions for organic milk production in frame of Agricultural School from Futog which entered the process of introducing organic crop and livestock production by Organic Control System Ltd. from Subotica. During the inspection, checking of documents and parcels registered for the first year of conversion to a total area of 14.80 ha was performed. On that parcels period of two years transition period began from the date of signing the contract. Sampling and analysis of soil on the content of hazardous substances on the reported parcels were performed. Part of livestock production which will be reported for organic milk production is dairy cattle, so a physical and chemical analysis of raw milk from the conversion period was performed as well as the contents of somatic cells and the total number of bacteria by standard analytical methods. Milk samples from transition period was analyzed monthly, from Holstein and Simmental cows, and the results are presented as mean values.

RESULTS AND DISCUSSION

In the transition period, conventional dairy farms establishe the conditions for the production on the principles of organic production. These activities include; assessment of requirements, selection of animals, provision of appropriate housing, care, nutrition and health monitoring, and production of quality milk and establish records of all activities on the farm management database, according to the requirements of certification bodies, which controls and monitors the production in the transition period. It is necessary to make a plan (sketch) of the parcels that go into a period of transition, as to make it easier to plan activities related to the plan of planting and rotating crops and forage, and ease of recording completed activities predicted by certification bodies (Figure 1).

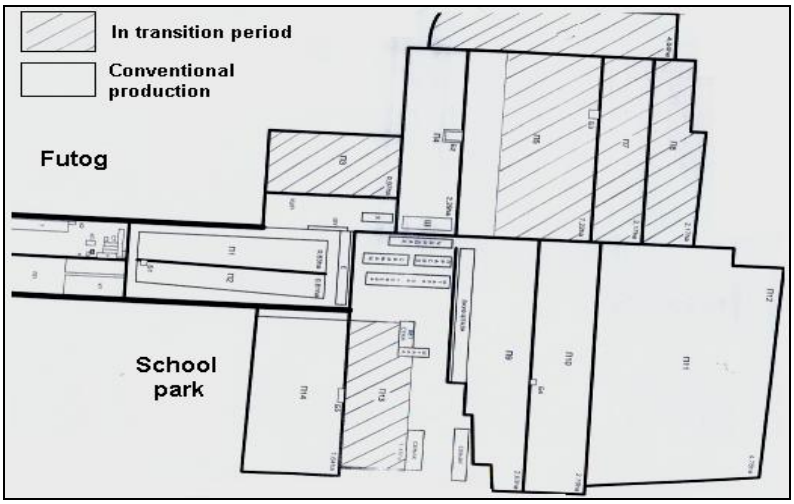

Figure 1. Sketch of parcels involved in the transition period

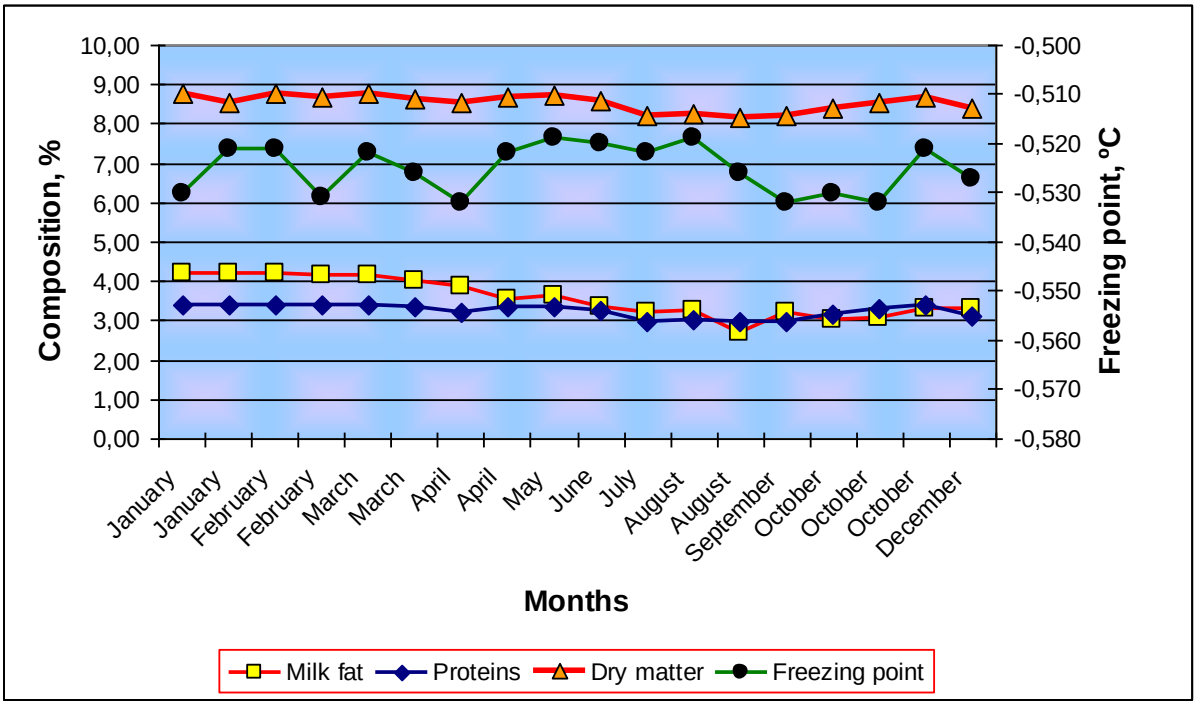
Milk from organic production is obtained from animals to which shall be provided growing conditions that allow expression of the natural functions and behaviors, because they form part of the agro ecological systems. In organic production, to farm animals must be given the appropriate conditions for breeding, counting on their wellfare and their health in accordance with the type and breed of animals. Cows are kept in open stables with enough space to move and to rest with protection from atmospheric conditions and the stress generated due to the occurrence of a large number of animals in small spaces as well as ammonia, Figure 2. Milking takes place in a modern milking parlor, which along with proper hygiene of milking and udder give milk with a small number of somatic cells and the total number of microorganisms. Milking parlor must be located and constructed so as to ensure satisfactory hygienic conditions during milking and easy to maintain hygiene (Krajinović et al. 2011). Today there are a lot of milk producers who are seriously considering about processing the whole or part of their production of milk into cheese within their household as a model of mini dairy. Given that investments in the small size household dairies are low, and products achieves a high price on the market, such forms of production are high profitable. The second production model could be a medium sized dairy plant (craft dairy manufacturers), which potentially involves higher volume of production that is sold on market, Figure 3. All ingredients used in the production and processing of organic milk and milk products should be organically produced, except for additives and auxiliaries allowed in the production of organic products (Miličić et al. 2010).

Figure 2. Stable for the free keeping system

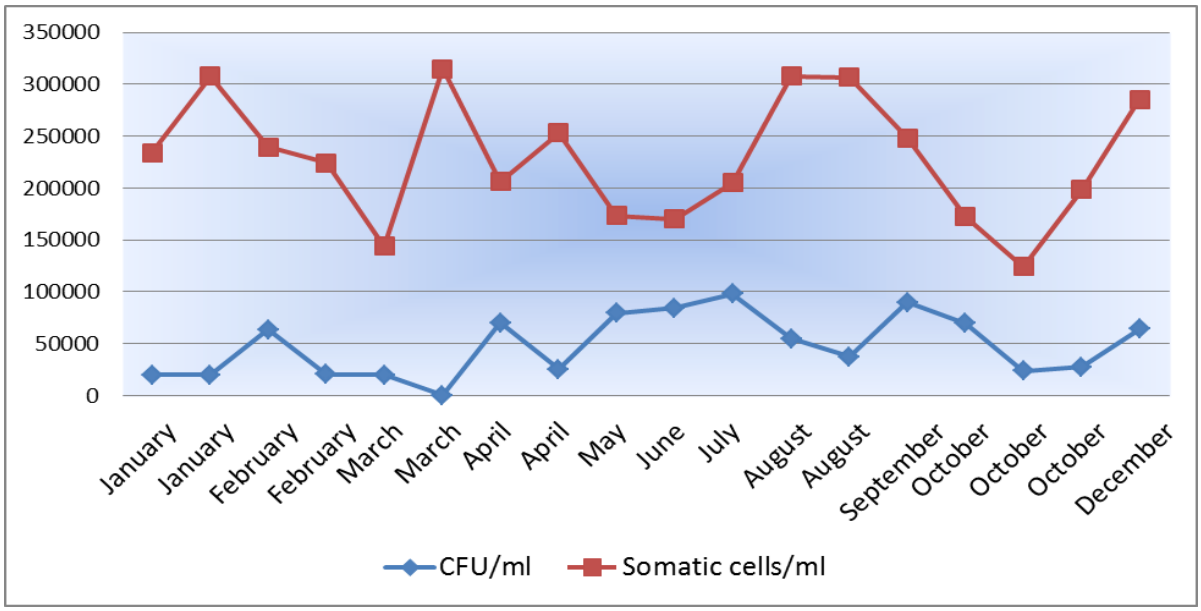
Figure 3. Dairy for the processing of organic milk

Animal health is a very important item to which the milk producers in the transition period must pay attention. Uterine infection and the occurrence of mastitis are two problems that organic farmers are often meeting. The appearance of mastitis is very important because it reduces the production, quality and income from milk and is a major problem, depending on the types of microorganisms that cause it. With good milk production managment, milking and hygiene can be reduced or completely eliminated the risk of mastitis (Tigner 2007). Therefore, intensive monitoring of udder health for early detection of new cases of mastitis, as well as proactive adaptation of mastitis control management strategies are essential for farmers who are engaged in milk production during transition period. If a contagious mastitis is present in the herd that are planned for conversion to organic production and processing of milk, all efforts should be focused on the identification, treatment, and/or excretion of infected animals before the conversion period (Tikofsky, 2010). It is necessary to continuously control the composition of milk in order to identify errors in the nutrition, hygiene and animal health and to eliminate faults, Graph 1.



Graph 1. Physical and chemical parameters of milk quality from the transition period

The analysis of milk from the period of transition was determined that the milk fat content ranged from 3.08 to 4.20%, protein content from 2.95 to 3.40% and dry matter without fat from 8.16 to 8.78%. Freezing point ranged from 0.519 to 0.532 ºC below zero. The quality of milk was constant throughout the year with certain variations caused by stage of lactation, season and other factors important for milk production. This is particularly marked for freezing point of milk which is in a large dependence on diet, season, water intake, cows breed, time of day (morning / evening milk), etc. Control of somatic cells contents and the total number of microorganisms is extremely important from the aspect of mastitis control and health status of dairy cattle, and hygienic conditions during production and milking. The total number of microorganisms in milk from the period of transition was below 100 000/ml, and somatic cell below 400 000/ml according to which milk was of the extra class quality, Graph 2.



Graph 2. Changes in the number of somatic cells and the total number of microorganisms in milk during the year

The average content of microorganisms in milk amounted to 48894.33 cfu/ml, and somatic cell 180,444.4/ml. Based on the results from graph 1 and 2 it can be established that the content of certain components of milk (milk fat, protein, dry matter) had a stable trend during the year, thanks to the proper nutrition of cows. The contents of somatic cells and the total number of bacteria showed a monthly variation in which the obtained values are not exceeded the maximum allowed. Bennedsgaard et al. (2003) found that cow health and milk quality of organic farms are better than conventional, and is directly proportional to the length of time that is spent in an organic farm production system, i.e the longer milk cows in the organic farming system are, the better is quality of milk. Milk from organic livestock production does not contain antibiotics and other harmful residues harmful to the health of consumers.

For the certification process and the transition of conventional to organic production, particularly important are professional control of authorized certification body, where reports should be prepared on: the plan and rotation of crops, number of hectares that go under transition (number of cadastral parcels), the history of each parcel during 3 years (previous culture, fertilizing, controlling weeds, pests and diseases), fertilization and types of fertilizers, the quality of water for irrigation, livestock, which resides on the farm (number and races of animals, housing and nutrition. Given that the fodder are supplied from own fields, it is necessary to analyze soil to determine the content of harmful substances that would eventually passed into the food or milk. Soil analysis results obtained, showed that the registered lands quality meets the requirements for growing the crops for dairy cows.

Table 5. The total content of hazardous and adverse substances in the soil from the transition period intended for the production of animal feed

Lab. No.	Cu	Zn	Co	Mn	As	Pb	Cd	Ni	Cr
	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg

MAC*	100	300			25	100	3	50	100

MAC*= Maximum allowable concentration. The maximum amount allowed by the Regulations on permitted amounts of hazardous and adverse substances in soil and water for irrigation and methods of their analysis (RS Official Gazette 23/1994).

CONCLUSIONS

Testing the quality of milk shows that there was no mastitis in the herd, because the determined number of somatic cells was at the level of completely healthy animals. The total number of bacteria in milk was on first class quality level (<100 000 cfu / l). The results of physico-chemical properties of soil have shown that land from the aspect of organic production is not contaminated with heavy matals and other chemicals. The animals were housed in a buildings that fits the requirements for organic livestock production. Animals were kept in accordance with the principles that allow welfare of animals (they have access to food and water at all times) and other conditions which ensures good health and maximum production of milk by the quality and quantity.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR 31095 financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT*:* Because they make up a large part of diets, corn grains cannot be considered only as a source of energy, as they provide significant amounts of protein as well. It is also recognized that cereal grains have a low protein concentration and that protein quality is limited by deficiencies in some essential amino acids, mainly lysine. For a balanced nutrition is important not only the amount of amino acids taken over, but the ratio between them, because the disproportion in feed of amino acids composition leads to a complex disorder of protein metabolism. The content of amino acids in plant biomass is affected by N nutrition. In this paper the protein content, and amino acid composition of corn grains was determined. Corn (Zea mays L.) was grown in a series of field plots which received various rata of applied nitrogen: 50 kgN·ha^{-1}, 100 kgN·ha^{-1}, 150 kgN·ha^{-1} and 200 kgN·ha^{-1}. Amino acid composition, after subjecting samples to conditions which would hydrolyze protein, was determined by ion chromatographic method. The analyses were made on samples with and without mycotoxins accumulation. The amino acid content varied significantly with protein content of the samples. Nitrogen rate that have a significant effect on the maximal accumulation of valine, isoleucine, leucine, phenylalanine, histidine, and alanine was 150 kgN·ha-1. Higher nitrogen application rates alter the amino acid balance thereby reducing the nutritional value. Mycotoxins accumulation took place in samples fertilized with 200 kgN ·ha^{-1}, which had lower amino acid content that samples without mycotoxins.
Key words: *corn, nitrogen fertilization, amino acid, protein*

INTRODUCTION

Corn or maize is one of the most popular cereals in the world. Because they make up a large part of diets, corn grains cannot be considered only as a source of energy, as they provide significant amounts of protein as well. The corn kernel is composed of approximately 72% starch, 10% protein, 5% oil, 2% sugar, and 1% ash with the remainder being water (Perry, 1988). It is also recognized that cereal grains have a low protein concentration and that protein quality is limited by deficiencies in some essential amino acids, mainly lysine.

Fertilization has a significant influence upon protein yield on surface unit and its quality. Fertilizers trough sortiments, doses and application periods determines protein and amino acids quantity in plants. Although the genetic potential is decisive for the protein content in plants, protein quantity and ratio of certain amino acids may be influenced by the fertilization (Radulov et.al., 2010).

Nitrogen (N) nutrition is one of the major factors limiting growth and production of crop plants (Losak et.al., 2010). The content of amino acids, important N-containing compounds, in plant biomass is also affected by nitrogen nutrition (Neuberg et al. 2010, Pavlík et al. 2010). Nitrate and ammonium are the major sources of N for plants. Ammonium-supplemented plants often show a higher concentration of amino acids than nitrate-supplemented plants, while higher N supply also causes an overall increase in amino acid content (Atanasova 2008).

Increasing nitrogen supply to corn generally resulted in increased grain and protein yields and increased grain protein concentration (Blumenthal et al., 2008). It is apparent that the amount of fertilizer nitrogen required to maximize grain yields is not the same as the amount that will produce maximum grain protein concentrations (Sander et al., 1987). MacGregor et al. (1961) found that amino acid concentrations of grain did not increase uniformly to nitrogen

fertilizer application, and that the concentrations of lysine, methionine, and phenylalanine did not increase. Rendig and Broadbent (1979) found that nitrogen fertilizer application decreased the concentrations of tryptophan, lysine, glycine, arginine, and threonine in protein, while concentrations of alanine, phenylalanine, tyrosine, glutamic acid, and leucine were increased.

Mullins *et al*., (1998) reported that, field experimentation involving different rates of nitrogen fertilizer increased forage protein content in corn. Where nitrogen levels are limiting, photosynthesis is not fully used in the synthesis of organic nitrogen compounds and sugars are accumulated. Heier et.al. (2005) showed that mycotoxin contamination in maize was influenced by N-fertilization rather than by the treatments. In 2001, the DON content was significantly increased due to the conventional N-supply. Immoderate N-fertilization however, can increase mycotoxin levels significantly even under conditions unfavourable for **Fusarium** spp.

Several factors influence toxin production in the field and in culture. One of these factors is nitrogen source. Stimulation of toxin production by amino acids is interesting for two reasons. First, water stress causes an increase in free amino acids. Of the amino acids that accumulate, proline usually accumulates to the greatest extent and is the amino acid that most consistently increases in several plant species, including corn. Second, proline has a variety of roles in microorganisms other than as a protein constituent. In non-halotolerant gram-positive bacteria, accumulation of specific free amino acids is important in cell osmoregulation, and in several species of bacteria proline appears to be the main amino acid involved in osmoregulation. Proline has also been reported to stimulate microbial growth, Payne and Hagler (1983) showed that proline with other amino acids and nitrogen sources are known to stimulate aflatoxin.

The aim of this work is to establish nitrogen fertilization and mycotoxin accumulation influence upon corn grains protein content and amino acids composition.

MATERIAL AND METHOD

A series of corn samples, hybrid Lovrin 400, fertilized with different fertilizers was studied, for ten years period, in pedoclimatical conditions from USAMVB Timisoara. The researches have been made on the cambic chernozem with middle texture, with following properties: total density ranged between 2.43 g|cmc and 2.58 g|cmc, total porosity has medium values, excepting the soil surface were total porosity has highest value: 47%; soil reaction is weakly acid, pH=6.18; humus content of soil is ranged between 3.28 si 2.10%, nitrogen index is ranged between 2.04 and 3.08 %; phosphorus soil content is low – 13.0 ppm, and potassium content of soil is medium– 184 ppm; the value of cationic exchange capacity of soil is 30.35 me/100g.

The samples were obtained from field plots receiving mineral fertilization: different doses of phosphorus and potassium P_0K_0 – control (0 kg P_2O_5 and $K_2O \cdot ha^{-1}$); $P_{50}K_{50}$ (50 kg P_2O_5 and $K_2O \cdot ha^{-1}$); $P_{100}K_{100}$ (100 kg P_2O_5 and $K_2O \cdot ha^{-1}$); $P_{150}K_{150}$ (150 kg P_2O_5 and $K_2O \cdot ha^{-1}$) on pre-fertilized plots with nitrogen N_0 – control (0 kg $N \cdot ha^{-1}$); N_{50} (50 kg $N \cdot ha^{-1}$); N_{100} (100 kg $N \cdot ha^{-1}$); N_{150} (150 kg $N \cdot ha^{-1}$); N_{200} (200 kg $N \cdot ha^{-1}$).

The corn samples were finely ground and dried for 24 hours at 60°C . Raw protein content from corn grain was determined by Kjeldahl method, as Kjeldahl nitrogen multiplied with 6.25.

The amino acids were assayed using ion-exchange chromatography after hydrolizing with 6 M HCl for 24h at 110°C. Methionine and cystine were analyzed by using formic acid protection prior to acid hydrolysis.

The chromatographic conditions are: DIONEX ICS-3000 Amino Analyzer, AMINOPAC PA10 Analytical Column (2x250 mm, P/N 055406), AMINOPAC PA10 Analytical Guard Column (2x50 mm, P/N 055407), Mobile phase: E1: water, E2: NaOH 250 mM, E3: NaAc 1 M, Reference electrode: pH/Ag/AgCl, Flush volume: 250 μL, Flow rate: 0,25 mL/min, Column temperature 30^0C. The minimum detection levels of standard was 5 ng/L for each of the amino acids and have been established based on signal to noise ratios of 3:1. The linear

dynamic range of the detector response was checked. The average correlation coefficient was between 0,9884-0,994.

The values obtained are expressed as per cent of a given amino acid in the whole grain. All values are expressed on the basis of the moisture free samples. The original samples contained 13 to 14% moisture. Statistical analyses were performed using SAS computer program.

RESULTS AND DISCUSSIONS

Nitrogen is of special importance because plants need it in rather large amounts, it is fairly expensive to supply, and it is easily lost from the soil. A major factor in successful farming is the farmer's ability to manage nitrogen efficiently. An abundant supply of the essential nitrogen compounds is required in each plant cell for a good rate of reproduction, growth, and respiration. The proper functioning of nitrogen in plant nutrition requires that the other essential elements, particularly phosphorus and potassium.

Protein content of corn grains, after nitrogen fertilization on plots pre-fertilized with phosphorus and potassium is presented in table 1.

Table 1. Nitrogen fertilization influence on raw protein content of corn grains (%)

Fertilization variant	kg ha^{-1} P_2O_5 and K_2O			
	0	50	100	150
	% raw protein			
0 kg ha^{-1} N	8,25	8,31	8,33	8,40
50 kg ha^{-1} N	8,57	8,67	8,71	8,78
100 kg ha^{-1} N	8,98	9,02*	9,00	9,05*
150 kg ha^{-1} N	9,68**	9,79**	9,24**	9,25**
200 kg ha^{-1} N	9,26**	9,40**	9,80**	9,78**

** * Significant at 0,1 percent level, * Significant at 1 percent level*

The highest protein content was determined in variants with high nitrogen fertilizers doses on all plots pre-fertilized with phosphorus and potassium. The raw protein content of corn grains rises as the nitrogen dose rise. Experiments done by Blumenthal et al., 2008, showed that increasing nitrogen supply to corn generally resulted in increased grain and protein yields and increased grain protein concentration. The corn samples from plots fertilized with 200 kg·ha^{-1} N and with no or low (50 kg·ha^{-1}) phosphorus and potassium fertilization presented mycotoxins accumulation. In this plots, raw protein content was lower than one in plots fertilized with 150 kg·ha^{-1}N. Although phosphorus and potassium does not influence raw protein content in such a large extend like nitrogen, they sustain nitrogen effect and attenuates negative effects of high nitrogen doses upon protein quantity and quality. The highest protein content of corn grains was determined after application of 200 kg·ha^{-1}N on plots pre-fertilized with 100 kg·ha^{-1}P_2O_5 and K_2O (9,80%) and 150 kg·ha^{-1}P_2O_5 and K_2O (9,78%). Corn samples from this variants didn`t presented mycotoxin accumulation. Similar results were presented by Heier et al. (2005) they showed that N-fertilization influenced mycotoxin contamination in maize.

Many researches showed that amount of fertilizer nitrogen required to maximize grain yields is not the same as the amount that will produce maximum grain protein concentrations. Nitrogen fertilization influence upon amino acids content of corn grains was determined only in plots pre-fertilized with 50 kg·ha^{-1}P_2O_5 and K_2O, which presented mycotoxin contamination, and 150 kg·ha^{-1}P_2O_5 and K_2O, without mycotoxin contamination.

Table 2. Amino acid content of corn grains fertilized after nitrogen fertilization on plots pre-fertilized with 50 kg·ha-1phosphorus and potassium (%)

Total	4,46	6,80	7,81	8,84	8,69

On plots pre-fertilized with 50 kg·$ha^{-1}$$P_2O_5$ and K_2O, total amino acid content rises with increasing dose of nitrogen fertilizer. Exception makes application of 200 kg·ha^{-1}N, were the content (8,69%) was lower than in variant fertilized with 150 kg·$ha^{-1}$$P_2O_5$ and K_2O (8,84%). Corn sample from plot fertilized with 200 kg·ha^{-1}N presented mycotoxin contamination. Among the amino acids the highest quantity was determined in glutamic acid in all fertilization variants (table 2). Experiments made by Seebauer et al. (2004) with increasing dose of nitrogen fertilizer (0 and 168 kg N/ha) had a variable effect on individual amino acid levels in young maize cobs. However increasing N concentrations were associated with decrease in crude protein of lysine, methionine, cystine, threonine, tryptophan and, generally, with increase in isoleucine, leucine, phenylalanine and glutamate (Losak et.al., 2010).

Table 3. Amino acid content of corn grains fertilized after nitrogen fertilization on plots pre-fertilized with 150 kg·ha^{-1} phosphorus and potassium (%)

AA	kg ha^{-1} N				
	0	50	100	150	200
Alanine	0,60	0,69	0,65	0,75	0,70
Arginine	0,42	0,46	0,45	0,50	0,53
Aspartic acid	0,61	0,63	0,64	0,75	0,75
Cystine	0,14	0,28	0,19	0,32	0,34
Glutamic acid	1,15	1,30	1,40	1,59	1,60
Glycine	0,23	0,24	0,28	0,45	0,46
Histidine	0,15	0,17	0,20	0,37	0,39
Isoleucine	0,25	0,26	0,30	0,38	0,40
Leucine	0,70	0,80	0,95	1,10	1,05
Lysine	-	-	0,10	0,28	0,24
Methionine	-	0,15	0,11	0,20	0,21
Phenylalanine	0,30	0,35	0,38	0,46	0,46
Proline	0,55	0,67	0,70	0,86	0,82
Serine	0,28	0,30	0,29	0,43	0,44
Threonine	0,30	0,30	0,30	0,40	0,41
Tryptophan	-	0,026	0,031	0,038	0,035
Tyrosine	0,28	0,34	0,36	0,45	0,48
Valine	0,42	0,43	0,45	0,55	0,58
Total	6,38	7,40	7,78	9,87	9,89

A possible reason for the lower values of total amino acids content in plots pre-fertilized with only 50 kg·ha^{-1}P_2O_5 and K_2O could be nitrogen fertilization applied in an exaggerated report to other nutrients, such a phosphorus and potassium.
In the variant were nitrogen wasn`t applied lysine, methyonine and tryptophan wasn`t determined (Table 2, and table 3). In variant were 50 kg·ha^{-1}N was applied only lysine was absent.
In plots pre-fertilized with 100 kg·ha^{-1} P_2O_5 and K_2O the amino acid total content was higher than in plot pre-fertilized with 150 kg·ha^{-1} P_2O_5 and K_2O. The total highest values was determined in plot fertilized with 200 kg·ha^{-1} N (9,89%). Application of highest nitrogen dose lead to a decrease of alanine, leucine, lysine, proline and tryptophan content. Losak et al. in their experiment made in 2008 determined that the highest N dose (treatment N2) significantly decreased the content of threonine, valine, iosleucine and leucine compared with the lower N dose. Kniep and Mason (1991) found nitrogen application increased grain yield, protein concentration and percent lysine of sample, but decreased percent lysine of protein. The predominant amino acids are aspartic acid and glutamic acid. Rendig and Broadbent (1979) found that nitrogen fertilizer application decreased the concentrations of tryptophan, lysine, glycine, arginine, and threonine in protein, while concentrations of alanine, phenylalanine, tyrosine, glutamic acid, and leucine were increased.

CONCLUSIONS

Application of highest nitrogen dose, on plots without phosphorus and potassium fertilization, determined mycotoxin accumulation in corn grains. In the variant were nitrogen wasn`t applied lysine, methyonine and tryptophan wasn`t determined. In variant were 50 kg·ha^{-1}N was applied only lysine was absent. Fertilization with highest nitrogen dose (200 kg·ha^{-1}N) lead to a decrease of alanine, leucine, lysine, proline and tryptophan content. Samples with mycotoxin accumulation had lower amino acid content that samples without mycotoxins.

ABSTRACT: Food production is the basis for country development. On the global market will always do well food producers whose costs are lower. Today, consumers demand of food requirements are increasing in quality, taste, healthy and cheaper price. The attention is also on environment of food production. The competition in market are focused on value for consumers where corporate various actors in food production. Suppliers, manufacturers, distributors, and retailers are all have various industry initiatives to gain competitive advantage. Whether these initiatives take the form of better service, lower prices, or some combination of both, they all share a common essence: integrating the supply chain. All of this has consequences for the way in which the various actors in the food chain cooperate. Investments must be taken place in the area of freezing foods, storage, packaging, fruit processing. It is also good to investing in new equipment and production lines for vegetable processing, greenhouse primary production and modern irrigation systems. However, the investments in our country are usually relatively small and may also stay relatively small in the future. This paper provides a general overview of the Serbian wheat supply chain, and the associated infrastructure and processes of the key elements of the export wheat supply chain. The export wheat supply chain producing Serbia is then summarized, including the participants in each segment of the chain. In this paper we give some basic guidelines for improving and increasing the efficiency of the supply chain for wheat with special emphasis on the qualitative and quantitative parameters of silos for wheat storing.
Key words: *supply chain, wheat, efficiency, improvement, silos*

INTRODUCTION

The literature in the supply chain management field defines a supply chain as a set of facilities, technologies, suppliers, customers, products, and methods of distribution (Arntzen et. al., 1995). The basis of supply chain management is logistics as opposed to accounting or strategy. The problem with the supply chain is essentially finding the optimal balance between cost and quality.
Logistics is the process of planning, implementing, and controlling the efficient, cost-effective flow and storage of raw materials, in-process inventory, finished goods, and related information from point-of-origin to point-of-consumption for the purpose of conforming to customer requirements (Lambert et al., 1998).

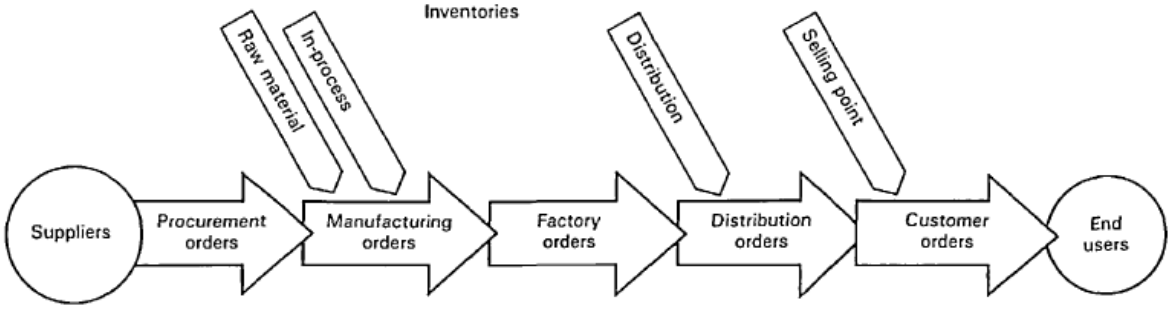

Figure 1. Supply chain management (Houlihan, 1985)

A basic barrier to the application of supply chain management is the traditional organization of most enterprises. Firms and supply chains are made up of separate production, distribution, and sales organizations often with conflicting objectives. To alleviate these conflicts, firms and managers must view their activities as a continuous flow of both products and information with the focus being to accelerate them. This focus on product and information flows is often depicted through the concept of a pipeline (Figure 2).

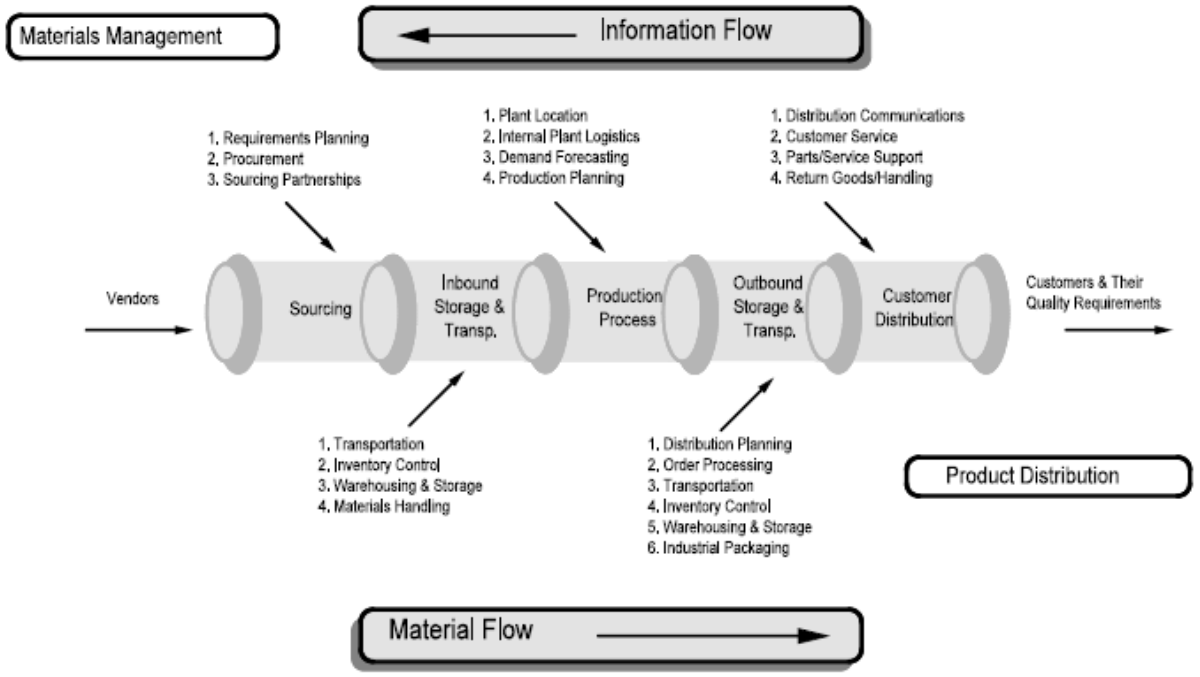

Figure 2. The logistics pipeline (Coyle et al., 1992)

WHEAT PRODUCTION IN TNE SERBIA

Serbia has very favourable climate conditions for agricultural production with 4.2 million ha of arable land (of the total of 5 million ha agricultural land) (Food Industry Study in Southeast Europe, 2010). Over the last few years, Serbia has established itself as a net exporter of cereals and edible oil. Agricultural products are mostly exported to CEFTA countries, EU and Russian Federation. However, most of the field crop production is with low yield, significantly below potential.

Flour production in the Serbia is currently running at over 500,000 tonnes per annum. The industry uses about 700,000 tonnes of wheat for this production, which represents only one third of the total wheat production of the country. This indicates the potential importance of the grey market in flour production. Official statistics are limited. Records about the production of bread and bakery products are also imprecise and the latest estimates say that the value of unregistered trade is about 10 billion Dinars. About 6500 companies are estimated to operate in this sector of which only 300 are registered. The Ministry of Trade has announced the possible introduction of excise stamps for flour in order to put an end to grey trade. Quality standards have been completely neglected in the supply chain of wheat, flour and bread production due to the current market conditions. This is why bread of poor quality is eaten in Serbia and the supply of special kinds of bread and other products made of flour is modest and expensive (Food Industry Study in Southeast Europe, 2010).

ELEMENTS OF THE WHEAT SUPPLY CHAIN

The wheat supply chain in Serbia are characterized by a lack of professional supervision in production process, incompetent market presence, and illegal sales. The supply chain is

comprised of producers, storage and processing facilities, industry, commodity market, wholesalers and retailers (Figure 3).

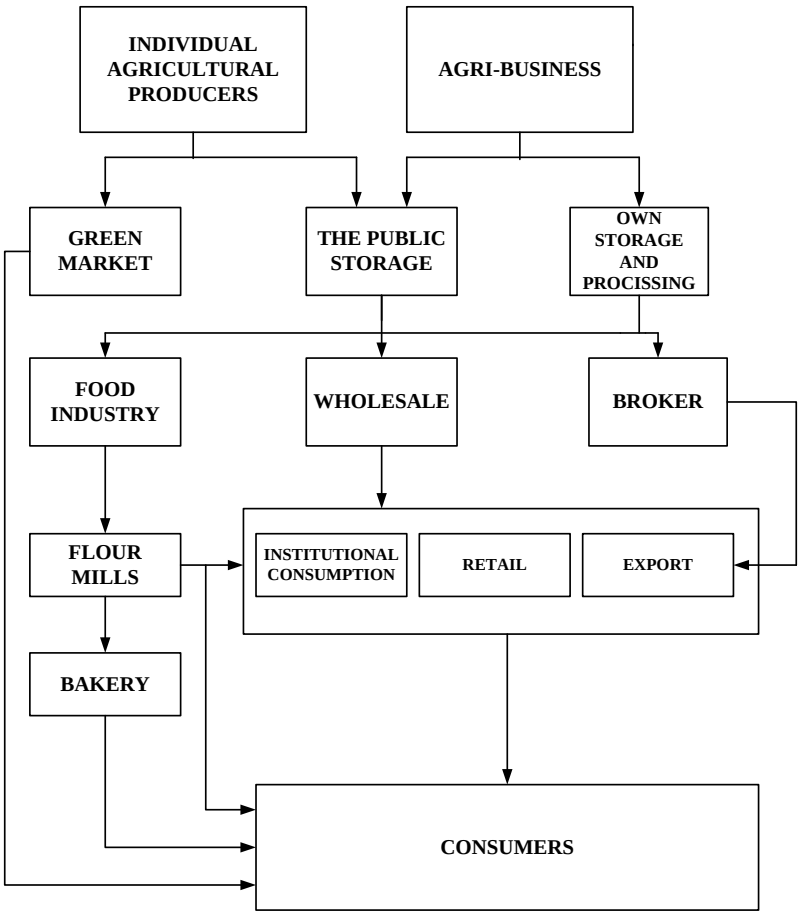

Figure 3. Wheat supply chain in Serbia

The structure of the wheat flour milling industry has changed in the last few decades. This industry segment is typical of the structural dynamics confronting other segments of the agricultural processing industry. Flour milling accounts for over 90 percent of domestic wheat processing use. The primary product is wheat flour for baking, while by-products are used for such things as livestock feed, pet food, and industrial applications.
Wheat processing capacity is around 1.2 million tonnes per year. There are enough storage and processing facilities, but they are mostly worn with low hygienic conditions.
There are three most important links in the wheat value chain: storage, flour millers, and bakers. Each of these links represents an important economic activity within the supply chain. Although heavily intertwined, each link competes in a unique economic environment. We considered in detail the storage technology.

STORAGE TECHNOLOGY

The role of storage is to preserve the quality of products received at the storage. Therefore the storage for wheat in the process of receiving goods in storage, preparation for storage, the storing and issuance of wheat from storage should comply with a set of activities presented in Figure 4. In addition to the above processes, storage should carry out the preparatory activities to enable the above processes be implemented in an optimal way (Vukicevic, 1995).

Quality preservation activities in the storage

In the order to preserve the quality, quantity and condition of stored wheat applied echnological operations: operations on elevators with or without fine cleaning, aeration, cooling, storage in an inert atmosphere and keeping with the addition of chemically inert dust.

In the storage for wheat in Serbia operations on elevators are dominant, and it could be said currently the only acivity that is widely used. This activities represent transfer process of stored wheat through a system of internal transport from one silo cell to another with or without grain leakage through the silo cleaning aspirater for fine grain cleaning. Plan for operations in elevator creates storage technologist on the basis of prevention planning for operations in elevator and intervention plan, made up according to the values determined critical indicators of stored wheat condition. This plan based on the guidelines of standardization and homogenization, too. As a rule, stored wheat, if there is no need for intervention operations in elevator, it is necessary and sufficient that 3 to 4 times a year pass through operations in the elevator.

In the operations in elevators reduces the wheat temperature, moisture balances, Aeris is, remove the foreign smells that may occur (the smell of stale). In order to achieve these effects completely, it is necessary to done that activities only when weather conditions are favorable for the performance of this technological measure, especially when the humidity is low and when there is no precipitation (Vukicevic, 1995).

CLASSIFICATION AND CHARACTERISTICS OF SILOS FOR WHEAT

Important element in the wheat supply chain are silo. Therefore, in terms of increasing efficiency of the supply chain we give a review basic types of silos, their characteristics and opportunities for process improvement of storing and other processes occurring in silo (Cooper et al., 1997).

In many silos in construction has been installed equipment to operate the silo and equipment for monitoring the condition of stored goods, but as a result of years of exploitation and technical advances come across a very bad picture of the condition of both pieces of equipment. Technically satisfactory those silos that are privately owned.

Generally, the problem is that capacities are not fully utilized, considered to be somewhere around 60% and that do not follow of possibilities in the range field, but it is processed by only the base product.

Cube-shaped silo may be constructed in a wide range of different cell number and total capacity. Size of the cubic cell is determined according to the needs of the customer or applied technology for processing, and their number by the total required capacity. According to the purpose and function of the cube-shaped silo can be constructed as: on farms silos, industrial silos, commercial loading silo, a silo complexes.

Silos on farms are less capacity appropriate to the quantities of wheat, which are produced and consumed on the farm. Equipped with the a admission line of road vehicles, equipment for cleaning, drying, filling and emptying. On the silos ground floor the optimal solution is to be installed mixers for the production of concentrated feed on the central part, from one side to form a storage for packaged components, on the other side of the pack, with a third party storage the finished product (concentrate in sacks). Triangular base of the pyramid-shaped silo allows approach from each of the three sides for loading or unloading packaged goods, so there is no crossing and mixing of material flows and the paths are shortest. Granular component (grains) are located in the cells above the silo mixers (their participation in the concentrate is about 60 - 70%), and in the processing are introduced simply by using gravity. In the basement under the silos can be three smaller rooms for administration, control samples, a workshop for minor repairs and spare parts for equipment. In the rest of the basement can be organized animal feed production, with use as raw grains from the silo. Classical solutions applied in the practice now have two to three times higher committed location, special facilities for the silo, blending, storage components, animal feed, administration, then the longer routes, equipment for connecting objects, long installation,

greater energy consumption, etc. In our case, all these functions are integrated into a single object on one basis, and investment savings are about 40% (Beamon, 1998).

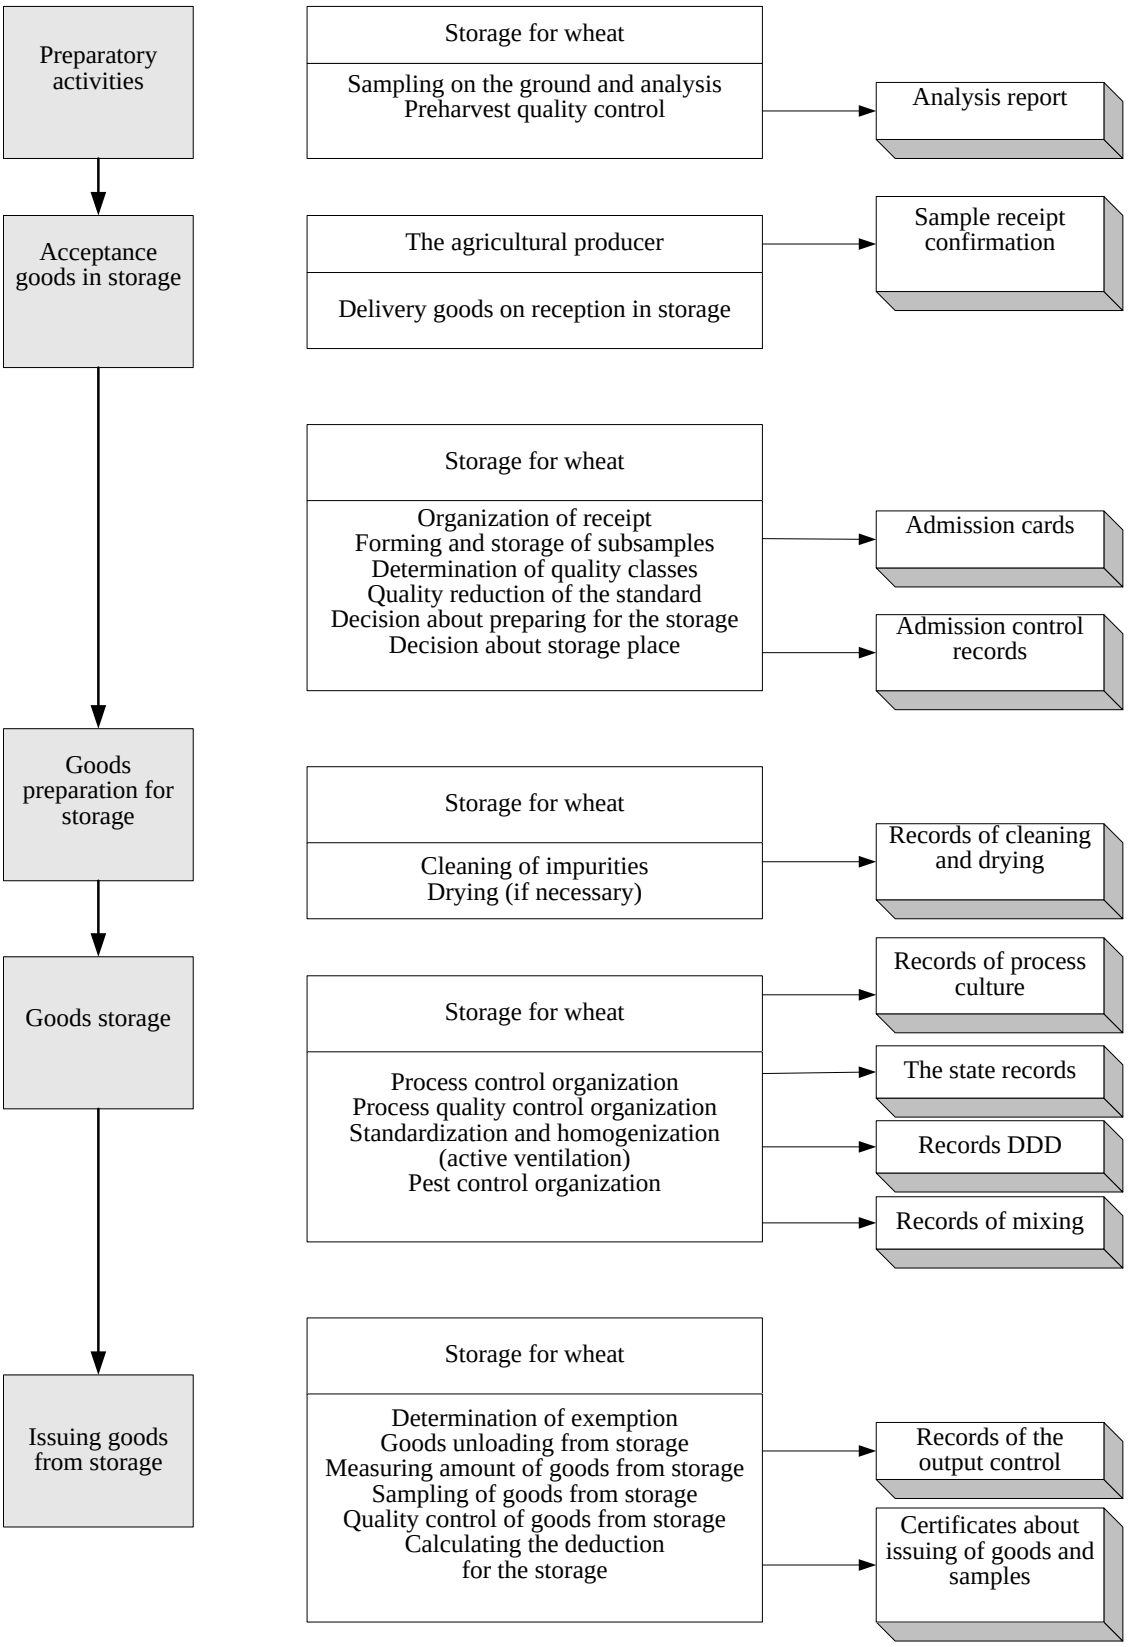

Figure 4. Flow chart of technological processes in storage for wheat (Mastilović et al., 2011)

Industrial silo are much larger capacity (10000-20000 tons) is required in a basic purpose. Can be constructed for receiving, drying, cleaning, storage and processing of wheat and other grains, corn, soybeans, etc. These silo have a larger capacity production lines, can have a railway terminal or more receiving lines. They can be built as single objects with processing facilities, such as mills for wheat, corn mills for human consumption, for the preparation of soybean plants, larger animal feed factories, etc. Then, they can be built near the existing silo and processing capacities, as an extension of grain storage in bulk, but should count on a considerable acreage under silo that are automatically granted with the silo construction. These surfaces can be used as a storage floor, as well as space for the installation of equipment for primary processing of grain, or installation of lines with several processing stages with a greater degree of product finalization, to the level of small packages based on resources from the primary production (wheat - flour - pasta, corn - flour - extruded products, soy - preparation - cattle feed), with additional programs such as sprouts for human consumption, etc. In the beer industry, for example, where silo can be constructed for barley malt, and that automatically gets a small space on the tight locations of breweries, several thousand square meters of storage floor, for example, crates for beer boxes and so on. One such silo could significantly reduce investment in a seed center and up to 40%, if in the cells were stored seed grain and in the area under silo can be located line for seed processing, packaging and storage until the time of distribution.
Reloading trade and port silo are generally large capacity silo (content of the goods) and large handling capacity of transport equipment. They are characterized by high frequency grain of various kinds. Therefore, it should be great to be able to accept all goods quantity as soon as possible carry out the same loading combinations: truck - silo - ship, truck - silo - railway wagon, railway wagon - silo - the ship and vice versa. So, they must have sufficient size and number of required terminals, but they are not equipped with the machines and dryers for cleaning, because the goods come dry and clean and a very short time remains for the silo. We particularly emphasize the importance of large storage floor at these sites that can often be more expensive than just buildings that are built on them, and storage facilities at ports are always in short supply, and storage services is very expensive.
Large silo complexes are largely with industrial character. They are built to the individual capacity of 20,000 tons and from a few of these silo can forming a complex on the principles of separation technologies that are not compatible, move closer to the rational connection of compatible technologies, rational transport organization, energy supply, installation, movement of workers and meeting their needs (Lambert et al., 2001).

CONCLUSIONS

The largest market for wheat from Serbia are the CEFTA countries. Serbia does not wheat quality for export. In the past four years, Serbia to the EU exported wheat for less than $ 40 million and wheat flour for about two million. Serbia is a price-competitive in the wheat production, primarily due to lower earnings of our farmers, on one hand, and lower land prices, on the other. However, wheat stocks are transferred from year to year and sown area decrease. The primary reason for this is - poor quality. Our wheat is most often classified as feed rather than food quality. The primary reason for this is very bad quality of our seeds. Seeds of wheat is expensive, which makes it in most cases, farmers do not buy, but they sow "from the attic". This seed can not achieve the required quality for export. Serbia has one seed house that has a monopoly on the market that behaves logical in a given situation: does not care about quality and price. So, as long as the market does not find a better and more productive wheat seeds, although Serbia will not significantly price-competitive export wheat in the EU. Serbia has the potential and all conditions to be a significant exporter of wheat (a large proportion of arable land in total land, favorable climate, small farmers' income expectations, sufficient storage space, etc.) and with the date of entry into the EU, be an important supplier of wheat in CEFTA countries and the EU. On the other hand, Serbia could easily become an occasional importer of wheat, if the manufacturer does not allow to have:
• Greater competition in the seed selection,

• Lower cost and higher seeds quality, which will allow greater use of the declared seed,
• Affordable control option for the application of mineral fertilizers,
• Merging the amount of subsidies to neighboring countries,
• Renewal and modernization of machinery and storage areas under favorable conditions.

To achieve this scenario, customs needed be abolished in whole or in less than 15% because high transport costs burdening the import (primarily due to the low value tonnes of wheat).

ACKNOWLEDGEMENTS

This paper is a result of the research within the project III 46001 “Development and application of new and traditional technologies in the production of competitive food products with added value for european and world market - Create wealth from wealth of Serbia”, funded by Ministry of education and science, Republic of Serbia.

ABSTRACT: Central and Eastern European countries experience significant socio-economic changes and are characterized by nutrition transition. They deal with persistent undernutrition and micronutrient deficiencies while being confronted with emerging consequences of overnutrition and diet related non-communicable diseases. Effective solutions will require investment in contextual drivers of diet, in particular in agriculture.
This study examines how national nutrition policies of Central and Eastern European countries published between 2004-2011, articulate agricultural measures to address nutritional challenges: undernutrition, micronutrient deficiencies, food safety and overnutrition using structured content analysis. Only 5 (24%) national documents (Bulgaria, Georgia, Moldova, Poland and Slovenia) out of 21 countries officially belonging to Central and Eastern European region were retrieved that met research criteria. Agricultural measures to tackle food security in vulnerable population groups mainly propose mechanisms to support agricultural production in rural settings and facilitated access (e.g. through subsidies) of healthy foods (e.g. fruits and vegetables) for vulnerable groups. Other strategies entailed education of producers and consumers about healthy food consumption, fortification of staples with micronutrients and establishment of food safety systems throughout whole food chain.
Strategies aimed at the agricultural sector for better diets in CEE region are interesting examples to generate lessons learned and provide information to further integrate agriculture and nutrition research for countries in nutrition transition.
Key words*: agriculture, nutrition, micronutrient deficiencies, food safety*

INTRODUCTION

Central and Eastern European countries have been experiencing vast political, economical and social changes in the last 10 years. They are however, still coping with persisting problems such as social inequalities, poverty and causally food insecurity. In many of these countries more than half of the population lives in rural areas and is poorer then urban citizens. They are predominantly engaged in agricultural activities as a mean of employment and income. Even though basic infrastructure services such as roads, electricity, clean water, education and health services are available, as a legacy from socialist system, there is a lack of integrated strategies to use the assets present to address numerous social problems (Mizik, 2010).
With regard to this, the nutrition status of the population in the region is one of the factors highly affected. Malnutrition is persistent amongst vulnerable groups- poor, mothers and children and elderly, and it is mainly characterized by nutritional deficiencies in iron, zinc or overall malnutrition due to poor diets (Rokx et al., 2002). Moreover, other nutritional problems such as overnutrition and obesity are prevalent and drive the development of diet related non-communicable diseases epidemic in the region. An estimated 80% of the adults are obese (Knai *et al*., 2007). The epidemic of non-communicable diseases contributes further to

an estimated 77% of the total loss in DALYs (%) and affects mainly poor and people in rural communities (Pomerleau *et al*., 2002).
Finally, food safety monitoring, that concerns quality of food available to the people and access to the foreign markets and international competitiveness, especially in EU, is poorly developed in the legal frameworks of countries in the region. In countries which joined the EU after 2004, the application for EU membership acted as a catalyst for adjustment of legal frameworks and implementation of food safety standards and guidelines. Similarly candidates countries for EU accession, such as Croatia, are passing through a similar adaptation process, while some other countries (Armenia, Georgia) that are coping with the poverty, experiencing difficulties in transition processes (Mizik, 2010).
The reality is that agriculture and nutrition (and health) are dealt with in separate contexts. A comprehensive approach at national level is seldom adopted. Food and nutrition which act as dominant cause of contemporary health conditions in various forms (malnutrition, deficiencies, overnutrition, food poisoning) is considered as an isolated issue under Ministries of Health or other, such as agriculture and social affairs. On the other side, the development in agriculture is usually observed through an increase in production, price trends, access to the markets and other economical indicators. Agricultural policies and strategies are designed under the supervision of Ministries of Agriculture and Economy which influence the trend of their development. In this context, nutrition remains idle in political and institutional frameworks (Fan & Brezska, 2012). So far, nutrition has not been widely used as an objective in development strategies considering both agriculture and health. There is a need for evidence based policy making and to formulate strategies for concerted action in nutrition. These strategies have to take into account activities such as the promotion of productivity growth of more nutritious foods; increase in demands for and access to nutritious foods along the entire food chain through consumer knowledge and awareness campaigns; breeding more nutritious varieties of staples that are consumed by the poor through the use of e.g. biofortification practices, or even the introduction of taxes on unhealthy foods and complementary subsidies on nutrient-rich foods.
Altogether, the nature of agricultural policies – essentially mostly perceived in terms of food production - equally needs to provide people with adequate quality and complete nutrition and provides livelihoods for the rural poor. The development of agricultural policies consequently has a significant public health impact. Despite this, however, broad societal and public health consequences of agricultural policies are usually neglected (Hoddinott J., 2012). To give consideration to such comprehensive approach, policy makers have to be informed on different aspects of implementation of nutrition strategies in public policies through information that includes data on nutritional patterns, micronutrient intake data etc. (Fan & Brezska, 2012).
This study analyses the nutritional policies of Central and Eastern Europe with the perspective of reviewing agriculture initiatives that are relevant for nutrition. It will examine how policies design agricultural strategies to address issues of undernutrition, overnutrition, nutrient deficiencies and food safety. It aspires to give an idea on current situation in terms of nutrition policy development in CEE countries and to point out alternative ways of thinking about plausible and clearly necessary segments in building new effective food and nutrition policies.

METHODS AND MATERIALS

Nutrition and diet related policy documents were retrieved by study group from Faculty of Bioscience Engineering, Gent University, using following inclusion criteria (i) officially approved policy of a WHO member state; (ii) publicly available document, published between 2004-2011 and (iii) written in English. Selection of the documents for this study was done from this collection, where we took all available documents for the countries that officially belong to Central and Eastern Europe group. The entire data set of policy documents was used for other research analysis by the study group, as well.

Information regarding the agricultural strategies was extracted manually from the text following a structured content analysis approach. In this analysis process, key issues regarding agricultural strategies were: food security, micronutrient deficiencies, food safety and overnutrition. The contextual of the policy documents was extracted for the various pieces of coded text to allow further consideration, interpretation and comparison. The extracted information was summarised and is presented in tables to facilitate comparisons and to allow a comprehensive evaluation.

RESULTS AND DISCUSSION

The Central and Eastern European sub-region consist of 21 countries out of which only 5 (24%) national documents (Bulgaria, Georgia, Moldova, Poland and Slovenia) were retained for review as they were the only available nutrition related policies officially approved, satisfying research criteria. Table 1 lists the documents used for analysis in the study.

Table 1. List of official national documents used for analysis

Country	Title	Publisher	Year
Bulgaria	Draft Food and Nutrition Action Plan	Council of Ministries	2005-2010
Georgia	"Food security, healthy eating and physical activity" national policy	Public Health Department of Georgia (Ministry of Labour, Health and Social Affairs)	2006-2010
Slovenia	The national programme of food and nutrition policy	Official gazette of Republic of Slovenia	2005-2010
Moldova	National Health Policy- Republic of Moldova	Ministry of Health	2007-2021
Poland	National prevention programme of overweight, obesity and non-communicable disease through diet and physical activity improvement	Ministry of Health, National Food and Nutrition Institute	2007-2016

Prior to presenting concrete results, it is key to point out that, even though a total number of endorsed policies are small, other countries in the region have been active in development of various strategies to address nutritional needs of their people and are at different stages of nutrition/food policy development. These activities could be seen through formation of capacity development network of regional professionals in CEE in 2006 suggested by UNU/SCN. This network have indentified major common nutritional challenges of all the countries in the region, which included: irregular meal patterns, low consumption of fruits and vegetables, milk and fish, low intake of micronutrients and high intake of fat, sugar and salt (Pavlovic *et al.,* 2009).

Countries such as Serbia, Hungary, Romania, Croatia, Albania etc. are facing various challenges in formulating policies. These problems are multifactorial e.g. limited interaction between ministries, governmental bodies and overall rigid political system which do not recognise the need for the policy, lack of coordinated nutritional activities i.e. monitoring systems. Furthermore, higher education and training on nutrition, which are prerequisites for the establishment of nutrition policy, are inadequate both for medical and agriculture professionals. Tools for building policies- food based dietary guidelines, recommended dietary allowances, food databases, are also randomly developed in those countries (Pavlovic *et al*., 2009).

The next section provides an overview of agricultural measure to address food security, micronutrient deficiencies, promotion of healthy foods and food safety in analysed CEE policies. Table 2 provides an overview of the main strategies for nutrition and agriculture in the analysed policies.

Table 2. Overview of agricultural strategies proposed in national nutrition and health policies in CEE region

	Country/ Strategies	**Bulgaria**	**Georgia**	**Slovenia**	**Poland**	**Moldova**
1	**Support agricultural productivity to ensure food security for vulnerable groups: children elderly poor disabled**	Develop mechanisms for production of food for elderly Economic and financial support for fruits and vegetable and fish production Create conditions for access to the market Milk and fruits for school children	Investment in agriculture to obtain food security in rural economy Subsidy program. for disadvantaged groups Programs of healthy foods in schools	Implement projects to facilitate access of poor to healthy foods Strengthening of self supply – anti-crisis	-	Support agriculture production and facilitate access of foods to vulnerable
2	**Measures to tackle problems of micronutrient deficiencies (MND)**	Fortification of staples with Fe, folic acid	Agriculture response to MND	Production of food for those with special needs	-	Apply new technology for fortification of staple food (Fe, I, folic acid)
3	**Promotion of food with health-benefit-production, processing, trade, distribution**	Improve awareness of food operators on healthy diet principles Incentives for healthy food production Tax on unhealthy foods Subsidies for healthy food	-	Facilitate access of healthy food to markets and institutions Raise awareness and promote healthy food to food operators and consumers Strengthen local production	Cooperation with food operators to produce food with pro-health values	Support culture and consumption of wholesome food
4	**Food safety system establishment - GAP, GMP, GHP- HACCP**	Establishments of FS system: Monitoring Control Training Research	-	Encourage and educate food operators for HACCP implementation Monitor and assess risk Inspectoral Control System	-	Increase application of HACCP systems among food operators

Agricultural measures to address food security in vulnerable population

Strategies to support agricultural productivity in ensuring food security for vulnerable groups - children, elderly, poor and disabled were found in 4 policies. The Bulgarian, Georgian and Moldavian policy measures mainly propose the development of mechanisms to support agricultural production in rural settings and facilitated access (e.g. through subsidies) of healthy foods (e.g. fruits and vegetables or fish) to vulnerable groups. Beside this, there are programs such as free milk and fruits for school children in Bulgaria and healthy foods in schools in Georgia or self-supply anti-crisis programs in Slovenia.

Measure to address problems of micronutrient deficiencies
The Bulgarian and Moldavian policies propose a fortification of staple foods with iron, folic acid and iodine. Slovenia encourages production of food for those with special nutritional needs, while Georgia asks for agricultural response to micronutrient deficiencies. None of the countries considers methods for bio-fortification as possible solution to address micronutrient deficiencies widely. The issue of fortification of staples in many of CEE countries is at the control of the state and is not regulated by the law i.e. law only regulates salt iodisation. The domestic food industry is commonly believed to lack technological and other knowledge and incentives to embark into these processes.

Promotion of food with health- benefit -production, processing, trade and distribution
Strategies to promote the production of healthy foods, facilitated access to the markets and education of producers and consumers were found in 4 policies. They are comprised of (i) Proposed activities to rise and approve awareness on healthy food consumption (in Bulgaria, Slovenia and Moldova), (ii) Giving incentives for healthy food production such as: subsidies for production (Bulgaria), facilitation of access to the markets, strengthening of local production (Slovenia), cooperation with food operators for development of pro-health food products (Poland).
There are few successful examples from other CEE countries (i.e. Poland, Czech Republic and Romania) which set certain taxes on fat (butter and snacks) and sugar (sweets, ice creams, confectionary) that had a huge impact on reduction of consumption of these commodities. Fruit and vegetables prices reduction at retailers has shown to be effective pricing strategy, as well (EHN, 2011).
However, agricultural policies in these countries have been tailored to produce cheap energy food supply with low nutritional profiles – low priced animal products with undesired fats and highly refined cereals, which were to satisfy basic needs of public and keep social ease. However, these policies have dire health consequences, reflected in rampant overweight, obesity and non-communicable diet-related diseases (WHO, 1998).

Food safety system establishment
The Bulgarian and Slovenian policies propose an integrative approach to establish a food safety monitoring system. This entails education and training on implementation of HACCP principles, assessment of risks, recommendations, monitoring, research (Bulgaria) and enforcing of inspectoral control system (Slovenia). Moldova however, still encourages food producers to implement HACCP systems in their processes. This situation clearly shows significant difference in development of food safety system establishment between those countries in EU and those countries which are still striving toward EU. Since implementation of food safety system entails financial, organizational and other resources such as well trained staff, it presents significant investing challenge for a food operator and a state and the whole process is slow. It is also important to mention that, while Western Balkan countries are building EU compatible regulatory systems, former soviet countries - Commonwealth of Independent States, use principles of Russian GOST “Gosudarstvennyy standart” system, which is now administered by the Euro-Asian Council for Standardization, Metrology and Certification, a standards organization chartered by the Commonwealth of Independent States which are not compliant to the WTO standards and are not recognized by most of the world’s trading countries (Mizik, 2010).

Other strategies
There are some other aspects projected in a few policies. For example, the policy of Georgia emphasizes the importance of development of monitoring systems for food availability and food consumption. Capacity Development Network for CEE countries recognizes the need for these systems and it can be expected that it will come up with their own databases and information systems which will help them to develop future policies (Pavlovic *et al.*, 2009).
The Slovenian policy stimulates development of local sustainable supply systems and economies and rural development and points out importance of consumer needs’

satisfaction. It is the only policy that recognizes the importance of preservation of local sustainable supply systems. While other countries have even more natural resources to do so, their traditional diets are vanishing and local commodities are being replaced with intensively imported foods e.g. tropical fruits in continental countries or intensively raised high-cropping easy-storing varieties of fruits and vegetables with lower content of vitamins or breeding of farm poultry with higher percent of fat and farm fish with lesser percent of poly-unsaturated fatty acids (EHN, 2011).

CONCLUSION

Strategies aimed at the agricultural sector for better diets in CEE countries' nutritional policies all together imply mechanisms such as production promoting mechanisms, nutrition education on different levels, market accessibility and regulation of food safety systems. The low number of available policies is an important indicator of the state at which countries of the region are in term of their capacity and resources to formulate and then take over proposed actions. Specific settings of the countries and historical background and development have to be taken into consideration. Nevertheless, there are prerequisite measures that are of crucial importance for further development – raising awareness of the important link between agriculture and nutrition among professionals from various fields-agriculture, nutrition, food technology, politics, economics, market, civil society etc. and bringing them together around building of capacity to tailor appropriate policy which will steer agricultural activities towards meeting nutritional needs for all.

ABSTRACT: The purpose of maintenance of hygiene is removing of all hazards that could result in food contamination; thus, its performance should be monitored and controlled. Direct methods of sampling of working areas, like swab method, are often used for detecting microorganisms presented on the working areas in meat industry facilities. The aim of this research was to evaluate the efficiency of the applied sanitation procedures in meat establishments. In this paper, microbiological safety of equipment, tools and working areas after disinfection during the certain steps of the technological procedure of meat processing and production was investigated. Swabs were taken from the same slaughterhouses during monthly routine controls from 2009 until 2011. Microbiological analysis were performed and following microorganisms were tested: *Salmonella* spp., *Escherichia coli*, coagulase-positive *Staphylococcus*, sulphidoreducing *Clostridium*, *Enterobacteriaceae,* as well as the total number of bacteria. From the total of 100 swabs taken from the working areas, tools and equipment in each year of research, 83% and 97% of the results in 2009 and 2011, respectively, were graded as acceptable. Comparing the period from year 2009 until 2011, the reduction trend of the number of unacceptable samples based on microbiological criteria is evident. This type of trend confirms that application of good manufacturing and hygienic practice is necessary to maintain high standard of hygienic and safe products.
Key words: *microbiological safety, hygiene of manufacturing plant, meat industry*

INTRODUCTION

Impurities, food residues and other waste materials attract pests and represent potential source of microbiological and physical contamination. Regular and thorough cleaning is necessary to remove impurities and maintain the facilities and equipment in a clean condition. Verification of the effectiveness of cleaning, washing and disinfection procedures as an addition and support to the process hygiene criteria in food production is achieved by analyzing the samples from the surfaces on certain microorganisms. While defining the areas to be sampled, the area sampling frequency, as well as eligibility criteria and possible corrective measures, the subject must take into account all available information about the potential dangers that can occur in the stages which are under its control.

In food industry, including production facilities for meat processing, there is a high risk of microbial contamination. In order to prevent the spread of contamination and risk to the human health, it is necessary to comply with good manufacturing practice (GMP) and good hygiene practice (GHP) and implement permanent control of production hygiene by taking all measures that help reduce risk, and economic damage in the meat industry (EU Concil Directive on the hygiene of foodstuffs, 1993).

In terms of microbiological safety, during meat production and processing, of particular significance are the following phases: bleeding, skinning/scalding, evisceration, cooling, deboning and grinding (Plavšić et al., 2007). Lack of skilled labor may contribute to the emergence and spread of contamination, leading to unsafe product which may represents a risk to the human health. Careless performance of bleeding and skinning can lead to meat surface contamination by impurities, therefore with the microorganisms (Bem and Adamič, 1991). Microorganisms like *Salmonella* species, *Escherichia coli*, *Proteus* species,

Clostridium species and others are regular inhabitants of animal intestines. However, their presence on other areas like meat surface is regarded as microbial contamination and possible cause of alimentary toxicoinfections and diseases. *Salmonellae* spp. is often pathogenic for humans and cause intestinal disease salmonellosis. *Clostridium* species are toxigenic and sporogenic microorganisms and may lead to serious toxicoinfections. *Escherichia coli* is indicator of fecal contamination, produce enterotoxins and cause enteritis (Plavšić et al., 2010; Plavšić et al., 2009; Plavšić et al., 2007). This indicates that in the stages of slaughter and carcass dressing, microbial cross-contamination may occur, either directly or via equipment, especially when the principles of GMP/GHP and HACCP are not followed (Malakaukas et al., 2006). Therefore, it is important that the principles of hygiene are met at every stage of the technological process of meat production.
New EU legislations concerning food safety regulate each level of food chain and describe the specific rules for food product of animal origin (Taylor and Holah, 2000). In order to assess the risk and take appropriate measures, control of hygiene facilities like equipment and tools, must be accompanied with the microbiological checking of hygiene maintenance by taking swabs (Barlow et al., 2002). With the implementation of HACCP principles, evaluation and control of hazards significant for food safety is performed. According to EC Regulation No 2073/2005, and with the implementation of HACCP programs, microbiological testing of hygienic status of carcasses, working surfaces, tools, supplies, equipment and machinery are provided (Commission regulation EC, 2073/2005).
The aim of this research was evaluation of the efficiency of the applied hygienic procedures on microbiological safety of equipment, tools and working areas after disinfection during the certain steps of the technological procedure of meat processing during the period of 2009 until 2011.

MATERIALS AND METHODS

The research included two facilities for meat production and processing during years 2009, 2010 and 2011. Five swabs were taken in each facility on a monthly basis during ten months. Surfaces from which swabs were taken were a table for cutting, knife, meat chopper, meat grinder and containers for meat disposal. Swabs were taken after sanitation procedure was performed. For taking the swabs, sterile set swabs with the test tube with 10 ml of sterile saline peptonic solution with neutralizer and metal templates (dimension 10x10cm) were used. Swabs were taken according to SRPS ISO 18593 (2008). Microbiological analysis of swab samples included following microorganisms:

- *Salmonella* spp
- *Escherichia coli*
- Coagulase-positive *Staphylococcus*
- Sulphitoreducing *Clostridium*
- *Enterobacteriaceae*
- Total number of microorganisms

Determination of these microorganisms was conducted using ISO standards (SRPS EN ISO 6579,2008; SRPS ISO 16649-2,2008; SRPS EN ISO 6888-1,2003; ISO 15213,2003; SRPS ISO 21528-2,2009; SRPS EN ISO 4833,2008)

RESULTS AND DISCUSSION

To check the hygiene of the facilities for production and sale of food, samples are taken from surfaces that are washed and disinfected. Since it is not defined in Regulation, the method, sampling frequency, the selection of microorganisms, and acceptance criteria should be outlined in the plan of self-control for food business operator. The guide for application of microbiological criteria for foods, chapter V, presents the microbiological criteria for objects,

surfaces and hands coming into contact with food, as a recommendation for food business operators (www.mpt.gov.rs).
In most cases, surface hygiene assessment is based on the number of microorganisms per cm^2 surface. In some cases, the specific bacteria such as *Escherichia coli* (an indicator of fecal contamination), *Staphylococcus aureus* (commonly found on the hands), *Salmonella* spp, *Enterobacteriaceae* are determined. Recommendations of national legislations are that if the contact surfaces have total number of microorganisms of 0-10 cfu/cm^2 and number of *Enterobacteriaceae* of 0-1 cfu/cm^2 they are evaluated as acceptable. Surfaces with total number of microorganisms and number of *Enterobacteriaceae* above the mentioned values are evaluated as unacceptable. Table 1 shows the results of swabs analyses during three year period (2009-2011).

Table 1. The percentage of acceptable and unacceptable results of analyzed swabs according to recommended hygiene criteria

Year	Total number of swabs	Acceptable	Unacceptable
	n	%	%
2009	100	83	17
2010	100	91	9
2011	100	97	3

Reasons for microbiological unacceptability of some swab samples were increased total number of microorganisms, increased number of *Enterobacteriaceae* and presence of *Escherichia coli* (table 2). During year 2009, 17% of swab samples were unacceptable due to increased total number of microorganisms, from which 14% of the samples had increased number of *Enterobacteriaceae,* and 11% of samples had *Escherichia coli* isolated. Detection of pathogenic microorganisms in the next two years tended to decrease. During year 2010 *Escherichia coli* was isolated from 7% of the tested samples, while 9% of total tested swab samples were unacceptable due to increased number of *Enterobacteriaceae* and total number of microorganisms. In year 2011 3% of the total tested swab samples were unacceptable due to the increased number of *Enterobacteriaceae* and total number of microorganisms. *Salmonella* spp, coagulase-positive *Staphylococcus* and sulphitoreducing *Clostridium* were not isolated in any of examined sample.
Total number of microorganisms in unacceptable samples was in the range of 60 to $2.1x10^3$ cfu/cm^2. Total number of *Enterobacteriaceae* in unacceptable samples was in the range of 20-190 cfu/cm^2. Number of *Escherichia coli* in unacceptable samples was in the interval from 35 to 100 cfu/cm^2. Since the swabs were taken from the clean surfaces after disinfection, findings and the presence of isolated microorganisms suggest that performed sanitary procedures were not efficient enough to remove microbial contamination.

Table 2. Results of analyzed unacceptable swabs (presence of microorganisms in % of samples)

Microorganisms	Year		
	2009[a]	2010[a]	2011[a]
Salmonella spp / cm^2	ND*	ND	ND
Coagulase-positive Staphylococcus / cm^2	ND	ND	ND
Sulphitoreducing *Clostridium* / cm^2	ND	ND	ND
Escherichia coli / cm^2	11%	7%	ND
Enterobacteriaceae / cm^2	14%	9%	3%
Total number of microorgansms /cm^2	17%	9%	3%

Legend: ND* - not detected
[a]The total number of examined swabs was 100 per year

Escherichia coli, as well as other *Enterobacteriaceae* are indicators of fecal contamination and suggest on insufficient hygienic performance of slaughter and carcass dressing operation. Stages of production such are dehiding and evisceration, if performed unprofessionally, may lead to contamination of meat, and also equipment and tools that are

in contact with meat, with microbial indicators of fecal contamination. During further stages of deboning and grinding, present microorganisms may multiply if these operations are performed unhygienically and without the maintenance of the cold chain, leading to further cross-contamination of the meat.
Introduction of HACCP principles, hazard analysis in each phase of production process, determination of the critical control points and implementation of control measures for management of the risks in meat production, are ultimately preconditions to safe meat production and hygienic and safe final product.

CONCLUSION

Reduction of the number of unacceptable swab samples of working surfaces in examined meat establishments indicates improvement of hygienic measures during the production process. Based on the fact that a large number of pathogenic microorganisms in the meat chain originate from the primary production or are introduced during meat processing, absolute imperative for improvement the safety of the meat and meat products is that meat establishments must comply with process hygiene criteria and good manufacturing and hygiene practice.

ABSTRACT: Environment protection, rational utilization of natural resources, reduction of pollution and use of natural resources, in a way to preserve and make them available for future generations, are some of many goals of sustainable development concept. The burden imposed on river ecosystems by polychlorinated biphenyls (PCBs) has great impact on sustainable development of our rivers. Properties of PCBs (resistance to photolytic, biological and chemical degradation) provide their broad distribution within the aquatic eco-system. Exposition to PCBs can cause harmful effects on aquatic biodiversity and, consequently, on animal and human health.
Objective of our study was to determine the level of contamination of fish by PCBs as bio-indicators of the contamination of the aquatic eco-system of river Sava.
In the period September-December 2011, 75 samples of river fish were collected (carp, crucian carp, pike, pike perch, bream and sturgeon) in the river Sava, upstream and downstream from Belgrade. Polychlorinated biphenyls were determined by GC/ECD on Thermo TG5MS capillary column (30m x 0.25mm i.d. x 0.25µm film thickness). Method detection limit is 0,001 mg/kg.
In the investigated fish samples the quantities of PCB residues ranged from 0,002–0,246 mg/kg (mean value 0,023 mg/kg). Compared to values obtained for 75 sea fish samples (hake, mackerel, sprat, sea bass, sea bream, etc), studied in 2011, where quantities of PCB residues ranged from 0,001-0,104 mg/kg (mean value 0,006 mg/kg), quantities of PCB determined in fresh water fish were four times higher, compared to sea fish.
The obtained results indicate that, the eco-system of river Sava, on the territory of the city of Belgrade, is compromised, and consequently it is necessary to implement measures for environment protection. These measures include strict prohibition of disposal of PCB into the river, collection and safe disposal of utilized oils (machine oil, transformer oil and oil used in the electronic industry, etc.), according to the National Strategy of Sustainable Development of Republic of Serbia.
Key words: *sustainable development, polychlorinated biphenyls (PCBs), fish, river Sava*

INTRODUCTION

The concept of sustainable development has become one of the most important concepts of our time. As multi-dimensional phenomenon, sustainable development has goal to integrate economic, ecological, social and institutional subsystems into a whole, taking care of their mutual influence. Environment protection, rational utilization of natural resources, reduction of pollution and use of natural resources, in a way to preserve and make them available for future generations, are some of many goals of sustainable development concept (Castro, 2004; Sarcevic et al., 2009). As it was said in the National Strategy of the Sustainable Development of the Republic of Serbia, every generation have same chance for using resources and healthy environment (Službeni glasnik RS, br. 55/05, 71/05 –ispravka 101/07). Realization keys for sustainable development concept are recongnized in prediction and prevention of risks in all areas of activity (Baras and Matekalo-Sverak, 2003; Sarcevic et al., 2011). Indicators of sustainable development include parameters used to monitor causes and consequences of human action of biosphere in order to find answers, i.e. establish actual activites which shall prevent the adverse impact (Baras et al. 2007; Baras et al 2004).
The burden imposed on river ecosystems by polychlorinated biphenyls (PCBs) has great impact on sustainable development of our rivers. Properties of PCBs (resistance to photolytic,

biological and chemical degradation) provide their broad distribution within the aquatic eco-system. Exposition to PCBs can cause harmful effects on aquatic biodiversity and, consequently, on animal and human health. Main concern is address to persistence and bioaccumulation through the food chain and their toxic effects (Janković et al, 2009). The main human intake of PCBs is by food consumption and particularly through consumption of fish. Fish consumption contributes up to 50% of intake of PCBs. Accumulation of PCBs in fish depends on their concentration in water, than on life stage, species and fat content of the fish (Bayarri et. al. 2001; Bordajandi et. al. 2001).From that point of view aquatic fauna might be used as indicator organisms for the evaluation of pollution of the aquatic environment with PCBs.

Mixtures of non-dioxin-like PCBs are assessed on the basis of analysis of the six so-called "indicator PCBs" - 28, 52, 101, 138, 153 and 180. These congeners are selected as suitable representatives for all PCBs because they are dominantly present in biotic and abiotic matrices.

Objective of our study was to determine the level of contamination of fish by PCBs as bio-indicators of the contamination of the aquatic eco-system of river Sava.

MATERIAL AND METHODS

In a year 2011, six different fish species have been collected from the Sava River: pike (*Esox lucius*), bream (*Abramis brama*), crucian carp (*Carassius carassius)*, pike pearch (*Stizostedion lucioperca*), sturgeon (*Acipenser sturio*) and carp (*Cyprinus carpio.*). Sampling points were separated in two locations: upstream and downstream from Belgrade.

Fish specimens were kept frozen at -20 °C before analysis. Samples were chopped into 2-3 cm thick portions and homogenized. In the fat extracted from sample with petrol-ether were determinated non–like dioxin PCB by gas chromatography.

Gas chromatograph GC Varian Model 3800 equipped with a ^{63}Ni electron capture detector (ECD) and Thermo TG5MS column (30m x 0,25mm i.d. and 0,25μm film thickness) were used for analysis of PCBs. Operating conditions were as follows: injector 250°C; detector 300°C; column oven program: initial 50°C raised to 200°C at 50°C/min, hold 2 min then raised 215°C at 2.5°C/min, hold 5 min and finally raised to 230°C at 2°C/min, hold 9,5 min. The highly purified nitrogen carrier gas flow was 1 ml/min. Data acquisition was performed by Varian Star software.

Analytical quality control was achieved by using certified reference material ERM-BB446 (IRMM, Belgium). Trueness and intermediate precision were fulfilled with specific requirements for determination of non dioxin-like PCBs (Specific requirements for determination of non dioxin-like PCBs, 2008).

The concentrations of target individual congeners (IUPAC numbers 28, 52, 101, 138, 153 and 180) were expressed in nanogram per gram on a fresh weight. PCBs congener IUPAC number 116 was used as an internal standard. The results are expressed as mean value ± Sd.

RESULTS AND DISCUSSION

The content of non dioxin-like PCBs in fish samples from Sava River is shown in table 1. PCB concentrations in fish from Sava River were in the range of 2 - 246 ng/g (mean 23 ng/g). Content of PCB in all samples were below the maximum residue limits (MRL) established by Serbian legislation - 3000 ng/g fresh weight (Pravilnik o količinama pesticida, metala i metaloida i drugih otrovnih supstancija, hemioterapeutika, anabolika i drugih supstancija koje se mogu nalaziti u namirnicama, 1992) as well as USA MRL – 2000 ng/g (Rockville, 2001). No maximum levels for non dioxin-like PCB in feed and food have been set in European Union. Several Member States have national provisions in place as regards to maximum levels for non dioxin-like PCB in foodstuffs. For

foodstuffs Belgium and France established maximum levels for the sum of seven indicator PCBs of 100 or 200 µg/kg fat, depending on the type of product. In the Czech Republic, maximum levels for the sum of seven indicator PCBs for various foodstuffs have been set in the range of 50-5000 µg/kg fat (AOAC, 1990). Content of non dioxin-like PCBs in our study, taking into consideration average fat content of examined fish species, is lower than levels mentioned above. Maximum levels for total PCBs established in Community legislative from 2006. were based on toxic equivalency factors (TEFs) and MRLs is expressed as sum of dioxins and dioxin-like PCBs and don't include non-dioxin-like PCBs (EC2006, 2006).

Table 1. Content of non dioxin-like PCBs in Sava fish (ng/g fresh weight)

Species	No	Σ PCBs ngg^{-1}		
		range	mean	**Sd**
crucian carp	12	5 - 31	17.6	7.3
pike pearch	12	2 - 21	12.5	4.8
carp	12	4 - 246	64.1	59.1
bream	15	6 - 40	18.6	9.7
sturgeon	12	5 – 28	17.9	6.6
pike	12	5 - 11	9.1	1.6
Σ	75	2 - 246	23.3	16.8

PCB concentrations in fish from Sava River were in the range of 2 - 246 ng/g (mean 23 ng/g). Content of PCB in all samples were below the maximum residue limits (MRL) established by Serbian legislation - 3000 ng/g fresh weight (Pravilnik o količinama pesticida, metala i metaloida i drugih otrovnih supstancija, hemioterapeutika, anabolika i drugih supstancija koje se mogu nalaziti u namirnicama, 1992) as well as USA MRL – 2000 ng/g (Rockville, 2001). No maximum levels for non dioxin-like PCB in feed and food have been set in European Union. Several Member States have national provisions in place as regards to maximum levels for non dioxin-like PCB in foodstuffs. For foodstuffs Belgium and France established maximum levels for the sum of seven indicator PCBs of 100 or 200 µg/kg fat, depending on the type of product. In the Czech Republic, maximum levels for the sum of seven indicator PCBs for various foodstuffs have been set in the range of 50-5000 µg/kg fat (AOAC, 1990). Content of non dioxin-like PCBs in our study, taking into consideration average fat content of examined fish species, is lower than levels mentioned above. Maximum levels for total PCBs established in Community legislative from 2006. were based on toxic equivalency factors (TEFs) and MRLs is expressed as sum of dioxins and dioxin-like PCBs and don't include non-dioxin-like PCBs (EC2006, 2006).
Contents of non dioxin-like PCBs in freshwater fish presented in the recent studies published in literature differ significantly between themselves.
Similar results to ours were published by Vojinovic-Miloradov et al. 2002 in regard to Danube fish perch, carp and pike – 6-22.5 ng/g (Vojinovic-Miloradov et al. 2002), Bosnir et al. 2005 in different fish species from Sava river - 8-177 ng/g (Bošnir et. al 2005), Mazet et al. 2005 in fish from Drome river (France) - 7,8-56,9 ng/g (Mazet et al. 2005) and van Leeuwen et al. 2007 in pike perch from Netherlands river - 37-87 ng/g (van Leeuwen et al. 2007).
Higher content than in our study were presented in Bazzani et al. 1997 in roach fish from river Arrone (Italy) - 1075,6 ng/g (Bazzanti et al. 1997) and Zhao et al. 2007 in crucian carp from China, up to 1451 ng/g (Zhao et al. 2007).
Vives et al. 2005 in brown trout from Redo lake in Spain founded 8.22 ng/g (Vives, et al. 2005) and Falandysz et al. 2004 - 3.8 ng/g non dioxin-like PCBs in perch from Odra river (Falandysz et al. 2004), which are lower content of PCBs than levels presented in our study.
In order to assess the level of contamination of the River Sava's eco system through fish, we examined 75 samples of six marine fish, most important in the diet of Serbian population: hake, mackerel, sprat, sea bass, gilthead and scorpanea. PCB concentrations in marine fish were in the range of 1- 104 ng/g (mean 6 ng/g).

The fact that average PCB value in fresh water fish is 4 times higher compared to sea fish indicates the problem of contamination of Sava's eco system as well as that the ecosystem of the Sava River in Belgrade area is at risk and the necessary measures for environmental protection should be implemented.

CONCLUSIONS

The obtained results indicate that the eco-system of river Sava, on the territory of the city of Belgrade, is compromised, and consequently it is necessary to implement measures for environment protection. These measures include strict prohibition of disposal of PCB into the river, collection and safe disposal of utilized oils (machine oil, transformer oil and oil used in the electronic industry, etc.), according to the National Strategy of Sustainable Development of Republic of Serbia.

ABSTRACT: In Serbia there are about 17 ha for growing trout pond and 8,940 ha for the cultivation of carp and other warm-water fish. According to the statistical data, on these production areas the production in 2010 amounted to about 7,000 tons of carp fish and 1,200 tons of fish species. The main obstacle in the chain of intensive fish production rests on the bacterial disease, somewhat less parasitic and virology etiology kind. Reproduction and growth of bacteria in adverse growing conditions (insufficient water changes, presence of toxic gases, overcrowding of fish per unit area, low hydro reclamation and zoo hygienic conditions in the preparation of facilities for hatching), causes the disease. Conditional pathogenic bacteria from *Aeromonas* are common causes of disease. Due to a lack of monitoring and laboratory examination, the antibiotics used to combat bacterial diseases are used without an established antibiograms and often inadequate doses. All of these factors are detrimental to the development of resistance of the applicable antibiotics. Sensitivity analysis of isolates to antimicrobial drugs showed the presence of significant resistance to Flumequin and Oxitetraciklyne over 35% to 40%, while resistance to Oxitetraciklyne is close to 20% of examined cases. The resistance to Flumequin is still very low and resulted in only 2 %.These findings show that the antimicrobial drugs are used in inadequate manner and in the future it can be expected to further increase resistance and reduce the number of effective drugs. Considering that microorganisms are in question *(Aeromonas hydrophila)* which can endanger public health, the contagion especially in the case of reduced sensitivity to antibiotics can result in the danger to people.
Key words: *fish, antibiotics, resistance, environment*

INTRODUCTION

The widespread use of antimicrobial agents and the ability of microorganisms to adapt to unfavorable environmental conditions have led to the emergence and spread of resistance of pathogenic bacteria in animal production worldwide (Levy, 1998; Witte, 1997). Some bacteria have become resistant to most or even all of the antibiotics and chemotherapy, which justifies the fear of the return of mankind in the age before antibiotics and the possible development of fatal infectious diseases (Asanin et al., 2001). The use of same or similar chemical and antimicrobial means for the people, animals, and plants contributed to the appearance and the expansion of bacterial resistance. The appearance of bacterial resistance which endangers the production of fishing is confirmed in the studies (Plavsa et al., 2001; Plavsa et al., 2007; Stojanov et al., 2010). Bacterial illnesses of the fish are very important in the overall breeding phase; in addition, they are a main problem for a successful fishing business. Moreover, bacterial illnesses are one of the limiting factors in the overall development in the fishing industry and they secure very quality and demanding fish meat. In the Republic of Serbia, 17 ha of water surface are designated for the breeding of trout while the surface for breeding warm water fish is 8,900 ha. According to the statistical data, the production on this water surface in 2010 was 7,000 tons of carp and 1,200 tons of other kind. Consumption of fish meat in Serbia is around 32 million kg on annual basis. Only one third of that is produced domestically but the rest is imported. The geographical position of Serbia is ideal for breeding freshwater fish; only China and Israel share the same position. Serbia is located at the latitude 40.0 and it has identical climate as Peking, a location that produces the most fish in the whole world. Considering the given facts and the advantages of breeding and producing fish meat, and that the Republic of Serbia imports 25 million dollars of fish

annually, it is reasonable that fishing experts and the state organize and intensify the production of fish meat. Along side the pathogenic causes of emerging fish illnesses; changing environment has a significant effect. The water in which fish lives is rich in organic material of different origin because of increasing number of fish per unit area and more nutrition. This kind of environment is susceptible for the development of pathogenic and conditionally pathogenic bacteria. Being that most fisheries are poorly maintained in the sense of implementation of mandatory preventive veterinary-sanitary measures, limited water supply for fisheries, optimal plantation density and the quality of planting materials, bacterial diseases can not be solved only by antibiotics. Treatment of exhausted and parasites loaded fish in the late stage of disease often results in poor outcome and large economic losses. The causes of bacterial diseases for fish are usually from Aeromonas group *(A. Hydrophila, A. Salmonicida, A. Punctata, A. Sobria*) and *Pseudomonas* (*P. Fluorescens*). Although these bacteria are known as pathogenic some of them may be normal inhabitants of the red flora in healthy fish. It is known that due to stressful situations such as high water temperature, low oxygen level, accumulation of waste products, especially ammonia, high-density plantations and others, these bacteria can modify virulence and contribute to high mortality rate. Negative relationship between these factors results in stressed organism of the fish; and the presence of pathogenic and conditionally pathogenic agents exert their effect when they are in greater concentration in a weakened organism. For these reasons, epizootic (eritrodermatitis, carp pseudomonosa, silver carp skin disease, columnaris disease) caused by bacteria erupts in fisheries. The key to successful treatment of bacterial infections in the early detection of the disease is accurate diagnosis and implementation of appropriate therapy. The most effective therapeutic means used via pellet to treat bacterial diseases of fish is antibiotics (Jovanovic et al., 2000, Plavsa et al., 2001). Necessary efficacy of administering oral medicine is achieved by the timely application of bacteriological diagnosis and effective antibiotics based on antibiogram results. If not treated in time, the disease spreads and the appetite of the fish decreases, all of which reduces the chance of successful treatment. Remedy must be accurately metered and the length of treatment depends on the intensity of disease and water temperature. The most commonly used antibiotics to treat bacterial diseases of fish are Oxitetraciklyne, Flumequine, Fluorphenicol, Olaqvindox. The most serious problem in the treatment of bacterial diseases is the emergence of resistance to the medicine. The resistance of microorganism occurs most commonly if the chosen antibiotic is given in smaller doses than prescribed (often very difficult because of the assessment of fish in large space) and a shortened period of time.
Our research is aimed at determining the extent and the presence of bacterial flora in carp ponds in Vojvodina, the effect of antibiotics on the isolated bacteria, and incidence of resistance to conventional antibiotics.

MATERIAL AND METHODS

The study material was represented by samples of carp from the pond where they were diagnosed with skin lesions and gills. Isolation of Aeromonas was carried out by direct plating of samples onto the nutrient medium (Trypticase soy agar with 5 % defibrinated sheep blood) and selective base McKonkey agar (Quin, 2002). Bases are incubated for 24 hours at 37 degrees Celsius. Identification of Gram-negative bacteria, which created a clear or slightly less hemolysis, was done by determining the physiological characteristics of isolates (API strip). Susceptibility testing of Aeromonas to antimicrobial drugs has been conducted with disk diffusion method on Mueller-Hinton plate. (Quin, 2002, NCCLS). Zone of inhibition appeared around each disc were measured and the sensitivity is determined in relation to the diameter of which appeared around the discs of antimicrobial drugs. The study was conducted on the basis of instructions (NCCLS), so that the zone diameter of less than 13 mm interpreted as a resistance (R), zone of 15-16 mm as intermediate (I), and zone of 17 mm or more as sensitive (S). The sensitivity of the isolates was tested against the following antimicrobials: Fuorphenicol, Flumeqvin, Olaqvindox and Oxitetraciklyne.

RESULTS AND DISCUSSION

The study was conducted in the 2010-2011 period. During this period a total of 175 clinical specimens were examined, of which 78 samples had changes in the skin and gills and all were isolated from Aeromonas hydrophila. Changing parts of the skin, necrotic and hyperemic edges in the middle, were the size of a few mm to over 20 mm (Table 1). During the susceptibility testing of isolates on antimicrobial drugs, with disk diffusion method, drugs commercially available in the market (Fluorphenicol, Flumequine, Olaquindox and Oxitetraciklyne) were used.

Table 1. Antimicrobial susceptibility testing of Aeromonas hydrophila isolated from skin changes of carp

	Antimicrobial drugs		Carp with skin changes	
		O (%)	I (%)	R (%)
1.	Flumequine	48,99	14,31	36,70
2.	Olaquindox	50,12	30,87	19,01
3.	Oxitetraciklyne	13,70	42,60	43,70
4.	Fluorphenicol	65,34	31,96	2,17

In our studies we found that the resistance to Flumeqvin Oxitetraciklyne was 36% and 43% respectively (for clinical specimens of diseased fish) and Olaqvindox as much as 19%, indicating multiresistantance to most antibiotics. Castro -Escarpulli et al., (2003) found that the best antimicrobial effect is achieved by applying the first-generation quinolone and the second and third generation cephalosporin and our studied showed high resistance to flumequin percentage (36%) and Olaqvindox (19%) as representatives of the quinolone. The least resistance is expressed in fluorphenicol with 2.17% percentage. In earlier studies (Plavsa et al., 2001, 2007) it was found that for 4 years the number of resistant type of *Aeromonas hydrophile* on Oxitetraciklyne increased from 21.7% to 77.2%, while that change for Flumeqin ranged from 12.7% of resistant type to 53.1% after 4 years. This increase of resistant types on mentioned antibiotics is a consequence of several important factors. These were the relatively low specific doses or doses that are translated by the quantity of food. It is known that sick fish has drastically decreased appetite, so that the amount of regular food intake and food with built in drug are reduced. On the other hand, in fisheries, unskilled professionals are often involved in the treatments causing multi-link and long-term damages. In last few years the problem of resistance has been solved by increasing the drug dose however that practice has no medical or economical perspective. The tendance of beta hemolozin in strains *A. Hydrophila* is not just in the relation with the multiresistance but also with virulence strains of this bacterium as indicated by the results (Daskalov, 2006). Interconnection between these characteristics is not only a medical problem for fishery but also for human population.

CONCLUSIONS

Fish diseases have always represented a significant problem of fisheries production, but in recent years by intensifying production, fish diseases especially bacterial etiology, have become a far more significant problem. These diseases are often present during breeding in both one-and-two year carp fish. The choice of antibiotics is smaller but the resistance is becoming a growing problem. All of this points to the need for more rigorous implementation of preventative and zoo hygienic measures. The study shows *Aeromonas Hydrophila* present in all processed carp sample signified with clinical changes on the skin and gills. Sensitivity analysis of isolates to antimicrobial drugs showed the presence of significant resistance to Oxitetacyclin, over 43% and Flumequine over 36%. Without improving the veterinary-sanitary conditions, regular examinations and early diagnosis, this disease along with other fish

diseases, represent a growing problem in the near future and will be a limiting factor in the development of fisheries.

ABSTRACT: The aim of this study was to characterize and conduct comparative analysis of corn dried distillers' grains with / without solubles (DDGc and DDGSc). These two animal feedstuffs are the main by-products of bioethanol industry. Representative samples of these subproducts were taken from the largest Bulgarian distilleries and analysed for DM, CP, EE, CF, NFE, ash, nutritive value (energy and protein nutritive value), aminoacid profile (relative and absolute value) and mineral content (macro- and microelements). The chemical analyses were made following AOAC, 2002. The nutritional assessment of both feeds included calculation of energetic and protein values by total or particular chemical composition. Based on the results of the conducted analyses it was concluded that corn dried distillers' grains with solubles (DDGSc) is superior to corn dried distillers' grains (DDGc). Potential correlations should be searched between protein (CP, PDI and BPT) and energy (FUG and FUM) nutritional value of both feeds and the expected animal performance.
Key words: *DDGc / DDGSc, nutritive value, amino acids, energy, protein*

INTRODUCTION

In recent years, following EU and global trends, in Bulgaria were put into operation some large bioethanol distilleries using cereals as raw material.
A revival of this branch is favored by accession of the country to the EU, subsidy programs, so-called "Green Thinking" boom and the production of biofuels from renewable materials. The main product in bioethanol industry is bioethanol and subproduct – distillers' grains (SC). Corn distillers' grains (DGc), in all its forms, represent a main by-product of ethanol production from corn grains. This byproduct obtained in plants producing bioethanol for biofuels as well as in the process of industrial production of ethanol and alcoholic beverages. Currently in this sector are accepted and standardized two basic manufacture methods - dry and wet distillation. The main manufacture method in Bulgaria is dry grinding of grains.
Based on the proportions of our country, current situation, an ad hoc policy, the fragmentation of our husbandry and smallcapacity farms (in size and number of animals). So it is established that dried version of the DCc (DDGc and DDGSc) is more applicable.
These products don't have discermable features and the difference between them is somewhat fuzzy and unclear in spide of the existing definitions for each particular by-product. In addition the amount of distillers' soluble inputs in the production of DDGSc varies within a wide range. Many scientific reports failed to present data about the nature of the feeds – wether they were with / without solubles. So actually DDGc often is identified with DDGSc [Schingoethe, 2006].
However, a review of available literature data about chemical composition and nutritive value for different forms of DGc confirms the common view about their extreme variability [Nuez-Ortín et al., 2010, Olentine et al., 1986].
The main producer of corn distillers' grains (DGc) worldwide is USA, while EU and Canada used wheat as a raw material for bioethanol and corn is ranked second.
The aim of this study was to characterize and make a comparative analysis of the main subproducts of ethanol industry - DDGc / DDGSc.

Bioethanol industry represent a complex and multistage process, which generally can be illustrated in the following scheme:

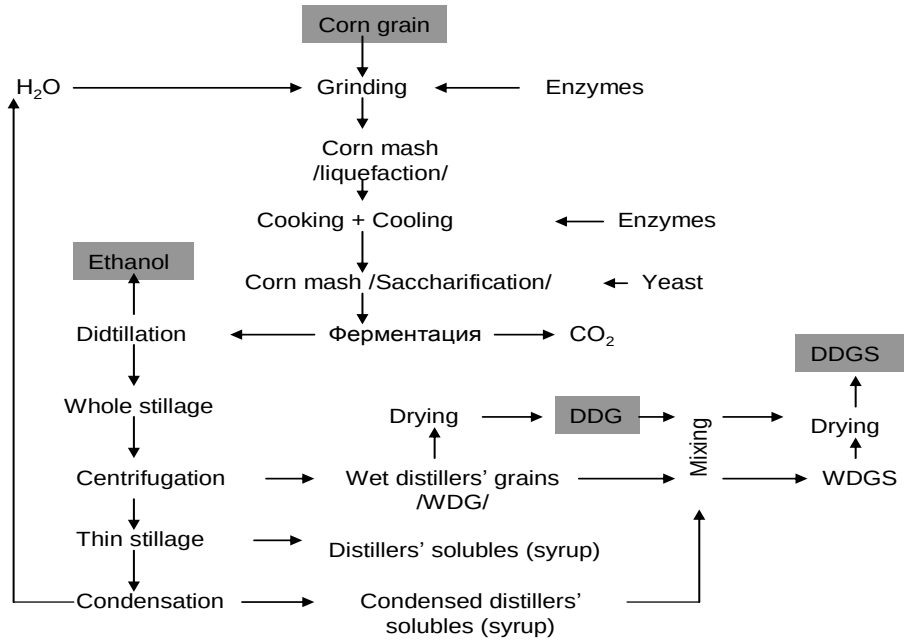

Figure 1. Schematic presentation of the manufacturing of DG products by dry method (www.trc.zootechnie.fr)

Our interest in this feed stems from the fact that it can be considered as a essential part of farm animals' rations. DDGSc is rich in proteins, moderately high in fats and relatively low in fibers, which allows to be used in the rations of different types and categories of farm animals [Hayes, 2008]. They can be added as both protein and energy source.

MATERIAL AND METHODS

Representative samples of DDGc and DDGSc were taken from the largest Bulgarian producers of bioethanol. Samples were stored in paper bags, and then - in glass bottles until laboratory analysed. The determination of dry matter (DM) was under AOAC [2002]. Total chemical analysis including following indices: dry matter (DM), crude protein (CP), crude fiber (CF), ether extact (EE) and ash (CA) according to [AOAS, 2002]. The amino acid profile and analysis of mineral substances have also been carried out according to AOAC [2002]. The results were analyzed using statistical package MS Office 2007.

RESULTS AND DISCUSSION

The results of the total chemical analysis are summarized and shown in Figure 2.
Data in the table above shows comparatively similar indices about DM, CP, and NFE, and variability in the other parameters of products - CF, Ash and EE.
DDDGc and DDGSc dry matter values were 85.19 and 87.42%, respectively. These relatively similar values are a good basis for comparison and interpretation of the chemical parameters, and their respective nutritive values.The protein content in both products is approximately the same - 25.03% in DDGc and 26.40% in DDGSc.

	DM, %	CP, %	CF, %	EE, %	Ash, %	NFE,%
DDGc	85,19	25,03	15,78	9,74	2,38	47,07
DDGSc	87,42	26,4	6,69	11,46	7,47	46,99

Abbreviations:
DDGc - dried distillers' corn grains;
DDGSc - dried distillers' corn grains with solubles;
DM – dry matter;
CP - crude protein;
CF – crude fiber,
EE – ether exract;
NFE – nitrogen-free extractives.
* Data based on our own analysis

Figure 2. Chemical analysis of DDGc and DDGSc* (DM basis) (n = 3 ± SD):

Our results for protein content are similar to those reported by Noblet et al., [1993], but lower than those found by Al-Suwaiegh et al., [2002]; Gibb et al., [2008]; Kessen et al., [2005]; Macken et al., [2004]; MAFF, [1990]; Moujahed et al., [2009]; Stalker et al., [2009]; Tjardes et al., [2002]; Uwituze et al., [2011]. Significantly lower levels of protein were reported by Carvalhoa et al., [2005]; [www.extension. astate. edu]; [Zarnela.pdf]. It is worth noting the difference in actual values obtained for fat content - 9.74 and 11.46%, respectively, in DDGc and DDGSc. Similar values were reported by Uwituze et al., [2011] and [Zarnela.pdf], unlike Kessen et al., [2005]; MAFF, [1990]; Noblet et al., [1993]; Stalker et al., [2009]; Tjardes et al., [2002], who found significantly lower values. Mosier et al., [2006] reported higher values.
It's worth to note the great difference in the actual value of the crude fiber. Almost a threefold advantage of DDGc (15.78%) to DDGSc (6.69%) for this index. The data correspond with those reported by Noblet et al., [1993], but are lower than those found by Moujahed et al., [2009]; Tjardes et al., [2002]; [Zarnela.pdf]. Ash quantity in DDGSc was several times higher (7.47%) comprelative for that in other research product - DDGc (2.38%). The calculated actual values for nitrogen-free extractives in both tested feeds are extremely close - 47.07 and 46.99%, respectively, for DDGc and DDGSc. These data are consistented with the fact that in the process of ethanol manufacturing starch is extracted from the raw material, while the rest of carbohydrates remains as so-called ''physiologically active fibers'' (Li et al. 2011).

	GE	OE	NEg	FUG	NEl	FUM	CP	PDI	BPR
DDGc	16,71	8,63	0,42	1,2	0,61	1,08	250,3	155	32
DDGSc	16,54	8,49	0,41	1,19	0,59	1,07	260,4	136,2	68,82

Abbreviations:
GE – gross energy,
DE – Digestible energy,
NEg – Nett energy for gain,
FUG – feed units for gain;
NEl – Nett energy for lactation,
FUM – feed units for milk,
CP– crude protein,
PDI– protein truly digestible in small intestines,
BPR– balance of protein in rumen.
* based on our own analysis

Figure 3. Nutritional value of DDGc and DDGSc * (in kg DM) (n = 3 ± SD):

Assessment of the nutritive value of both feeds was based on comparison of their energy and protein nutritive values. For that purpose were conducted series of differential balance experiments with the wethers reared at the experimental facilities of the Institute of Animal

Science Kostinbrod. The results are summarized and presented in Figure 3. Calculated values for energy and protein are consistent and logical consequence of the actual chemical composition. Energy nutritive value of both feeds, compared together, is presented in international units - NE, OE, NEl and NEg, as well as in forage units - FUG and FUM. The obtained values were significantly lower than those calculated by Gibb et al., [2008] and NRC [2007]. There was a trend towards slight superiority of DDGc over DDGSc. Values about FUG and FUM in DDGc and DDGSc were as follows - 1.20, 1.19, 1.08 and 1.07. They are significantly lower than those published by Tjardes et al., [2002], but similar with data obtained Crawshaw [2007] and MAFF [1990]. Lower values were obtained by Dimova et al., [2009].

The assessment of protein nutritive value was based on the following items: CP, PDI and BPR. Crude protein content in DDGc and DDGSc was 250.30 and 260.40g/kg DM, respectively. That's a contrast of 10.10g/kg DM. The calculated values for PDI in DDGc and DDGSc, based on conducted balance experiments [Yossifov et al., 2011] were as follows - 155.0 and 136.17g/kg DM. The lower values of PDI in DDGSc were due to differences in the technological processing and especially to the heat treatment. Therefore, higher temperatures probably led to denaturation of some protein components and fractions. Thus reducing DDGSc crude protein degradation, and the amount of PDI respectively.

Yet, BPR correlated positively with the amount of crude protein - (32.0) and (68.82) in DDGc and DDGSc, respectively. These data come to show that both feeds secured satisfactory supply of rumen microorganisms as evidenced by microbial protein synthesis. The values of BPR and PDI were lower than those established by Tjardes et al., [2002] and higher than those reported by Dimova et al., [2009].

The amino acid profile of both feeds is presented in Table 1:

Table 1. DDGc and DDGSc amino acid profile (n = 3 ± SD):

Value		% (g/100g feed)		% (g/100g CP)	
Feedstuff		DDGc	DDGSc	DDGc	DDGSc
Amino acid:	Aspartic acid,%	1.36	1.54	6.57	7.34
	Threonine,%	0.91	0.85	4.40	4.03
	Serine,%	0.77	1.27	3.75	6.04
	Glutamic acid,%	4.33	4.36	20.95	20.72
	Proline,%	2.12	2.38	10.26	11.34
	Cystine,%	0.58	0.40	2.83	1.89
	Glycine,%	0.84	0.69	4.06	3.26
	Alanine,%	1.29	1.76	6.25	8.39
	Valine,%	1.09	0.88	5.30	4.16
	Methionine,%	0.35	0.20	1.69	0.90

	Phenylalanine,%	1.02	1.05	4.92	5.01
	Histidine,%	0.69	0.64	3.33	3.06
	Lysine,%	0.55	0.69	2.67	3.29
	Arginine,%	0.80	0.73	3.88	3.48
Total, %		20.66	21.03	100.00	100.00

The quantity of individual amino acids (AA) was well balanced and apportioned according to the persentage of CP in the feeds included in the livestock diets. Individual AA can be combined into three groups, according to their quantitative distribution in the studied feed:

- AA which are relatively constant (variability within 10.0%) - threonine, glutamic acid, leucine, histidine, phenylalanine, arginine;
- AA which are relatively volatile (variability within 20.0%) - proline, aspartic acid, glycine, valine, tyrosine;
- AA which are highly variable (variability over 20.0%) - serine, cysteine, methionine, isoleucine, alanine, lysine.

Based on the analysis, it's worth to note the low percentages of AA lysine and methionine. This will inevitably reflect on the expected performance in both high-productive ruminants and monogastric species.

Regarding the AA differences between both feed, DDGc exceled DDGSc in the quantity of the following nine AA - threonine, cystine, glycine, valine, methionine, isoleucine, leucine, histidine and arginine. The quantity of the remaining eight AA (lysine, phenylalanine, tyrosine, alanine, proline, serine, glutamic and aspartic acid) as assessed in 100g sample was higher in DDGSc, relative to DDGc. Similar results were found regarding AA content in 100g crude protein. In this case DDGc was superior to DDGSc at 10 AA - threonine, glutamic acid, cystine, glycine, valine, methionine, isoleucine, leucine, histidine and arginine. The superiority of DDGSc was at 7 AA - aspartic acid, serine, proline, alanine, tyrosine, phenylalanine and lysine.

AA content in DDGc and DDGSc, calculated on DM basis, was 20.66 and 21.03%, respectively. As a percentage of protein, were 82.54 and 79.66% in DDGc and DDGSc, respectively. The remainder to 100% CP (so-called non-protein nitrogen (NPN)) was 17.46 and 20.34% in DDGc and DDGSc, respectively. The effect of theso-called Maylard reaction should be taken into account, when interpret the factual data in Table 3. Due to this reaction some of the AA (especially lysine) bind to physiological fibers toform insoluble compounds, mainly acrylamide, which further reduces the bioavailability of individual AA in the gastrointestinal tract.

Table 2 shows the content of minerals in the investigated feeds:

Table 2. Mineral composition of DDGc and DDGSc (n = 3 ± SD):

Item		DDGc	DDGSc
Menerals:	Ca^{+2}, %	0.19	0.44
	P^{+5}, %	0.44	1.21
	K^{+}, %	0.20	NA
	Na^{+}, %	0.24	NA
	Mg^{+2}, %	0.078	NA
	Fe^{+2}, ppm	218.0	86.41
	Zn^{+2}, ppm	39.0	59.73
	Mn^{+2}, ppm	19.0	21.21
	Cu^{+2}, ppm	21.0	6.80
	Ni^{+2}, ppm	NA	3.24
	Cr^{+2}, ppm	NA	0.35
	Pb^{+2}, ppm	-	-

Calcium and phosphorus are traditionally taken as a limiting factor in the utilization of by-products of ethanol industry by the animals and achievement of optimum productivity and environmental protection. The content of calcium kations in DDGSc, evaluated on DM basis, was twice lower of compared to that in DDGc, and amounted to 0.44 and 0.19%, respectively. The amount of phosphorus, however, showed even greater variability - 1.21 and 0.44%. The levels of calcium and phosphorus were close to those published by Tjardes et al., [2002], but lower than those found by Gibb et al., [2008] and Uwituze et al., [2011] and higher than thoses found by [Zarnela.pdf].

Potassium, sodium, copper and sulfur concentrations are of great importance, since these elements could inflict toxicosis, when their concentrations exceed phisiological range. Heavy metal concentrations in both feeds were within the admissable norms.

Based on a series of experiments, chemical analyzes and determination of several parameters (chemical composition, in vivo digestibility, energy and protein nutritive value) of DDGc and DDGSc were obtained factual data that can be used for full evaluation and grading of feed, subject of this study.

Our data, based on the conducted chemical analysis of DDGc and DDGSc, confirm the view reported by Nuez-Ortín et al., [2010], Olentine et al., [1986] and Petkova et al. ., [2011]., that these feeds show great variability with respect to each of the chemical item in its

composition. This view isn't consistent with the information reported by Schingoethe et al., [2009].

CONCLUSIONS

- Data obtained on the chemical composition of DDGc were: DM - 85.19%; CP - 250.30g/kg DM, EE - 90.74g/kg DM; CF - 157.80g/kg DM, NFE - 470.70g/kg DM, Ca^{+2} - 0.19g/kg DM and P^{+5} - 0.44g/kg DM, and DDGSc: DM - 87.42%; CP- 264.00g/kg DM, EE- 114.60g/kg DM, CF -66.90g/kg DM; NFE - 469.90g/kg DM, Ca^{+2} - 0.44g/kg DM and P^{+5} - 1.21g/kg DM. These data confirm the variability in composition of the investigated by-products of ethanol industry;
- Energy nutritive values expressed as FUM and FUG were 1.08 and 1.20 in DDGc, versus 1.07 and 1.19 in DDGSc;
- DDGc and DDGSc protein nutritive value was evaluated by CP (250.30 and 260.40g/kg DM), BPR (32.00 and 68.82) and PDI (155.00 and 136.17g/kg DM);
- Individual AA in the investigated feeds were well balanced and apportioned according to % of CP with clearcut pattern;
- The quantity of total AA in DDGc and DDGSc assessed on DM basis was 20.66 and 21.03%, respectively. As a percentage of CP, these values are 82.54 and 79.66%, respectively about DDGc and DDGSc. The remainder to 100% CP is so-called non-protein nitrogen (NPN). Their value in DDGc and DDGSc were 17.46 and 20.34%;
- Lysine and methionine content in 100g feed (DDGc / DDGSc) was as follows: 0.35 / 0.20 and 0.55 / 0.69g.

ACKNOWLEDGEMENTS

This paper is a result of a research within the project **«**Effective utilization of feed and reduction of environmental damage by feeding traditional, nontraditional, by-products from manufacturing process and feed additives**»**, financed by Agricultural Academy, Republic of Bulgaria.

IMPROVEMENT OF TECHNOLOGY OF PRODUCTION OF THE MIXED FEED FOR CHICKENS

Bogdan Iegorov[1], Nina Vorona[1]

[1]Odessa National Academy of Food Technologies, 112 Kanatnaya St., Odessa, Ukraine

ABSTRACT: The technologies of production of starting mixed feed don't consider the requirements of the poultry in homogeneous mixed feed with the high content of protein. The aim of the study was to increase the efficiency of production and use of mixed feed by extruding mixtures of the grinded grain and sub-standard eggs without shell.
Analitical and mathematic-statistical methods have been used in the work.
The technological way of enrichment of grain raw material by protein of an animal origin provides receiving of a preliminary mixture of the grinded grain of corn and sub-standard eggs without shell in the ratio 1:1, mixing of the preliminary mixture with the grinded corn which remained, and extruding received mixtures. The optimal quantity of eggs in the mixture is 10 %. The recipes of starting mixed feed have been developed on the basis of studying of requirements in nutritious and biologically active substances for chickens.
The improved basic technological scheme of manufacture of starting mixed feed for the poultry provides possibility of manufacture of the extruded feed additive (EFA) on the equipment of the feed mill. The necessity of receiving of preliminary mixture of microcomponents and extruded feed additive by two-phases mixing of them in the ratio 1:1 at the first stage of mixing and 1:2 at the second stage has been established experimentally. It is necessary for uniform distribution of microcomponents in mixed feed taking into consideration weight of single consumption of a forage by the poultry.
Key words: *poultry, mixed feed, technology, production, sub-standard eggs*

INTRODUCTION

Recently the tendency of increasing the requirements to quality of mixed feed, improving of technologies, cost cutting on production were observed in the mixed feed industry. In Ukraine the greatest share of the market is occupied by mixed feed for the poultry (47 %) which is the most exacting to quality and composition of forages (Yegorov, 2010). Producers try to use all possibilities for receiving the maximum profit with the minimum expenses, however it is necessary to support high quality of products for the market competitiveness.
Today out-of-date norms of feeding of the poultry are used. They don't meet the requirements of passports of up-to-date breeds, of chemical composition of raw material and of technology of production of the mixed feed. Recently the requirements in nutritious and biologically active substances for chickens have increased in connection with the use of high-productive breeds of the poultry that have high potential and are more sensitive to the quality and composition of feed (Taranu, 2000, Hunton, 1997, Gill, 2004, Brillard, 2001). At the same time the chemical composition of raw material for manufacture of mixed feed, first of all grain components, has been worsened considerably. The content of crude protein in wheat and corn has decreased on 1…2 absolute percent because of reduction in fertility of soils, intensive and wrong crop rotation, infringements of agrotechnology and unbringing organic and mineral fertilizers that makes difficult mixed feed balancing (Fushiki et al., 1985).
This problem can be solved by enrichment of grain raw material with animal protein which is assimilated easily. However, their use leads to growth of the cost of mixed feed. The peculiarities of digestion and high genetic potential of productivity of chickens cause necessity of using of high-quality mixed feed with the high content of the protein for its feeding, namely starting mixed feed.
In the first days of life daily giving of a forage is very small to the poultry, and furthermore single giving is. For chickens of egg lines daily giving is 7…8 g, and single – 0,88…1,33 g; for broilers – 15 g, and single – 1,88…2,5. All nutritious and biologically active substances provided with the recipe should be in each point of volume of a single portion of mixed feed for the poultry. Mixed feed should be homogeneous (Duncan, 1988, Behnke, 1994).

Everywhere used technologies of production of starting mixed feed for the poultry don't consider increased requirements to uniformity of distribution of nutritious and biologically active substances in the microvolumes. Their portions shouldn't exceed single consumption of mixed feed by the poultry. Consequently there was some need of searching of economically effective ways of increasing of fodder value of grain raw material and uniform distribution of nutritious and biologically active substances as a part of mixed feed.
The aim of the study was to increase the efficiency of production and use of mixed feed by extruding mixtures of the grinded grain and sub-standard eggs without shell.

MATERIAL AND METHODS

A complex of the standard analitical and mathematic-statistical methods of the research have been used in the work for studying of physical and chemical, biochemical and microbiological indexes of the extruded feed additive, starting mixed feeds and raw material.

RESULTS AND DISCUSSION

We offer a technological way of enrichment of corn by extruding of mixture of grains grinded to necessary size and eggs without shell, taking into consideration possibility of processing humidified grain to 16…18 % in grain extruders.
As a result of experimental researches it has been determined the necessity of mixing in two stages for obtaining of the high-quality homogeneous grinded corn enriched with egg protein. They are the obtaining of a preliminary mixture of components in the ratio 1:1 in the frame mixer during 180 sec and the basic mixing of the preliminary mixture of components and a part of the grinded corn which remained in the paddle mixer during 120-180 sec. The coefficient of variation of the received mixture is 2,7 %.
It has been determined experimentally that the optimal quantity of eggs without shell in the mixture with the grinded corn is 10 % under conditions of the minimum specific expenses of the electric power on manufacture and the best indexes of quality of EFA (Figure 1, 2).

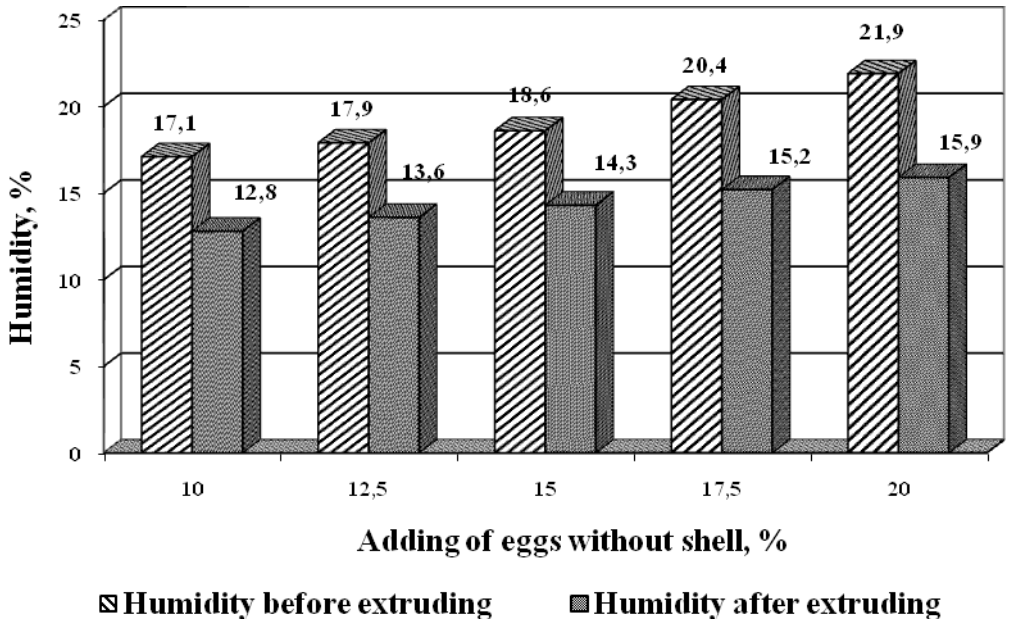

Figure 1. The changes of humidity in extruding depending on quantity of eggs in a mixture

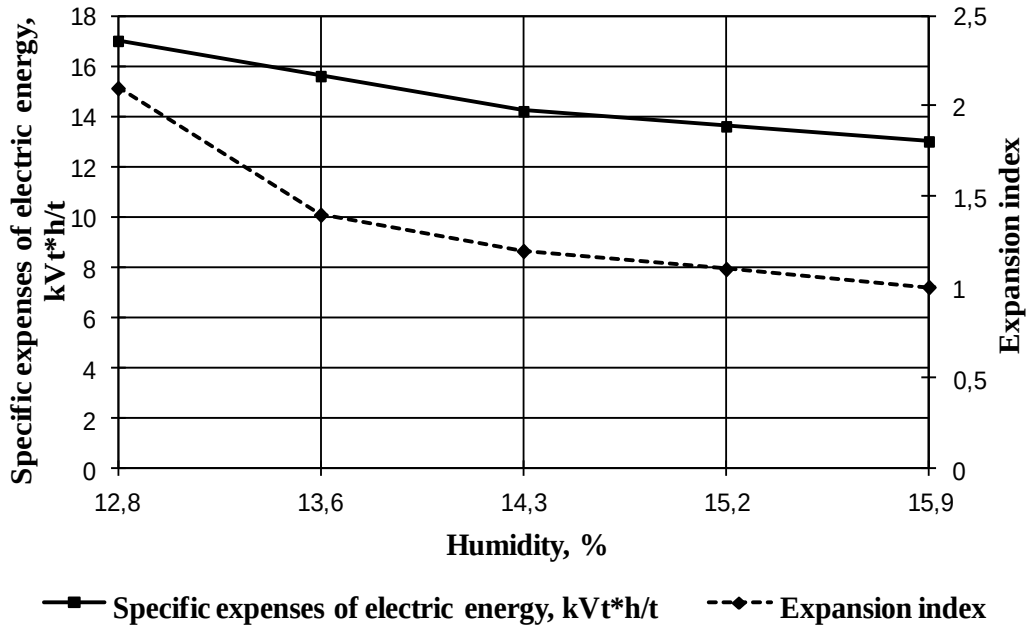

Figure 2. The dependence of specific expenses of the electric power and expansion index from humidity in EFA

On the basis of the experimental researches the basic technological scheme of manufacture of the EFA for the poultry and starting mixed feed have been developed (Figure 3). There are technological lines for manufacture of mixed feed:

1) of preparating of a portion of the clean and grinded grain raw material;
2) of preparating of a portion of mineral and mealy raw materials which don't need grinding;
3) of preparating of a portion of a preliminary mixture of microcomponents;
4) mixing of all prepared portions;
5) pelleting of mixed feed.

Adding of EFA is provided on the two technological lines simultaneously according to the improved technology (obtaining a portion of components which don't need any grinding, and a portion of microcomponents). As it was mentioned above, the single giving of starting mixed feed is very small and all nutritious and biologically active substances should be distributed uniform in it. The greatest problem is caused by distribution of microcomponents. Some of them contains in the recipe in quantity less than 0,1 %.
We have carried out the researches of the change of uniform distribution of microcomponents in samples depending on increase of their weight. It is offered to receive preliminary mixture of microcomponents and EFA by the way of their mixing in two stages in the ratio 1:1 at the first stage of mixing and 1:2 at the second stage (Figure 4). As we see, the less the weight of sample is, the more the mixture ununiform is. The coefficient of variation of preliminary mixture of microcomponents and EFA is 2,3 % after mixing in two stages in paddle mixer for 120-180 sec in sample weight of 0,5 g.
Production of EFA can be carried out on the equipment of the feed mill with adding of some equipment according to the developed basic technological scheme of manufacture of starting mixed feed for the poultry. This leads to considerable decreasing of capital investments on realization of improved technology of enrichment of grain raw material with animal protein.

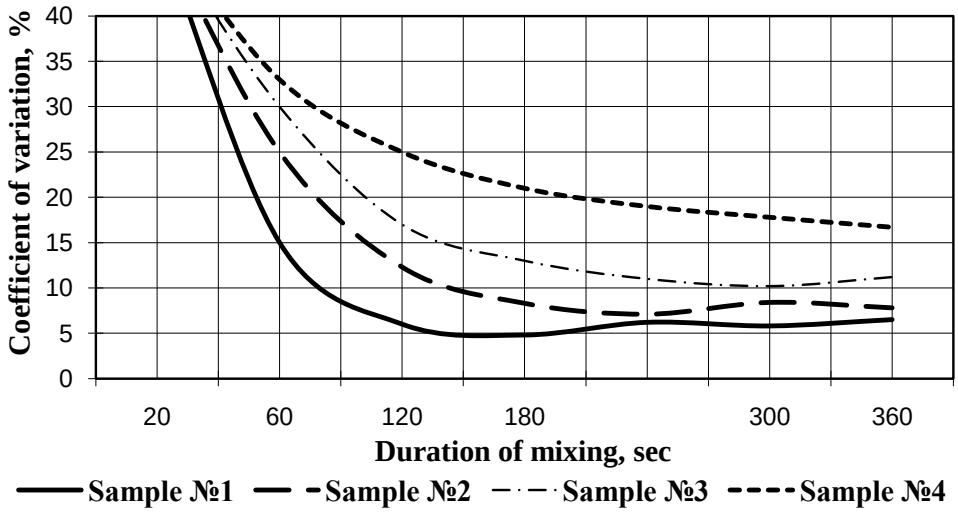

Figure 4. Estimation of uniformity depending on weight of sample:
1 – m = 2 g, 2 – m = 1,5 g, 3 – m = 1 g, 4 – m = 0,5 g

CONCLUSIONS

The technology ofproduction of mixed feed is improved on the basis of theoretical and experimental researches. It have been proved that the microvolume in which all components of mixed feed should be uniform distributed shouldn't exceed single consumption of mixed feed by the poultry.

The technological way of enrichment of grain raw material by protein of an animal origin provides receiving of a preliminary mixture of the grinded grain of corn and sub-standard eggs without shell in the ratio 1:1, mixing of the preliminary mixture with the grinded corn which remained, and extruding received mixtures. The improved basic technological scheme of manufacture of starting mixed feed for the poultry provides possibility of manufacture of the extruded feed additive (EFA) on the equipment of the feed mill. The necessity of receiving of preliminary mixture of microcomponents and extruded feed additive by two-phases mixing of them in the ratio 1:1 at the first stage of mixing and 1:2 at the second stage has been established experimentally. It is necessary for uniform distribution of microcomponents in mixed feed taking into consideration weight of single consumption of a forage by the poultry.

ABSTRACT: The key focus of the paper is to analyse the attitudes of pig and cattle breeders towards the collective action typical of contemporary supply chains. We investigated in detail the benefits or burdens from participation in a vertical chain. The data were collected in a survey including 313 farmers engaged in pig or cattle production. Respondents were asked to evaluate statements related to organizational forms of collective action and its benefits, express their attitude towards the supply chain coordination, evaluate currently established relationships, etc. The hierarchical cluster analysis was used to group the respondents regarding their agreement levels on different aspects of supply chain relationships. Other parts of the questionnaire were used to form and describe cluster profiles. The results have shown that obsolete and inefficient organizational forms of supply chain relationships prevail in Slovenian pig and cattle breeding sectors, however, farmers significantly differ according to their attitude towards vertical coordination. Moreover, alternative forms of collective activities are set up in order to overcome weakness and inefficiency of the prevalent vertical chains.
Key words: *red meat supply chain, vertical coordination, collective action, supply chain relationships, breeders attitude, cluster analysis*

INTRODUCTION

Vertical supply chain integration brings economic benefits to all chain participants, especially to smaller and weaker partners, assures market competitiveness, improves efficiency of production process and sale, and also improves product quality. Several studies of vertical co-operation on mature markets have proven the advantages of vertical integration. Therefore, effective collective action is the key approach to improve competitiveness, especially in post-transitional economies, i.e. economies in the final stage of adaptation to globalized market circumstances (Boger et al., 2001; Boger, 2001; Kuhar et al., 2010). Agriculture in Slovenia is part of this process as well. Slovenian agriculture is characterized by dispersed farm structure, which is beside lack of efficient supply chain operation an important factor for unfavourable economic performance. Among the subsectors of Slovenian agriculture, the red meat supply chain shows several symptoms of a sector in intensive transformation, yet many characteristics are annotating pre-transitional operation models (Kuhar et al., 2010). The unfinished transformation process of the sector dictates investments of additional efforts to conclude the transition period of *the formation of* economically efficient agriculture. For effective encouragement of collective activities it is necessary to be acquainted with breeders' aspect of supply chain relationships. The main focus of the paper is therefore to analyze the attitudes of pig and cattle breeders towards the collective action typical of contemporary supply chains and the importance that pig and cattle breeders attribute to a collective activity. Information about breeders' attitude towards co-operation is very important to formulate an effective strategy for stimulating quality collective activities (Kuhar et al., 2010).

To obtain information about breeders' attitude towards collective action the respondents were inquired to evaluate statements related to organizational forms of collective action and its benefits, such as higher product quality, prices and lower business risks, to express their attitude towards the supply chain coordination, to evaluate currently established relationships, etc. Clusters of breeders with a similar attitude towards co-operation were

formatted regarding the agreement levels on different aspect of supply chain relationship. - Furthermore, we described cluster profiles with socio-demographic breeders' characteristics such as age, level of education, employment status of farmer, number of animals fattened for sale and planned farm extent changes. Cluster members' profiles are also explained through most frequently used marketing channels and evaluation of their economical efficiency, main buyer category and buyer to whom most fattened animals have been sold. Information about a mode of co-operation with the main buyer and the evaluation of consideration of the eventual pre-contract were also used for cluster profiles formation.
In this paper we will present our research in three following sections. In the first section, we will explain research procedure and methods used to generate results demonstrated in the second section. First, we will present cluster characteristics (for cluster formation we have applied a hierarchical cluster analysis), and second, we will describe defined cluster profiles using fundamental descriptive statistics. In the final section we will report research conclusions and indicate abilities of applicative use.

MATERIAL AND METHODS

Data were collected between November 2009 and March 2010 through a postal survey of Slovenian cattle and pig breeders. The sample included 1000 cattle and 700 pig breeders enrolled in a central register of breeders at the Ministry of Agriculture. The response rate was 18 %, which means that the questionnaire was answered in by 313 respondents. Breeders were asked about relationships in an agrifood supply chain, cooperation modes, prevalent and main buyers. Survey data were analysed by a multivariate statistical technique and fundamental descriptive statistics. Respondents were first classified in three clusters according to their evaluation of statements related to organizational forms of collective action and its benefits such as higher product quality, prices and lower business risks, and according to their attitude towards the supply chain coordination (Boger et al., 2001). A hierarchical cluster technique – Ward's method was used for classification. Dissimilarity of standardized variables was measured by Euclidean distance. After close examination, the dendrogram three-cluster solution was considered the most appropriate (Ferligoj, 1989). Later, we described each of the three cluster profiles according to breeders' socio-demographic characteristics, most frequently used marketing channels, modes of cooperation and relationships with buyer. Cattle and pig breeders differ in marketing and also in cooperation modes, which we had already taken into consideration when formulating questions, and later, when formulating cluster profiles. The fundamental descriptive statistics were used for cluster profiles formulation.

RESULTS AND DISCUSSION

Differences among animal breeders about their attitude towards collective activities and their beliefs about benefits of cooperation enabled us to classify them in three different clusters. The first cluster, named *traditional co-operative breeders,* includes members who prefer cooperation and are aware of its benefits. According to their opinion, agricultural co-operative (a traditional form of agricultural co-operative that has existed on the Slovenian territory for nearly a century) is still the best agent between farmers and food industry. Traditional co-operative breeders represent the majority (45.6 %) of all respondents. The second cluster, *non-co-operative breeders,* represents 18.6 %, that is the least of all respondents. Non-co-operative breeders are not in favour of collective action. They disagree that collective action provides better prices, reduces business risk and expenses, and improves meat and meat product quality. The third cluster is characterized by progressive breeders, who have a positive attitude towards collective action, but a negative attitude towards cooperation in traditional agricultural co-operatives. Progressive breeders represent 35.6 % of the respondents.

Table 3. Clusters with a similar attitude towards collective activities (N = 239)

Statement (1 – totally disagree, 5 – totally agree)	**1** n=109	**2** n=45	**3** n=85	**Total mean**
If breeders co-operated fully, their economic situation would improve.	4,35	3,07	4,47	**4,15**
Agricultural co-operation is a first-rate agent between the farmer and food industry.	3,95	2,18	1,82	**2,86**
Agricultural co-operative service helps farmers to reach a better economic situation.	3,88	1,62	1,79	**2,71**
Agricultural co-operatives should sell food factories they own.	2,22	2,47	2,80	**2,47**
Profit among farmers, co-operatives, food industry and traders are fairly distributed.	1,83	1,22	1,15	**1,47**
Farmer and food processor co-operation brings about better meat and meat products' quality.	3,32	1,89	3,06	**2,96**
Contract with the buyer reduces farmers' business risk.	3,83	1,87	4,06	**3,54**
Contract with the buyer assures a better price than the sale on the open market.	2,75	1,42	2,41	**2,38**
Long-term co-operation with the buyer helps farmers' business economics.	3,90	2,18	4,00	**3,61**

Traditional co-operative breeders are breeders whose socio-demographic characteristics are closest to the characteristics of an average Slovenian animal breeder. The majority is between 40 and 60 years old (63 %) and almost 2/3 of them have high school education, while one third have elementary school education only. Among cattle breeders there is a major part of small breeders, the majority of pig breeders own large pig farms. In the first cluster, the highest (23 %) percent (above average (10.6 %)), is the one of cattle breeders that do not sell fattened animals. On average, 62 % of all breeders are not planning any changes in breeding extent in the following year, the next largest part are in favour of decreasing breeding extent. Traditional co-operative breeders act in the same way. Most frequently used marketing channels among first cluster cattle breeders are agricultural co-operatives or a permanent buyer without any pre-contract. The vast majority of members (85 %) do not avail themselves of contractual breeding or sale to a random buyer. In 52.5 %, most animals are sold through agricultural co-operation, but only 44 % of respondents consider this way the most economically efficient. Sale to a permanent buyer without a pre-contract is the most economically efficient in the opinion of 41 % of respondents, and 39 % of breeders sell most cattle through this channel. Pig breeders' marketing channels are more heterogeneous than cattle breeders'. The prevalent marketing channel is contractual breeding for a large pig farm, however, it is also frequently used to supply very small permanent and random buyers with pigs, usually to stick them at home. This channel cannot apply to cattle breeders, because cattle slaughter at home is illegal in Slovenia. Most fattened pigs are sold through contractual breeding by 46 % of pig breeders, but only 22 % of them value it as economically most efficient. On the other hand, 51 % of farmers think that sale to a permanent buyer is the most economically efficient, but only 39 % sell most animals through this channel. First cluster pig breeders often ascribe economical efficiency to the sale to a random buyer, but do not practice it a lot. According to their belief that agricultural cooperative is a first-rate agent between farmers and agro-industry, traditional co-operative breeders sell most of their animals through agricultural co-operatives. Agricultural co-operative is the main buyer for 78 % of cattle breeders and 37 % of pig breeders. For other 34 % of pig breeders, the main buyer is a large Slovenian processor.

40 % of farmers sell most pigs through contractual breeding. A greater part of traditional co-operative cattle breeders most often co-operate with the main buyer (60 %) without contract or through agricultural co-operative (32 %)Traditional co-operative pig breeders most often practice contractual breeding, agricultural co-operation or a precise oral agreement. More than 30 % of pig breeders think that pre-contract is fully considered and 50 % that it is considered in major part.

Table 2. Attributes determinating cluster profiles

ATTRIBUTES OF CO-OPERATION	TRADITIONAL CO-OPERATIVE BREEDERS (n=109)		NON-CO-OPERATIVE BREEDERS (n=45)		PROACTIVE BREEDERS (n=85)	
	Cattle breeders (57 %)	**Pig breeders (43 %)**	**Cattle breeders (49 %)**	**Pig breeders (51 %)**	**Cattle breeders (33 %)**	**Pig breeders (67 %)**
Please select mode of sale for fattened animals. (1 - never, 5 – exclusively)	Co-operative (3.6) Permanent buyer without pre-contract (2.9)	Contractual breeding for farm (2.6) Small buyer without pre-contract (2.6) Small random buyer (2.3)	Permanent buyer without pre-contract (3.3) Co-operative (3.0)	Small (3.1) and medium (2.6) permanent buyer without pre-contract Small (2.8) and medium (2.1) random buyer Large permanent buyer (2.3)	Permanent buyer without pre-contract (3.8) Co-operative (2.6)	Contractual breeding for farm (2.4) Small (2,8) and medium (2.2) random buyer Small permanent buyer without pre-contract (2.1)
In which of listed modes did you sell most of your fattened animals in the past three years?	Co-operative (52. 5 %) Permanent buyer without pre-contract (39. 3 %)	Contractual breeding (46. 2 %) Permanent buyer without pre-contract (38. 5 %)	Co-operative (40. 9 %) Permanent buyer without pre-contract (40. 9 %)	Permanent buyer without pre-contract (52. 4 %) Contractual breeding (28. 6 %)	Permanent buyer (66. 7 %) Co-operative (29.6 %)	Permanent buyer without pre-contract (47. 2 %) Contractual breeding (32. 1 %)
Which of listed modes is in your experience the most economically efficient?	Co-operative (44.1 %) Permanent buyer without pre-contract (40. 7 %)	Permanent buyer without pre-contract (51. 4 %) Random buyer (27 %)	Permanent buyer without pre-contract (42. 9%) Co-operative (38. 1 %)	Permanent buyer without pre-contract (47. 6 %) Random buyer (28. 6 %)	Permanent buyer without pre-contract (68. 0%)	Permanent buyer without pre-contract (45. 3 %) Contractual breeding (28. 3 %)
In which mode do you co-operate with your main buyer?	Without pre-contract (60. 0 %) Co-operative (31. 7 %)	Contractual breeding (34. 1 %) Co-operative (22. 0 %) Precise oral agreement (17. 1 %)	Without contract (72. 7 %) Co-operative (18. 2 %)	Without any agreement (45. 0 %) Contractual breeding (15. 0 %) Co-operative (15. 0 %) Precise oral agreement (15. 0 %)	Without contract (88. 9 %)	Without any agreement (33. 3 %) Contractual breeding (27. 5 %) Precise oral agreement (17. 6 %)
Experience with compliance with the contract	No contract (61 %)	High compliance (52 %) Full compliance (32 %)	No contract (76 %)	High compliance (33 %) Full compliance (33 %)	No contract (89 %)	Full compliance (59 %) Other options 13 % each
How often in the past three years did you sell fattened animals to listed buyers? (1 - never, 5 – exclusively)	Co-operative (3.8) Local trader (2.7)	Co-operative (2.9) Large processor (2.5)	Co-operative (3.3) Local trader (2.9)	Large processor (2.1) Co-operative (1.9) Small processor (1.7)	Co-operative (2.6) Local trader (2.2) Small processor (2.1)	Large processor (2.4) Co-operative (2.0) Medium-sized processor (1.7)
To which buyer did you sell most fattened animal in the past three years?	Co-operative (81. 4 %)	Co-operative (42. 9 %) Contractual breeding (40. 0 %)	Co-operative (71. 4 %)	Contractual breeding (25.0 %) Co-operative (18. 8 %) Local trader (18. 8 %) Large , medium-sized and small processor (12. 5 % each)	Co-operative (50. 0 %) Local trader (30. 0 %)	Contractual breeding (39. 5 %) Co-operative (28. 9 %)
In which category of buyers is your main buyer placed?	Co-operative (78. 3 %)	Co-operative (36. 6 %) Large processor (34. 1 %)	Co-operative (68. 2 %) Medium-sized processor (13. 6 %)	Surrounding households (23.8 %) Distant household (14. 3 %) Large processor (14. 3 %) Small processor (14. 3 %) Co-operative (14. 3 %)	Co-operative (37. 0 %) Local trader (22. 2 %) Small processor (22. 2 %)	Surrounding households (26. 4 %) Large processor (24. 5 %) Distant household (15. 1 %) Co-operative (15. 1 %)

Non-co-operative breeders could be further subdivided into three sub-clusters– part-time breeders that do farm besides a full-time job and do not live of farming income. Among second cluster members, there is a higher percentage of respondents who work on farm and are employed. In the second sub-cluster, there are breeders that will gradually abandon farming. 29 % of cattle breeders and 22 % of pig breeders stated that they would reduce animal breeding production. In the third sub-cluster, there are larger, self-sufficient breeders who can ensure their farm's economic success independently. Non-co-operative breeders' marketing channels do not differ from traditional co-operative breeders. The most frequently used channels among cattle breeders are still agricultural co-operative (41 %) and the sale to a permanent buyer without contract (41 %). Pig breeders most frequently sell fattened pigs to small permanent or random buyers. Sale to a small buyer is economically most efficient for almost 80 % of all respondents. The most frequent mode of fattened animals sale among pig breeders is in 29 % contractual breeding, for 24 % it is even the most economically efficient one. The main buyer for cattle breeders is in 68 % agricultural co-operative, through which 71 % of cattle breeders sell most animals, and in 14 % medium-sized processor. Pig breeders sell fattened animals to many different categories of buyers, mostly to surrounding households (24 %), distant households, large and small processors and co-operatives (14 %). Most animals are sold through contractual breeding or agricultural co-operative by 25 % of pig breeders. Non-co-operative breeders co-operate with the main buyer without pre-contract (73 % of cattle breeders) or without any oral agreement (45 % of pig breeders), which is expected behaviour according to their attitude to contracting (Table 1.).

Progressive breeders are representatives of active, flexible farmers, seeking new, favourable marketing channels. The percentage of younger breeders is above average, for 62.5 % farming is the only employment. Both, cattle and pig breeders declare for increasing production – the former in 18.5 %, the latter even in 21.4 %. Cattle marketing channels are similar to other clusters: sale to a permanent buyer without pre-contract or agricultural co-operative among cattle breeders and sale to a small permanent buyer, contractual breeding or sale to a small random buyer among pig breeders. 67 % of breeders that are in favour of new modes of cooperation sell fattened animals to a permanent buyer most frequently and 67 % of them find this mode the most economically efficient. The great majority still co-operates with the main buyer without any pre-contract. Pig breeders (47 %) most frequently sell animals to a permanent buyer without pre-contract, which is for 45 % of breeders the most economically efficient, or through contractual breeding (32 %), the most economically efficient mode for 28 % of breeders. The rest evaluate sale to a random buyer as the most economically efficient, this mode of sale is most frequently used for 21 % of pig breeders. Progressive breeders practice contractual breeding (27.5 %)in major part, one third co-operate with the main buyer without any oral agreement and 17 % on the basis of a precise oral agreement. 60 % of pig breeders have positive experiences with contract compliance. Cattle breeders' main buyers are in 37 % agricultural co-operative, 50 % sell most animals to them, in 22 % the main buyer is a Slovenian trader and small processor. Pig breeders sell most animals through contractual breeding or agricultural cooperative. The main buyer for 26.4 % of breeders is in the category of surrounding households, for 24.5 % large processor and for 30.1 % distant households and agricultural co-operative.

CONCLUSION

As we predicted breeders have different attitudes towards collective action. Majority of them is in favour of cooperation since they recognise its benefits. But there still exists a minor group of breeders who do not want to co-operate for a variety of reasons. Differences among breeders that want to act collectively mostly show inclination for organisational form. Therefore, traditional co-operative breeders cooperate with agricultural co-operative to a higher degree but the question is if they co-operate because of an actual economic efficiency that is often criticized, or because of breeders' inertness and disability to change activities. Traditional agricultural co-operative has played an important role in Slovenian agriculture since the beginning of the 20th century, and before reestablishment of the capitalistic market

organisation it was the only mode of collaboration, but during the transition was not able to adapt to changed market conditions and consequently lag behind in economic efficiency (Avsec & Nose, 2001). Cattle breeders remain loyal to traditional agricultural co-operation because they still operate in relatively favourable market environment where reduction in meat price and feed price rise do not force them to rationalize the production process and where the cut-out of income compensate by subsidy direct payment. On the other hand, global pig meat sector recession requires better, more efficient organisation of breeders (Kuhar et al., 2010). For this reason pig breeders prefer progressive, market-oriented collective action forms and operate this way as well. Heterogeneous marketing channels indicate the direction of searching for the most advantageous sale mode. Analysis of marketing channels and main buyer types shows that a theoretical attitude towards collective action is in reality in accordance with breeders' activity. In this way, traditional co-operative breeders mostly co-operate with agricultural co-operation and evaluate it as the most economically efficient, progressive breeders, however, prefer other modes of collaboration but not practice them. Sale to a small permanent or random buyer or to households leads us up to opportunistic behaviour of breeders. Opportunistic behaviour is in our opinion an expression of lack of understanding principles of collective acting and awareness of vertical chain benefits. Understanding of vertical coordination and awareness of vertical chain benefits are of great importance for improvement of sector conditions. Therefore, it would be reasonable to pay more attention to this topic, especially by state institutions.

USEFULNESS OF UREA AND PROTEIN CONCENTRATIONS IN MILK AND BLOOD AS INDICATORS OF NITROGEN UTILIZATION IN THE SIMMENTAL AND HOLSTEIN-FRIESIAN LACTATING DAIRY COWS

ABSTRACT: The aim of this study was to determine the protein status in Simmental and Holstein-Friesian cows, as well as use possibilities of milk and blood urea values as indicator of nitrogen utilization. The digested N is mainly absorbed as free amino acids and is used by the animals for protein synthesis, or as ammonia, which needs to be detoxified by the liver into urea. The forms in which N is absorbed are critical in determining the proportion of digested N that is available to support protein synthesis. Investigation has been conducted on 17 lactating Simmental cows and 10 Holstein-Friesian lactating dairy cows divided into groups regarding to milk production (under 15 kg (S<15; H<15) and over 15 kg (S>15; H>15) and to lactating stages (under 100 days S<100d; H<100d and over 100 days). Blood pH and electrolytes (Na^+, K^+, Cl^-) have been determined by the RapidLab 348 (Bayer, Germany) analyzer. Blood metabolites (BUN, TP and albumin) have been measured by Beckman AU400 automatic analyzer. MUN (milk urea nitrogen), protein and fat content have been determined by infrared spectrophotometric method on Combi-Foss analyzer FT 6000.
Simmental cows (S<100d) had the lowest BUN and significantly lower MUN concentrations and lower MUN has been noticed also in H<15kg. Significantly higher TP concentration was noticed in H<15kg group and H>100d due to raised globulin count, probably because of inflammation. H>15kg had the lowest rumen pH, but blood pH was in referent interval in all groups. There was no correlation between BUN and MUN (r=0.32 in S>15L) which is related to the ratio of dietary CP to energy, because of excess of microbial requirements.
In the condition of low milk production as a consequence of low dietary protein and energy, MUN concentration is not relevant enough as an indicator of protein/energy supply.
Key words: *milk urea concentration, dairy cows, low protein diet*

INTRODUCTION

It is really important to establish good dairy farm management based on proper cows' nutrition because diet cost gets around 40 to 60% of the total milk production cost. Milk urea nitrogen (MUN) and milk protein are used as indicators of the protein-energy balance and for monitoring feeding disorders. Rumen degradable protein (RDP) is used by rumen microorganisms to synthesize microbial proteins, so ammonia has a great role in symbiosis maintenance between rumen micro flora and cow (Huntington and Archibeque, 1999). There are different reports dealing with the factors which influence MUN values: BUN, the effect of parity, time of lactation, milk yield, energy and protein metabolism in the rumen (Carlsson et al., 1995; Eicher et al. 1999, Arunvipas et al., 2003). During protein fermentation amino acids have been deaminated and ammonia occurs which is used by microorganisms for their own proteosynthesisIn case of insufficient energy supply more toxic ammonia accumulate, diffuse into ruminal epithelium and enter circulation. In the liver toxic ammonia is being converted into non-toxic urea. Urea is a hydro soluble molecule which can be found in blood, milk, urine and saliva. It is synthesized in the liver from ammonium obtained as a product of decomposition of food protein. Urea goes along to the kidneys and saliva glands, after that in saliva in the mouth and in the rumen again. Ammonia is absorbed across all sections of the

digestive tract of ruminants. Before diffusion through the gut epithelium the ammonium ion is converted to ammonia, diffuses into epithelial cells as ammonia, then protonated to re-form an ammonium ion. There are mechanisms providing transport of the ammonium ion, such as association with bicarbonate or VFA (volatile fatty acids) anions (Parker et al. 1995), but urea recycling may not only play a role in supplying nitrogen for microbial growth, but also in the maintenance of ruminal pH (Zhonyan et al., 2011). Milk protein consists of approximately 95% true protein and 5% non-protein nitrogen. About half of that non-protein fraction is urea, depending on the protein and energy supply (Geerts et al., 2003). The importance of MUN and BUN control is seen as follows: high amount of dietary protein had negative effect on reproduction (Hammon et al., 2005) and milk yield. High protein intake requires more energy to convert NH_3 to urea in the liver and releases more N into the atmosphere contributing to environmental pollution (Reynal and Broderick, 2005). According to Kauffman and St-Pierre (2001) there is a strong correlation (0.88 – 0.98) between MUN and BUN, therefore it is cheaper to use MUN as efficient parameter for N utilization in cows. Jonker et al. (1998) emphasised that MUN values for cows that were fed according to the National Research Council recommendation were from 10 to16 mg/dl depending on milk production.
The aim of this study was to examine the usefulness of BUN and MUN concentration under low diet protein condition for the assessment of nitrogen utilization.

MATERIAL AND METHODS

The trial was carried out on two dairy farms, one Simmental and one Holstein lactating dairy cows, average 2,4 parities divided recording to milk production (under 15 kg (S<15; H<15) and over 15 kg (S>15; H>15) and regarding to lactating stages (under 100 days S<100d; H<100d and over 100 days S>100d, H>100d). Blood for the biochemical parameters and acid base status was collected after morning milking, two hours after feeding from v. caudalis into sterile vacuum tubes. The blood pH and electrolytes (Na^+, K^+, $HCO3^-$, Cl^-) have been determined by the RapidLab 348 (Bayer, Germany) analyser, on the ion selective electrode principle. Blood urea nitrogen (BUN), total protein, albumin, Mg, Ca, P were assigned by Beckman Coulter AU 400 automatic analyser. MUN (milk urea nitrogen), protein and fat content have been determined by infrared spectrophotometric method on Combi-Foss analyzer FT 6000. The statistical analyses were performed by using the general linear model procedure of the StatSoft, Inc. Statistica (2008).

RESULTS AND DISCUSSION

Dairy cows were fed with TMR which nutritional composition is shown in the Table 1.

Table 1. Chemical analysis of TMR for dairy cows Simmental and Holstein breed

Ingredient, % of DM	Simmental	Holstein
DM	50.03	69.8
CP	11.4	12.68
Fat	1.9	2.7
Crude fibre	24.29	18.5
Ash	6.84	6.24
NEL MJ/kg DM	6.59	6.59

The mineral concentration was in referent interval in both breeds except chloride concentration which was low in Holstein cows. Low BUN concentration was in Simmental cows with lower milk yield. Total protein (TP) concentration was significantly lower in S<15 in relation to H<15, but albumin concentration was normal, probably due to higher globulin concentration. This is in accordance with Šamanc et al. (2011) who found low TP and

albumin concentration in cows with fatty liver. Cows of both breeds had very low milk protein (S<100d; H<100d).

Table 2. Blood minerals, metabolite concentration and milk compound in dairy cows according to days of lactation

	S<100d	S>100d	H<100d	H>100d	Breed x DIM P-value

DIM-days post-partum
^{a,b} *different superscript differ significantly (P<0.05)*

MUN was significantly (P<0.05) lower in S<100d. Regarding the milk yield, the lowest BUN concentration had cows with low production (S<15), as well as TP concentration in relation to the Holstein cows. Cows H<15 had MUN concentration under referent limit (Table 3).

Table 3. Blood minerals, metabolite concentration and milk compound in dairy cows according to milk yield

^{a,b} *different superscript differ significantly (P<0.05)*

It is known that decreasing RDP (rumen degradable protein) intake results in linear decreasing of milk true protein content, MUN, and blood urea-N (Reynal et Broderick, 2005). Castillo et al. (2001) studied the effect of supplementing grass silage diet with isoenergetic concentrates containing 2 levels of protein concentration at 3 levels of protein degradability on N use and found that milk yield (mean 23.8 kg/d), milk composition, and faecal N excretion were not affected by protein concentration or degradability. The main route for dietary N output in excess of requirements was via the urine (Broderick, 2003).

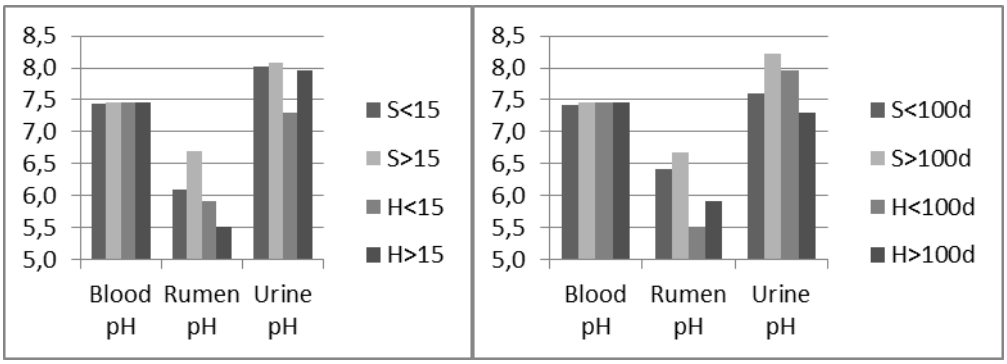

Figure 1. Blood, urine and rumen pH values in dairy cows according to milk yield and days of lactation

There is some speculation that feeding with RDP below the requirements for maximal rumen microbial growth can compromise microbial protein production, ruminal digestion, and energy and protein availability to the cow. In our study there was no significant correlation between BUN and MUN, but there was significant positive correlation between blood pH and total protein (r=0.74) in S>15 and S>100d (r=0.64) as well as blood protein and MUN (r=0.62). Following severe reduction in the protein content of the diet, a decreasing of BUN concentration is expected (Campanile et al, 1998).
As it is shown in Figure 1, blood pH was in the narrow lines, but rumen pH was the lowest in H<100d and H>15. Urine pH was significantly lower in H>100d and H<15. The rumen pH values were in referent range (except H<100d and H>15), which indicates that digestive processes run optimally.

CONCLUSION

Except nutritional factors, there are many non-nutritional factors which influence milk urea nitrogen levels in dairy cows. In the condition of low milk production due to low dietary protein and energy intake, MUN concentration is not relevant enough as an indicator of protein/energy supply. We found low BUN and MUN concentration, but weak coefficient correlation shows that nutritional processes are not rational and other metabolic pathways are included.

ABSTRACT: Inclusion of fish meal in the diet increases the cost of fish production and this problem can be overcome with replacement of it with local available plant ingredients. The aim of the study was to determine the impact of the complete replacement of fish meal with soybean meal and sunflower meal in the diet of two years old common carp on the growing parameters and proximate composition. Fish were grown in two groups with three replicates in the six earthen ponds each of 1 ha. In the diet 1 was not added feedstuffs of animal origin, while in the diet 2 fish meal was included. The both diets were manufactured using a twin screw extruder. Twelve samples of two years old carp were taken from each group during the harvesting. Also, samples of both extruded diets were taken for analysis. At the end of the rearing period the average harvesting weight was 1622,12 and 1719,2 g; survival rate was 82 and 85%, total stocking density was 300 and 300 kg/ha and harvesting density was 3325,35 and 3612,5,45 kg/ha; feed conversion ratio was 2,3 and 2,1 in common carp fed with diet 1 and diet 2, respectively. The chemical composition was not significantly different between groups ($p>0,01$). These results support the use of adequately processed plant protein sources as important replacement for fish meal in extruded feeds for common carp.
Key words: *formulated feed, soybean meal, sunflower meal, fish meal, common carp*

INTRODUCTION

The main type of fish production in Serbia is the semi-intensive system for cyprinid production, carp being as the major species. In addition to natural food, cereals are supplemented to meet protein requirement. Some fish farms increase meat quality of fish (Ćirković et al., 2011) and production by introducing extruded completed feed mixtures (Ćirković et al., 2005). The cost of inputs per unit of fish weight is higher than in semi-intensive farming, especially because of the high cost of fish feed that contains a high level of protein with a balanced amino acid composition. Fish meal is the first choice as an ingredient in fishfeed production for its high quality of protein with a well-balanced amino acid profile (Gatlin III et al., 2007). The cost of fish meal increased constantly, which caused the need to find alternative protein sources for fish diets. High cost can be overcome by replacing animal origin feedstuffs with local available vegetable-derived protein ingredients. Soybean meal is regarded as an economical and nutritive value feedstuff with high protein content and favourably balanced amino acid profile (Carter and Hauler, 2000) compared to other plant proteins (Gatlin III et al., 2007). In our country, soybean meal is the most commonly used plant protein sources (Ćirković et al., 2005) which could be replaced expensive fish meal in order to develop sustainable and economical carp production. Beside soybean meal, sunflower meal also represents a valuable protein source for fish feed industry. Sunflower meal is an excellent source of linoleic acid, dietary fiber, some amino acids (especially tryptophan), Vitamin E, B Vitamins, and minerals such as copper, manganese, potassium, magnesium, iron, phosphorus, selenium, calcium and zinc. Additionally, it is rich in cholesterol-lowering phytosterols (Ćirković et al., 2002).
The use of plant-derived materials such as legume seeds and different types of oilseed cake, as fish feed ingredients is limited by the presence of a wide variety of antinutritional

substances. Important among these are protease inhibitors, phytates, glucosinolates, saponins tannins, lectins, oligosaccharides and non-starch polysaccharides, phytoestrogens, alkaloids, antigenic compounds, gossypols, cyanogens, mimosine, cyclopropenoid fatty acids, canavanine, antivitamins, andphorbol esters (Francis et al., 2001). Extrusion cooking is used to make plant proten more available to animals through denaturing termolabile antinutritional factors (Barrows et al., 2007), resulting in improved nutrient digestibility and palatability. Heat treatment of soybeans is necessary to denature endogenous trypsin inhibitors and maximize nutritional value, but overheating can damage protein and reduce nutritional value (Barrows et al., 2007).
The aim of the study was to determine the impact of the total replacement of fish meal with soybean and sunflower meal in the diet of common carp on the growing parameters, chemical composition and the amount of total cholesterol of two-year old common carp (Cyprinus carpio L.) in comercial rearing conditions.

MATERIAL AND METHODS

Pond management and diets

Fish were grown in the six earthen ponds each of 1 ha and average depth of 1 m, which were left dry and untreated during winter. Three replicate ponds per dietary treatment were used. Fish were hand-fed twice daily (8:00 and 15:00) for 180 days. In the diet 1 was not added animal feed, while in the diet 2 fish meal was presented in the amount of 32%. The both diet were manufactured using a twin screw extruder. Heat treatment of vegetable origin feedstuffs is necessary to denature termolabile antinutritional factors and maximize nutritional value, but overheating can reduce the availability of protein, reduce protein digestability or cause loss of essential amino acids (Deng et al., 2005) and therefore the extrusion process was strictly controlled.
The fishponds were stocked in April and harvested in October. All fish were reared under variable natural atmospheric conditions. The production of natural food was based on the natural production of benthic and planktonic organisms that were increased by application of agrotechnical measures such as drying of fish ponds during winter, soil treatment, fertilization and adding lime. Livestock manure (2000 kg/ha) was applied to the bottom of empty pond and later biweekly over the water surface (4000 kg/ha during growing season). Agricultural limestone was applied to the bottom of empty pond and over the water surface. The ponds were supplied with well water. The amount of natural food and its influence was not considered because pedologic composition of all 6 ponds was the same, without significant difference, and agriculture measures for improved natural production were the same for the all ponds. Aeration of fish ponds was provided. At the beginning of the feeding trial, a pooled sample of 12 fish was randomly collected to serve as an initial carcass sample.
At the end of the trials, during the harvesting four fish were randomly collected from each pond (n=12, for each dietary treatment) for final carcass analysis. Also, samples of extruded formulated feed were taken for analysis. Fish meal, soybean meal, sunflower meal and other ingredients of the diet were obtained from commercial suppliers.

Growth performance

Growth-performance indicators [specific growth rate (SGR, % weight day^{-1}), feed conversion ratio (FCR), weight gain (WG, %) and survival rate (SR, %)] were measure using following formulas:

SGR = 100 (Ln (mean final body weight)-Ln (mean initial body weight))/time (days);
FCR = dry feed intake (g)/wet weight gain (g);
SR (%) = (Final fish number/initial fish number)*100;
WG = Final body weight (g)- initial body weight(g) (g fish^{-1});

After weighing, twelve samples from each group were stored at a temperature of –18ºC. Before examination, the fish were left at room temperature, in order to partially defrost and

remove skin easily, and separate head, tail, and viscera. Fish fillets were blended (Braun CombiMax 600). To examine total cholesterol content samples were stored in dark plastic bags at temperatures of –18ºC. The meat from dorsal muscles was used for chemical analyzes.

Chemical analysis

Chemical composition of fish muscle tissue and experimental feed mixtures was determined using standard SRPS ISO methods. Protein content was determined by Kjeldahl method (Kjeltec Auto 1030 Analyzer, Tecator, Sweeden). Water content was determined by drying at 103±2ºC to constant weight. For determination of total fat, the samples were hydrolyzed with 4M hydrochloric acid and extracted with petroleum ether by Soxhlet apparatus. Ash content was determined by combustion at 550±25ºC.

Cholesterol determination

Cholesterol in carp fillets (from direct saponification) was measured using HPLC/PDA system (Waters 2695 Separation module/Waters photodiode array detector, USA), on a Phenomenex Luna C18 (2) reverse/phase column, 150 mm x 3.0 mm, 5µm particle size, with C18 analytical guard column, 4.0 x 2.0 mm as described by Maraschiello et al. (1996). The injected volume was 10 µL. The mobile phase was isopropanol-acetonitrile (20:80, v/v) at a flow rate of 1.2 mL/min. Detection was performed at 210 nm and total analysis time lasted 10 min.

Statistical analysis

Intergroup differences were determined ($P<0.01$) using the Student t-test (Statistica 10, StatSoft Inc., Tulsa, USA). The data were presented as means ± SE.

RESULTS AND DISCUSSION

The formulation and chemical composition of experimental diets are given in Table 1. The amount of crude protein and crude fat was almost the same in both mixtures. Diet 1 contained soybean meal in the amount 480 gkg^{-1} and sunflower meal in the amount 100gkg^{-1}, while diet 2 as the main protein source contained fish meal in the amount 320gkg^{-1}.

Table 1. Composition and proximate analysis of the extruded formulated diet

[1]*Vitamin mix(mg kg-1 of diet): vitamin B1, 15; vitamin B2, 10; vitamin B6, 20; vitamin B12, 0,15; vitamin K3, 15; inositol, 250; Ca-pantothenic acid, 80; nicotinic acid, 100; folic acid, 1; vitamin H (biotin), 1; vitamin E, 140; vitamin C, 500; vitamin A, 20 000 IU; vitamin D3, 6 000 IU; choline chloride, 1 800, and cellulose was used as a carrier.*

[2]*Mineral mix (mg kg-1 of diet): Cu 20, Fe 40, Mn 30, Se 0.4, Zn 125 , and cellulose was used as a carrier*
[3]*NFE, nitrogen-free extract, g.kg-1 DM = 100 – (CP + CF + CA)*
[4]*Calculated based on the following conversion factors: CP – 24 kJ g-1, CL – 39 kJ g-1, NFE – 17 kJ g-1 13 (Jobling 1994)*

The growth performance of the fishes in terms of weight gain, SGR, FCR and survival rate are presented in table 2. Survival rate of the fishes in the first group was 82% and in the second 85%, which is according recommendation of Ćirković et al (2002). Fish mortality was recorded in all replicates of the treatments and no feed related mortality was observed during the 180 days of the experiment. All growing parameters were better in group which consumed the diet with fish meal, but except in harvesting density, no statistically significant difference was not observed. Among several plant protein sources, soya bean meal was reported to be most efficiency utilized by the fingerlins of rohu when supplemented with methionine and fortified with minerals; though at their higher inclusion levels, the growth was reduced (Khan et al., 2003) Suboptimal amino acid balance, low protein contents and presence of antinutritional factors of plant ingredients seem to be responsible for the decrease in the growth of the fishes at their higher inclusion level in fish diet, especially for marine fish (Tacon, 1997). It has been demonstrated that dietary incorporation of property heated soybean meal improved the growth performance, feed intake, feed efficiency and reproductive performance of common carp (Viola et al., 1983), which is in agreement with our results. Different oilseeds and their by-products usually constitute a major source of dietary protein within aquaculture feeds for warm water omnivorous and herbivorous fish species, so soybean products have been successfully used as partial substitutes for fish meal in diets for Mozambique tilapia (Davies et al., 1989), hybrid tilapia and African catfish (Balogun and Ologhobo, 1989). Sunflower meal has been used as partial substitutes for fish meal in diets for Atlantic salmon (Gill et al., 2006). The majority of published research on the use of plant proteins in fish feeds has focused on the inclusion of soybean meals in feeds for rainbow trout (Gomes et al., 1995, Oliva-Teles et al., 1994; Kaushik et al., 1995) and for salmon species (Hardy, 1996; Carter et al., 1994; Refstie et al., 1998). According to results of these previous studies there are wide range of the amount of vegetable protein sources suggested for the partial replacement of fish meal with vegetable proteins in the diets for salmonids, while in some species, including carp, completed replacement of fish meal with vegetable proteins is possible (Viola et al., 1982; Garg et al., 2002; Khan et al., 2003), which significantly decreases the cost of production.

Table 2. Growth performance of common carp

Variable[2]	**Rearing system**	
	Soybean and sunflower meal	**Fish meal**
Initial number of fish (ind ha^{-1})	2000	2000
IBW (g)	150±16.04	150±24.92

Final number of fish (ind ha^{-1})	1640	1700
Survival rate (%) SR	82	85
Stocking density (kg ha^{-1})	300	300
Harvesting density ($kgha^{-1}$)	3325.33±75.03a	3612.5±100.25b
WG ($gfish^{-1}$)	1877±67.86	1975±89.68
SGR (%·day^{-1})	1.45	1.47
FCR (g·g^{-1})	2.3	2.1

[1]*Data are means ± SE (n = 12). Values within the same row with different letter supercripts differ at p<0.01, IBW, initial body weight; FBW, final body weight; SR, survival rate; SGR, specific growth rate; FCR, feed conversion ratio; WG, weight gain;*

Fillets proximate composition values of the fish at the beginning and end of the 180-day feeding trial are shown in Table 3.

Table 3. Proximate composition of common carp

Variable	initial	Soybean and sunflower meal	Fishmeal
Moisture (g kg^{-1})	829	782.6±6.56	780.5±4.58
Crude protein (g kg^{-1})	141.1a	169.48±2.59	171.42±2.31
Crude lipid (g kg^{-1})	20.9a	37.25±0.35	37.08±4.72
Crude ash (g kg^{-1})	9.8a	10.7±2.01	11.0±1.54
Total cholesterol (mg kg^{-1})	511.3	512.83±11.48	515.75±19.78

[1]*Data are means ± SE (n = 12). Values within the same row with different letter supercripts differ at p<0.01*

No significant differences were found in the chemical composition of carp fillets between dietary treatments, but differences were notably between chemical composition of initial and final fish samples (P<0.01), except for the total cholesterol content of fish fed the both diet and initial sample (P>0,01). Inclusion of plant proteins in the diet of carp has shown that the total replacement of fish meal is feasible.

CONCLUSIONS

These results support the use of adequately processed soybean meal, sunflower meal and other local available feedstuffs as important replacement protein sources for fish meal in extruded feeds for common carp. Fish meal is expensive and mostly imported feedstuff. The use of plant-derived materials as fish feed ingredients are limited by the presence of a wide variety of antinutritional substances, so appropriate heat treatment is necessary.

ABSTRACT: In the technological process of either trade or seed wheat cleaning before drying and storage, organic and inorganic impurities are separated. The amount of separated impurities depends on various factors and can range up to several percent. In the structure of organic impurities, beside broken, shrunken and other cereals kernels, also weed seeds, moldy and smutty grains are present. According to the Serbian Chamber of Commerce, last year 2.093.198 tons of wheat is gathered form 492.989 hectares. In case 2-3% of wheat organic impurities are valorized as feed, this quantity amounts between 42 and 63 thousand tons. It is also important to emphasize that by extrusion process this waste material can be turned into nutritionally and hygiene safe product. Prior extrusion, total count, *Coagulase-positive Staphylococci* and *Clostridium perfringens* were 160.000, <100 <10 cfu/g, respectively. *Salmonella* was not detected in 50 g of the sample, while the total number of yeasts and molds and *Sulphite-reducing clostridia* were 100 and <10 cfu/g, respectively. After extrusion of broken wheat kernels, total count decreased to 17.000 cfu/g, while the number of *Coagulase positive Staphylococci*, *Clostridium pergringens*, *Salmonella* spp, the total number of yeasts and molds, as well as the number of *sulphite-reducing Clostridia* was below the limited value. Extrusion process contributes to physico-chemical changes in the material, primarily in the structural change of starch which is reflected in the increase of sucrose and reducing sugar content in the extrudates. Prior to extrusion, wheat broken kernels were grinded in a hammer mill with screen hole of Ø 4mm, then moisture content of ground material was adjusted to 14.80%. Extrusion was performed on single screw extruder "METAL-MATIK" Beočin, at 90ºC, capacity 150-170 kg/h of grain extrudates. Extrusion head had 8 dies of Ø 10mm. Extruded wheat broken kernels were characterized with moisture, crude ash, crude fiber, crude fat and starch content of 11.81%, 1.68%, 4.43% 1.99% and 69.39%, respectively.
Key words: *wheat broken kernels, organic impurities, extrusion, extrudates*

INTRODUCTION

Food production in the world, and here is one very important problem that arises in both the developed and even more so in underdeveloped parts of the world. Lack of food for the population that each year at the global level significantly increases makes the problem even more important. The solution for increasing the amount of food for humans and animals is the application and use of new technologies and in biotechnology, i.e. bio-industry (Lazarevic et al., 2005). From the technological point of view, here are developed new technological procedures aimed at increasing the nutritive value of food intended for humans or animals, parallel to evaluation of waste products of food and primary agricultural production.
Today in the world in use are different methods for thermal processing of oilseeds and cereal grains such as toasting, extrusion, hydrothermal process, micronization, microwave treatment, and dielectric heat treatment (Thompson, 1987; Sakač et al., 1996; Marsman et al., 1998), but in our country, based on knowledge from practice and literature (Sakač et al., 2001, 2002, 2003) commonly used are extrusion and the hydrothermal process, which provide extruded, or hydro-thermally treated products. Thermal treatments of cereals are used to improve their nutritive, hygiene, physical, chemical and other characteristics, i.e. it increases the nutritive value of some nutritients, improve sensory properties (increases

"sweetness" in the processing of corn) and provides microbiology safe products (Jansen, 1991, Verheul, 1997) and inactivate possibly present heat labile nutrients. Extrusion process leads to changes in the grain complex carbohydrate i.e. decrease in starch content due to its degradation to dextrin. These changes bring about an increase *in vitro* and *in vivo* digestibility of starch, since starch gelatinization provides increased availability of enzymes that break down starch, and parallel to the above, leads to inactivation of the α-amylase inhibitor (Douglas et al., 1990; corp, 1999, Filipovic et al ., 2003). In addition, it was found that extrusion also leads to the increased water absorption and improved hygiene and improvrd physico-chemical characteristics of extrudates (Filipovic et al., 2004, 2005a, 2005b, 2005c). Due to extrusion complex carbohydrates undergo significant physical and chemical changes, which affect the digestibility and utilization of energy from starch. During extrusion, starch particles swell change their solubility in cold water and viscosity of the released amylose and amylopectin in the starch granules. Due to Maillard's reaction, during the extrusion process the content of soluble sugars (reducing) and carbohydrate can be reduced up to 80% (Douglas et al., 1990). Extrusion also leads to significant changes in organoleptic terms, which is directly related to changes in the starch complex.
In this paper the technological parameters for extrusion process, physical-chemical characteristics and microbiology of broken wheat kernels before and after extrusion are presented.

MATERIAL AND METHODS

Extrusion of wheat fracture was performed on the single screw extruder produced by "METAL-MATIK" - Beočin, with 8 dies Ø10mm and a knife at a temperature of 95ºC. Before extrusion wheat broken kernels were grinded in a hammer mill with screen openings Ø4mm and moisture content was adjusted to14.80%.
The basic chemical composition (moisture, crude protein, crude fiber, crude fat and ash) and starch content in the starting raw materials and extrudates was determined by the methods of the Regulations on sampling methods and methods of physical, chemical and microbiological analysis of animal feed (1987). Total sugar content was determined by the Regulations on the physical and chemical methods of analysis for quality control of grain, milling and bakery products, pasta and deep frozen dough (1988).
The total number of microorganisms is determined by the method of BS EN ISO 4833:2008, coagulase positive staphylococci by method EN ISO 6888-1:2008, Clostridium perfringens by BS EN ISO 7937:2008, Salmonella spp by method EN ISO 6579:2008, the total number of yeasts and molds by method ISO 21527-2 and sulphate-reducing clostridia by 15213:2003 ISO method.

RESULTS AND DISCUSSION

Particle size distribution of grinded broken wheat kernels prior to extrusion, is presented in Table 1. Optimum particle size distribution is a prerequisite for the extrusion process. In the process of conditioning added water needs to be quickly and evenly distributed in the conditioner thus enabling optimizing heat treatment in the extruder (Filipovic et al., 2005c). Matz (1993) also stated the importance of particle size of untreated material for the extrusion process in the production of expanded snack products.

Table 1. Particle size of grinded broken wheat kernels

Sieve opening Ø (mm)	Overtails on sive (%)
2,00	0,69
1,25	9,50
1,00	11,90
0,63	31,48
0,25	28,36
0,125	8,84
0,063	6,55
bottom	2,68

The process of extrusion of wheat broken kernels is greatly affecting physical and chemical properties and contributes to reduction of microorganisms in the extrudate. Table 2 shows the chemical composition of wheat broken kernels before and after extrusion at a temperature of 95°C.

Table 2. Chemical compositions of wheat broken kernels prior and after extrusion

Quality parameters	Wheat broken kernels		Extruded wheat broken kernels	
	% in sample	% in d.m	% in sample	% in d.m
Moisture content	14,13	-	11,20	-
Crude protein content	10,49	12,22	10,49	11,81
Fat content	1,72	2,01	1,77	1,99
Crude celullose content	2,29	2,67	3,93	4,43
Ash content	1,38	1,62	1,49	1,68
Starch content	62,77	73,10	61,62	69,39
Total sugar content	3,25	3,78	2,05	2,31

The extruded wheat broken kernels are characterized by significantly reduced moisture content (from 14.82% to 11.20%), making it suitable from the standpoint of keeping quality, i.e. storage. During extrusion, there is a change in the structure of proteins, which often leads to a decrease of protein solubility (Filipovic et al., 2003, 2005) and total crude protein content (decrease in protein extrudates was 3.56% compared to the initial wheat breakage), while the decrease in crude fat content of about 1%, is in accordance with the statement of Venou et al. (2003). Namiki (1990) found increased lipid oxidation in extruded cereals, due to increased contact surface of extrudate with air. In the extrusion process gelatinization of starch occurs parallel with the degradation of its structure and therefore, increases the availability of starch to enzymes in the digestive tract (Douglas et al., 1990, Zhou and Erdam, 1995).

Despite a relatively low temperature of extrusion process (95 0C), it is positively contributing to the reduction of microorganisms in a very short time extrusion (6-10 sec). Very high pressure of extrusion ranging from 30-40 bar, may explain the reduction total number of microorganisms, Table 3.

In the investigated nutrients molds, yeasts and other microorganisms were recorded. For the development of molds feed with high moisture content (over 14%) are particularly suitable. Molds that develop on feed mostly belong to the genera *Aspergillus, Penicillium, Fusarium Altelnaria, Mucor,* and others. (Adamović et al., 2001)

Table 3. Microbiology profile of wheat broken kernels before and after extrusion

Microorganism	Wheat broken kernels	Extruded wheat broken kernels
Total number of microorganisms	160 000 cfu/g	17 000 cfu/g
Coagulase positive staphylococci	< 100 cfu/g	< 100 cfu/g
Clostridium perfringens	< 10 cfu/g	< 10 cfu/g
Salmonella spp	not detected in 50 g	not detected in 50 g
Total number of yeasts and molds	1 000 cfu/g	1 000 cfu/g
Sulphate-reducing clostridia	< 10 cfu/g	< 10 cfu/g

The total number of microorganisms in wheat broken kernels before the extrusion was of 160,000 cfu / g, and after extrusion of microorganisms decreased to 17,000 cfu/g.

CONCLUSIONS

- Process of extrusion of wheat broken kernels at 95ºC leads to physical and chemical changes of the treated material, primarily in changing the structure of a protein and starch, which contributes to a better nutritive value of feed for young animals, fish and pets;
- The process of extrusion of wheat broken kernels contributes to the decreases of the total number of microorganisms thus increases hygiene and feed safety.

ABSTRACT: Investigation was performed to observe the changes of crude protein (CP) content in lucerne plant during the first three vegetation cycles within one vegetation season, with the aim to optimize the lucerne utilization in ruminant nutrition. A total of 143 samples were collected from 7 April 2010 (the start of the spring vegetation) to 9 August 2010 (the end of the third vegetation cycle). The sampling was done by cutting a randomly chosen area of 0.1 m^2. Crude protein (CP, expressed in dry matter) was analyzed in all samples with standard Kjeldahl procedure. Samples were collected in all stages of the three vegetation cycles, from the early vegetation to the ripe pod phase.
There were large differences in plant protein content changes during different vegetation cycles. During the first vegetation cycle, which had the highest yield of plant green mass, there was a sudden drop in the protein content that was coinciding with optimal cutting moment. In absolute values, this drop was more than 8 percent points of CP during the 10-day period. Second and third vegetation cycles had slower and more uniform decreases in CP content during vegetation.
Postponing the cutting moment in order to obtain higher yield, during the first vegetation cycle may lead to radical decrease of the nutritive value in lucerne. Adequate and rapid evaluation of the right moment for lucerne cutting is very important in order to obtain quality forage rich in protein.
Key words: *lucerne, crude protein, cutting*

INTRODUCTION

Lucerne (*Medicago sativa L*.) is one of the most important forage species. It has a long life, high yields and is rich in protein. Those characteristics are making it one of the most important feedstuffs on all locations where there are conditions for its production. In the diets for dairy cows it is almost indispensible component. In high yielding dairy cows the lucerne hay, silage and haylage provide important part of crude protein (CP) and calcium. Because of all that, the quality of lucerne hay, silage and haylage is of the utmost importance.
High level of CP in lucerne hay, silage and haylage can be provided only if the plant is mowed at the adequate moment. The classical method for evaluation of precise cutting moment is based on the recognition of certain morphological development phases in lucerne, first of all buttonization and flowering. Depending on the aim, which may be production of the high quality or high yield and quantity, The American Society of Agronomy (Undersander et al. 2004) recommended cutting lucerne in the interval between the beginning of buttonization and the beginning of flowering.
The aim of this work was to determine changes in CP content in lucerne plant during the first three vegetation cycles, and to examine the classical method for evaluation of the right cutting moment, considering its quality in animal nutrition.
There are very few data available in the literature about the changes in CP level in lucerne plant during vegetation, and mostly they show the CP content in the distinctive development (Mejakić et al., 1997; DLG, 1997; UK Ministry of Agriculture, Fisheries and Food, 1992).

MATERIAL AND METHODS

Collection of samples was done on a farm close to Belgrade, from the lucerne field of the Banat cultivar in the third year of production. The field was founded in the spring 2008 and standard agrotechnics were used without irrigation. During 2010 From April 7 to August 9, the total of 143 lucerne samples were collected. Each sample was collected by cutting the

area of 0.1 m^2 at the height of 3.5 cm, which provided between 40 and 200 shoots, depending on the vegetation period. Samples were taken during the first three vegetation cycles at approximately every third day. The interval between two samplings varied depending on weather conditions and vegetation phase. Number of samples in one day depended on the phenophase in lucerne development. In the phases that are most important for animal feeding four samples were collected each day. The beginning of vegetation during the first cut period was the moment when forming of first green shoots was observed (March 21). In the second and third cutting cycles the beginning of vegetation was taken to be the cutting day of the first (May 25) and the second (July 1) swath.
In all three vegetation cycles sampling covered the whole vegetation, from the moment when shoot height was about 10 cm (first sampling) to the phase when lucerne seeds were ripe (last sampling). A total of 72 samples were collected in the first vegetation cycle, 35 during the second and 36 during the third. The first cycle, which happens in the spring, is having the greatest yield of green plant mass and longest lasting vegetation, which is the reason why the largest number of samples was then collected. Collection of samples in the second vegetation cycle was a bit late because of unfavorable weather conditions.
Sampling procedure was following: after the cutting, samples were placed in plastic bags and brought to the laboratory in portable refrigerator, where plants were cut and placed in freezer (-20°C). The estimation of the beginning of buttonization and flowering was done in the laboratory, before samples were chopped, based on the examination of all plants present in the sample. After minimally three days on -20°C the samples were placed in plastic boxes and dried for 48 h in forced draught dryer at 60°C, and the data collected for calculation of dry matter percentage. After the drying, samples were grinded in the laboratory mill with the sieve size of 1 mm. Samples prepared in such way were analyzed for crude protein by Kjeldahl procedure according to ISO standard 5983-2 (2005). Statistical analysis was performed by analysis of variance using Statistica v. 6 software package (2003).

RESULTS AND DISCUSSION

In Serbia all first three vegetation cycles are having substantially different weather conditions. During the first vegetation cycle very low temperatures were recorded and rainy weather, which slowed down lucerne growth. Cold and wet period lasted until the middle of the second vegetation cycle (mid June), while after that moment very high temperatures started, which followed the end of the second and the whole of the third vegetation cycle. The Figure 1 shows the changes in CP% (Dry matter basis) during the three vegetation cycles.
It is possible to observe the decreasing trend in CP% during vegetation. The first vegetation cycle had sudden drop in CP%, until the 40-th day of vegetation, when CP% was stabilized around 17%, and remained at that level until the end of the cycle. The other two vegetation cycles had more balanced decrease in CP%. The period between the beginning of buttonization and the beginning of flowering was shown on the Figure 1 among the dotted vertical lines. In this period during the first vegetation cycle the significant decrease in CP% was observed. On the 34-th day of vegetation, which was the day when buttonization started, plant mass had 26.63% CP while at the beginning of flowering it had 17.12% CP (Table 1).

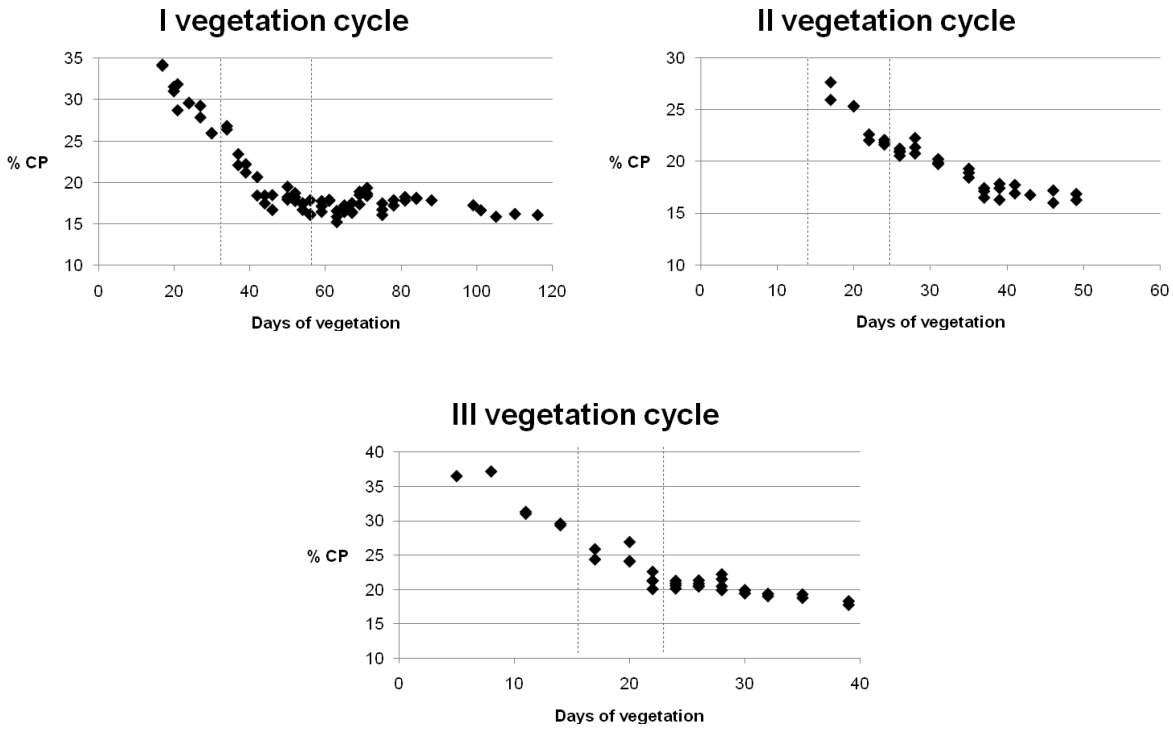

Figure 1. Changes in CP (%DM) during vegetation in I, II and III vegetation cycle

Table 1. Mean value of CP % (%DM) in the beginning of buttonization, flowering and ripe seed during vegetation cycles

Vegetation cycle	Stage of development	Sampling date	Days from beginning of vegetation	Number of semples taken that day	% CP mean value
I	Begining of buttonization	25.4.2010.	34	2	26.63
	Begining of flowering	19.5.2010.	59	3	17.12
	Ripe seed (last sampling)	15.7.2010.	116	1	16.07
II	Begining of buttonization	10.6.2010.	17	3	26.81
	Begining of flowering	17.6.2010.	24	3	21.87
	Ripe seed (last sampling)	18.7.2010.	55	1	16.28
III	Begining of buttonization	18.7.2010.	17	2	25.17
	Begining of flowering	23.7.2010.	22	4	21.35
	Ripe seed (last sampling)	9.8.2010.	39	2	18.08

During the buttonization period of the first vegetation cycle the decrease in CP% was about 9.5% in absolute or 36% in relative value. During the second and third cycle this decrease was much less pronounced – about 5% in absolute value. At the end of the vegetation season when plants had ripe seeds, CP % in lucerne was 16.07; 16.28; 18.08 in first, second and third vegetation cycle respectively (Table 1).

Table 2. Analysis of % CP variation (% DM) during the first vegetation cycle, form midbud to the end of vegetation

Interval	Days	Number of samples	%CP mean value	Sd
Midbud - Beginning of flowering	44-59	19	17.61^{ns}	0.91
Beginning of flovering - End of vegetation	60-116	33	17.30^{ns}	1.00

^{ns}*-Non significant*

Considering only CP% in the first vegetation cycle at May 6 (44-th day from the beginning of vegetation), the CP level was decreased to 17.96%, which in absolute values is more than 8.5%, alredy on the tenth day since the buttonization started. In those samples there was not a one shoot in the flowering phase, while buttonizing plants dominated. Analysis of variance did not show statistically significant differences in samples collected in the following stages: Midbud - Beginning of flowering and Beginning of flowering - End of vegetation (Table 2). Results of this investigation show that during the first vegetation cycle the decrease in CP% reached lowest values during the phases that are recommended as best moments for cutting.

The changes in protein content during the first vegetation cycle were characterized with the sudden decrease in CP during the buttonization phase and beginning of flowering, which is different from the observation of McDonald et al. (1996) according to whom the protein content is comparatively high and declines only slowly with maturity.

According to the recommendations of The American Society of Agronomy (Undersander et al. 2004): when harvesting for the highest yield of high quality, the first cutting should be at bud stage, the second at midbud and subsequent cuttings at 10 to 25% bloom. However, the results obtained in this investigation show that depending solely on the evaluation of the lucerne development phase (from the beginning of the buttonization phase to the beginning of flowering), as a method to determine the moment for lucerne cutting, is of doubtful value if the aim is to produce highest amounts of protein in lucerne hay, silage or haylage. In this investigation this was especially prominent during the first vegetation cycle, when CP% decreased by 8% in the buttonization period alone. Considering that there are inevitable losses when lucerne hay is balled or haylage (silage) is prepared, especially in leaves, this further decreases the CP% of the feedstuff. The shown values are theoretical for lucerne dried in the laboratory, while in the field we can only expect that the losses may be higher.

CONCLUSIONS

The production of lucerne hay, silage or haylage with high protein content requires not only optimization of manipulative procedures, but also the adequate evaluation system for making decision when to cut the green mass. Our investigation showed that relaying only on morphological development phases was not precise enough during the first (and the most important) vegetation cycle. This problem could be resolved by developing a new system for the evaluation of lucerne cutting time, with the aim to obtain the maximum nutritive value from this important forage species.

ABSTRACT: An overview of current trends in lucerne use in animal nutrition in different forms: fresh lucerne, preserved lucerne - hay and haylage, or a component of mixtures as dehydrated lucerne and protein-carotenoide concentrate of lucerne juice are presented in paper.
The nutritive value of lucerne is directly affected by the stage of maturity, method of preservation, processing and utilization in animal diets. Based on morphological changes the chemical composition of alfalfa plants can be estimated with high correlations (above 90%). Due to numerous factors that affect on chemical composition of lucerne hay, the nutritive value is highly variable, and using of lucerne hay in rations for ruminants is minimal, according to requirements for optimal digestion and ruminal function. The cut length of lucerne haylage affects average particle length of total mixed rations for ruminants. The physical form and effectiveness of ration is significant parameter for regular rumen function, digestibility of nutrients, and production performances of ruminants, particularly high-yielding lactating cows. The largest reasons for difficulties in preserving lucerne as haylage are in its high buffer capacity, the insufficient content of fermentable sugars and fast degradation of nitrogen compounds. The most favorable results were obtained with simultaneous use of carbohydrate supplements with homofermentative lactic bacteria for wilted plant material.
In spite of relatively high content of crude fiber, lucerne may be significant for nonruminant nutrition after specific treatment and processing, particularly for hen feeding with the purpose of yolk color modification. Lucerne juice may be particularly important for this purpose because it is a protein-carotenoide concentrate.
It can be concluded that lucerne still remains one of the main feedstuffs due to its high nutrition value and exceptional biological characteristics.
Key words: *lucerne, preserving, processing, ruminants, nonruminants, nutrition*

INTRODUCTION

Lucerne is the second most important animal feedstuff in Serbia, after corn. According to the statistical data Statistical Office of the Republic of Serbia, in the May 2010 the total of 3 065 745 ha was seeded in Serbia, of which 187 286 ha (6.11%) was seeded with lucerne. This shows the importance of this culture, considering that it is perennial plant. Lucerne has high nutritive value (high protein content, calcium and carotene), high yields (to 40 tha^{-1}; Đorđević and Dinić, 2007), longevity (5-7 years of production), several cuts during a vegetation (to 8 when watered) and various opportunities for its use (as fresh forage, hay, silage of haylage, meal and protein concentrate). However, lucerne yields were just 5.837 tha^{-1} (Statistical Office of the Republic of Serbia) during the 2011 in Serbia, which is significantly below its potentials. The main reason for that is in inappropriate agrotechincs. It is also evident that lucerne is usually cut late, when its nutritive value is reduced. Lucerne contains some antinutritive substances (saponines, estrogens and other) and when fresh it easily causes bloat in ruminants. Due to its high fibre content its use is limited in nonruminants. The important imperfection in lucerne is that it cannot be produced on acidic soils (Kammes et al., 2008). In spite of all that, the majority of lucerne is used as hay in Serbia, which is the most variable feedstuff according to its nutritive value (Đorđević et al., 2010, 2011).

LUCERNE AS FRESH FORAGE

All methods of lucerne conserving are producing certain losses in nutritive value, due to mechanical loss of chemical transformations of nutrients. The use of fresh lucerne as pasture

or cut and given to animals in the stall is good solution for those problems. However, lucerne is rarely used as pasture because it does not stand well animal trampling. Some low breeds were selected for that purpose in the past (Mejakić et al., 1997). The other problem with the use of fresh lucerne is that it is somewhat limiting dry matter and energy intake (Bargo et al., 2002), and because of that the cow ration needs to be supplemented with concentrates and conserved feeds. The bloat is also a serious threat with lucerne, and also low pH value of rumen fluid, low content of NDF and high ammonia concentration in the rumen. The use of Monensin in dairy cows fed on lucerne pasture diets is used to reduce methanogenesis, and it results in the increase of milk yield with decrease in milk fat content (Gallardo et al., 2005). Modern concepts in dairy cows feeding are based on conserved forages and concentrates, combined in „total mixed rations" (TMR), where fresh forage is not normally used (Đorđević et al., 2006).

LUCERNE HAY

The most variable type of hay is produced from lucerne, considering its nutritive value and chemical composition. Therefore it may limit the milk production in high yielding cows, if used as sole or dominant forage. It is also expensive feedstuff, but minimal amounts of hay with its physical properties are indispensable for normal functioning of the ruminant digestive system (Grubić et al., 1999). The combination of lucerne hay and corn silage in dairy cow diets is optimizing their dry matter (DM) and energy (NEL) intake, which leads to the increase in production of milk, protein and lactose (Kowsar et al., 2008). High amounts of lucerne hay or haylage in the diets of prepartum cows may lead to milk fever due to high content of calcium cation (Grubić and Adamović, 2003). This type of feeding is common on small family farms in Serbia. According to Stojanović and Grubić (2008) the Dietary Cation-Anion Difference (DCAD) value for lucerne hay is +431 mEq/kg DM, which significantly contributes to the DCAD value of the whole diet. The diets for dry cows should have negative DCAD value. It is therefore recommended to add a mixture anionic salts (Đorđević and Dinić, 2011) if lucerne is the only available hay. Goff et al. (2007) used chlorine fertilizers (NH_4Cl and $CaCl_2$, and their mixtures) in the amounts of 56, 112 and 116 kg Cl/ha, and discovered the increase in chloride content in lucerne forage from 0.52% to 0.77, 0.87 and 0,89%. These results show that it is possible to add chlorine to the soil and increase its content in the obtained forage, which is decreasing DCAD value in lucerne hay or haylage.

LUCERNE SILAGE (HAYLAGE)

High moisture content in the moment of cutting and high buffer value are the main problems for successful ensiling of legumes, and this was the reason for several experiments performed during the past couple of decades (Đorđević and Dinić, 2003). Today the more attention is also given to the changes nitrogenous matters which occur during the ensiling process (Đorđević et al., 2004). In living plants 75 – 90% of total nitrogen is in the form of true protein, while in silages it is just 30 – 50%, according to Slottner and Bertilsson (2006). Compared to other plants from the *Fabaceae* family lucerne has more soluble nitrogen matters. Protein solubility is in positive correlation with ruminal degradability (Wattiaux, 1994), which may reduce their utilization or lead to health problems in animals. According to Broderick (1995) other legumes have less soluble proteins compared to lucerne, due to higher presence of condensed tannins. Such results were experimentally obtained by Albrecht and Muck (1991) for sainfoin, lespedeza, and *Lotus pedunculatus*. According to the same authors, species such as red clover or *Kura* clover do not contain condensed tannins, but their proteins have low solubility. The lesser degree of proteolysis in red clover silages was explained with the presence of soluble enzyme polyphenol-oxidase, which in presence of oxygen reacts with O-diphenol creating very reactive O-quinone, which creates polymers with other molecules such as proteins (Getachew et al., 2009; Graber, 2009; Lee et al., 2009).

Various methods are used in order to maximally control the process of nitrogen matter degradation during the legume ensiling process, such as wilting, carbohydrate stimulation, inoculation and chemical conserving (Nadeau et al., 2000; Guo et al., 2008). Aside from these technologies the cultivars of legumes are selected to have lower degradability (Broderick et al., 2004), and also genetically manipulations were done with the same purpose (Getachew et al., 2009).

On larger farms in Serbia lucerne hay and haylage are given in a mixture with other feedstuffs as TMR. One of important factors for the use of forages is their cutting length which is important for their physical effectiveness. The minimum content of physically effective fibre (PEF) is needed for chewing activity, saliva production and contractions of the reticulo-rumen (Stojanović et al., 2010). The content of PEF in the complete dairy cow ration has influence on animal health, ruminal fermentation, intake and digestibility of the diet, and also on yield and chemical composition of milk (Bhandari et al., 2008). Stojanovic et al., 2012) in their experiment on dairy cows discovered that when forage feed particles are reduced, the feed conversion ratio is improved, and also digestibility and milk yield, while protein content in the milk was reduced (Table 1).

LUCERNE MEAL

Dehydration and processing of lucerne with high temperatures in the process of meal production has little effects on content and composition of proteins, their biological value and biological value of their amino acids. Along with high protein content lucerne meal has high level of minerals, carotene, B complex vitamins and also C, K and E vitamin. By sieving lucerne meal the fraction for nonruminant feeding is obtained, with 23-25% protein and 15-17% crude fibre. Delić et al. (1976) were not able to substitute soybean meal even with double amounts of de-cellulosed lucerne meal (27% protein and 14% fibre), in the feeding of fattening pigs. They explained those results with low digestibility of lucerne. Arshad Al-haweizy and Yasin Al-Sadrady (2007) included lucerne meal as 4, 8, 12 and 16% of the mixture for laying hens and discovered that with the hens' age and level of the meal the conversion ratio is decreased. Because of negative effects on diet digestibility the use of lucerne meal nonruminant feeding is decreasing. Also, the correction of amino acid profile in the diets is today applied easily with synthetic amino acids, which is decreasing the importance of lucerne meal (Đorđević et al., 2007).

Lucerne meal has higher content of undegradable protein compared with fresh lucerne or hay (Grubić et al., 1994). This may be the reason for its use in dairy cow nutrition, in order to obtain the required balance between degradable and udegradable proteins in the diet.

LUCERNE PROTEIN CONCENTRATE

Protein concentrate produced from the fresh lucerne juice is important protein source, but also of carotene, which is givig color to some animal products (broiler chick skin, egg yolk). In near future it may became important protein source for human nutrition, about which there were some experiences from the Second World War (Đorđević et al., 1997).
The procedure of juice production is consisting of sqeezing the fresh chopped green mass with special presses, while proteins from the juice is extracted by coagulation and filtration. Domestic product is alowing production of 9.09% protein concentrate from lucerne dry matter (Sredanović et al., 1991). Lucerne protein concentrate has high amount of essential amino acids, xantophyle, β-carotene, α-tokoferol, and some stimulative and other biogenic materia. Kuzmicky and Kohler (1977) discovered that when protein concentrate from lucerne leaves (62.8% protein) was included 2.5, 5.0, 7.5 and 10.0% in the diets of broiler chicks there was no significant differences in their body mass and feed conversio ratio. Olvera-Novoa et al. (1990) replaced 35% of fish meal in mixture for tilapia (*Oreochromis mossambicus*) feeding with protein concentrate from lucerne leaves and there was no depression in their growth.

CONCLUSION

High nutritive value of lucerne is most eficiently utilized in the form of conserved feedstuffs. Along with hay, silages and haylages have increasing importance for high and economic production in cattle, in combination with feeds that are cheap energy sources. In the world there is a trend of reduction of hay production and use, and increase in the production of lucerne silage/haylage. Lucerne hay and haylage are indispensable components of total mixed ratios for dairy cattle, with particular care taken to the chopping length (physical effectiveness). Problems with production of quality lucerne silage and haylage can be solved with the use of various methods of fermentation induction or stimulation, also with the reduction of proteolysis. Lucerne meal has limited use as protein-vitamin additive in nonruminant diets, because of its high fibre content. In the near future protein concentrate produced from lucerne juice may be important source of nutrients not only for animals but also for humans as well.

ABSTRACT: Mineral deficiencies in goats in many countries are caused by low or variable contents due to season and maturity of plants and low digestibilities. The reliability of body tissues as an indicator of deficiencies varies greatly with mineral elements. Major performance improvements have been achieved, nevertheless, where mineral supplementations were applied correctly. Requirements of macro- and microelements, or minerals for short, are based on evidence of metabolic functions, which are structural and/or catalytic.
Mineral supplementation on this basis has yielded improvement in milk production, reproduction, feed intake and reduced heat stress in other species. It also has been pointed out, that even in the best studied species, cattle, there is no academic agreement as to the feeding recommendation levels of minerals, and there is less agreement and knowledge about the other less studied species, such as the goat. Copper is an essential element for the synthesis of hemoglobin, the iron absorption in the small intestine and the mobilization of Fe in body depots and oxidation. The function of selenium in metabolic processes is a close related to vitamin E. So, diseases caused by deficiency of Se can atribute to deficiency of Se and vitamin E. Deficiency in Se caused a great numbers of diseases with goats: degeneration of heart and sceletal muscles, more affinities to dysentery, disorderes in reproduction etc
Key words: *the goat, minerals, production traits*

INTRODUCTION

Providing animals with trace elements is done through food, special supplementation (premix) or in water. The intensive production of adding them is mandatory, because only thus can provide in sufficient quantities for optimal health and performance (Memiši et al., 2004ab; Memiši and Bauman, 2007). Minerals activate enzymes, are essential cofactors of metabolic reactions, act as carriers of proteins, regulate digestion, respiration, water balance, muscle reactions, transmission of nerve, influence and maintain skeletal strength, balance pH, and even mental balance, protect against disease, antagonists were or synergistic and other elements play a vital role in the resistance, adaptation and evolution of new breeds and lines (Solaiman et al., 2001).
Regardless of the fact that some of the trace elements present in sufficient quantity in food, often occurring subclinical or clinical signs of deficiency, because their efficiency varies and is a trace element found in unusable form. Resorption of trace elements depends not only on content in food, but also of animal age, electrochemical reactions in the intestine and form in which the trace is located. Depending on the type of soil, none of them provides an optimal level of minerals. In addition, plant species, their exclusion maturity and climatic conditions have also an important role in the content of minerals in kabastoj food. When talking about the lack of minerals in the diet of goats, then the first thought that their depletion leads to severe clinical manifestations and the emergence of easy identification of symptoms (Memiši et al., 2003,Memiši and Bauman, 2003d).
However, as noted in Figure 1, subclinical manifestations of the lack of certain minerals that are reflected in reduced immunity, growth, fertility, will be manifested long before the classic clinical features (Farzana, 2005). Subclinical deficiency of minerals in the diet is common and occurs in flocks of goats, however, producers are very difficult to notice their absence.

Animals seem to have normal growth, development and reproduction but it is at a lower level of a normal production. For these reasons, the diet of goats in all stages of the production cycle is commonly used supplements of minerals in order to maintain adequate and efficient production. For this purpose, commonly used salt minerals and oxides, carbonates, chlorides and sulphates. Today it is increasingly beside the form of inorganic minerals, using the so-called "chelate" form, ie, organically bound trace elements (Memiši et al., 2004a, 2007; Memiši and Bauman, 2003a,b,c).

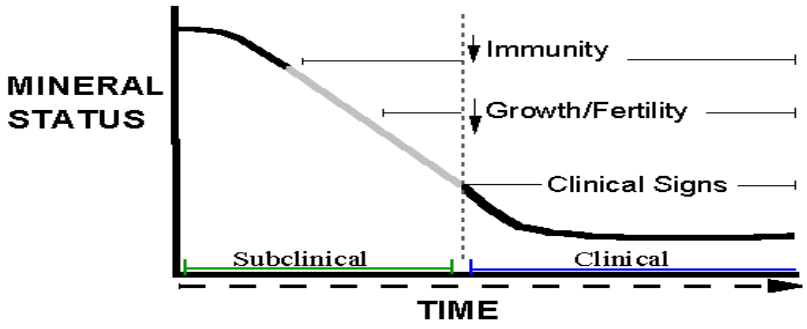

Figure 1. The relationship between mineral status and onset of subclinical and clinical disease symptoms

Requirements of goats in copper and selenium

Quantity of some minerals in foods is not as important as there's availability for the animal itself. This availability varies widely, and it affects a number of factors such as the form in which there is an element in the food, the stage of development of plants, the presence of other minerals and substances in foods that bind them and make available, then age and sex of animals, etc. In order to prevent deficiencies of certain mineral elements in nutrition of goats, there are many possibilities and application of certain procedures and methods to eliminate them and these are primarily: the treatment of forages with different fungicide, adding elements in the processing of land used for production of forage, use ready-made and complete mineral mixture in diet, and ultimately increase the organic reserves in the body of animals - goats can be made, giving injections or capsules with a slow and prolonged action.

Significant differences in mineral requirements between species, among other items, established for Cu and Se (Devendra, 1990). The lower the minimum needs of goats in selenium, depending on the stages of production (Kessler, 1991; Haenlein, 1991) ranges of 0.1 - 0.2 mg / kg dry matter intake. Chronic poisoning with Se in the skin (as in sheep) occurs when during the long period of time, consume feed containing more than 3 ppm Se in dry matter. Excess Fe, Cu and Ca in the diet increase the need to selenium.

Table 1. Effect of Cu (mg) supplementation on growth performance of goat kids (Solaiman et al., 2004)

Days	**0 Cu**	**100 mg Cu**	**200 mg Cu**	P- value
	Average daily gain, g			
28	156.6	144.5	167.7	0.61
42	147.6	156.6	134.1	0.39
56	137.4	149.6	129.9	0.19
70	134.9	153.1	119.2	0.02
84	131.7	147.6	116.6	0.01
98	129.2	147.3	122.5	0.04

When it comes to copper, the symptoms of toxicity in sheep can be observed with 10-20 mg Cu/kg DM entered the food, while cows submitted to 100 mg Cu/kg DM. The diet with the addition of higher levels of 100 mg Cu as a positive influence on the increase daily gain in

the young category and contributes to the improvement of immune function in goats (Table 1).

Research around the world have shown that in some countries as regards the presence of certain minerals in the soil there are different variations in terms of their deficits and surpluses, which could help in directing and creating programs to resolve problems (Solaiman et al., 2004). Such examinations of soil and plants should be placed in connection with the specific characteristics of metabolism of various species, and accept that the analysis of animal tissue is definitely the right diagnostic measures, but different tissues have different affinities to the macro-and micronutrients, and some of them do not have, and so their value as indicators is different, as is the case with these two mineral elements (Table 2). Thus, the status or supply with copper and selenium in the body skin is best tested through the coat (and over its content in blood plasma), which is one of the best indicators of the presence of this mineral in the body skin. In addition to hair good indicators supply the trace elements can be either internal organs (Anke et al., 1988), which are primarily the liver, then the brain, spleen, muscle, milk and others.

Table 2. Significant differences Cu i Se in tissue contents in goats, mcg/kg DM (Anke et al., 1988)

Minerals	Tissue	(n=31)/ Controls	(n=22)/ Cu and Se deficient
Cu	Brain	14.0	6.0
	Hair	4.7	3.0
	Plasma	0.7	0.4
	Liver	10.0	5.3
Se	Muscle	387	146
	Plasma	130	36
	Hair	350	150
	Milk	247	93

Copper is required goats at a level that is usually included in the diets of dairy cows, in contrast to sheep, which are sensitive to such levels, so that in such cases for them to develop and toxicity (Solaiman et al., 2006). Copper is an essential element for the synthesis of hemoglobin, the iron absorption in the small intestine and the mobilization of Fe in body depots and oxidation. Sheets and certain browsing contain higher levels of copper than stem forage, but their concentration decreases with the progress of maturity of plants for 40 to 60%. Deficiencies of copper in goats can be prevented by adding 0.5% copper sulphate in a mixture of minerals.

Lack of copper causes sudden weight loss goats, depigmentacion and hair loss, anemia, retarded growth, reduced milk production, diarrhea, the occurrence of hidden oestrus, the bones become brittle and deformed and others. If they enter the higher concentration of Cu can accumulate in the liver without major problems in animal health. Deficit of Cu in goats (less than 2 mg Cu / kg DM / day to 8 mg of Cu in the control group of goats, increased the content of Zn in the liver and ovaries and reduced food intake by 50%. In the burden of the Cu, goats that were fed higher levels of copper, had a 6 to 9 times lower levels of copper in the liver in the control group in the study, indicating individual differences between animals in the exploitation and resistance to the toxicity of Cu (higher levels in ration), which might be related to hepatic soluble protein that binds Zn for Cu (Zervas et al., 1989). However, the diet with high levels of sulfur (> 0.35% based on dry matter), molybdenum (> 2 ppm of molybdenum in food or the ratio of Cu: Mo <5:1), Fe (more than 250 ppm), Ca, Zn, Mn and Co can significantly reduce the absorption of copper (Solaiman et al., 2004).

For selenium deficiency in the diet of goats can be suspected in areas of his deficits in the soil, when the goats appeared various reproductive problems, early embryo mortality, recurrent estrus, retention of the placenta after giving birth to kids, metritis, weak newborn kids, degeneration of cardiac and skeletal muscle (white muscle disease), diarrhea, dyspnea (difficulty breathing), etc.

Intramuscular injection in goats with preparation selenium - vitamin E, a month before kidding can prevent the occurrence of these symptoms in the newborn kids, but adding 0.2 ppm of

selenium in the diet of goats provides stable protection during the entire production cycle. Status of selenium in the body skin is the best way to test his analysis in milk or blood, and in hair samples. Selenium in minimum amounts in the diet of goats needed to avoid problems in the reproduction of goats and retention of the placenta, then important for the functioning of the immune system, whereas in its operations is closely related to vitamin E.

Table 3. Requirements of goats in Se (NRC, 2007)

Physiological state	Requirements
Maintenance	0.015 mg/kg DMI + 0.083 mg/AC
Growth	0.5 mg/kg LWG/AC
Pregnancy	0.0021 mg/kg LBW/AC
Lactation	0.10 mg/kg MY/AC
Mohair	0.38 mg/kg

DMI- dry matter intake; AC-Apsorption coefficient (forages-0.31 and concentrates 0.60); LWG – Live weight gain kg/d; LBW – Litter birth weight, kg; MY – Milk yield, kg/day

Se be absorbed from the diet to a much greater extent than eg. Fe, Cu, Zn and Mn, and does not depend on the chemical form of selenate, selenite or selenides (Hart, 2008). Goats are related to the casein in milk and about 3% of ingested Se occurs in the milk of the correlation coefficient of r = 0.7. As for the metabolism in the body, it can absorb and release the body to the fullest extent through the lungs (10 to 50%), but most of it is expelled through the kidneys, while the fecal excretion of about 10%.

Because goat is largely used for feeding browsing of shrubs, bushes and trees, weeds and grasses that do not belong, and which are largely studied analytically, it is necessary to know its chemical composition (Devendra, 1990). When it comes to the use type of travel and poor grass in the diet of goats, one should bear in mind that many species of plants for the browsing of limited value because of one or more inhibitors that can bind, or otherwise to prevent the use of nutrients (mainly minerals) from them. Based on this fact is the addition of minerals in the diet of domestic animals (including goats) which largely led to the improvement of milk production, reproduction, food intake and reducing stress due to heat in other species.

On the basis of specific experiments on goats, the wording needs in the minerals is less dependent experiments were conducted on sheep and cattle (Haenlein, 1991; Kessler, 1991) (Table 4).

Table 4. The latest minimum mineral requirements of goats (Kessler,1991)

Minerals	
Cu	8 - 10 - 23 mg/kg - DM/day
Se	100 - 200 mcg/kg - DM/day

CONCLUSION

High production and milking goats requires a larger number of macro - and trace elements due to which growth and the need for them. Their adequate balance in the diet of goats is difficult because of specificity in the diet of goats, respectively, for the use of nutrients whose nutritional value not known. Goats are tolerant of high doses of Cu and Se with no obvious bad effects on their health, in contrast to sheep and cattle. Lack of copper causes sudden weight loss goats, hair loss, anemia, retarded growth, reduced milk production, diarrhea, the occurrence of hidden oestrus, the bones become brittle and deformed. Therefore, adequate nutrition of goats requires the maximum balance of nutrient meal, which is achieved by using different feed and using mineral mixtures. Diet with higher levels of Cu addition of 100 mg per day has effect on daily weight gain in younger categories and contributes to improved immune function of goats. The lowest minimum of goats need in selenium, depending on the stages of production, ranges from 0,1 to 0,2 mg/kg of ration dry matter. Therefore, adequate

nutrition of goats requires maximum balance of nutrients, which is achieved by usage of different feed and the usage of mineral premix.

ABSTRACT: Rapeseed meal (RSM) is a good protein source for animal nutrition, but there are some concerns about its effect on digestibility and gut health, especially in young animals such as broiler chickens. Study was carried out to determine the effect of rapeseed meal in broiler chicken diets on nutrient digestibility. Three groups of chickens were formed and fed either with corn-soy based diet (control group) or with inclusion of 10% (RSM 10%) or 15% of rapeseed meal (RSM 15%) respectively. Feed was composed to meet nutritional requirements of used broiler strain and balanced to same energy and crude protein level. To determine digestibility, 20 Ross 308 male chickens of average weight were used per treatment. Acid insoluble ash was used as marker. At 21 days of age, chickens were sacrificed to obtain samples for determination of ileal digestibility. Digestibility of dry matter, crude protein and energy was determined. No significant differences (P>0.05) were observed in any measured digestibility parameter. It is concluded that addition of up to 15% of rapeseed meal in well balanced diets of young broiler chicken does not have an adverse effect on digestibility of nutrients.
Key words: *rapeseed meal, digestibility, broilers*

INTRODUCTION

World production of rapeseed *(Brassica napus)* is growing (Marinković et al., 2010) driven by increased use of rapeseed for production of biodiesel and oil for human consumption. Rapeseed is also one of the major protein sources in European organic livestock production, since climate in large part of Europe is not suitable for soybean growing (Blair, 2011). It can be assumed that rapeseed production in Serbia will increase in future (Popović, 2010), and that larger quantities of rapeseed meal for animal feeding will be available.

Rapeseed meal is by-product from the manufacture of rapeseed oil, obtained by solvent extraction of rapeseeds, and is a good protein source for animal nutrition. It usually contains 34% of crude protein (INRA-AFZ, 2002). Amino acid profile of rapeseed protein is good. It contains 1.8% of lysine (more than sunflower meal, and less than soybean meal) and 1.51% methionine and cystine (more than both sunflower and soybean meal). It has more fibers then soybean meal, but less then sunflower meal (12.4% of crude fiber, 28.3% of neutral detergent fiber and 19.6% of acid detergent fiber). Energy content of rapeseed meal for different domestic animals, including poultry, is also between values for sunflower and soybean meal, two protein sources commonly used in Serbia.

In the past, main problems with use of rapeseed and its products in human and animal nutrition were erucic acid and glucosinolates, but contents of these compounds are reduced to very low and safe levels in modern group of cultivars called canola or double zero rapeseed (Leeson and Summers, 2001). Rapeseed meal also contains some other compounds that can possibly affect its nutritional value and its use in animal nutrition, like tannins, phytic acid and, in particular, sinapic acid and sinapine. Sinapic acid and sinapine are compounds that are responsible for unpleasant odor of eggs from brown-shelled egg layers fed rapeseed meal (Leeson and Summers, 2001). Sinapine generates bitter, astringent and pungent taste and irritating flavor (Trozyńska, 2004), but it seems that it does not negatively affect feed intake in broiler chickens (Qiao et al., 2008) or laying hens (Johnson et al., 2008). Johanson et al. (2008) even found positive effects of sinapine on

energy and protein digestibility in laying hens. On the contrary, Qiao et al. (2008) found that sinapic acid can reduce digestibility of amino acids when fed in larger quantities, but concluded that sinapic acid and sinapine are not toxic to broilers. Rapeseed also has high level of sulfur that can disturb mineral balance and induce leg problems in broilers (Leeson and Summers, 2001). However, main factor limiting the use of rapeseed in animal nutrition is its high level of fibre, resulting in low energy value and suboptimal use of proteins (Slominski et al., 1999).
Aim of this study was to determine if broiler diets with 10 and 15% of rapeseed meal can be used without negative effects on digestibility of nutrients.

MATERIAL AND METHODS

Six hundred day-old Ross 308 chickens were obtained from local hatchery. Chickens were randomly distributed into 15 pens, 40 chickens per pen. Pens were randomly assigned to 3 treatments, with 5 replicates per treatment. Stocking density was 16 birds per m^2 and wheat straw was used as litter. Feed and water were supplied *ad libitum.* Air temperature was adjusted in accordance with the recommendation of the strain producer (Aviagen, 2009). The three treatments were as follows: Control - diet without rapeseed meal; RSM 10% - diet with 10% of rapeseed meal; RSM 15% - diet with 15% of rapeseed meal. Rapeseed meal used in diets was made from “canola quality” rapeseed. Composition of diets is shown in table 1. All diets were balanced to same level of crude protein and ME.
At 14 days of age chickens were weighted, and 20 males of average body weight were taken from every treatment, four from every pen. They were randomly (within treatment) distributed into wire mesh cages, five chickens per cage. Four cages per treatment were used, 12 cages for the whole trial. Water and feed were again supplied *ad libitum*. After two days of adaptation period, marker was added in diets. Celite was used as a source of marker - Acid insoluble ash (AIA). One percent of Celite was mixed with 99% of diets. Diets were sampled after Celite addition, and analysed. After six days of consuming diets with Celite, broilers from cages were slaughtered and small intestines were removed. Digesta samples for digestibility analysis were obtained from the most distal 10 cm of ileum. This part represented approximately one fourth of total ileum length. The last centimetre of ileum before ileocecal junction was not used to avoid mixing ileal and cecal digesta. Digesta samples were obtained by gentle squeezing to avoid contamination of samples. Samples from all birds from one cage were mixed together. Immediately after collection, samples of digesta were frozen, and they were kept frozen until analysis. In diets and ileal digesta samples, dry matter, AIA, crude protein and gross energy content were analysed. AIA was analysed according to *Vogtman et al*. (1975). Crude protein was analyzed using Kjeldahl procedure. Gross energy content was analysed using bomb calorimetry (*c200 Calorimeter, IKA®*). Apparent ileal digestibility for dry matter, crude protein and energy, was calculated with the following formula:

$$Digestibility = 1 - (AIA_{diet} \times N_{digesta}) / (AIA_{digesta} \times N_{diet})$$

where AIA_{diet} is percentage of AIA in diet, $N_{digesta}$ is nutrient parameter (percentage of dry matter, percentage of crude protein or gross energy expressed as MJ/kg) in ileal digesta, $AIA_{digesta}$ is percentage of AIA in ileal digesta, and N_{diet} is nutrient parameter in diet. All values are expressed on dry matter basis.

Table 1. Composition of experimental diets

	Control	RSM 10%	RSM 15%
Diet composition (g/kg)			
Corn	490	450	430
Full fat soybean	138	141	150
Soybean meal	280	210	168
Rapeseed meal	0	100	150
Yeast	30	30	30
Soybean oil	18	27	30
Monocalcium phosphate	15.5	13.5	12.5

Salt	3	3	3
DL-methionine	1.5	1.5	1.5
Vitamin and mineral premix	10	10	10
Calculated nutrient composition			
AME (MJ/kg)	12.8	12.8	12.8
Crude protein (g/kg)	226	225	226
Crude fibre (g/kg)	41.5	46.7	49.2
Lysine (g/kg)	12.6	13.0	13.2
Methionine (g/kg)	5.1	5.3	5.4
Ca(g/kg)	9.0	9.2	9.7
P, total (g/kg)	7.6	7.8	8.0

All procedures were performed following standard ethical norms and birds were not subjected to undue stress. Digestibility data were analyzed by one way ANOVA, with using general linear models. Results were considered significant when $P<0.05$. Analysis was performed using Statistica software (StatSoft Inc., version 8.0, 2008).

RESULTS AND DISCUSSION

Observed ileal digestibility values are shown in Table 2. Digestibility of dry matter, crude protein and energy were numerically lower in groups consuming rapeseed meal, but these differences were far from statistical significance. Digestibility of all three parameters were lower in the RSM 10% group then in RSM 15% group.

Table 2. Ileal digestibility of dry matter, crude protein and energy of diets with or without rapeseed meal (%)

	Control	RSM 10%	RSM 15%	SEM	P value
Dry matter	68.6	66.4	67.6	0.92	0.662
Crude protein	80.0	77.6	79.0	0.78	0.516
Energy	73.4	71.1	71.9	0.87	0.582

SEM-standard error of mean

Dry matter digestibility values were similar to values determined by Juanpere et al. (2005) using diets based on corn and soybean, chickens of similar age and total collection method. Protein ileal digestibility values for all treatments were within usual range for this method, somewhat lower then values reported by Marsman et al (1997), higher then values reported by Schnietz et al. (1998) and Hernandez et al. (2004), and very similar to values reported by Namkung and Leeson (1999). Lee at al. (1995) demonstrated that rapeseed meal have higher amino acids digestibility (and similar metabolizable energy level) compared to flax meal, when fed to White Leghorn roosters. Digestibility of some amino acids and level of metabolizable energy is higher in expeller extracted rapeseed meal than in solvent extracted canola meal, when fed to three weeks old broilers (Woyengo et al., 2010). Apparent metabolizable energy was lower in diet with 30% of rapeseed meal then in diet with 20%, but apparent digestibility coefficient of nitrogen was not significantly affected with level of rapeseed meal in diets of 43 days old broiler chickens (Mushtaq et al., 2007). Also, enzyme

(xylanase and glucanase) supplementation did not have effect on examined parameters (Mushtaq et al., 2007).
Observed digestibility levels indicate good intestinal health and undisturbed digestion in broilers consuming rapeseed meal. Lack of negative effects of rapeseed meal on nutrients digestibility of broiler chickens in this trial is a result of: (1) using meal from "canola quality" rapeseed with low level of antinutritive factors; (2) using moderate levels of rapeseed meal (10 and 15%) compared to much higher levels in some other studies (Mushtaq, et al., 2007); and (3) using well balanced rations, where rapeseed meal was combined with increased levels of energy dense feeds-soybean oil and full fat soybean. These results are in agreement with performance study reported by Ahmad et al. (2007), and their conclusion that high quality canola meal can be included in broiler diet up to 20% without negative effects.

CONCLUSIONS

From the results of this study, it can be concluded that addition of up to 15% of low erucic acid, low glucosinolate, "canola quality" rapeseed meal in well balanced diets for young broiler chicken does not have an adverse effect on digestibility of nutrients.

ABSTRACT: Production of fish in Serbia is insufficient despite of favorable climate properties. Dominant form of national aquaculture system is semi-intensive carp breeding. Except cereals, in the recent years extruded and pelleted feed are increasingly used for carp nutrition in Serbia. The aim of this study was to compare the lipid content and the fatty acid (FA) profile of carp (*Cyprinus carpio*) raised in carp fish farms with traditional breeding technology based on maize as well as complete extruded feed. Total lipids of fish fillets were extracted by accelerated solvent extraction (ASE) and FA profile was determined by gas-liquid chromatography equipped with flame ionization detector. Results were compared by multivariate data analysis. Principal Component Analysis (PCA) of the total FA profile clearly differentiated carp according to diet. Carp fed maize contained higher amount of total lipids (8.59%) compared to carp fed extruded feed (4.71%). Content of saturated fatty acids (SFA) of two groups of carp was similar. Carp fed extruded feed had lower content of monounsaturated fatty acids (MUFA) (42.43%) and higher content of polyunsaturated fatty acids (PUFA) (32.56%) than carp fed maize (61.78%, 12.99%, respectively). A higher content of n-6 (27.99%) and n-3 (4.57%) PUFA as well as better n-3/n-6 PUFA ratio (0.16) were found in carp fed extruded feed than in carp fed maize (11.75%, 1.24%, 0.10, respectively). Obtained results reveal that diet significantly influence the quality of carp flesh. Lipid content significantly decrease and PUFA content as well as n-3 to n-6 ratio increase when using extruded feed.
Key words: *carp, maize, extruded feed, fatty acids*

INTRODUCTION

Aquaculture is the fastest growing sector of food production in the world that provides more than half of the total amount of fish demand (FAO, 2010). Out of the total cyprinid production in the world, carp (*Cyprinus carpio*) accounted for 18% of the total production (Takeuchi et al., 2002).Carp is the most important warm-water fish in some European countries.

Production of fish in Serbia is insufficient despite of favorable climate properties. Dominant form of national aquaculture system is semi-intensive carp breeding. Semi intensive farming system is based on combination of natural food in the fishpond and additional food mostly simple grains such as wheat, corn and barley. In the last few years there have been taken measures, which might contribute to intensification of aquaculture by improving breeding technology.

Fish diet has a large influence on the chemical and fatty acid composition (Caballero et al., 2002, Tocher et al., 2004, Steffens and Wirth, 2007). The increased nutritional value of fish by using complete feed mixtures as fish diets enables to improve production quality and increase economic yields in fishpond (Markovic, 2010). Recent years, extruded and pelleted feed are increasingly used in carp nutrition in Serbia.

The aim of this study was to compare the lipid content and the fatty acid profile of carp (*Cyprinus carpio*) reared in carp fish farms with traditional breeding technology based on cereals and carp fed complete extruded feed. Investigation of the effect of diet on the lipid content and fatty acid composition of carp would contribute to the promotion of aquaculture and of the quality of carp flesh.

MATERIALS AND METHODS

Eight samples of two-year old carp were caught from two fishponds with semi-intensive breeding which are situated in the northern, lowland area of the country, in October 2009. Average weight of fish was 1900 g. In the first fish pond, maize was used as complementary feed (8.58% proteins, 4.5% lipids). In the second one fish was additionaly fed complete feed mixture consisting of maize, soybean meal and fish meal (23.81% proteins, 6.97% lipids).
Lipids of fish fillets for fatty acid determination were extracted with hexane/isopropanol mixture by accelerated solvent extraction (ASE 200, Dionex, Sunnyvale, CA), (Spirić et al., 2010). Solvent was removed under the stream of nitrogen at 50ºC until dryness. Total lipids were further converted to fatty acid methyl esters (FAMEs) by trimethylsulfonium hydroxide (EN ISO 5509:2000). FAMEs were determined by gas-liquid chromatography (GLC, Shimadzu 2010) equipped with flame ionization detector and capillary HP-88 column (length 100m, i.d. 0.25 mm, film thickness 0.20 μm). Injector and detector temperature were 250ºC and 280ºC, respectively. As carrier gas nitrogen was used at flow rate of 1.33 mL/min. The injector split ratio was set at 1:50. Total analysis time was 50.5 min. The chromatographic peaks in the samples were identified by comparing relative retention times of FAME peaks with peaks in Supelco 37 Component FAME mix standard (Supelco, Bellefonte, USA). Results were expressed as mass of fatty acid (g) in 100 g of fatty acids. Statistical analysis was carried out by applying principal component analysis (SAS Institute Inc. JMP 8.0.1 software).

RESULTS AND DISCUSSION

Fatty acid profile of carp fed maize and carp fed extruded feed from two semi-intensive rearing systems are presented in Table 1. Content of SFA, MUFA and PUFA as well as n-3 and n-6 PUFA and n-3/n-6 ratio was calculated.
Two groups of carp had similar content of SFA. Carp fed extruded feed had lower content of MUFA (42.43%) and higher content of PUFA (32.56%) than carp fed maize (61.78%, 12.99%, respectively). A higher content of n-6 (27.99%) and n-3 (4.57%) PUFA as well as better n-3/n-6 PUFA ratio (0.16) was found in carp fed extruded feed than in carp fed maize (11.75%, 1.24%, 0.10, respectively).
Carp fed maize contained higher amount of total lipids (8.59%) compared to carp fed complete extruded feed (4.71%). Steffens, 1997; Viola and Arieli 1983 found similar results for carp breed on supplementary maize feeding.

Fatty acid profile may be a useful tool for identifying fish according to ingested food. Comparison of fatty acids using multivariate data analysis (PCA) and linear regression have shown that the composition of fatty acids in flesh of fish fed different type of food is clearly distinguished and it is similar to fatty acids of their feed (Barrado, et al. 2003).
Principal Component Analysis (PCA) of the total FA profile (e.g. considering every FA as a variable) clearly differentiated carp according to diet (Figure 1 and 2). PCA of the fatty acid profile resulted in three principal components model describing 85.7% of the total data variability. The score plot of the first two principal components revealed grouping of samples in two distinct clusters along the first principal component direction (Figure 1 and 2).

Table 1. Fatty acid composition of carp (n=8) fed maize and carp fed extruded feed (% of total fatty acids) and total lipid content (%)

Fatty acid	Carp (maize) (n=8)	Carp (extruded feed) (n=8)
14:0	0.74±0.11	0.84±0.07
15:0	0.11±0.06	0.19±0.04
16:0	18.43±1.29	17.81±0.76
16:1	6.97±0.77	5.01±0.83
17:0	0.15±0.07	0.34±0.08
18:0	5.16±0.57	4.49±0.28
18:1cis-9	50.38±4.33	33.09±2.46
18:1cis-11	2.74±0.26	2.57±0.18
18:2n-6	10.05±2.19	26.09±1.81
18:3n-6	0.26±0.09	0.34±0.05
18:3n-3	0.80±0.54	2.23±0.27
20:1	1.69±0.32	1.76±0.24
20:2	0.33±0.07	0.68±0.09
20:3n-6	1.11±0.17	0.88±0.10
20:3n-3	0.06±0.09	0.48±0.11
22:1+20:4	0.65±0.29	1.35±0.28
20:5n-3	0.14±0.11	0.58±0.14
22:5 n-3	0.06±0.12	0.28±0.08
22:6n-3	0.18±0.19	1.01±0.27
SFA	24.58±1.29	23.66±0.80
MUFA	61.78±4.28	42.43±2.93
PUFA	12.99±3.03	32.56±2.37
n-3	1.24±0.99	4.57±0.66
n-6	11.75±2.30	27.99±1.91
n-3/n-6	0.10±0.07	0.16±0.02
Total lipids	8.59	4.71

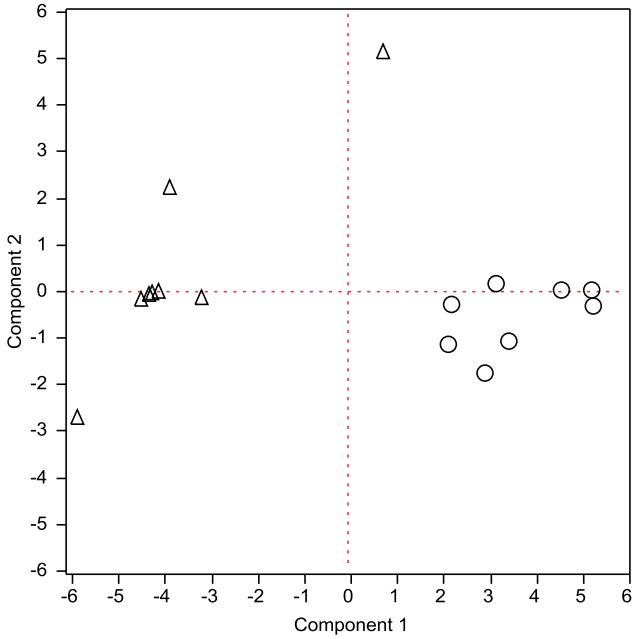

Figure 1. Principal component analysis score plot of the fatty acid profile of conventionally reared carp on maize (marked with triangles) and carp fed extruded feed (marked as circles)

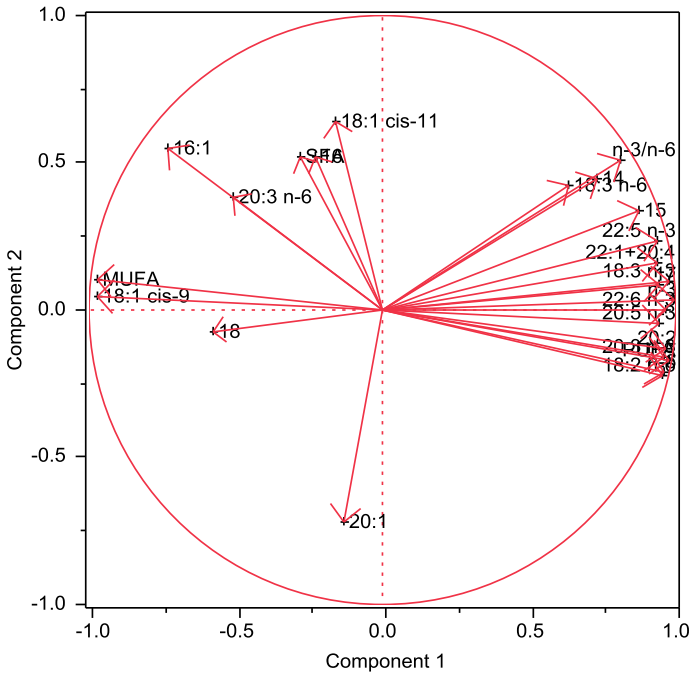

Figure 2. Principal component analysis loading plot of the fatty acid profile of conventionally reared carp on maize and carp fed extruded feed

Figure 2 indicate that two groups of carps with different feeding regime are clearly distinguished. Among fatty acids which mostly contribute to the variability on the negative part of the first principal component are C18:1cis-9, C16:1, C20:3n6, C18 and MUFA corresponding to carp fed maize which contains higher quantities of these fatty acids. Fatty acids which contribute to the positive part of the first component are C18:2n-6, C18:3n-3, C20:2, C20:3n-3, C20:5n-3, C22:5n-3, C22:6n-3 and PUFA corresponding to the groups of carp fed extruded feed. Thus, separations between two groups of carp may reflect differences in fish feed.

Research of Farkas et al.,1978 have shown that diet of carp rich in carbohydrates and poor in fats content (diet based on corn and wheat) increases of biosynthesis of C16 and C18:1 FA. Higher content of oleic acid in carp fed grains only resulted in a higher MUFA content, what is in accordance with results of Buchtova et al., 2007 and Fajmonova et al., 2003. Supplementary feeding of carp with maize resulted in lower content of n-3 and n-6 essentially FA in fish flesh. This is due to lower share of natural feed in the diet of carp that was supplementary fed grains (Steffens, 1997).

CONCLUSION

Obtained results reveal that diet significantly influence the quality of carp flesh. Fatty acids are essentialy important in human nutrition, particularly EPA and DHA. Quantities of these fatty acids and n-3/n-6 ratio are some of the indices of nutritional value of fish. Lipid content significantly decrease, PUFA content and n-3 to n-6 ratio increase by feeding carp extruded feed.

ABSTRACT: In modern poultry farming, requirements regarding to nutrition and health care are more demanding because high productivity of poultry hybrids aproches its biological potentials. In the paper, the nutritional requirements and most frequent deviations are analyzed in detail, such as: the structure and distribution of feed, feeding space, expert and technical aberrations in composition of commplete diets. Proper and forehand elimination of factors that had lead to particular nutripathy, directly linked to feed or feeding technology, represent the key of successful poultry production.
Key words: *poultry, feed quality, feeding technology, disease, control*.

INTRODUCTION

Aiming for profitable food production that contains no harmful substances, high requirements for the new very demanding poultry lines must be provided (Kapetanov, 1997). High productivity that reaches close to the biological maximum of poultry implicates high requirements related to nutrition and health protection that are not easily acomplished. Thus in our poultry farming numerous problems occur with impact to the quality of final products and health status of birds (Kapetanov i sar., 1997). These problems are defined as nutripathy.
In the paper most frequent causes and consequences of nutripathies in poultry production are presented and means to recognize, reduce or eliminate them.

THE CHARACTERISTICS OF FEED TYPES

Feed granulation. Poultry is natural seed-eater. Roughly mashed diets are used in chickens and adult poultry. If the content of very small particles is high or the granulation is too large, selective intake of feed and certain components may occur (Pavkov i sar., 1993). During the warm months when ventilation system is on the forced regimen, too many fine, powder-like particles containing essential nutrients are pooled out. White dust cover surfaces in front and around the outlets including roof and parts of farm surrounding.
The type of diet differs because the meal can be provided as mashed, pelleted or extruded. In some regions of the world it is common to mix whole grains in complete diets before feeding. In general, pelleted or extruded feed is easier to handle in compair to mashed one. It is known that single particles should not extend 3 mm in diameter in chick starter and 5 mm in grower diets.

The size and hardness of pellets. The size and hardness of pellets must be adjusted to the poultry species, age and category. However, large and hard pellets are not so rarely found. This may be evident immediatelly after the first body weight measuring that tend toward rapid growth decrease. On clinical examination small number of birds is seen around the feeders throwing out the pellets in search for adequate by size and hardness. The rest of the flock follow man consistently pecking the footware. The significant amount of feed is located around the feeders but sometimes it is necesary to remove the superficial litter to discover it. In case of prolonged consumption mechanical damage in oral cavity may occur. From our

experience such cases were often seen in fattening turkeys. It is possible to test the pellets by disolving them in a glass of warm water, that has to take no longer than five minutes.

Feeding with whole grain in mating period. It is observed that many peacocks die during the mating period after consumption of whole corn seed. In the spring, males produce very loud sounds to atract the females when they find feed. Females respond to the call and the male swallow the whole seed of corn, which sometimes ends in trachea („the jewish end"). For several hours males try to take out the corn by moving backward with their neck outstreched. In time the corn swell up causing dyspnoe and death. This is why males should not be fed with whole grain, especially corn in the mating period.

FEEDING SPACE AND FEED DISTRIBUTION

The optimal feeding space is essential in any type of feeding. Insufficient feeding space influence reduced weight gain and threaten flock uniformity. Nowadays, in the first ten days of life in broiler production biodegradable paper is used (chick paper) as additional feeder; it is wide 1 to 1.5 meters and the length is one third of the building. This method provides enough quantity of complete diet but also its availability. Often chicks „take a nap" in feeders thus reducing the overall feeding space, especially during the colder months.
Insufficient feeding space and poor feed distribution in growing flocks of layers or parents, that include feed restriction may cause health problems and poor production. The decrease of growth may occur, inadequate flock uniformity and high variation interval. Because the birds compete over the feed, they can get injuries, most frequently on head, necks and legs. Between 8 and 15 weeks of age, swollen joints on one or both legs are often seen and infection with *Staphylococcus aureus* (Kapetanov i sar., 1999). Mechanical injuries are mostly seen in heavy line males, sometimes causing the lower reproductive ability in later, mature age. Frequently birds compensate reduced feed consumption by feeding with litter, particularly fresh straw or wood shaving. In such cases clostridiosis was diagnosed on numerous occasions (Kapetanov i sar., 2008).
In growing flocks in which anticoccidials are used to prevent coccidiosis instead of vaccination, sometimes feed restriction is over seen. The clinical coccidiosis is very common in such flocks, particularly if feeding technology is not proper. In our cases, mixed infections, coccidiosis and clostridiosis was quite often seen.
In layers, kept in cages during the production feeding system becomes deformed over time, causing uneaven distribution of meal.
Insufficient feeding space and inadequate distribution of feed cause the increased mortality. In the structure of mortality dominate: suffocation, „hungry mortality", technological discard, mechanical injuries and its consequences (Kapetanov i sar., 1997; Kapetanov i sar., 2000; Kapetanov i sar., 2003; Orlić i sar, 2005; Živkov-Baloš, 2007).

TECHNICAL ABBERATIONS IN COMPLETE DIETS

Drug toxicity. When certain therapy is indicated precausion must be taken in flocks fed with complete diets that contain coccidiostats. The simultaneous use of some drugs, for example ionophore antibiotics and tiamulin, monensin and suplphonamides or erithromycine etc., favor its toxicity even in therapeutical dose. Side effects are expressed in short time with excitation, frequent and hard breathing, swollen head, exudative and haemorrhagic diathesis and death in position with streched neck and legs. Thus every shippment of feed must have declaration in which added substances and contraindications must be documented.

Calcium deficiency. The consequences of calcium deficiency in complete diets were found in all production stages, however the most prominent and detrimental effects were during the peak of egg production. After viral infections are excluded, it is diagnosed easily at this production phase since large number of cracked eggs and soft egg shell are found. However,

if pre-lay rations have less protein and calcium content, the diagnose is more difficult. In our experience clinical features in layers include lie with head put down, ruffled neck feathers, sometimes streched legs and pinguine position, moving with the help of wings, softened and deformed beak and deformities on brest region caused by flexure of keel, ribs and spine.

Deficiency of vitamine E. Low content of vitamine E in poultry rations induce two syndromes, that can occur solitary or together, encephalomalathia and exudative diathesis. Cases of encephalomalatia are mainly seen at the age of 2 to 4 weeks, sometimes earlier at 7 days, with clinical signs of: drowse, ataxia, movements in circle, tremor, uncontrolled shiverring, torticolis. The death is usually in side position. On postmortem examination cerebral oedema and solitar petechial haemorrhagies are present, also possible subcutaneous oedema on neck, chest and abdomen and cold and blue colouration of adjecent skin. From our experience, cases of deficiency occur during the summer in broiler flocks with exellent weight gain. The incriminated feed in cases of exudative diathesis had specific aroma like unsaturated fat**,** particularly pronounced after it was rubbed between palms. The successful therapy was application of vitamine E and selenium, for example 50 ml per 1000 kg body weight of commercial preparation Evitaselen, for three days. Also multivitamine preparations containing high vitamine E and A gave good results.

Intoxication with inadequately heat treated soy products. Besides high valuable nutrient content, soy bean has some undesireble and toxic substances. Crude soy beans contain tripsin inhibitors, lipid oxidase, hemagglutines and allergenes. All these substances are proteins that are denaturated during heat treatment and thus decrease their activity to the harmless level. In our two year investigations significant percentage of soy bean products was under or too much heat treated: 19.56% of 19,56% soy bean meal, 28.95% of extruded soy bean meal and 14.29% of soy cake. Intoxication with unsufficiently treated soy bean products was determined mostly in broilers, because they use such nutrients at most. The clinical signs were evident usually at the age of 3 to 4 weeks, including: impaired uniformity, low vitality and grouping around the heaters, paresis and paralysis and dysrupted behaviour with the pecking of litter, wall, feeders and drinkers. Wet litter was observed because of yellow to pale redish diarhoea and undigested feed particles. The weight gain was poor. Based on case history, clinical signs and section findings of catarrhal enteritis and underdeveloped gizzard, the chemical analysis of soy products was advised. Substitution with safe product and treatment with multivitamine preparations with essential amino acids provided good results (Kapetanov i sar., 2010).

The use of freshly harvested grains in complete rations. Feed producers and farmers often use freshly harvested grains like wheat or corn, because of shortage or high market prices. The moisture content and histamin level are too high in these grains. Shortly after consumption, clinical ilness begins, with symptoms of paresis, paralysis, exudative diathesis, protruding diarrhea with significant amount of undigested particles, catarrhal enteritis. Combined treatment with vitamine E and selenium was beneficial and the problem was eliminated. Such cases were most frequently observed in broilers.

CONCLUSIONS

The adequate and forehand removal of condition that caused certain nutripathy linked to feed or feeding technology, represent the key for successful poultry production.

ABSTRACT: The feed industry has a target to produce variety feed that fully satisfy the nutritional needs of certain types and categories of animals. Complete feed meals for animal feeding have to fully meet the nutritional needs of certain types and categories of animals. The energy level of a feed meal can be achieved by adding appropriate amounts of fat and grains. In the production of feed, in relation to other cereals, corn is the leader due to its high energy (about 16 MJ/kg) and starch and low fiber content. In comparison to other cereals, corn is attributed with the best digestibility and taste. Before drying and storage, in the technological process of either trade or seed corn cleaning, significant quantity of broken grains is separated. Complete feed meals for animal feeding and feed have to fully satisfy Regulations concerning hygiene and quality. Improving hygiene and nutritive value of broken corn grains can be achieved by extrusion. In this research, broken corn grains were processed in the single screw extruder at a temperature of 90ºC. Total count and total number of yeasts and molds decreased from 270.000 to 12.000 and from 540.000 to 10.000 cfu/g, respectively. Due to extrusion process, certain physico-chemical changes occurred in raw material, primarily manifested in structural changes of starch, which is reflected in the increase in sucrose (from 2.28% to 5.19%) and reducing sugars (3.36% to 5.88%) content in extrudates.
Key words: *broken corn grains, extrusion, hygiene*

INTRODUCTION

According to the Directive of the European Union no. 178/2002 (Article 3, paragraph 4) "Feed for the animals is each component or product, including additives, whether processed, partially processed or unprocessed, intended for oral feeding of animals." For the modern intensive livestock production mixtures of different concentrated feed with supplements that have nutritive or some other significance are of particular importance. These compounds are being produced in accordance with contemporary standards, and meet the high demands of modern species and hybrids. Maximum homogenization of certain nutrients and supplements is experienced in modern plants, equipped with the most modern technology controlled by computer (Djordjevic and Dinić, 2011).

Complete feed for animals must fully meet the nutritional needs of a particular type and category of animals as well as the energy demand. The energy levels of compounds can be achieved by adding appropriate amounts of cereals and fats. In the production of feed, corn has a leading position compared to other cereals. The reason is its high energy content (16.2 MJ/kg), high content of starch, and relatively great amounts of fat and low fiber (Bekrić, 1999). Beside the best digestibility, corn also has the best taste in comparison to other cereals. Complete feed mixes for animals as well as feed must be hygienically safe and completely in accordance with the requirements of the Regulations on the quality of feed (2010). Before the drying and storing of corn, significant amounts of broken kernels are separated. Broken kernels are susceptible to contamination of molds that produce aflatoxin, which have a negative impact on growth and development of animals. In case microbiologically contaminated corn is used as a component of feed hygienically incorrect mixture that is a major threat to animal health is obtained.

Improvement of hygienic, nutritional, physical and chemical characteristics and viability of corn broken kernels can be achieved by extrusion process. This procedure contributes to: increased nutritive value of some nutrients, improved sensory properties (increased "sweetness" in the processed corn), microbiologically safe products (Jansen, 1991; Verheul, 1997) but also may inactivate possibly present thermo labile antinutrients. Extrusion is a heat treatment that includes high temperature/short time (HT/ST) principle of extrusion cooking, i.e. process in which the material is short time exposed to the high temperatures (Filipovic et al., 2004).
In this paper the technological parameters for extrusion process, physical-chemical characteristics and microbiology of broken corn kernels before and after extrusion are presented.

MATERIAL AND METHODS

Broken corn kernels, separated in the process of corn cleaning prior to artificial drying are used in the experiment. Before extrusion, moisture content of material should be adjusted to approximately 18%. That is a prerequisite for controlled extrusion temperature regime (Filipovic et al., 2008). Before extrusion corn broken kernels are grinded in a hammer mill with screen openings Ø4mm and moisture content was 18,74%. Extrusion is performed on the extruder with three heating segments, capacity of 150-170 kg/h extrudates. Installed electric power of extruder is 22 kW. Extrusion is performed at a temperature of 90°C. Extruded broken corn kernels are cooled in the vertical cooler in the intensive air stream generated by the fan.
The basic chemical composition (moisture, crude protein, crude fiber, crude fat and ash) and starch content in the starting raw materials and extrudates are determined by the methods of the Regulations on sampling methods and methods of physical, chemical and microbiological analysis of animal feed (1987). Total sugar content was determined by the Regulations on the physical and chemical methods of analysis for quality control of grain, milling and bakery products, pasta and deep frozen doughs (1988).
The total number of microorganisms is determined by the method of BS EN ISO 4833:2008, *Coagulase positive staphylococci* by method EN ISO 6888-1:2008, *Clostridium perfringens* by BS EN ISO 7937:2008, *Salmonella* spp by method EN ISO 6579:2008, the total number of yeasts and molds by method ISO 21527-2 and *Sulphite-reducing clostridia* by 15213:2003 ISO method.

RESULTS AND DISCUSSION

Chemical composition of broken corn kernels prior and after extrusion is presented in Table 1.

Table 1. Chemical compositin of broken corn and extruded broken corn kernels

Quality parameters	Broken corn kernels		Extruded broken corn kernels	
	% in sample	% in DM*	% in sample	% in DM*
Moisture content	18,74	-	14,45	-
Crude protein content	7,40	9,11	7,48	8,74
Fat content	3,37	4,15	2,76	3,23
Crude celullose content	3,17	3,90	2,62	3,06
Ash content	1,58	1,94	1,57	1,84
Starch content	61,17	75,28	61,19	71,53
Total sugar content	2,16	2,66	5,18	6,05

*DM-dry matter

Energy feed is produced by extrusion of broken corn kernels. Extrusion process significantly reduces the moisture content of tempered raw material (from 18.74% to 14.45%), which is

very important in terms of storage and keeping quality of extrudates. This fact is confirmed by the earlier results of Filipovic et al. (2005) and Filipovic et al. (2008).
In the extrusion process essential changes are occurring in starch complex, which is manifested in the increase of total sugars (from 2.66% in the d.m. 6.06%), reduction of starch content (from 75.28% to 71.52% d.m.) parallel to significant change in organoleptic properties. Extrusion process leads to changes in the carbohydrate complex of corn, i.e. decrease in starch content due to its degradation to dextrins and the total sugars increase. These changes bring about an increase *in vitro* and *in vivo* digestibility of starch, since starch gelatinization provides increased availability of enzymes to starch, and parallel to the above, leads to inactivation of the amylase inhibitor. Related to crude protein and minerals in broken corn kernels prior and after extrusion changes in the quantity are not registered. Similar conclusions are met by Kormanjoš et al. (2007) in studies on the impact of extrusion on hygiene of enriched corn meal. Table 2 presents the results of microbiology of broken corn kernels prior and after extrusion

Table 2. Content of microorganisms in the broken corn kernels prior and after extrusion

Microorganism	Broken corn kernels	Extruded broken corn kernels
Total number of microorganisms	270 000 cfu/g	12 000 cfu/g
Coagulase positive staphylococci	< 100 cfu/g	< 100 cfu/g
Clostridium perfringens	< 10 cfu/g	< 10 cfu/g
Salmonella spp	not detected in 50 g	not detected in 50 g
Total number of yeasts and molds	540 000 cfu/g	10 000 cfu/g
Sulphite-reducing clostridia	< 10 cfu/g	< 10 cfu/g

Due to the increased total number of yeasts and molds (540 000 cfu/g) broken corn kernels do not meet the requirements of the Regulations on the quality of feed (2010). Extruded broken corn kernels in relation to the starting raw material have significantly reduced total number of yeasts and molds (10 000 cfu/g) as well as total count of bacterial (12 000 cfu/g). This reduction was confirmed by Kormanjoš et al. (2008), in the process of corn grain extrusion. According to the Regulations on the quality of feed, broken kernels after extrusion are hygienically safe and can be used as a component in the preparation either complete or complementary animal feed.
Despite a relatively low temperature (90ºC)and a very short time (6-10 sec) of extrusion process, it is positively contributing to the reduction of microorganisms. Very high pressure of extrusion ranging from 30-40 bar, may explain the reduction total number of microorganisms.

CONCLUSIONS

- ✓ Extruded broken corn kernels is highly valuable energy feed that can be used for the preparation of animal feed
- ✓ In the extrusion process of major changes are occurring in starch complex. Increases the total sugar content in the extrudate is leading to the reduction in starch content.
- ✓ The process of broken corn kernels extrusion contributes to the reduction in the number of microorganisms thus providing a hygiene safe nutrient with long shelf-life.

ABSTRACT: Feed monitoring for the presence of ingredients of animal origin is performed in order to prevent transmissible spongiform encephalopathies. When it was found that the source of infection was feed, i.e. infectious ruminant protein processed in meat and bone meal (MBM), legislation which prevented these nutrients to enter a food chain was introduced all around Europe. Today in Serbia, as well as in EU, usage of MBM is completely banned for all farm animals. But, until 2011 presence of these nutrients had been officially banned just in the diets for ruminants. Such a partial limitation in Serbia was the reason for more frequent cross contamination of feed for ruminants with prohibited ingredients. Therefore, feed producers were obligated to separate lines for feed for ruminants, or otherwise, not to use MBM and fish meal. Control of such regulations has been carried out by laboratory testing of feed for ruminants, as well as feed for pigs and poultry, for the presence of constituents of animal origin by classical microscopy (Regulation (EC) No 152/2009 Annex VI). The most examined was feed for different categories of cattle. During year 2010 among 162 of these feed samples it was found 3.09% of positives, while the result for 2011 (1.85%) represents an improvement. Comparing the latest results to those from previous years we can conclude that better compliance to European standards is obvious in Serbian feed industry.
Key words: *feed, MBM, microscopy*

INTRODUCTION

After bovine spongiform encephalopathy (BSE) was first diagnosed, it was soon determined that this disease was transmitted through feed, i.e. through infectious ruminant protein processed in meat and bone meal (MBM). Eradication process had immediately started and one of the most important measures was the establishment of legislation which prevented these nutrients to enter the food chain (WHO, 2002).

In the European Union, according to Regulation 999/2001 and Regulation 1234/2003, use of processed animal proteins, including different types of MBM, is prohibited for all farm animals entering the food chain, excluding fish meal for nonruminants. Such a measure was taken in accordance to the fact that these nutrients represent a potential source of infection not only for animals, but also indirectly, through food of animal origin, for the people. Due to this strict approach epizootiological situation today is much better in Europe what shows that applied "BSE management" was mostly successful (Paisley et al., 2008).

Control system in Serbia, compared with the European Union, was more complex, due to the differences in legislation and applied preventive measures. In 2001 (Pravilnik, Sl.list 38/2001) feedstuffs of animal origin for the first time were officially banned in the diet for ruminants, but their presence was still allowed in the mixtures for monogastric animals. Identical measures were also prescribed by next Regulation (Pravilnik, Sl. glasnik 4/2010) which came into force in May 2010. However, as a final step in approaching EU legislation, the latest Regulation which came into force in April 2011 brought to Serbia identical feed ban as in the EU countries (Pravilnik, Sl. glasnik 96/2010).

Previous partial restriction on the use of feedstuffs of animal origin, on the one hand reduced the negative economic consequences of their complete elimination and kept all the benefits of these nutrients to animal production and performances, but on the other hand, the possibility of cross contamination of feed intended for ruminants by prohibited ingredients, coming from feed for monogastric animals, was largely opened. For this reason, feed manufacturers were obligated by the Veterinary law Art. 110 (Zakon o veterinarstvu, Sl.

glasnik 91/05) to separate the special line for the production of feed for ruminants, or otherwise, to eliminate animal feedstuffs from all rations completely. Control of these conditions was carried out as part of a special program of the Veterinary Directorate and in accordance to Directive for preventing, detecting and eradication of transmissible spongiform encephalopathies (Naredba, Sl. glasnik 17/2006). The laboratory testing of feed for different animal species for the presence of constituents of animal origin (MBM and fish meal) has been done by conventional microscopy according to the official EU procedure.
The aim of this study was to compare the results obtained over the last two years, especially bearing in mind the change in regulation that occurred last year. From this point it is necessary to assess the effectiveness of new measures.

MATERIAL AND METHODS

In order to assess the success of applied regulations, we compared the results of microscopic analysis of 251 feed samples for cattle, sheep, goats, pigs and poultry in 2010 and 310 samples in 2011. All examinations for the presence of ingredients of animal origin were carried out using conventional microscopy, ISO 17025 accredited method in the Institute of Veterinary Medicine of Serbia, which was applied in accordance to Regulation (EC) No 152/2009 of 27 January 2009 laying down the methods of sampling and analysis for the official control of feed, Annex VI.

RESULTS AND DISCUSSION

During 2010 total of 251 samples of feed mixtures for different animal species were tested by classical microscopy. Most of them were feed samples for cattle - 162 in total. Among them 3.09% were found positive for the presence of particles of animal origin (MBM or fish meal), what made them unusable as intended, because they did not correspond to Article 51 of the Regulation for the quality of animal feed (Pravilnik, Sl. glasnik, 4/2010), as well as to the Regulation on the establishment of measures for early detection and diagnosis of infectious diseases transmissible spongiform encephalopathies, methods of their implementation, as well as measures to prevent the spread, prevention and eradication of infectious diseases (Pravilnik, Sl. glasnik 96/2010).

Table 1. Results of microscopy testing in 2010

	cattle	sheep	goats	pigs and poultry
TOTAL	162	8	6	75
Negatives	157	8	5	69
Positives	5	0	1	6
% of positives	3.09	0	16.67	8

Feed samples for sheep did not contain any constituents of animal origin, while one among six samples of mixtures for goats was contaminated. Feed for pigs and poultry was fortified mostly with fish meal and percentage of such samples averaged around 8%.
Total of 310 feed samples for cattle, sheep, goats, pigs and poultry were examined in 2011. Among 162 samples of feed for cattle only 3 positive cases were found, what was significantly lower percentage – 1.85% comparing to previous year. No contamination was detected in feed for other ruminants, while presence of feedingstuffs of animal origin in mixtures for pigs and poultry was at the similar level – 8.33% and also mainly derived from fish.

Table 2. Results of microscopy testing in 2011

	cattle	sheep	goats	pigs and poultry
TOTAL	162	15	1	132
Negatives	159	15	1	121
Positives	3	0	0	11
% of positives	1.85	0	0	8.33

Comparing the results of monitoring of mixtures for different categories of the most common animal species bred in Serbia, obtained during the period 2010 - 2011, a significant improvement in the presence of prohibited components of animal origin could be observed (Table 1 and 2). Actually, the lowest percentage of positive samples in feed for all ruminants was found in 2011, while presence of animal particles in samples for monogastric animals stayed at the similar level and still corresponded to regulations, as those were usually fish meal ingredients. Such downward trend is expected to continue also during this year, especially having on mind that new regulation, which brought complete MBM ban for all farm animals in Serbia, came into the force in April 2011. That means that risk of cross contamination has become extremely reduced since that time.
Such a favorable situation and the obvious improvement can be interpreted as a consequence of successful harmonization with EU legislation by introducing several new regulations in Serbia: Veterinary Law (Zakon o veterinarstvu, Sl. glasnik RS 91/05) and the Law on Food Safety (Zakon o bezbednosti hrane, Sl. glasnik RS 41/09), as well as a number of other regulations which contribute to better control and progress in the food and feed industry. This also proves the success of BSE risk management which has been established in the EU and confirms positive results of European steps that we follow (Paisley et al., 2008).

CONCLUSIONS

Based on the results of microscopic examination of feed for cattle, sheep, goats, pigs and poultry for the presence of constituents of animal origin it could be concluded that in recent years there has been a general improvement of the production quality in our feed industry. In many cases the highest European standards have been applied, what makes our manufacturers competitive on foreign markets. On the other hand, laboratory analysts and other professionals close to those profiles, by better future engagement and pragmatic cooperation in this area, can contribute to further progress in the safe food production.

ACKNOWLEDGEMENTS

This paper has been published thanks to project III 46009 “Improvement and development of hygienic and technological processes in the production of food of animal origin in order to obtain high-quality and safe products competitive on world markets“ financed by the Ministry of Education and Science of Republic of Serbia.

ABSTRACT: Aspergillosis is frequent fungal disease of different avian and mammal species, caused by fungi of genus *Aspergillus*. The disease is characterized by inflammatory changes in the respiratory system and sometimes has generalized onset when more organ systems are affected. These fungi are well known aflatoxin producers which, besides other microorganisms, can also be found in feed raw materials. However, the presence of fungi is not a proof of mycotoxins contamination, because they are produced in specific conditions. In this paper are presented results of examination of a flock of turkey poults, 21 days old, at one farm in Serbia. Clinical signs of central nervous system disorder were observed. After necropsy, in ten out of twelve necropsied turkey poults multiple yellowish-white granulomas on lungs were found. In nine out of twelve necropsied turkey poults solitary yellowish-white granuloma on sagital section of the cerebrum or cerebellum were found. Mycological finding revealed fungi *Aspergillus fumigatus*. Two stain methods were used: haematoxylin-eosin (HE) and Grocott methenamine silver (GMS). Histopathological analysys of lung and brain has revealed the presence of granulomatous foci and caseous necrosis with surrounding region of proliferation including giant cells, macrophages, heterophils and lymphocytes and outer capsule of connective tissue. The fungal hyphae were hardly visible or not in HE stained sections, while septed and arborized hyphae were easily demonstrated by GMS method predominantly in central parts of granuloma. Mycological examination of feed showed the presence of *Aspergillus fumigatus and Aspergillus flavus*, as well as ELISA detectable level of aflatoxins (3.00 µg/kg).
Key words: *Aspergillus, aflatoxin, turkey poults, granuloma*

INTRODUCTION

Aspergillosis is frequent, economically important, fungal disease of different avian and mammal species caused by fungi of the genus *Aspergillus*. The disease is characterized by inflammatory changes in the respiratory system and sometimes has generalized onset when more organ systems are affected. Clinical signs of aspergillosis depend upon which organ or system organ are involved and whether infection is localized or generalized. Pathomorphological substrate of this disease is mycotic granuloma (*aspergiloma*) which is commonly found in lungs and air sacs. Numerous reports have described encephalitic or meningoencephalitic aspergillosis in turkey poults, ducklings and chickens (Knežević and Matejić, 1996; Ivetić et al., 2003; Ozmen and Dorrestein, 2004; Saif, 2008; Singh et al., 2009, Kureljušić et al., 2011). For diagnostic of mycotic infection is necessary to use more methods included clinical examination of flock, macroscopic examination of carcasses, isolation of pathogens, as well as histochemical methods for detection tissue lesions and fungal elements. Histochemical methods which can be used are routine hematoxylin-eosin staining method, periodic acid-Schiff (PAS) and specific staining method for fungi Grocott methenamine silver method (GMS) (Ozmen and Dorrestein, 2004).

Although detrimental effects of mouldy food and feed have been well known for a long time, *Aspergillus* fungi and their metabolites called aflatoxins were not determined until the 1960's. A few hundred mycotoxins have been identified so far, but only a fraction of these are considered harmful to humans (Riley, 1998). Additionally, 20-30 mycotoxins have medical, nutritional, ecological and economic significance, due to their incidence and toxicity,.

According to the target tissue aflatoxins are hepatotoxins which represent a mixture of several chemical substances. They are heterocyclic secondary metabolites of *Aspergillus* fungi. Their synthesis depends on environmental conditions in which fungi grow, but their production is also dependant on the fungus strain (Pasteiner, 1998). Although it is well known that aflatoxins are metabolites of *Aspergillus flavus, Aspergillus parasiticus* and more recently *Aspergillus nomius* (Rodrigues et al., 2007), there are certain strains of these fungi which are not toxin producers at all. Fungi produce aflatoxins in conditions of high moisture content, temperature and adequate substrate. Synthesis is highest when humidity is above 13% and temperature is between 24^{o}C and 37^{o}C. That is why warm and wet geographic regions are the most favorable environments for aflatoxins. *Aspergillus flavus* is the main producer of the well known carcinogenic aflatoxins. It is a fungus widely spread in nature which can be found in different cereals and many other feedingstuffs. It is particularly typical for peanut which is infested underground, especially in tropical and subtropical regions.
According to its frequency of occurrence and its toxicity aflatoxin B_1 is the most important among all in the group (Beuchat, 1987). Aflatoxicosis is manifested by different pathomorphological changes, especially in the liver, but also in kidneys, cardiovascular and nervous system. Moreover, it exerts detrimental effects on performances, primarily in broiler and layer production, but also in swine breeding and all other modes of animal husbandry. Residues can be found in the liver, muscles, guts, kidneys and fatty tissue, as well as in meat, milk and eggs of animals which ingested contaminated feed (Resanović and Sinovec, 2005).
Besides clinical and patomorphological manifestation of aspergillosis in turkey poults, this paper also presents results of mycological and mycotoxicological examination of feed which, as well known, is very often contaminated with moulds.

MATERIAL AND METHODS

In this paper, we examined the carcasses of 12 turkey poults, three weeks old which originated from one farm in Serbia. The mortality rate in the flock was 7,2%. Clinical examination of the flock revealed moderate depression of many turkey poults and nervous symptoms which were expressed in the form of ataxia, torticollis, paresis and paralysis of legs and wings were observed. Food consumption was reduced leading to reduced weight gain. After necropsy, for histopathological and mycological examination samples of lung and brain tissue were taken. Samples for histopathological analysys were fixed in 10% buffered formalin, routinely processed and embedded in paraffin blocks. Paraffin sections about 5 μm were stained with hematoxylin-eosin (HE) and Grocott methenamine silver (GMS) methods. Samples for mycological examination were inoculated onto *Sabouraud dextrose agar* and incubated at temperature of 25^{o}C under aerobic conditions for isolation of infectious agents. To avoid bacterial contamination in the substrate was added 20 IU/ml penicillin G and 40 mg/ml streptomycin sulfate. Macroscopic and microscopic examination of colonies were performed according to Quinn et al. (2002). Samples of feed and litter were also taken for mycological analysys.
Mycological analyses of feed samples were done with the aim to identify the level of contamination with fungi of *Aspergillus* genus and also to detect the presence and level of contamination with their metabolites aflatoxins.
Samples were tested in accordance to ISO 21527-2:2008 procedure. Presence of aflatoxins was detected using ELISA method as directed in the instructions of commercial kit (Neogen). Results were compared and interpreted according to the national regulations (Pravilnik, Sl. glasnik RS, br. 4/2010).

RESULTS AND DISCUSSION

External examination of turkey poults carcasses indicates less feathering of the skin especially in the region of chest. In ten out of twelve necropsied turkey poults granulomatous pneumonia with multiple yellowish-white granulomas, one to three millimeters in diameter on lungs were found. In two out of twelve cases granulomas were found on the cranial part of the cerebrum, and in one case granuloma was situated on central part of cerebellum. Granulomas were solitary, yellowish-white in colour, three to five millimeters in diameter, and on sagital section of the cerebrum or cerebellum were found (Figure 1).

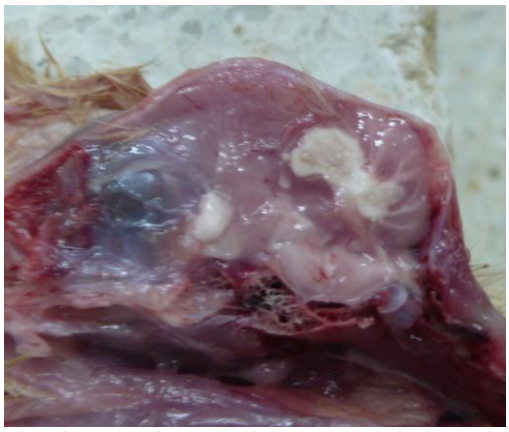

Figure 1. Brain of turkey poult, granuloma on sagital section of cerebellum

Data from litarature indicate that aspergilous granulomas (aspergilomas) usually occur in the lungs and air sacs although there are data on the occurrence of aspergilomas in the cerebellum, just for turkey poults (Schulz, 1991; Ozmen and Dorrestein, 2004; Saif 2008, Kureljušić et all, 2011). Interestingly, the granulomas occur either in cerebrum or the cerebellum (Saif, 2008), which is confirmed in this case. Rarely, aspergillomas occur simultaneously in both parts of brain (Saif, 2008). In addition to this finding, in all necropsied turkey poults hyperemia of brain blood vessels were found. In other organs there were no macroscopically visible changes.

Mycological finding revealed fungi *Aspergillus fumigatus*. Growth in the medium was observed after 24 hours, and after four days, grown colonies were white and about 2 cm in diameter. By the seventh day the colony diameter increased to 3.5 cm, and there was a color change in the central part of the colonies from blue-green to the gray-green, while the edges remained white (Figure 2). Based on macroscopic and microscopic characteristics of colonies, the culture was identified as *Aspergillus fumigatus.*

Figure 2. Growth of Aspergillus fumigatus on *Sabouraud dextrose agar*

For the evaluation of histopathological changes and demonstration of fungal hyphae, two stain methods were used: haematoxylin-eosin (HE) and Grocott methenamine silver method.

Histological finding in the lung and in the brain was the same. Granulomatous reactions with central caseous necrosis were observed in the HE stained slides. There was surrounding region of proliferation including giant cells, macrophages, heterophils and lymphocytes and outer capsule of connective tissue (Figure 3, Figure 4).

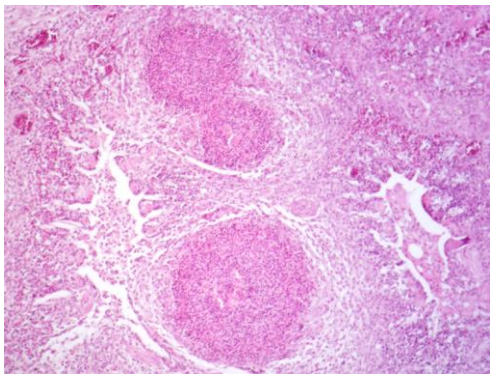

Figure 3. Lung, turkey poult, multifocal granulomatous pneumonia, HE, X200

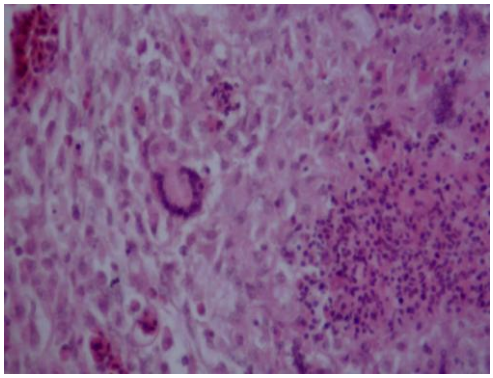

Figure 4. Lung, turkey poult, infiltrate of granuloma consist of giant cells, macrophages, heterophils and lymphocytes, HE, X400

The fungal hyphae were hardly visible or not in HE slides, while septed and arborized hyphae were easily demonstrated in all samples stained by Grocott methenamine silver method predominantly in central parts of granuloma (Figure 5).

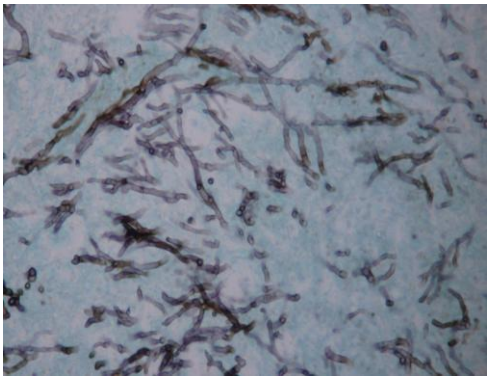

Figure 5. Brain, turkey poult, arborized and septed hyphae, GMS, X400

In some cases, in the sections of brain and lung stained by HE method, granulomatous changes were characterized only by presence of smaller or larger number of necrotic foci, which are infiltrated with macrophages, giant cells and heterophil granulocytes. These changes are described in the literature as early initial lesions (Jensen et al., 1997). In three out of twelve cases in HE stained sections fungal hyphae were not apparent. Grocott methenamine silver method in all twelve cases revealed septed and arborized hyphae.

Grocott methenamine silver method is described in the literature as a very reliable method for direct visualization of the different fungal elements in tissues (Ozmen and Dorrestein, 2004; Singh et al., 2009).
Mycological examination of feed showed the presence of *Aspergillus fumigatus and A. flavus*, as well as certain level of aflatoxin - 3.00 µg/kg. Although this level did not exceed limit layed by actual legislation, having on mind cumulative effects and possibal chronical exposure to the harmful influence, as well as indirect loses due to drop of performances and production and occurence of secondary infections, even such amounts must not be neglected. Mycological analysys of litter revealed also *Aspergillus fumigatus*. It is known from literature that contaminated litter and feed are often the source of *Aspergillus fumigatus* (Saif 2008).

CONCLUSIONS

Microscopic finding of typical mycotic granulomas in the lung and brain with central caseous necrosis and fungal hyphae surrounded by macrophages, giant cells, lymphocytes, heterophils and capsule of connective tissue pointed to aspergillosis. For diagnostic of mycotic infection is necessary to use more methods included clinical examination of flock, macroscopic examination of carcasses, isolation of pathogens, as well as histochemical methods for detection tissue lesions and fungal elements. Beside aspergillosis in turkey poults, in this case *Aspergillus fumigatus and A. flavus*, as well as certain level of aflatoxin - 3.00 µg/kg were confirmed in the feed. However, in the case of lower levels of mycotoxins still remains the risk of rigid interpretation of the regulations, as it is well known that the use of feed with low content of mycotoxins in the longer time period shows similar effects as short-term use of feed with higher amount of mycotoxins. The problem is getting more complicated as the interaction of mycotoxins present in feed increases harmful effects. Therefore, the assessment of utilization of feed should be depend on the institutions and experts that deal with this problem as one of the special scientific and professional activities. Also, on the basis of everything above, it can be concluded that solving these problems requires a multidisciplinary team approach.

IMPORTANCE OF ZOOPLANKTON AS LIVE FEED FOR CARP LARVAE

ABSTRACT: Zooplankton is a very important source of natural food for larvae of many aquaculture species. In semi-intensive systems, which are the dominant type of carp production, many fish species feed on both zooplankton and zoobenthos as adults, while larvae and fry rely mostly on zooplankton. It provides them with high quality nutrients and other molecules such as proteolitic enzymes, hormones and growth factors, which support digestive processes in immature larval gut.
Larviculture, especially start feeding of early larval stages, appear to be a critical point in fish culturing. However, artificial diets formulated for larvae show poor digestibility. Use of live feed of small dimensions, good nutritive characteristics and locomotion that provides visual stimulus, overcome that problem. Zooplankters commonly used for mass production as live feed for fish larvae are Rotifers (*Brachionus plicatilis* and *B. calyciflorus*) and brine shrimp (*Artemia salina*).
Shortly after hatching, carp larvae are transferred to nursing ponds for further rearing. Ponds are previously prepared through agrotechnical measures in order to provide nutrient enrichment and stimulate production. During the first days of exogenous feeding, larvae consume only the smallest zooplankters such as Rotifers and naupliar larvae of Copepods, while later they move on to bigger pray as Cladocerans.
However, due to variable environmental conditions, predation, competition or infections in earthen ponds, mortality in nursing ponds is often very high, reaching over 90%. Thereby, modern approach suggests rearing in indoor tanks in controlled systems and use of automatic feeding systems to provide precise portions of zooplankton.
Key words*: zooplankton, larviculture, semi-intensive system*

INTRODUCTION

Zooplankton is an important component of nutrition and protein source for both larvae and adults of many aquaculture species cultured in all three main types of production systems: extensive, semi-intensive and intensive. As live feed, they have crucial role in nutrition of early life stages of many fish species particularly for first exogenous feeding, but also play an important role as natural food for juveniles, adults and marketable size fish.
Main groups of zooplankters that may be found in earthen carp ponds are Protozoans, Rotifers and two groups of Crustaceans: Copepods and Cladocerans. In older ponds, they develop partly from egg bank stored in top layers of the sediment, and partly arrive through water bodies used for water supply (Dulic et al. 2011). Zooplankton dynamics depends on primary production of phytoplankton, that is determined by nutrient content in pond waterbody, in particular phosphorous and nitrogen. Nutrients derive from various sources – surface and underground waters, pond sediment, biochemical processes in water bodies, but also agrotechnical measures applied in earthen carp ponds. (Vollenweider 1968, Biro 1995). Larger zooplankters, cladocerans and copepods, show pronounced seasonality in abundance throughout the year, with maximum development during spring and early summer. In midsummer, when environmental conditions in fish ponds are optimal for carp growth, there is usually a decline in zooplankton abundance that develops strong need for added feed in order to maintain maximal growth of cultured fish (Dulic 2007, Dulic et al. 2009).
Zooplankton represents a high-quality food for fish larvae regarding its nutritive content. It provides them with high quality proteins, amino acids, lipids, fatty acids, vitamins, minerals and enzymes (Kibria et al. 1997) but also proteolitic enzymes, hormones or their regulators

and some nutritional growth factors which support and enhance digestive processes in immature larval gut. Biochemical composition and therefore nutritive quality of zooplanktonic organisms are genetically determined, but also influenced by their origin, life stage, season and type of ingested food (Mitra et al. 2007).
In aquaculture production, start feeding of early larval stages appears to be the most critical point. Some fish species, such as salmonids, have structurally and functionally fully developed digestive system before switching from endogenous to exogenous feeding, which enables them to digest complex molecules in artificial feed (Dabrowski 1984, Lavens and Sergeoloos 1996). Those species pose less of a problem with initial feeding, but many other species, common carp being one of them, have immature alimentary tract at larval stage. They are able to digest only very simple food particles at first feeding and require live planktonic organisms as first food (Garcia-Ortega et al. 1998). Although a lot of effort has been put in formulating artificial feed for larval stages and encouraging results have been obtained, live feed is still accepted as most suitable feed for most aquaculture species, which provides better growth and survival of early larval stages (Mitra et al. 2007, Sales 2011).
During last two decades, many reaserch have been done on developing alternative feed, mostly as microparticulate diets (MPD), but more investigations are needed to develop the right formulation which will provide results as good as live feed (Callan et al. 2003, Lazo et al. 2000).

LARVICULTURE AND PRODUCTION OF LIVE FEED

During first few days of early life, carp larvae feed on egg sac content. After absorption of yolk, before total depletion of egg sac, they start feeding exogenously. During first ted days larvae consume small zooplankters such as Rotifers and naupliar larvae of Copepods. After that time, they shift to consume bigger pray, as Cladocerans or zoobenthic organisms. Upon one month of age, carp juveniles show strong dietary preference for Cladocerans (Billard 1999), which also dominate in nutrition of older juveniles and adults, along with benthic fauna (mainly Chironomids and Oligochaeta), aquatic plants and some phytoplankton groups (Sakia and Das 2009).
In semi-intensive production systems, carp larvae are usually transferred to outdoor nursing ponds shortly after hatching. The size of the ponds may vary, depending on the time of rearing (usually from 3 to 6 weeks), prior transferring the fry into growing ponds for further culturing to marketable size. In order to provide optimal rearing conditions, ponds are previously prepared through application of different agrotechnical measures. Drying of the ponds, sunlight exposure and disinfection eliminate pathogens and prevent disease outburst, while fertilization with organic manures provide nutrient enrichment and stimulate production. (Markovic 2010). By use of insecticides, larger Copepods and Cladocerans may be removed from the ponds, thereby stimulating growth of small zooplankters preferred during first feeding of carp larvae.
Under natural conditions, effects of external factors plays dominant role in larval culturing. Due to variable environmental conditions, predation by frogs, birds or large insects, competition or infections in earthen nursing ponds, mortality often reaches as high as 90%. Therefore, intensive production system under controlled conditions is considered to be much more efficient in larviculture of carp. Indoor rearing in tanks, based on cultured zooplankters as live feed, provides reduction of losses, better growth and survival rate (Yoav et al. 2007). In closed systems, when external culture conditions are maintained within optimal range, larval performance at the initial feeding is mainly affected by husbandry practices - food, digestion and rearing density (Sharma and Chakrabarti 1999). Beside enhanced fingerling production, indoor rearing allows off-season seed production for better use of growing season and economical efficiency. During past decades, following enhancement of intensive production methods, using cultured live food, larvae production has rapidly increased (Barr et al. 2007).
Production and culturing of live feed is reported to be relatively easy (Lavens and Sorgeloos 1996, Moretti et al. 1999). The only zooplankters commonly produced in mass quantities are

two species of rotifers (*Brachionus plicatilis* and *B. calyciflorus*) and brine shrimp (*Artemia salina*). Rotifers are widely used as first feed for marine fish larvae and may be cultured and harvested in automated systems at high densities (Hagiwara et al. 2001). Freshly hatched *Artemia* nauplii are generally used as alternative to natural zooplankton in intensive carp larviculture, but costs of their production may be very high, reaching up to 79% of total expenses in larviculture (Kolkovski 2001, Stankovic et al. 2011). Rising costs of *Artemia* cysts of high hatching quality has put more focus on developing alternatives, as use of decapsulated cysts as direct food or pond grown zooplankton for live feed in hatcheries in different regions (Vanhaecke et al. 1990, Evjemo et al. 2003). When maintained on organic manures in ponds or tanks, production costs for live feed may be significantly decreased. Wastewaters or possibly effluents from fish ponds may also be used for zooplankton culture, providing low-cost production system and decreasing environmental pollution from aquaculture (Kibria et al. 1999).

LARVAL NUTRITION AND FIRST FEEDING

Processes of digestion, absorption and assimilation as well as nutritional requirements of fish differ significantly among life stages. After hatching, digestive system of carp larvae is still immature and developing, represented by histologically undifferentiated straight tube, supplied with few active enzymes able to digest only very simple food particles (Dabrowski 1984). Each enzyme develop independently during ontogenesis, and show relatively lower activity at early stages compared to adults. In such species, when digestive system is not fully functional at first feeding, transition to external food is more difficult and usually require live feed as part of their diet (NRC 1993). Poor digestion of artificial diets with complex molecules of proteins, carbohydrates and other nutritional components, shown at this life stage, is partly caused by low affinity of proteolitic enzymes for the proteins present in formulated diets, but also absence of some enzymes, hormones or their regulators, and growth factors that are naturally present in live feed (Dabrowski 1984, Lauff and Hofer 1984). Proteolitic activity of the carp larvae depends on the developmental stage and nature of food (Sharma and Chakrabarti 1999). Through consumption of zooplankton, carp larvae are not only supplied with their enzymes (proteinases, peptidases, amylases, lipases) and other molecules that enhance digestion processes, but also activation of zymogens present in undeveloped digestive tract takes place. Protein and lipid fractions extracted from live feed may serve as precursors or activators in assimilation processes. Furthermore, high water content makes zooplankters easily digestible, unlike artificial feed with 60 to 90 percent of dry matter (Kolkovski 2001).

The size of the mouth gape determines dimensions of feed particle that fish larvae may consume. This variable is correlated to body size, egg diameter and duration of endogenous feeding. Carp larvae have small yolk sac which is usually absorbed in 3 to 5 days after hatching. At first exogenous feeding they can only consume particles lower than 0,5 mm (Dabrowski and Bardega 1984), weighing daily 50 to 300 percent of their body weight, compared to 2 to 10 percent of body weight for adults (NRC 1993). Small dimensions of cultured zooplankters (50 to 200 µm for *Brachionus* sp. and 400 to 550 µm for *Artemia salina*), their nutritive characteristics, digestibility and constant locomotion, that provides a visual stimulus, puts live feed ahead of inert compound diets for first feeding of carp larvae (Rønnestad et al. 1999, Kolkovski 2001).

Different sources of zooplankton, according to culture conditions and their geographical origin, may have variable nutritional quality, mostly related to fatty acid composition (Dabrowski 1984, Watanabe et al. 1983). In freshwater zooplankton, lipid content is influenced by seasonal dynamics and succession of phytoplankton species and may significantly differ between populations (Jeffries 1970). Fatty acid content and amount present in live food strongly affect growth and survival of fish larvae, which are very sensitive to deficiency of (n-3) PUFA, polyunsaturated fatty acid (Watanabe et al. 1983, NRC 1993). Therefore, enrichment of zooplankton organisms with fatty acids through special nutrition or by using lipid suspensions, in some cases may be necessary to compensate for differences

between natural and cultured live feeds, in order to provide quality production of larvae and juveniles (NRC 1993, Yoav et al. 2007).

CONCLUSION

A lot of research has been done on formulating artificial feed for first feeding of fish larvae. These attempts consider not only the right combination of ingredients and their digestibility, but also ontogenetic development of digestive system and enzyme activation (Kolkovski 2001). However, dietary needs of growing larvae differ significantly from those of adult fish. Use of artificial feed in early life stages often leads to stunted growth and high mortality, while use of live feed still provides much better performance of larvae of many aquaculture species, including common carp. Both frozen and freeze-dried zooplankton represent an excellent food source for hatchlings of many species which normally require live plankton for growth. Their nutritional quality fulfill the needs of young larvae and contribute to digestion and absorption processes resulting in better growth and survival rate then when fed on artificial feed alone.

ABSTRACT: A 60 days test on 90 Lohmann Brown layers aged 40 weeks was conducted to evaluate the effect of the dietary Camelina meal on layer performance. The hens was housed in cages (3 layers/cage) and assigned to three groups (C, E1 and E2). Feeding was ad libitum with one meal per day. The control diet (C) had as basal structure: corn (57.47%), soybean meal (15%), corn gluten (4 %) and sunflower meal (9.5%). The experimental diets (E1, E2) were differentiated from C by inclusion of Camelina meal in percentages of 3% (E1) and 6% (E2) respectively. Throughout the experimental period the feed intake, egg production, egg weight and egg quality parameters were recorded on a daily basis. The results show that the feed conversion ratio (g feed/g egg) of group C (1.908±0.10) was significantly (P≤ 0.05) higher than in E1 (1.883±0.10) and E2 (1.817±0.15). However, egg production of E2 (93.68±2.26%) was significantly (P≤ 0.05) lower than in the other 2 groups (97.22±1.76% for C; 97.99±1.99 for E1). The weight of E2 eggs (64.00±2.31 g/egg) was comparable with the weight of C eggs (64.61±2.48).
Key words: *layers, Camelina, meal, intakes, egg*

INTRODUCTION

Camelina sativa is an oil seed crops in the Brassica family (Cruciferae) with mustard, cabbage, rapeseed, broccoli, turnips, Brussels sprouts, cauliflower that has an oil content of approximately 40% (Cherian and col. 2009). Is known as "false flax" or "gold of pleasure". Originally from Northern Europe and Central Asia. Camelina (Camelina sativa) is considered a low-input culture requiring small amounts of water and reduced fertility compared to other species of nuts (Putnam et al., 1993). Can be used as a rotation crop for wheat. The plant has gained popularity in recent years due to the discovery that camelina oil can be used as biofuel for aircraft industry.

Camelina meal as an animal feed additive has been studied and was found beneficial in increasing the ω-3 fatty acid content in eggs and the meat quality of laying hens and broiler chickens (Ryhanen et al., 2007, Rokka et al., 2002). Camelina meal is a new byproduct that remains after oil extraction for biodiesel production and might be considered as an alternative to flaxseed for poultry nutrition as an n-3 fatty acid source because of the residual oil (Zubr, 1997). If growing camelina becomes a viable crop, the integration of the resultant meal into local diets would further increase the value of the crop. Camelina meal typically contains 10-15% residual oil and 40% crude protein, minerals and 10-12 % crude fiber and has a moderately-low glucosinolate content.

Previous studies (Cherian et al., 2009) on the nutrient composition of camelina meal (a byproduct obtained from camelina seeds after oil extraction) indicated that the meal contains between 35-40% PB, 4688 kcal/kg EB, 11 to 12% fat, α-linolenic acid (n-3) representing 30% of total fatty acids. Omega-3 polyunsaturated fatty acids play an important role in brain function, in growth and body development. It also reduces the risk of heart disease, reduce inflammation and may improve chronic disease risks (heart disease, cancer and arthritis. Some of the symptoms of deficiency of omega-3 are: poor memory, dry skin, heart problems, mood swings and depression, circulatory problems.

Regarding the use of camelina as a forage crop, due to its high content in linolenic acid (20-39%) and being considered a low-input ingredient, camelina began to be regarded as a staple fodder. For inclusion in compound feed as forage plant, seeds, oil, and especially camelina meal can be used. This happened after the Directive 2008/76/EC of 25 July 2008 when camelina was removed from the list of undesirable substances in feed intended for animals kept in intensive system rearing, due to the EFSA opinion (European Food Safety Authority) of November 27, 2007.
In other studies by Cherian and col., (2009), and Aziza al., (2010), Camelina meal was used 10% in laying hens and broilers ratio. These authors reported a significant increase in omega-3 fatty acids in eggs and in the muscle tissues of broiler chickens. In addition to omega-3 polyunsaturated fatty acids, the camelina meal contains other bioactive compounds such as tocopherols and phenolic (Matthäus, 2002, Salminen et al, 2006). This phenolic compounds can help prevent lipid oxidation both in combined fodder and in eggs or meat obtained from birds fed rations high in polyunsaturated fatty acids (McCarthy et al, 2001; Cherian et al. 2002).
Researchers Amy Batal and Nick Dale (2009) have shown that completely new ingredients became available for feed manufacturing industry, so in 2009, has been shown a particular interest concerning camelina meal utilisation. Based on the analyzes performed in laboratories at the University of Georgia, Athènes (USA) on the camelina meal, Batal and Dale (2009) included this variety in *Ingredient Analysis Table: 2010 Edition*.
The aim of the paper is to assess the effect of 3 and 6% Camelina meal addition in laying hens diets, on their bioproductive parameters.

MATERIAL AND METHODS

The experiment was conducted on a total of 90 laying hens, light breed, aged 40 weeks, Lohmann Brown hybrid for a period of 60 days. The animals were divided into 3 groups: control (C) and two experimental (E1, E2), housed in battery structured on three levels allowing to register the daily intake and daily egg production. Experimental hall lighting was provided by a scheme with up to 16 hours daily light and temperature was maintained at 25° C throughout the experimental period. For this experiment, were produced 3 types of feeds: a control variant (CF 21-5) and 2 experimental variants, E1 (with an inclusion rate of 3% of camelina meal) and E2 (with an inclusion rate of 6% of camelina meal). All these types of feeds and raw materials that went into their component analyzes were subjected to determine their chemical composition. Thus, we determined DM, CP, Fat, Fiber, ASH, amino acids, fatty acids according to the ISO methods (The Romanian Standardized Association-ASRO- Standardized Bulletin, 2010): SR ISO 6496/2001; ISO 5983-2/2009; ISO 6492/2001; ISO 6865/2002; ISO 2171/2010; SR ISO 13903/2005; SR ISO/TS 17764-2/2008. Also it were determinated the degradation of fat (index peroxide ml thiosulphate 0.01N / g fat, acidity fat mg KOH / g fat and KREISS reaction) according to STAS 12266-84.
Feeding was done ad libitum in a single allowance / day. Daily amount of feed given was weighed separately for each cage and the fodder left uneaten was also weighted (in the morning). Consumption were recorded daily, health status and egg production. Eggs were weighed daily. Chickens were weighted at the beginning and at the end of the experiment.
During the experiment were collected 4 sets of eggs / batch of 18 samples each, from each lot, for a period of 5 days, every 2 weeks. A number of 3 eggs were used of the 18 samples collected in order to achieve an average sample, resulting in 6 samples / group, from which separate samples of white, yolk and shell were taken. At all harvesting, egg physical parameters were determined: egg weight, yolk weight, weight whites, shell weight, color intensity, degree of freshness, pH yolk and whites and shell thickness, using standard methods for determination. For determination of statistical data of the experimental results regarding zootechnical and eggs quality parameters it has been used STATVIEW soft. All these determinations were made in the Laboratory of Chemistry and Physiology of Nutrition - IBNA Balotesti.

RESULTS AND DISCUSSIONS

To establish the nutrient value of camelina meal used in experimental laying hens feeding, chemical composition and gross energy have been determined alongside the fatty acids concentration (Table 1).

Table 1. Chemical composition and fatty acids concentration of camelina meal

Item	Camelina meal
DM, %	91.0
CP, %	36.47
Fat, %	7.48
Fiber, %	10.84
ASH, %	5.58

Other fatty acids	0.32
Σ SFA	11.13
Σ MUFA	35.73
Σ PUFA	51.73
n-3:n-6	0.949

Where: Σ SFA – total saturated fatty acids;
Σ MUFA – total monounsaturated fatty acids;
Σ PUFA – total polyunsaturated fatty acids.

Camelina meal was found to be rich in linoleic (18:2n-6) and linolenic acid (18:3n-3), and these constituted 24.76 and 23.91%, respectively. Oleic acid (18:1) and eicosenoic acid (20:1) constituted 21.11 and 11.51%, respectively, in the Camelina meal. The n- 3 fatty acid and n-6 fatty acid content of Camelina meal makes it a potentially suitable plant of essential polyunsaturated fatty acid source in poultry diets (Aziza et al., 2010).
Amino acids composition (Table 2) of the camelina meal was determinated. Lysine, methionine, and cystine are usually the first-limiting acids in poultry nutrition, which makes Camelina meal a potential source of protein for poultry (Aziza et al., 2010).

Table 2. Amino acids composition of the camelina meal

Item	Camelina meal g/100 g camelina meal
Aspartic Acid	3.000
Glutamic Acid	6.289

Commercial premix	1	1	1
Total	100,00	100,00	100,00
Analized			
GE (kcal/kg)	3886	3894	3881
DM	89.83	89.71	89.58
CP	20.28	19.38	20.02

Fatty acids concentration is presented in Table 4. Fatty acids C18: 3n-3 is significantly higher in groups E1 and E2 while fatty acids C18: 2n-6 did not differ within the composition of these 3 types of feeds. The high concentration of linolenic acid, especially in combined fodder of E2 variant makes that ratio between fatty acids n-3: n-6 to be significantly better in this group compare to C (0.05) or E1 (0.08). Total PUFA is higher in the experimental rations compared with a control group. In addition to linolenic acid, there are other fatty acids that differentiates, respectively, C18: 4n-3 and C22: 5n-3 all in favor of the experimental variants.

Table 4. Fatty acid concentration of the experimental diets

Fatty Acids	C g % fat sample	E1 g % fat sample	E2 g % fat sample
C18:2n6	44.60	44.37	43.03
C18:3n3	1.71	2.87	4.34
C18:4n3	0.06	0.17	0.26
C20:5n3	0.37	0.33	0.32
C22:5n3	0.12	0.18	0.18
Other fatty acids	53.13	52.08	51.87

Σ MUFA	35.89	32.02	32.3
Σ PUFA	46.86	48.05	48.5
n-3:n-6	0.05	0.08	0.12

Where: Σ SFA – total saturated fatty acids;
Σ MUFA – total monounsaturated fatty acids;
Σ PUFA – total polyunsaturated fatty acids.

Evidence of fat degradation, meaning index peroxide ml thiosulphate 0.01N / g fat (admitted limit 1.2), acidity fat mg KOH / g fat (admitted limit 50) and KREISS reaction (admitted limit - negative) was calculated (Table 5). Recorded value at E2 group (the richest in PUFA, Table 4) for fat acidity was above the allowable. The other parameters of degradation of fat were normal.

Table 5. Fat indices degradation

Index	C	E1	E2
Index peroxide ml thiosulphate 0.01N / g fat	0.58	0.95	0.89
Acidity fat mg KOH / g fat	36.28	48.09	54.71
KREISS reaction	negative	negative	negative

Introduction of camelina meal in poultry diets (3% and 6% in experimental groups), impacted zootechnical parameters (Table 6).

Table 6. Zootechnical parameters obtained, averages / group / experimental period

Item	C	E1	E2
Average Daily Intake *, g/day/hen	123.26±7.52	117.20±6.58	116.27±12.46
Egg production **, %	97.22±1.76	97.99±1.99	93.68±2.26
Egg weight *, g	64.61±2.48	62.36±1.81	64.00±2.31
Feed conversion **, g feed/g egg	1.908±0.10	1.883±0.10	1.817±0.15

**no significant differences among treatment means; **significant differences among treatment means*

Note that the registered laying percentage of the experimental group E2 (6% camelina meal) was significantly ($P \leq 0.05$) lower compared with that obtained from other 2 groups (C, E1 respectively). When Camelina meal constituted more than 10% of the diet fed to laying hens, a reduction in egg production was observed (Cherian, 2009). Also, the feed conversion ratio (g feed/g egg) of group C (1.908±0.10) was significantly ($P \leq 0.05$) higher than in E1 (1.883±0.10) and E2 (1.817±0.15). For the other 2 parameters (average daily intake and egg weight) no significant differences were registered. Decreased feed intake during the starter phase in birds fed Camelina cake or Camelina meal were reported by Ryhänen et al., 2007 and Pekel et al., 2009. The weight of E2 eggs was comparable with the weight of C eggs (Table 6).
The results of weight components and physical parameters of the eggs collected during the experiment are presented in Table 7.

Table 7. Data on weight components and physical parameters determined on eggs (valori medii/lot)

Item	C	E1	E2
Albumen weight, g	38.97±2.82	37.46±3.35	38.46±2.79
Yolk weight, g	17.14±0.34	16.88±0.21	17.17±0.25
Eggshell weight, g	8.50±0.54	8.02±0.42	8.37±0.34
Thickness eggshell, mm	0.34±0.02	0.34±0.02	0.34±0.02
pH albumen	8.75±0.20	8.84±0.12	8.87±0.18
pH yolk	6.14±0.06	6.16±0.07	6.10±0.02
Yolk colour intensity*	5.61±0.96	6.00±0.92	6.40±0.88

*The yolk color is defined according to the Roche Yolk color Fan and colors should be withing the range 1 to 15 (1 represent bright yellow color and 15 represent dark yellow color)

No difference due to diet was observed for weight components and physical parameters determined on eggs.

CONCLUSION

The compound feed incorporated with camelina meal was found to be rich in PUFA and could be used into local poultry diets as a source of energy, protein and especially essential fatty acids.
Introduction of camelina meal in poultry diets (3%) has not negatively impacted zootechnical parameters but a higher percentage (6%) affected significant the egg production.

ACKNOWLEDGEMENTS

This paper is a result of international cooperation, FP7 REGPOT-2007-3 project Feed-To-Food GA No 207043 funded by EC and the research within the project III46012 financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: The research was carried out on in two repetitions on Ross 308 male hybrid chickens. Chickens were divided into five groups (five dietary treatments differing in source and concentration of plant oil and fish oil). Feeding chickens with diets of determined composition from 22nd to 42nd day of fattening resulted in altered fatty acid profile in white meat and dark meat, and in significantly lowered n-6/n-3 PUFA (polyunsaturated fatty acids) ratio in white meat. The respective ratio was lowered from 10.85 to 2.67 in white meat, and from 12.14 to 3.27 in dark meat. Trained sensory panel was assessing the samples using scale from 0 (imperceptible) to 9 (extremely perceptible), according to the intensity of the following sample characteristics: chicken odour and flavour, fishy odour and flavour, and rancid odour and flavour. Overall impression was assessed by scale from 1 (poor) to 5 (typical). Characteristics of chicken odour and flavour were graded as of moderately high intensity in dark meat and of white meat, and there was no difference determined between the control and experimental treatments. Slightly noticeable rancid odour and flavour was determined in all meat samples, however the differences were not statistically significant ($P>0.05$). Although all experimental treatments were assessed as having more fishy odour and flavour than the control sample, statistically significant difference between samples was found only for fishy flavour in dark meat ($P<0.05$). In repetitions, upon altering the feeding treatment (without fish oil), and seven days prior to slaughtering of chickens, the intensity of fishy odour and flavour was assessed with "none" to "slightly noticeable", and differences between samples were not statistically significant ($P>0.05$). This research proved that, if applying certain dietary treatments, it was possible to produce chicken meat of satisfactory sensory characteristics enriched with n-3 PUFA, with n-6/n-3 PUFA ratio of 4.48 in white meat and of 4.57 in dark meat.
Key words: *chicken, meat, FA profile, n -3 PUFA, sensory characteristics*

INTRODUCTION

Anthropological and epidemiological studies indicate that humans have evolved with respect to nutrition which had n-6 PUFA / n-3 PUFA ratio of 1, while today that ratio in so called western nutrition amounts from 15/1 to 16.7/1 (Calvani and Benati, 2003; Simopoulos, 2006). Similar values (17.1/1) were also obtained in some studies in Croatia (Kralik et al., 2001; Primorac et al., 2003). High PUFA n-6/PUFA n-3 ratio is related to occurrence of many diseases - cardiovascular, inflammatory and autoimmune diseases, and cancer (Connor, 2000; Simopoulos, 1998, 2006; Mozaffarian, 2008). This is the reason why animal products, which are mostly consumed and which fatty acid content can be easily modified, tend to be subject to increase of n-3 PUFA portion, especially of long-chain eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) (Lopez-Ferrer, 1999). However, increased portion of these acids in animal feed, and consequently in a product, can cause unwanted changes in sensory characteristics, which is also affecting product acceptability (Scaife et al., 1994; Lopez-Ferrer, 2001) and effects the meat quality (Wood et al., 2003). The aim of this study was to determine in what way different combinations and concentrations of plant oils and oil preparations enriched with EPA and DHA affected fatty acid profile in meat and its sensory characteristics.

MATERIAL AND METHODS

The research into effects of dietary treatments on sensory characteristics of meat was carried out on Ross 308 chickens within two experiments. Dietary treatments in the 1st experiment:

- K (control) 5% sunflower oil;
- A 2.75% sunflower oil, 2% linseed oil, 0.25% PBE1 oil;
- B 2.75% sunflower oil, 2% linseed oil, 0.25% PBE2 oil;
- C 2.50% sunflower oil, 2% linseed oil, 0.5% PBE1 oil;
- D 2.50% sunflower oil, 2% linseed oil and 0.5% PBE2 oil.

Dietary treatments in the 2nd experiment:

- K (control) 3% soybean oil;
- A 3% linseed oil;
- B 2.9% linseed oil and 0.1% PBE1 oil;
- C 2.9% linseed oil, 0.1% PBE2 oil.

Seven days prior to slaughtering chickens were fed diets without PBE1 and PBE2 oil. PBE1 is oil of sea organisms containing 15.36% EPA and 9.99% DHA, and PBE2 is also oil of sea organisms with 10.55% EPA and 22.10% DHA.
Chickens were slaughtered after 42 days of fattening. Samples of white meat (breasts) and dark meat (drumsticks with thighs) were taken for chemical analysis. Fat content was determined by the Stoldt method (Hungarian Standard No. 6830-66). Fatty acid profile in meat samples was determined by the Chrompack CP 9000 chromatograph equipped with flame ionization detector. From the homogenised sample, dependent on fatty acid composition, 2-4 g was measured for fatty acid composition in a glass equipment and 5 cm^3 n-heptane and in order to eliminate water content of the sample 2-4 g dry sodium-sulphate was added to it. From the heptane solution containing fat that is free from water, 0.5 cm^3 was pipetted to a test tube, and 0.5 cm^3 sodium-metilate was added to it, the mixture was heated at 60 ^oC for 60 minutes, and during this time the mixture was shaken up intensively every 10 minutes. After this 1 cm^3 n-heptane and 1 cm^3 distilled water was added to the mixture, it was homogenised, the heptane phase was separated from the water phase, (the excess of the reagent was removed), the heptane phase was dried by dry sodium-sulphate, and dependent on fat content of the sample, 0.5-2.0 μl was injected into the column of the gaschromatograph (300 x 025 mm, quartz capillary). The humid phase (active phase) was Cp-Sil-88. The temperature of the injector and the flame ionisation detector was 220^oC, the temperature of the column at the start was 100^oC, the speed of the warm up of the column was 6^oC /minute until 210^oC, and this temperature was used at the end of the analysis. For quantitative evaluation, the weight percentage proportions of the methyl esters were regarded as equal to the proportions of the corresponding peaks in the chromatogram. The fatty acid composition for unknown samples was calculated as a function of the comparative mass percentage of fatty acid methyl-esters (Csapó et al., 1986). Cooled, boneless and frozen meat was stored for 30 days at -20^oC until sensory analysis. Thawing was carried out in refrigerator for 16 hours. Preparation / roasting and sensory analysis of white and dark meat were done separately. Meat samples of each treatment were separately wrapped in aluminum foil and roasted in the oven at a temperature of 175^oC, 60 minutes for white meat and 50 minutes for dark meat. Based on previous research, these conditions were proved as optimal. Before serving, the samples were cut into pieces and heated in glass containers with lids in a water bath at temperature of 55-60^oC. Samples (20 g) were served in covered plastic containers labeled with three-digit number. Panel of seven selected assessors evaluated the intensity of following sample characteristics: chicken odour and flavour, fishy odour and flavour and rancid odour and flavour, using scale from 0 (imperceptible) to 9 (extremely perceptible), while the overall impression was assessed by scale from 1 (poor) to 5 (typical). All samples were served simultaneously. Assessment was carried out in 4 replications with different coding, from 2 to 4 pm. During training that lasted for several days panelists were

presented samples of chicken meat from different dietary treatments, and different types of oil (fish, linseed, sunflower and rancid oils), for the purpose of developing common terminology and scale usage (Meilgaard et al., 2000Average values and standard deviations were calculated for each parameter ($\bar{x} \pm$SD). Sensory analysis data were tested by Friedman's test, while the fatty acids content was tested by ANOVA, both using Statistica 7.0 software.

RESULTS AND DISCUSSION

Analysis of fatty acid profile in chicken meat lipids (Table 1) from the 1st experiment showed that both meat types changed as a consequence of n-3 PUFA and n-6 PUFA ratio in dietary treatments. White and dark meat of the control (K) contained 3.35% and 3.54% of n-3 PUFA, respectively, while portions of EPA (0.09% and 0.12%, respectively) and DHA (0.91% and 0.65%, respectively) were insignificant. White meat enriched with n-3 PUFA contained 0.62% - 0.85% EPA (P=0.005) and 1.74% - 4.62% DHA (P=0.002) in total content of fatty acids. Dark meat also exhibited identical changes in the fatty acid profile. It contained 0.49% - 0.80% EPA and 1.34% - 2.61% DHA (P=0.01) in total content of fatty acids, as depending on the dietary treatment. White and dark meat of the control contained only 0.09% and 0.12% EPA, respectively, and 0.91% and 0.65% DHA, respectively. The n-6/n-3 PUFA ratio in white meat of the control was 10.85, and in dark meat it was 12.14. Application of described dietary treatments the mentioned ratio was lowered from 2.67 - 3.05 in white meat, and from 3.27 – 3.50 in dark meat.

Sensory assessment of meat samples (Table 2) showed that differences between samples for the characteristic of chicken odour and flavour and rancid odour and flavour were not statistically significant (P>0.05) for either white meat or dark meat.

All dark meat samples were assessed as having more fishy odour and flavour than the control, but statistically significant difference was only for flavour (P<0.05).

White meat samples were also noticed to have more intensive fishy odour and flavour than the control samples, however, the differences were not statistically significant (P>0.05).

This could be explained by the fact that chicken dark meat contains more fat than white meat, so the characteristic of fishy flavour was more expressed in this type of meat.

According to overall sensory assessment, control sample was better assessed than other samples of both white and dark meat, although differences were not statistically significant (P>0.05).

Analysis of fatty acid profile in chicken meat of the 2nd experiment (Table 3) proved that applied dietary treatments had effect on the deposition of some fatty acids in chicken muscle tissue. Increase of n-3 PUFA in chicken diets (treatments A, B and C) resulted in increase of those fatty acids in white and dark meat. The increase was mostly related to content of αLNA, as during the last 7 days of fattening chickens had diets with reduced content of EPA and DHA due to exclusion of PBE1 and PBE2 oils. That procedure aimed at improvement of organoleptic characteristics of chicken meat in order to avoid unwanted occurrence of fishy flavour in dark meat, which was the case in the 1st experiment.

All white and dark meat samples were assessed having strong chicken odour and flavour (Table 4), and slightly noticeable rancid odour and flavour but the differences between samples were not statistically significant (P>0.05), neither for chicken or rancid odour and flavour. Intensity of fishy odour and flavour was assessed as none to slightly noticeable, and slightly higher values were obtained in dark meat. Differences between samples were not statistically significant (P>0.05).

CONCLUSIONS

The research proved that dietary treatments in the 1st experiment resulted in significant deposition of n-3 PUFA in white and dark chicken meat, which improved the n-6 PUFA/ n-3 PUFA ratio. At the same time, according to sensory analysis, weak, yet still noticeable fishy odour and flavour was noticed in all samples, but statistically significant difference was found only for fishy flavour in dark meat (P<0.05). Involvement of PBE1 and PBE2 oils in dietary treatments in the amount of 0.25% (A and B) and 0.5% (C and D) had positive influence on deposition of EPA and DHA in chicken meat, however it caused poorer sensory characteristics of meat.

Results of the 2nd experiment proved that modification of diet content with respect to concentration and sources of oils can result in production of chicken meat enriched with n-3 PUFA having satisfactory sensory characteristics.

ABSTRACT: Fish nutrition based on combination of natural food (zooplankton and bottom fauna) as main protein source, and added food, mostly cereals, as energy supply, is one of the main features of the world prevailing, semi-intensive farming system. In the recent years in several countries of South East Europe instead of cereals pelleted and extruded feed is used in carp nutrition in periods of depression of natural food. This is the way to overcome the lack of proteins and lipids, of required amino and fatty acids composition.
Bottom fauna organisms represent natural food of greatest importance for fry and cultured consumable carp. Because of its mass development in spring and lesser in autumn, Chironomidae larvae are particularly rich source of nutrients for carp. They are an easily noticeable pray because of their body dimensions (till several centimeters) and clear red color (coming from hemoglobin). Chironomidae larvae are invaluable protein source of adequate amino acid composition for carp body growth. Also, this is a source of lipids, particularly rich in omega 3 and omega 6 fatty acids. High omega 3 fatty acid content is present in Chironomidae, especially in *Chironomus plumosus,* the most frequently observed species in fish ponds. In *Chironomus plumosus* larvae, omega 6 fatty acids content compared to omega 3 content is higher. This is of particular importance providing higher needs in omega 6 for carp.
Considering that omega 3 and omega 6 fatty acids ratio in farmed fish is lower compared to natural populations; that the consumption of farmed fish is increasing together with requirements to increase omega 3 content, and optimally balance omega 3/omega 6 ratio; research in carp meat improvement are of utmost importance. Stimulation of natural food development particularly Chironomidae larvae in carp ponds is one of the approaches for enhancement of farmed carp meat quality.
Keywords*: Chironomidae, bottom fauna, carp, semiintensive farming system, meat quality*

INTRODUCTION

The most commonly represented carp production system is semiintensive (Tacon and De Silva, 1997). It is based on combining natural food as main protein source and added feed as main energy source. Due to relatively low prices and availability, cereals are the most frequently used added feed. Since carbohydrates make the largest part of cereals, the carp converts it into fat (Kaushik, 1995), making it less attractive for human consumption. In order to decrease the fat content of carp, but also to overcome the natural food deficit in the summer period, in several Easter European countries (Serbia, Bulgaria, Romania, and Bosnia Herzegovina) instead of cereals, pelleted and extruded concentrated feed is increasingly used. While employing cereals, carp meat quality can be improved by stimulating natural food development. When using concentrated feed, in order to decrease production costs, natural pond potential is maximally exploited. Obviously in both cases natural food is an important source of nutrients for carp. One of the central components of natural food are larvae of insects from the family Chironomidae. In some part of the season they represent a dominating component of carp natural food. As inestimable protein source of adequate amino acid content for building carp body, as well as source of lipids, primarily

omega 3 and omega 6 fatty acids, an increased attention is directed towards these organisms.

NATURAL FOOD AND ITS SIGNIFICANCE IN CARP PRODUCTION

In the semiintensive system carp natural food primarily consists of zooplankton organisms (Rotatoria, Cladocera and Copepoda) and bottom fauna (Chironomidae and Oligocheata). Carp consumes also macrophyte grains and young plant buds. The significance of zooplankton and bottom fauna organisms for carp rearing is primarily their nutritive composition. These organisms are crucial source of amino acids, lipids, fatty acids, vitamins, and enzymes for all age categories of cultured carp. Lack of natural food results in deficiency of vitamins, minerals and essential amino and fatty acids. This reduces fish diseases resistance and health condition, and even increases diseases frequency and mortality (Marković, 2010).
From the natural food, zooplankton and bottom fauna, carp obtains building components – proteins. Protein dry matter content in zooplankton organism represents over 40 % (Daphnia – 46.6%, Copepoda 41.6%), while in bottom fauna organisms proteins occupy over 50% (Chironomidae – 55.2%, Tubificidae - 54% proteina, Marković, 2010). Carp starts consuming natural food intensively as early as at 5 – 6 ^{o}C. In the beginning of the growing season zooplankton makes 60 % of natural food and bottom fauna 40%, while at the end of the growing season this ratio changes in favor of bottom fauna, except in cases when bottom fauna is exhausted - than fish switches again to zooplankton consumption (Marković, 2010).
In fish ponds natural food expresses significant seasonality in terms of development maxima of particular species: Rotatoria have their maximum in spring period, Cladocera end spring - beginning of summer, and Copepoda are the most abundant in autumn. Generally, zooplankton biomass is the highest in spring, in May, when it can reach several tons per hectare (Marković, 2010; Dulić et al., 2011). Highest biomass values for Chironomidae larvae is in the beginning of spring, in April-May, although sometimes in carp ponds there is a second maximum (much lower than the spring one) at the end of the summer period (second half of August, first half of September). Oligochaeta are the most abundant in summer.

Bottom fauna

In productive fish ponds bottom fauna is represented by insects' larvae – Chironomidae and annelid worms – Oligochaeta. These organisms are a very important natural food for carp fry and cultured consumable carp. A known fact is that in the first months of life carp consumes zooplankton, while adults prefer feeding on bottom fauna (Horvath et al., 2002). In order to make natural food available to the fish during the whole production season, it is necessary to stimulate natural food development in fish ponds by agrotechnical measures.
Dynamics of bottom fauna is influenced by fish stocking density, therefore high stocking density deplete bottom fauna. Its abundance is the effect of a range of factors, particularly: fertilization, age of the pond, physical and chemical properties of the water, to mention the most important.
In carp semiintensive production the yield on the farm, the quantity of added feed used, as well as the health status, and therefore a profitable and stable production depend on the quantity and composition (quality) of the available natural food.

Chironomidae

Chironomidae adults lay eggs in the water, where later larvae emerge. Larvae C*hironomidae* are dominant in many shallow lentic habitats, carp ponds included (Broza et al., 2000). Larval stage consists of four stages. At the end of each, a chitin head capsule is rejected. Larval stage, depending of water temperature, lasts for several weeks to a year. They feed on green algae and detritus. At the end of the fourth stage larvae becomes pupae (pupation), and later adults that do not feed appear. In the stages of pupae and adult these organisms live only few days.

Larvae Chironomidae are a widely distributed group of aquatic invertebrates that inhabits different types of water reservoirs. Their mass development in spring and lesser in autumn represents a valuable source of nutrients for carp (Marković, 2010). These larvae are an easily noticeable pray because of their body dimensions (till several centimeters) and clear red color coming from the respiratory pigment hemoglobin. Their body movements are distinctive "S" shaped wriggling, thus the carp reacting to pray motion can find and eat it easily.
In fish feeding experiments Chironomidae larvae usually serve as control feed, since growth and weight gain results obtained with these larvae are comparable to the results obtained using concentrated feed (Wolnicki et al., 2006).

FACTORS AFFECTING FISH MEAT QUALITY

In addition to its content of biologically important proteins, minerals and vitamins, fish meat is one of fundamental sources of essential fatty acids in human nutrition. Particularly important are omega 3 and omega 6 fatty acids that reduce level of triglycerides and cholesterol in serum (Steffens, 1997), lower the risk from coronary diseases (Wang et al., 2006), and hypertension (Berry and Hirsch, 1986). Lipids in fish contain more polyunsaturated fatty acids (*PUFA*), particularly omega 3 (such as alpha-linolenic acid, eicosapentaenoic acid – *EPA*, and docosahexaenoic acid - *DHA*) compared to warm animals meat (beef, pork, sheep meat) and vegetal oils (Ackman, 2000; Abbas et al., 2009; DeFilippis et al., 2010). In human body omega 3 fatty acids (*EPA* and *DHA*) synthesis from precursors of plant origin is not sufficient, therefore their intake must be provided from the food (Williams and Burdge, 2006; Lecerf, 2007).
Lipid and fatty acid content in fish tissues depends on different factors: environmental conditions, feeding type, genetic predisposition (Łuczyńska et al., 2012). The quantity of essential fatty acids varies accordingly to: fish feeding type (herbivorous, omnivorous, carnivorous), whether the fish is wild or cultured, age of fish, origin and composition of feed (Steffens, 1997). Feeding period and season also affect fatty acid content (Guler et al. 2008). According to Mareš et al. (2009) blue green algae bloom has significant effect on individual fatty acid content in carp muscles. Besides salts dissolved in water, its temperature has a significant effect on fatty acid content in fish tissues. At low water temperatures unsaturated long-chain fatty acids concentration increases, i.e. omega 3/omega 6 fatty acids ratio decreases (Amal et al., 1990).
Investigation of fatty acids content in carp have shown that different production and feeding methods cause important variation in the omega 3 and omega 6 *PUFA*. Carp fed additionally with cereals contains lower quantities of omega 3 *PUFA* (Steffens and Wirth, 2007). omega 3/ omega 6 *PUFA* ratio in carp additionally fed commercial pelleted feed is very similar to omega 3/omega 6 ration in the feed. Content and type of lipids in the feed affect content and quality of lipids in carp meat. Numerous research point out that fatty acid content in feed affects fatty acid content in fish meat (Steffens and Wirth, 2007). Feed rich in omega 3 *PUFA*, under the same breeding conditions, markedly increases omega 3/ omega 6 *PUFA* ratio in fish tissues.
Carp is less sensitive to essential fatty acid deficit than fish from the Salmonidae family. It has been found that 0.5 % of highly unsaturated fatty acids (*HUFA*) in carp feed is more effective than 1 % essential linoleic fatty acid (Watanabe et al., 1975).
The best weight gain and feed utilization is reached by combining 1 % linolenic and 1% linoleic acid in carp feed (Csengeri et al., 1978). This combination of fatty acids can be successfully replaced with 0.5 to 1 % omega 3 *HUFA* (*EPA* and *DHA*). Also, excessive quantity of essential fatty acids in feed for carp has as a consequence their decomposition and conversion in oleic acid, while lowering of fatty acid content below fish needs causes carp growth retardation and other disorders. Bogut and Opačak (1996) report most frequently observed symptoms of lack of essential fatty acids: fatty liver degeneration, myocarditis, decrease of hemoglobin concentration in the erythrocytes, increased breathing frequency, reduced feed utilization, retardation of growth, slow fin growth, increased stress tendency. On the other hand Kamler et al., 2008 reported that fin deformation in Cyprinids is the effect

of high concentration of omega 3 fatty acids (26.9% of total lipids belong to *DHA*) and lower concentration of omega 6 *PUFA* (4.9%) in the added feed. It has been demonstrated (Kamler et al., 2008) that by replacing commercial dry feed with natural one rich in omega 6 originating from Chironomidae (containing a total of 28.8% linolenic and arachidonic acid) that are poor in omega 3 (5.9% omega 3 *PUFA*), there is decrease in deformities of fish fry. It is recommended that commercial feed for fish fry should resemble as much as possible their natural invertebrate food (Kamler et al., 2008).

IMPORTANCE OF FEEDING ON CHIRONOMIDAE LARVAE FOR CARP MEAT QUALITY IMPROVEMENT

Among many sources of natural carp food, Chironomidae larvae occupy an important place. In stagnant aquatic ecosystems, because of its dominance (up to 80% of benthofauna biomass in stagnant water is this group of organisms – Janković, 1966) these larvae represent the irreplaceable link in the food chain by transporting energy towards higher trophic levels – fish. It has to be mentioned that proteins, amino and fatty acids usage from Chironomidae body depends on water temperature, dissolved oxygen concentration, and period of carp feeding with added feed.

According to literature data on fatty acid content of Chironomidae, content of saturated, monounsaturated and polyunsaturated fatty acids varies in our geographic region (North-East Croatia, central Serbia). Results of Živić et al., (2011) have pointed out higher content of saturated fatty acids in larvae *Chironomus plumosus* (45.36 i.e. 53.47%) compared to results of Bogut and co-workers (26.12%, Bogut et al., 2007). Unlike that, monounsaturated fatty acid content was somewhat lower – 28.11% (Živić et al., 2011) compared to results published by Bogut and collaborators (30.42%, Bogut et al., 2007), as well as *PUFA* content of 28.85 i.e. 16.38% (34.03%, Bogut et al., 2007).

High concentration of omega 3 fatty acids in Chironomidae, particularly in the species that is frequently found in fish ponds, *Ch. plumosus* (from 4.48 to 8.22% - Živić et al., 2011, to over 15.22% - Bogut et al., 2003), represents a supply of important fatty acids not only for carp, but for humans as well. From the omega 3 fatty acids in the lipid fraction of *Ch. plumosus* larvae, highly represented are linoleic – 7.21% (Bogut et al., 2007) i.e. 7.78% (Živić et al., 2011), *EPA* from 1.27% (Živić et al., 2011) to 4.36 % (Bogut et al., 2007) and *DHA* (2.49 %) (Bogut et al., 2007). High linolenic acid content is probably the consequence of green algae presence in phytobenthos that serves as food for *Ch. plumosus* (Sushchik et al., 2004).

Highest percentage of omega 6 fatty acids in larvae *Ch. plumosus* belongs to linoleic acid and varies from 13.76% to 21.37% (Bogut et al., 2003, 2007; Živić et al., 2011). *Ch. plumosus* larvae are richer in omega 6 than omega 3 fatty acids (from 18.81 - Bogut et al., 2003; to 22.31% - Živić et al., 2011). This is very important for cyprinid fish provided their higher needs in omega 6 than omega 3 fatty acids (Radünz-Neto et al., 1996). Established ratio of omega 6 and omega 3 fatty acids of 0.21 to 0.81% in the mentioned studies (Bogut et al., 2003, 2007, Živić et al., 2011) makes *Ch. plumosus* larvae excellent source of natural food for carp fry.

Having in mind the importance of Chironomidae in carp feeding, their development in fish ponds can be stimulated by using fertilisation as agrotechnical measure. Results of experiments performed imply increase in abundance and biomass of Chironomidae larvae when fertilization is applied. Chironomidae are actively cultured in Hong Kong by fertilizing a chosen field (before it turns into a pond) with chicken manure. Chironomidae adults lay eggs in water, so the lake becomes rich in these “blood worms”, they are easily collected and used as fish feed (Köksal et al., 1997).

CONCLUSION

Due to the following facts: in reared fish lower value of omega 3/omega 6 fatty acid ratio compared to this ratio in fish from natural habitats (Van Vliet and Katan, 1990), increased

consumption of cultured fish in human diet, tendency of consuming fish with high omega 3 content, and appropriate omega 3 / omega 6 ratio; research in improvement of fish meat quality are of utmost importance. This is confirmed by the studies realized. Among organisms that makes cultured carp natural meal, due to the rich content in *PUFA*, particularly omega 3 and omega 6, a family Chironomidae occupies an essential position.

ACKNOWLEDGEMENT

The present study was supported by the Serbian Ministry of Education and Science, through the project Improvement of production capacities of carp (*Cyprinus carpio)* through nutrition and selective breeding programs (TR 31075).

ABSTRACT: The aim of this study was to investigate the possibility of using different feed compound for pigs in order to increase content of n-3 fatty acids in adipose tissue, as well as improving relation n-6/n-3 fatty acid that is known to be disordered in the modern way peoples diet.
In this trial to view this crossbred pigs were used (Yorkshire x Landrace), with an initial body weight of 60 kg. The pigs were divided into two groups of 10 pigs and fed standard diets for fattening pigs of 60-100 kg (finisher), provided differences between groups only in the S experimental group which had a full-fat soybean in feed mixtures (S), and a second group enriched linseed (L) in the recommended amount of 2.5% in the feed mixture (Vitalan, Vitalac, France). Vitalan contained 85% of extruded linseed and the rest were wheat bran and antioxidants. The mixtures were balanced and fully meet the requirements of the animals at this stage of fattening. Samples were collected for testing of complete mixtures of chemical composition and fatty acid content. Pigs were kept until weight of 105 kg. At the end of the experiment, after slaughtering, processing and cooling carcass samples of adipose tissue (back) were taken of each pig in both groups. The adipose tissue was examined of fatty acid composition.
Chemical analysis of fatty acid composition (a gas chromatograph GC/MSD GC 6890, MS 5972/73) complete feed mixtures showed that the feed with linseed (L) had significantly lower ($P < 0.001$) content of SFA, and significantly higher content ($p<0.001$) PUFA from feed mixtures with full-fat soybean (S). Also the ratio of n-6/n-3 in feed mixture in L group (5.567) was lower compared to feed mixture in S group (11.00) which is statistically highly significant ($P<0.001$).
By analyzing the fatty acid composition of pigs fat statistically significant differences were found between experimental groups. In adipose tissue of pigs in the groups with linseed (L) in mixtures was achieved significantly ($p<0.001$) higher content of n-3 fatty acids, or 1.97% compared to 1.42% in groups receiving full-fat soybean (S) in feed mixtures, and significantly ($p<0.001$) lower content of n-6 fatty acids, or 20.09% compared to 24.91%. Ratio n-6/n-3 in adipose tissue for the L group was significantly lower ($p<0.001$) or 10.23 relative to the group S (17.74).
Key words: *pigs, feed, linseed, fatty acid*

INTRODUCTION

Numerous medical findings show that a significant role in development of cardiovascular and other chronic diseases in humans have relationship between the two groups of polyunsaturated fatty acids in the diet: omega-6 acids, whose main representative is linoleic acid (C18: 2 n-6) and omega-3 fatty acids, whose main representative is alpha linolenic acid (C18: 3 n-3).
Unsaturated fatty acids have mutually differences in chain length, number and position of double bonds in molecules. The abbreviation "ω-6" (or n-6) indicates that the first double bond in the molecule of fatty acid is at the sixth carbon atom, as for "ω-3 '(or n-3) indicates that the first double bond in the molecule of fatty acid is at the third carbon atom, counting from the methyl group. In the natural resources most often reportered unsaturated fatty acids belong to the ω-6, ω-3 and ω-9 series.
The human body can not synthesize essential fatty acids, but retains the ability to translate basic essential fatty acid ingested by food (linoleic and α-linolenic) in the so-called long-chain

polyunsaturated fatty acids with specific roles in the body. In these biotransformation are involved enzymes desaturase and elongase and through out their activities, as well as the amount of substrate, depends the intensity and efficiency of these reactions. Desaturases are the enzymes responsible for the introduction of new double bond in fatty acid chain. There is a competition for these enzymes among fatty acids of ω-3 and ω-6 series. Elongases are the enzymes responsible for fatty acid chain extension by two carbon atoms, that is for introduction of two new methylene group.

Numerous studies confirm that increased intake of ω-3 fatty acids can affect on decreasing the risk of heart disease and vascular disorders, but also alleviating symptoms and improving the clinical picture in some autoimmune and inflammatory disorders.

Interest in the role of polyunsaturated fatty acids have been launched by investigations in 70th of the last century, which have revealed a very low occurrence of vascular disease in the population of Greenland Eskimos, despite their diet rich in fat and based on marine mammals and fish whose food chain is based on algae and plankton rich in omega-3 polyunsaturated fatty acids. Similar observations were later confirmed by epidemiological studies in other populations with a similar diet, for example in coastal areas of Japan (Karolyi, D. 2007).

In the period 1927-1930. The Evans and Burr, pointed to a number of disorders caused by eating fat-free diets, and then was introduced (Burr and Burr, 1930) term essential fatty acids for all those fatty acids that the body can not synthesize and that must be taken through out food in order to avoid the appearance of deficiency symptoms. From that time until today does not stop the interest of scientists in chemistry, metabolism and health significance of fat and individual fatty acids, and special attention is paid to the fatty acids of ω-3 and ω-6 series (Šobajić, 2002).

In the pigs nutrition are used soybean, sunflower and other oilseeds that contain fatty acids of ω-3 series and fatty acids of ω-6 series (Baltic et al., 2011, Markovic et al., 2011).

Flax (*Linnum usitatissimum L*.) is one of the oldest cultivated crops in the world market and also one of the most economically important crops. Flax seed contains about 35 to 45% oil compared to the mass of dry material (Karleskind, 1996). More than 70% of this oil contains polyunsaturated fatty acids, primarily alpha-linolenic acid (ALA), an essential ω-3 fatty acids and linoleic acid (LA), essential ω-6 fatty acids.

It should be noted that flax meal contains the fatty acid profile that is similar if not identical, as flax seed, considering that the total oil content of the meal is variable depending on the method used for extraction of oil, which affects the energy value of this nutrient.

Because of the many potential benefits of ω-3 fatty acids in the diet, consumer demands increase for ω-3 enriched products. Recommendations for daily intake of ω-3 fatty acid throughout diet, for adult men are 1.6 g, and for adult women 1.1 g (National Academy of Sciences, 2005).

A large number of products are now produced with the aim of enriching with ω-3 fatty acids. These products include ω-3 enriched eggs, bread, pasta, dairy products, baby food, milk, cereals juices, salad and meat dressings, and they are all available to purchase at most stores.

The ability of producing ω-3 enriched meat products of pigs is very interesting for many producers and consumers, as noted above. In monogastric animals such as pigs, fatty acids are absorbed from the gastrointestinal tract with small changes. In fact, the fatty acid profile of tissue directly reflects the profile of fatty acids in animal nutrition. In ruminants, however, the fatty acids from food in the digestive tract are changed under the influence of the process of microbial fermentation and biohidrogenation, prior to absorption from the gastrointestinal tract (Baltic et al., 2011b, Markovic et al., 2011b).

In modern human nutrition ratio of ω-6: ω-3 polyunsaturated fatty acids is relatively wide (10-15:1), so that today in human diet are made efforts to enrich food with ω-3 fatty acids, so that this relationship could be approximate to optimal (4:1).

MATERIALS AND METHODS

For the experiment were used crossbreed pigs Yorkshire x Landrace, with initial body weight of 60 kg. The pigs were divided into two experimental groups of 10 pigs and were fed with standard mixture (NRC, 1998) for the final fattening pigs of 60-100 kg (finisher), with the differences between groups only in that the I experimental group, a group (S) received a soybean meal in the diet, and Group II received a preparation of linseed (L) in the recommended rate of 2.5% in the mixture (Vital-Vitalac, France).
The Vitalan preparation of flax seed contains 85% of extruded flax seed, and the rest of the preparation are wheat bran and antioxidants.
The mixtures were balanced and fully met the demands of the animals at this stage of fattening.

Table 1. Ingredients and chemical composition of swine mixtures, %

Samples were taken from the complete mixtures for the determination of chemical and fatty acids composition. At the end of the experiment, after slaughtering, processing and cooling carcass samples of adipose tissue (back) were taken from each pig in both groups. In adipose tissue fatty acid composition was examined.
Total lipids for fatty acid determination were extracted from pigs mixtures as for pork fat tisue with hexane / isopropanol mixture by accelerated solvent extraction (ASE 200, Dionex, Germany). After evaporation of solvent until dryness under the stream of nitrogen, total lipids were converted to fatty acid methyl esters (FAME) by trimethylsulfonium hydroxide. Fames were determined by using Shimadzu 2010 gas chromatograph equipped with flame ionization detector (FID) and cianopropyl HP-88 capillary column (100m x 0.25 mm x 0.20μm) (Spirić et al., 2010).

RESULTS AND DISCUSSION

In this study were investigated the amount and relations of fatty acids in pigs adipose tissue depending on the fatty acid content in the feed that were a part of mixtures for swine diet. From the results of the total fatty acid content in the feeds that were used (Table 2) we see that there were significant differences between complete feed mixtures for these groups. Complete feed mixture of L group, that received preparation with extruded linseed had a significantly lower content of SFA and significantly higher content of PUFA ($p < 0.001$) compared to S group. The trials showed that more than 70% of flax seed oil consists of polyunsaturated fatty acids (mainly alpha-linolenic acid (ALA) and linoleic acid (LA) (Nikolovski et al., 2008).

Table 2. Fatty acids in the feed – total content

Group	SFA (%)		MUFA (%)		PUFA (%)	
	$\bar{X}$	Sd	$\bar{X}$	Sd	$\bar{X}$	Sd
S	20,17$^{\alpha}$	0,32	25,51	0,32	54,33$^{\alpha}$	0,48
L	18,38$^{\beta}$	0,60	25,46	0,26	55,99^{ß}	0,70

Different letters α, ß denote significance of $p < 0.001$ (Table 2-5)

Table 3 presents content of n-6, n-3 fatty acids and their ratio n-6: n-3. Complete mixture for swine, which is in its composition contained flax preparation, had a significantly higher ($p<0.001$) content of n-6 and n-3 fatty acids, and their ratio n-6: n-3 was also significantly lower (5.57) compared to the total mixture without flax preparation (11.00).

Table 3. The total content of n-6, n-3 and ratio of n-6: n-3 fatty acids in the feed

	$\bar{X}$	Sd	$\bar{X}$	Sd	$\bar{X}$	Sd
S	49,79$^{\alpha}$	0,41	4,54$^{\alpha}$	0,22	11,00$^{\alpha}$	0,54
L	47,46$^{\beta}$	0,60	8,53$^{\beta}$	0,22	5,57$^{\beta}$	0,14

Fatty acid profile of the carcass directly reflects the profile of fatty acids in the diet of animals (Eastwood, 2002). Since flax seed has desirable fatty acid composition, many producers are interested in including it in the finisher pig diets and therby improve the fatty acid composition of meat.

In this experiment, the total content of SFA and MUFA of fatty acids was significantly higher ($p < 0.001$) in adipose tissue of pigs that were fed with diet that contained flax, compared to another group of pigs, but the amount of PUFA in the adipose tissue of those pigs was significantly lower ($p < 0.001$) (Table 4).

Table 4. Fatty acids in adipose tissue - total content

Group	SFA (%)		MUFA (%)		PUFA (%)	
	$\bar{X}$	Sd	$\bar{X}$	Sd	$\bar{X}$	Sd
S	31,30$^{\alpha}$	0,52	41,91$^{\alpha}$	0,48	26,32$^{\alpha}$	0,40
L	33,16$^{\beta}$	0,51	44,42$^{\beta}$	0,26	22,05$^{\beta}$	0,46

One of the first studies that examined effects of feeding with flax seed on lipid profile of pigs carcass was performed by Cunnane et al. (1990). The pigs were fed with diets containing 5 per cent of flax aged from 2 weeks unil 10 weeks of age. Pigs had significantly higher level of ALA in their liver, kidney, heart, skin, subcutaneous adipose tissue and muscle, and significantly higher level of DHA and EPA in the liver, kidneys and heart. This study provides evidence that including of Flax seed improves the omega-3 fatty acids profile of pigs carcasses.

After that, more research have been conducted in order to determine the optimal level of inclusion of flax seed and appropriate duration of feeding flax seed to ensure the enrichment of omega-3 fatty acids, with no negative impact on carcass quality. Romans et al. (1995 a,b) conducted two trials in order to acquire answers to these questions. In the first study, pigs were fed with diets containing 0, 5, 10 or 15% flax seed 25 days before slaughter. Researchers have obtained a linear increase of ALA in the back fat and bacon of animals. The levels of ALA in the pigs back fat were 10, 23, 37 and 53 mg/g tissue with inclusion of flax seed at 0, 5, 10 and 15% respectively. The authors concluded that flax seed should not be used in finisher for pigs above the level of 15% due to changing sensory properties of meat.

In another study of Romans et al. (1995 b), the pigs were fed with a level of 15 percent of flax seed, but the duration of treatment varied. The pigs were fed during 7, 14, 21 or 28 days before slaughter. ALA content of adipose tissue back (backfat) increased significantly linearly with increasing duration of using allowancse with flax seed. It is also important to note that the allowances used in two studies Romans et al. (1995a, b) were based on corn. Since corn is rich in omega-6 fatty acids (linoleic), the effect of inclusion of flax seed will not be as good as when allowances with wheat and barley. Fontanillas et al. (1998), Matthews et al. (2000), Enser et al. (2000) and Thacker et al. (2004) are just some of the studies that show similar effects of feeding with flax seed on fatty acid profile in pigs carcasses obtained from finishing pigs.

Application of flax seed preparation (group L) led to significantly ($p < 0.001$) lower (20:09) total content of n-6 fatty acids in adipose tissue, and significantly ($p < 0.001$) higher (1.97) content of n-3 fatty acids compared to the group of pigs (S) that did not receive this preparation (Table 5). Also the ratio n-6: n-3 in the experimental group L was significantly lower (10.23) compared to S group (17.74)

Table 5. The total content of n-6, n-3 and ratio of n-6: n-3 fatty acids in adipose tissue of pigs

Grupa	n-6 (%)		n-3 (%)		n-6:n-3	
	$\bar{X}$	Sd	$\bar{X}$	Sd	$\bar{X}$	Sd
S	24,91 $^{\alpha}$	0,43	1,42$^{\alpha}$	0,13	17,74 $^{\alpha}$	1,89
L	20,09 $^{\beta}$	0,47	1,97$^{\beta}$	0,09	10,23 $^{\beta}$	0,57

Okanović et al. (2010) have been determing the impact of food enriched with flax seed on the omega-3 fatty acids content in swine until the mean weight of 110 kg. Treatment with feed that contains flax seed resulted in higher concentration of omega-3 fatty acids (>7 mg/100 g) which reduced the ratio of omega-6 and omega-3 fatty acids in meat (<3) making it, from a health perspective, the better for human nutrition.

Stanislawa Raj et al. (2010) used in their trial gilts weight 60-105 kg divided into four groups (control group, group with linseed oil - L, rapeseed oil - R, beef tallow -T and with fish oil - F). All groups received allowances that were balanced in energy but with different ratios of PUFA and SFA, and linolenic acid (C18: 2n-6) to α-linolenic acid (C18: 3n-3). The linear relationship was established between the intake and utilization of C18: 2n-6 and C18: 3n-3 in the body. Efficiency of utilization of C18: 2n-6 was lower than C18: 3n-3.

Vaclavkova and Beck (2007) have examined the effect of different contents of flax seed on meat quality of pigs with body weight 37-98 kg. The pigs were divided into four groups: control (group with no flax in the diet -LO, group with 6.7% flax seed - L1, group with 13.4% of flax seed -L2, and group with 13.4% flax seed with the addition of 103 mg α-tocopherol - L3). Adding flax seed into the allowance for pigs significantly ($p < 0.05$), increased the content of linoleic acid, α-linolenic ($p < 0.001$), arachidonic ($p < 0.05$) and eicosapentaenoic (EPA) acids ($p < 0.05$) but had no effect ($p > 0.05$) on the content of docosahexaenoic (DHA) acids in muscle tissue. The ratio n-6: n-3 was lower in the experimental groups, but not significantly ($p > 0.05$). The total content of n-6 and n-3 fatty acids was the lowest in the control group.

In trial conducted by Mourot and Hermier., 2001, were compared effects of the three allowances (supplemented with beef tallow, with rapeseed or with flax seed oil) on fatty acid composition of broilers and pigs muscle. Among these three allowances, diet supplemented with flax seed oil led to the highest content of N-3 PUFA in the pigs and broilers muscles, and the lowest n-6/n-3 ratio. Kouba et al., (2003) in his trial examined total fatty acid content in *M.longissimuss* of pigs fed with 6% flax seed in the allowances during 20, 60 and 100 days. They have determined a significant reduction of n-6: n-3 ratio in these groups, and increased PUFA / SFA compared to the control group.

CONCLUSION

Diet enriched with extruded linseed had a beneficial impact on the content of n-3, n-6 acids and the ratio of n-6: n-3, which is significant for the health of consumers.

ACKNOWLEDGEMENTS

The experiment and researches have been accomplished within the Project TR 31034 "Selected biological hazards to the safety/quality of food of animal origin and the control measures from farm to consumer", funded by the Ministry of education and science of Government of Republic of Serbia.

ABSTRACT: Biological treatment of feeds includes its exposure to the influence of exogenous enzymes in digestive tract of animals, i.e. exposure to the process of fermentation under the influence of microorganisms (pre-digestion) in fementors. Basic reason for adding endogenous enzymes into animal diets is the activity of already existing unused nutrients into outer space. The technology of pre digestion of food includes exposure of food to the process of action of added enzymes in fementors which enable undisturbed and successful fermentation. Microorganisms isolated from rumen of ruminants dissolve cellulose, hemicellulose, lignin and other difficultly digestible polysaccharides using their own enzymes, and the products of dissolution (simple sugars) are used for the synthesis of microbial protein of high biological value. They use nitrate and nitrite nitrogen from food and from the air. They synthesize vitamins of B complex, D, E, and K vitamins and they also dissolve mycotoxines, making the food contaminated with mycotoxines less harmful. Through the process of fermentation of feeds, under the influence of microorganisms of rumen ("Biofermix" preparation) examined in Russian scientific research institutes, in cases of certain animal feeds (e.g. wheat bran), the increase in the protein content was determined from 13 to 25%, as well as reduced content of cellulose from 8 to 2%, which contributes to the greater utilization of such feed, to the better production reproductive and health performances of animals and to the protection of the environment as well. In order to gain new experience and to obtain additional arguments on efficacy of utilization of microorganisms in the process of biological treatment of animal feed it is necessary to perform research work with raw materials which is used under our conditions.
Key words: *Animal feed, microorganisms, enzymes, fermentation*

INTRODUCTION

Newly formed genotypes of highly productive animals demand greater amounts of quality feed, which points out to the need of rational usage of all available resources for its production. Especially important segment in this plan is rational usage of inadequately used resources, first of all by-products from plant production and food industry. Such resources of feeds are mostly in the form or in the shape which does not allow simple or immediate use in animal feeding. Therefore, it is necessary to prepare it for storage and for later usage. Different procedures for food processing are available nowadays and they could be classified as physical, chemical and biological procedures. Physical procedures include chopping or mixing, water treatment, cooking under pressure or without pressure and exposure to gamma rays. Chemical procedures include exposure of feeds to different compounds such as: sulfur dioxide, sodium hydroxide, alkaline hydrogen peroxide, potassium hydroxide, ammonia, ammonia hydroxide or ammonia bicarbonate, and urea and calcium hydroxide (Grubić et al., 1995). The aim of such treatment is to break or to weaken lignocellulosic connections in feed and to increase the area of the effect of digestion process of enzymes of endogenous or exogenous origin. Biological treatment includes exposure of feed to the effects of enzymes brought into the body with feed (mixed into feed), i.e. exposure of feed in solid state of the fermentation process in fermentors in the presence of certain microorganisms (Nasseri et al., 2011; Irfan et al., 2011; Popov 2007; Grujić et al., 1995).

Lynd et al., (2002) claim that, since the time the processes of enzyme conversion of celluloses were determined, dominant factors, which refer to human benefits and which became sustainable sources of energy certainly provide energy and global climate changes. These significant influences increased the need to pay greater attention to using these sources of energy. Great efforts were invested into examinations and development of practical processes for conversion of celluloses into energy and substances which could be of usage. The most important aspect of such processes implies decomposition of cellulose using microorganisms.

DEVELOPMENT AND BASIC CHARACTERISTICS OF BIOLOGICAL TREATMENT OF ANIMAL FEEDS

Development and basic characteristics of animal feeds through exposure to enzymes started during sixties of the last century. Enzymes are substances of protein nature which decompose feed to simple compounds that are suitable for adsorption, but they also enable a whole line of metabolic processes. The basic reason for adding of exogenous enzymes into animal feeds is to supplement the activity of endogenous enzymes of animals, that is, acceleration of feed into forms which are available for the resorption of nutrients and for reduction of excretion of unused matters into environment. Enzymes used for this purpose are produced by modern biotechnological procedures via controlled fermentation of substrates of chosen strains of fungi (e.g. *Thricoderma viridae, Aspergillus oryzae and Aspergillus niger*) and bacteria (*Bacillus subtilis, Bacillus licheniformis* and other). Isolated microorganisms excrete the enzyme into medium which is then filtered, purified and then put into appropriate carrier (powdered or fluid) depending on the equipment for their application in factories for animal feed production. It first started by adding separate enzymes (protease and amylase). In later stages it was shifted to application of adding enzyme preparations which contained more enzymes. Enzymes were added into feed during mixing in small amounts (under 1%), which means they did not require special equipment for application. Lately, enzymes are produced in liquid form and they demand appropriate equipment for application, but their efficacy is greater. They are added into feed after pelleting or extruding, which excludes a possibility for their exposure to high temperatures and damages. The greatest need and justification for using enzymes is in feeding young animals, especially pigs and chicken, because the enzyme systems of their gastrointestinal tract is underdeveloped (Sinovec, 2003). Especially interesting enzymes are hemicellulases, cellulases, pectinases, beta-glucanases; xylanase and alfa-glucosidase, which decompose structural carbohydrates (plant cell walls). Using enzyme preparations in feeding pigs and poultry has a positive effect to the health of animals and their production results (growth, intake and feed conversion). Described effects are especially expressed in broilers fed on grains (barley, wheat, and oats) and plant protein feeds (sunflower meal, peanuts meal and rapeseed meal). Application of enzymes in hen feeding has positive influence on laying and quality of eggs, thickness and firmness of egg shell (Cmiljanić et al., 2007). Using enzyme preparations which contain a cocktail of enzymes in meals for poultry with greater content of non-starch polysaccharides at the same time makes better usage of greater number of nutrients (Lević and Sredanović, 1999; Steen 2003; Hryby 2004; Slomijski 2005; Cmiljanić et al., 2006). During the last years the enzyme phytase is used in order to decompose phytic acid and release of phosphorus in substrate (feed) which reduces the need for adding inorganic phosphorus in animal meals (Jongbloed et al., 2000; Mellor, S. 2004). This is especially important because 50-80% of phosphorus is tied to phytic acid (Simons et al., 1990; Šefer and Sinovec, 1998). Considering localization of phytates in aleuronic layer of plant material, a combined usage of phytase with cellulolytic enzymes, such as beta-glucanases and pentozonase, is recommended.

When using enzymes in cattle feeding, one should keep in mind they fall under the influence of enzymes of microorganisms of the rumen which decompose them and make them less active. Three groups of microorganisms are present in the rumen of ruminants: bacteria,

protozoa and fungi. One group of these microorganisms decomposes nutrients brought into the rumen by feed, and the other group uses the products of their decomposition.
In fattening calves, proteases and amylases could be used, especially in cases of early weaning of calves (less than 6 weeks of age) when it is necessary to provide them with feed of high digestibility and high energy concentration. Dawson (1999) proved that exogenous enzymes (cellulases and xylanases) influence increase of digestibility of dry matter and NDF (neutral detergent fiber), higher production of evaporable fatty acids was also proved with the improvement of ratio of acetic and propionic acid and the increase of pH value of the content of rumen. The same author also states that milk yield of cows increased for 0.82-2.8 kg when using protected enzymes. Appropriate biotechnological procedures which enable the protection of exogenous enzymes from the influence of rumen microorganisms are nowadays being developed in the world. The procedure is based on the principle of glycolysis, used in the nature by fungi which excrete secretion and in that way protect their enzymes from the environmental proteases in which they develop. Zinn (1999) established that application of protected enzymes in feeding fattening calves contributes to increasing of digestibility of organic matter from 61 to 63.2% and NDF from 28.22 to 34.7% with the increase in growth from 1.33 to 1.41 kg/day and to reduction of feed per kg of growth for 1.89%. Protected cellulolytic enzymes, apart from positive effect on the consumption and efficacy of utilization of feed and production performances of animals cannot be adequate replacement for poor quality of forages and poor management in its production (Howes, 1996). Conditions that an enzyme has to fulfill are: expressing its activity at an optimal pH value of the environment, resistance to endogenous proteolytic enzymes and low pH of the stomach, stability during storage and thermo stability. Enzymes can influence the reduction of unwanted effects of certain anti nutritive matters (beta glucans, arabinoxylans, pectins, galaktosides, inhibitors of proteases and amylases, tannins, lectins, glycosides, phytates, alkaloids and other) in feed such as soya, lupine, millet, rapeseed and other.

PRODUCTION AND UTILIZATION OF MICROBIAL PROTEIN

Thanks to the modern biotechnological achievements nowadays it is possible to produce microbial origin, so called single cell protein (SCP). For the microbiological synthesis of proteins (Bhala et al., 2007) use bacteria (*Cellulomonas sp. Bacillus subtilis, Aeromonas hydrophylla* and other), yeasts (*Candida utilis, Saccharomyces cereviciae, Amoco torula and other*), fungi (*Thrichoderma viridae, Aspergillus niger, Aspergilus oryaze, and other*) and algae (*Spirulina sp., Chlorella pyrenoidosa, Scendesmus sp.* and other). These microorganisms in a short time interval of only few hours can multiply the quantity of protein with very favorable amino acid content, bacteria for 0.5 – 2 hrs, yeasts 1-3 hrs, algae for 2 – 6 hrs. Protein production is performed in fermentors on different substrates under aerobic conditions (except for algae), under the controlled temperature and pH value. By-products of agricultural production and food industry (sugar factories, starch, beer, dairy plants, wood manufacture, fruits and meat) are used as a substrate for their cultivation by the procedure of feed in solid state fermentation. At the same time, apart from protein production, this contributes to the solution of the problems of environmental pollution. For microbial bio-mass protein production under slightly different and more complex biotechnological conditions and by different procedures, natural gas, n-alkanes, paraffin, gas oil, methanol, ethanol can also be used (Đorđević and Dinić**,** 2007; Popov 2007). Chemical content of microbial biomass, (Nasseri et al., 2011) is given in Table 1.

Table 1.Chemical contents of biomass of different microorganisms (% dry matter)

Indicator	Fungi	Algae	Yeasts	Bacteria
Protein	30-45	40-60	45-55	50-65
Fat	2-8	7-20	2-6	1-3
Ash	9-14	8-10	5-10	3-7
Nucleic acid	7-10	3-8	6-12	8-12

Similar example of protein production in nature is oyster mushroom *(Pleurotus ostreatus),* which grows on substrate rich in cellulose, hemicelluloses and lignin (straw of wheat, soya, sawdust, bark of a tree, and other). Using its enzymes, this mushroom decomposes lignocellulosic ingredients up to simple compounds which, including nitrogen from the air, uses for feed and for the production of fruitful body.
Undissolved and dissolved residues which the mushroom did not use, as well as mycelium (hyphae made of chitin macromolecules) can be used, in limited amounts, for feeding of animals (Adamović et al., 1998). Grujić et al., (1995), investigated a possibility of protein production on a substrate made of hydrothermically treated wheat straw and cornstalk using cellulolytic moulds *Chaetomium cellulolyticum and* Chaetomium *globosum* by the solid state fermentation of feed. The results obtained showed that in case of mould *Chaetomium cellulolyticum* during five days of fermentation under aerobic conditions, the quantity of protein was increased nearly 100% (Table 2).

Table 2. Efficiency of Chaetomium *cellulolyticum* in the production of protein of microbial origin

Parameter	Start	End	Index
Wheat straw			
Protein,% DM	6.0	11.5	192
Cellulose,% DM	49.0	36.0	73
Cornstalk			
Protein,% DM	5.5	13.5	245
Cellulose,% DM	44.0	32.0	72

Similar results of fermentation of hydrothermal treatment of wheat straw and corn stalk were obtained when using *Chaetomium globosum.*

UTILIZATION OF «BIOFERMIKS» PREPARATION IN ANIMAL FEEDING

The scientists of the Moscow Agricultural Academy “K.A. Timirjazev” Russia, worked on the development of “Biofemiks” preparation, approved by the Pharmacology Council of the Ministry for agriculture and food of Russia (TU 9337-001-46391307-98). According to the given description, the preparation is in powder form and contains more than 40 species of microorganisms, first of all bacteria and fungi isolated from the rumen content of deer species moose. These microorganisms through their enzymes in by-products of agricultural and food industry (straw, corn stalk, husk, cob, chaff, wheat bran, raw brewer’s grains, sugar beet pulp and other similar products of plant origin) decompose celluloses, hemicelluloses, lignin and other difficultly digestible polysaccharides. In that process, microorganisms use the products of degradation (simple sugars), as well as nitrogen originating from nitrates and nitrites, including nitrogen from the air, and they synthesize microbial protein of high biological value. At the same time, they can use nitrogen from urea, nitrogen phosphates and diamonium phosphate. They synthesize vitamins of B complex, vitamins D, E and K. These enzymes also decompose mycotoxins, making the feed contaminated with mycotoxins less harmful.
Apart from microorganisms, “Biofermiks” enzyme preparation contains extracts of active substances of many herbs of high biological value. “Biofermiks“ is used in the amount of 5 g/1000 kg fermented feed. The mentioned amount is mixed with 3-4 kg of corn meal or wheat bran, and 3-4 L of warm water is added. Everything is mixture and let for 3-4 hrs at 20-30 ºC. In such a way prepared mass is mixed in fermentor with fragmented feed moistened with warm water (humidity 55-65%) and kept at 50-55 °C.
The length of fermentation depends on the content of cellulose in treated material and it ranges from 3-4 hrs for the level of cellulose of 5-8%, to 10-12 hrs for the level of 30-45%. Table 3 presents the results of the effect of preparation “Biofemiks“ on chemical content of wheat bran (Lesnov and Puzankov, 2006).

Table 3. Chemical content and nutritive value of wheat bran

Parameter	**Without „Biofermiks“**	**With „Biofermiks“**
Energy, MJ	8.8	10.5
Protein, %	13	25
Cellulose,%	8	2
NFE,%	52.6	50.2
Fat, %	4.1	4.2
Sugar, %	4.7	4.9
Calcium ,g/kg	1.80	1.80
Phosphorus ,g/kg	10.10	10.10
pH	6.5	6.5

It is obvious that the fermentation of wheat bran under the influence of “Biofermiks” preparation, as its authors stated, caused a great increase of the content of energy and proteins, i.e. the reduction of cellulose, which makes the results very interesting. The authors of this paper, however, are of the opinion that the confirmation of these results should be looked for in further investigations with the same or similar preparation. At the same time, they think that a full-scale evaluation of this preparation requires the results of their own research work.

In a trial performed by Savič Čahmahčev, (2000) the pigs in the experimental group were given 20% of mixture fermented with “Biofermiks “preparation and they had growth of 441 g/day, which was 31.6% greater than the growth of control group (335 g/day). For 1 kg of growth of the experimental group, 4.4 kg of fodder mixture was used and 5.5 kg for the control group. The feeding cost for one kg of growth in the experimental group was 20% smaller than in the control group. The pigs of the experimental group had the increase in the number of erythrocytes and the content of hemoglobin, glucoses and proteins. The increase of gamma globulins, albumins, alpha and beta globulins, calcium and phosphorus was observed which points out the positive effect of the preparation examined to the exchange of nutritive matters in pigs. The experimental group had a smaller number of incidences of illness of organs for digestion (16.3 : 40.6%). The same author found a positive effect of the preparation „Biofermiks“ in fattening pigs (Table 4) to the body mass, growth and for the content of proteins and fat in meat ($p<0.05$).

Table 4. Body mass, growth and physico-chemical content in pig meat

Indicator	**Without „Biofermiks“**	**With „Biofermiks“**
Body mass at the beginning of the trial	57.0	58.5
Body mass at the end of the trial	87.5	103.0
Growth, g/day	358	532
Chemical content of meat,%		
Humidity,%	69.38	71.41
Protein,%	19.11	22.28
Fat,%	3.24	4.07
Ash,%	0.92	0.86

In the second trial, the positive effect of “Biofermiks” preparation to the growth of fattening pigs was also established. The growth of experimental group (511 g/day) was greater than in the control group (449 g/day), for 13.8%, while the number of culled animals from fattening in the control group was greater for 13.3%.

In a trial performed on two groups with 50 cows in each group, (Lesnov, 2008) the effect of wheat bran fermented by preparation ”Biofermix” to the production of dairy cows was investigated. The experimental group of cows received 0.6 kg of fermented wheat bran (45% DM) during 25 days which is approximately equivalent to 0.35 kg of additional fodder mixture. Average milk yield of the experimental group of cows (on the 11^{th} day of the trial) was greater for 0.94 L or 4.40%, that is on 25^{th} day it was 1.86 L or 9.18%, which points toward appropriateness of using such technology in feeding lactating cows.

Based upon the data from the available literature, it could be concluded that most of the recommendations point to the limit of the quantity of 20-30% of microbial protein out of total proteins in diets of non ruminants. In diets for pigs, without any greater consequences, microbial protein could be substituted up to 55% of proteins of fish flour and soybean meal. Ruminants can use better microbial protein and the possibilities for substitution of conventional proteins are somewhat greater. There are data referring to sheep rations where these proteins could be used, without any greater consequences, up to 75% of protein in a diet. (http://www.fao.org/ag/AGA/agap/frg/ AFRIS/Data/734.htm)
When using proteins of microbial proteins there are certain limitations. One among the first is the content of nucleic acids. Metabolism of these acids increases the share of uric acid in urine and in blood serum. Uric acid, if present in greater amounts, creates kidney stones. Nowadays, however, there are methods and procedures (chemical and enzymatic) by which the reduction of nucleic acid could be influenced (Nasseri, 2011). Depending on the quality, there is a possibility for slower degradation of proteins in digestive tract, as well as certainty of occurrence of allergic reactions, contamination by pathogenic microorganisms and by toxic substances.

CONCLUSION

Use of contemporary biotechnological methods and procedures, based on the utilization of enzymes and microorganisms, can contribute to the more complete usage of insufficiently used feed resources. First of all by decomposing cellulose and improvement of protein quality, as well as the protection of the environment. In order to obtain necessary experience and additional arguments, it would be needed to perform further investigations and provide answers to other questions as well, particularly in the field of biological and economic justification of application of solutions discussed under our conditions.

ACKNOWLEDGEMENT

ABSTRACT: The purpose of this experiment was to establish the effects of the addition of animal and vegetable fats to broilers' nutrition on the chemical contents of red, white meat, liver and gizzard after 42 days of breeding. The Cobb 500 broiler was used in this experiment, in total 240 animals, placed in four separate treatment. In chickens' nutrition, there was increased content of fats by 3% (treatment I – lard; treatment II – soybean oil; treatment III – tallow; and treatment IV – sunflower oil). With analysis of chemical parameters we comprised analysis of contents of water, total ash, crude protein and crude fat. Highly significant difference ($p<0.01$) was found in the red meat for the contents of total ash, while the other parameters of chemical contents showed no statistically significant difference ($p>0.05$). Highly significant difference ($p<0.01$) was found in the white meat for the contents of water, total ash, crude protein; for crude fat is established statistically significant difference ($p<0.05$). Analysis of liver showed highly significant difference ($p<0.01$) for the contents of crude protein and crude fat, while highly significant difference ($p<0.01$) was established for the all chemical parameters in gizzard. Addition of sunflower oil to broilers' nutrition resulted with higher contents of total ash in the red and white meat, as well as of crude proteins and crude fats in the white meat, liver and gizzard of broilers.
Key words: *broiler meat, liver, gizzard, chemical contents, vegetable fats, animal fats*

INTRODUCTION

Poultry has a leading position in the demand for all types of meat in the world's most developed countries. This is the result of a series of factors, and the most important are: very short feeding duration, high concentration of live weight of poultry in the poultry house, the great reproductive power of breeding flocks, excellent feed conversion, nutritive value of poultry meat, relatively low selling price and the suitability through so-called " – fast food". Chicken is a significant diet animal product in human nutrition. It is characterized by high contents of undiminished protein and low fat content. The chemical composition of chicken's meat depends on various factors such as: age, rearing, nutrition and the body region, or a particular torso section. The meat on breast and leg meat with upper legs differ from one another in nutrients (Bašić, 2009). Given that there is a possibility to modify the content of desired ingredients in chicken meat, numerous studies are now turning in the direction of "designing" chemical composition of chicken meat. Using different sources of fat in the chickens' diet was the subject of study of many authors. The enrichment of chicken meat with the essential linoleic and linolenic acid is possible when as a food additive sunflower oil and soya oil are used instead of lard (Božić, 1997). Crespo and Esteve-Garcia (2001) suggest that feeding chickens with sunflower and linseed oil significantly reduce abdominal fat and cholesterol content in red meat ($p <0.01$) compared to consumption of chickens with lard and olive oil. Crespo and Esteve-Garcia (2001) analysed the contents of fats and proteins in the red and white meat of broilers in the experiment in which they supplemented to broiler's nutrition tallow, olive oil, sunflower oil and linseed oil (6% or 10%). Male broilers received the fats in their nutrition from 21. to 42. days of live, and female broiler's received the fats from 21. to 49. days of live. Results indicated that contents and type of fats did not significant influence on the weight and percent of drums an breast and contents of crude fat and crude protein in the mentioned tissues. Kirshgessner at all. 1993) have found the

enhancement contents of crude fat in the white meat of broilers which received in their nutrition higher percent of linoleic acid. Chickens fed with low-protein food (18% crude protein) supplemented with the oil enriched with 2% or 4% conjugated linoleic acid had low triglycerides of liver, a relatively high concentration of saturated fatty acids and relatively low concentration of monounsaturated fatty acids in lipids of liver and adipose tissue than chickens fed without the addition of conjugated linoleic acid. Chickens fed with low-protein food without the addition of conjugated linoleic acid had higher concentrations of triglycerides in the liver than chickens fed with high-protein food (23% crude protein) without the addition of conjugated linoleic acid (Aletor et al., 2003). When chickens were fed with 5 and 7.5% soybean oil and higher protein than the NRC recommendations (NRC x 1.1), Tabedian et al., (2005) there were recorded higher values of liver weight which mentioned authors attributed to increased activity of the liver for metabolism of these nutrients.

MATERIAL AND METHODS

The experiment was set up and implemented in the facilities for the production of chicken meat “Koka – Sana” from Sanski Most. Laboratory samples of chicken meat, liver and gizzard were performed at the Biotechnical Faculty, University of Bihać.
Day-old Cobb 500 broiler hybrid were placed in four separate boxes (treatments), and there were 60 broilers in each of them. All chickens were held on the floor in facilities fitted for broiler breeding. During the experiment, which lasted for 42 days, temperature, humidity and lighting were regularly controlled. Chicken breeding was split in two periods. From day one to day 15, chickens were bred with the initial mixture containing approximately 23% of proteins. From day sixteen to 42, they were bred with the final mixture containing approximately 20% of proteins, so the final mixtures were isoproteinic and isoenergetic. In chickens’ nutrition, there was increased content of fats by 3% (treatment I – lard, treatment II – soybean oil, treatment III – tallow, and treatment IV – sunflower oil). The chickens consumed food and water *ad libitum*. Having turned 42 days of life, chickens were marked with rings, for each treatment separately, and after 12 hours of fasting were killed at slaughterhouse facilities. After slaughter and meat packing processing of chickens’ carcasses, the carcasses and offal are chilled to a temperature of 0-4 ° C and then frozen at -18 °C until the moment of analysis, and on the day of analysis thawed to room temperature.
With analysis of chemical parameters of meat and offal we comprised analysis of contents of water, total ash, crude protein and crude fat according to to Official Methods of Analysis of AOAC International, AOAC International, Gaithersburg, USA (2000). The results obtained in the experiment were analyzed by ANOVA test and found differences were analyzed using Tukey’s test.

RESULTS AND DISCUSSION

In the Table 1 are shown the contents of nutrients in the broilers’ feeding. In the Table 2 are shown the chemical parameters of red and white meat. In the Table 3 are shown the chemical parameters of liver and gizzard.

Table 1. Contents of the mixtures used for feeding broilers from 0. to 15. days of life and from 16. to 42. days of live

By using Tukey's test it was found highly significant difference (p <0.01) in the content of ash in the red meat of broilers between treatment I - lard and IV - sunflower oil.

By using Tukey's test it was found highly significant difference (p <0.01) in the content of water and dry matter in the white meat of broilers between treatments I and II, treatments I and III, and treatments I and IV. Highly significant difference (p <0.01) in the content of ash is established between treatments I and IV, and I and III. For the content of crude protein, highly significant difference is established for the treatments I and IV, and III and IV. Significant difference (p<0,05) is established for the content of crude fat between treatments II and IV.

F – values of Fisher test, $\overline{X}$ - mean value, SD – standard deviation, CV – coefficient of variation, NS – Inside examined tretmans did not establish significant difference (p>0.05)
*** Highly significant difference (p<0.01) between treatments*

We were found highly significant difference (p <0.01) in the content of crude protein between treatments III and IV, and crude fat between treatments I and IV and II and IV in the liver of broilers. Highly significant difference (p <0.01) was established in the content of water and dry matter between treatments I and II, I and III, I and IV in the gizzard; for the content of ash we were found highly significant difference (p <0.01) between treatments I and II, I and IV; for the content of crude protein we were found highly significant difference (p <0.01) between treatments I and IV, III and IV, III and IV; for the content of ash we were found highly significant difference (p <0.01) between treatments II and III, II and IV in the gizzard.

CONCLUSIONS

Addition of animal fat and vegetable oil to broiler's feeding were significantly influenced on the contents of ash of red meat of broiler chickens, while the other parameters of chemical contents did not influence, but for the chemical parameters of white meat, addition of animal fat and vegetable oil to broiler's feeding were significantly influenced on the contents of water, dry matter, ash, crude protein and crude fats. Addition of sunflower oil to broilers' nutrition resulted with higher contents of total ash in the red and white meat, as well as of crude proteins and crude fats in the white meat of broilers. For the chemical parameters of liver and gizzard, addition of animal fat and vegetable oil to broiler's feeding were significantly influenced on the contents of crude protein and crude ash.

ABSTRACT: Common carp fingerlings were fed five diets in triplicate containing 0, 2, 3, 4 and 5% linseed oil for 75 days to determine effect of different concentration of LO on chemical and fatty acid composition of fish. Fish, average initial weight 200± 4 g, were stocked in 15 cages. Fish fed the 3, 4 and 5% LO diets had significantly better growth parameters compared to fish fed the 0 or 2% LO diets. Lipid content in muscle increased from 1.25% in the 0% LO, to 1.46%; 1.56 %; 1.94% and 2.37% in the 2, 3, 4 and 5% LO treatments, respectively. Fatty acid profiles in muscle tissue reflected the diet concentrations with significant increases ($p < 0,01$) in 18:3n-3 in fish fed the 2, 3, 4 and 5% LO diets. Other fatty acids showing significant ($p < 0,01$) muscle concentration increases in fish fed the LO diets were: C20:3n-3, C20:5n-3, C22:5n-3, C22:6n-3, as well as polyunsaturated fatty acids (PUFA), total n−3 fatty acids, and the n-3/n-6 ratio. Fatty acids which showed significant decreases ($p<0,01$) were saturated fatty acids (SFA). Fish fed the 5% LO diets had twice much n−3 fatty acids (7.05%) than those without LO (2.65%). N-3/n6 ranged from 0.14 in fish fed without LO to 0.33 in fish fed 5%LO. Inclusion of 5% LO in diets showed the most favourable effects on content of essential fatty acids in tissue of carp as well as on other tested parameters.
Key words: *common carp, cages, chemical composition, fatty acid, linseed oil*

INTRODUCTION

Regarding the fact that the intake of linoleic acid relative to α-linolenic acid in modern human diets is very high, dietary linseed oil can prove to be a key feed ingredient in the establishment of common carp meat as a food useful for decreasing the risk of cardiovascular diseases in humans (Zelenka et al., 2003). Linseed oil is acceptable from the viewpoint of human nutrition based on the innate ability of cyprinids to convert dietary α-linolenic acid to eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) (Buzzi et al., 1996; Bell et al., 2001). The tested vegetable oil was selected because of its availability and price, which make it suitable for fish feed industry. It has long been known that, providing their essential fatty acids requirements are met, many freshwater fish can be successfully reared on diets containing vegetable or terrestrial animal oils (Sargent et al., 2002).
Feed composition becomes very important in intensive fish farming, apart from hydroecology, genetics and pathology, because natural feed loses its significance in cage fish farming conditions (Bogut et al., 2002).
The effect of linseed oil on growth and meat characteristics of young common carp was carried out at a fish farm in Grabovo, Croatia, in duration of 75 days, started on April and finished on June.

MATERIAL AND METHODS

The cage platform with 15 cages was set up in a 650-m2 fishpond. Water was added after the fishpond had been disinfected with 160 kg of Ca (HCO3)2. Five experimental fish groups (C, L2, L3, L4 and L5) were included in the trial. Each dietary treatment was tested in three replicates. At the beginning of the experiment each cage was colonized with 60 1-year-old common carp; mean body mass per cage ranged from 198 to 206g/ind. Prior to the experiment the fish were bred under fishpond conditions in a monoculture and fed with pelleted feed.

Feed mixtures

Composition of the fish feed is presented in Table 1. Pellet diameter was 4.5 mm. Fish in the first three cages received feed without addition of linseed oil (control group C, cages 1, 2 and 3), while the other cages received the same quantity of feed with different quantities of linseed oil: 2.0% in L2 (cages 4, 5 and 6); 3.0% in L3 (cages 7, 8 and 9); 4.0% in L4 (cages 10,11 and 12) and 5.0% in L5 (cages 13, 14 and 15) (Table 1).
Daily feed amount was given in three rates at 8.00, 13.00, and 17.00 h; the schedule was determined according to feeding tables on the basis of water temperature, dissolved oxygen concentration and other physical and chemical water parameters. The fishes were not fed during the stocking day or during control fishing.

Analyses

Upon experiment completion, the body mass of all fishes was determined. Three fish were taken from each cage for further chemical analysis. The fishes were chilled and the bones and skin separated from the muscle tissue. Chemical composition of fish muscle tissue and experimental feed mixtures was determined using standard SRPS ISO methods as described by Trbović et al. (2009). Protein content was determined by Kjeldahl method (Kjeltec Auto 1030 Analyzer, Tecator, Sweeden). Water content was determined by drying at 103±2ºC to constant weight. For determination of total fat, the samples were hydrolyzed with 4M hydrochloric acid and extracted with petroleum ether by Soxhlet apparatus. Ash content was determined by combustion at 550±25ºC. Fatty acids determination was performed according to Spirić et al. (2009) by capillary gas chromatography. Group effect was determined using one-way ANOVA (Statistica 10.0, StatSoft Inc.). Inter-group differences were attained by the Tukey HSD test at $p \leq 0.01$. The results were presented as means±SE.

Growth performance

Growth-performance indicators [specific growth rate (SGR, % weight day-1), feed conversion ratio (FCR), weight gain (WG, %) and survival rate (SR, %)] were measured using following formulas:

SGR = 100 (Ln (mean final body weight)-Ln (mean initial body weight))/time (days);
FCR = dry feed intake (g)/wet weight gain (g);
SR (%) = (Final fish number/initial fish number)*100;
WG = Final body weight (g) - initial body weight (g) (g fish^{-1}**).**

RESULTS AND DISCUSSION

Chemical analysis results in the meat of common carp that had been fed with different linseed oil quantities are presented in Table 3. The increase in linseed oil content is accompanied by a slight decrease in fish meat water content, ranging from 79.16% in C to 77.84% in L5. On the contrary, the fat and protein content increases with higher linseed oil content, ranging from 1.25% in C to 2.37% in L5 and from 17.13% in C to 18.87% in L5, respectively. The ash content was the same in all analysed groups.

The addition of linseed oil to fish feed influenced the fatty acid composition of the fish meat fat (Table 4). Increased linseed oil content in feed is accompanied by a lower saturated and monounsaturated fatty acid content in fish meat. At the same time, detected was an increase in polyunsaturated, especially n-3 fatty acids, as well as a pronounced increase in the ratio of n-3 versus n-6 fatty acids (Table 4).

[3]NFE, nitrogen-free extract, g.kg-1 DM = 100 – (CP + CF + CA)

Growth performance was significantly affected by addition of linseed oil in fish diets (Table 2). It should be noted that the growth rate of carp fed diets supplemented with linseed oil in this study was significantly faster than that of fish fed diets without supplementation of linseed oil. Concentration of added oil also showed significant influence on the growth performance. This could indicate that linseed oil has a favourable impact on the growth of common carp. Similar results were reported by Bogut et al. (2002) for catfish and (Zakes et al., 2010) for tench.

The fatty acids profiles of fish body is strictly linked to their dietary content (Bell, 1998; Zakes et al., 2010; Ćirković et al., 2011) and this means that fatty acid profiles of tissues can be modified by altering the types of fats and oils used in feed (Francis et al., 2006; Sargent et al., 2002; Turchini et al., 2003).

CONCLUSIONS

The addition of 2-5 % linseed oil to the feed of common carp has multiple beneficial consequences on fish breeding. It improves fish growth indicators and fish meat quality (increases the protein content and polyunsaturated fatty acids proportion).

ABSTRACT: This report was designed to compare the efficacy of Artemisia absinthium L. powder and amprolium on the basis of weight gain feed conversion ratio, oocyst count and mortality rate. A total of 90, day-old broiler chicks of both sexes were randomly divided into six groups (A to F). From first day onward, ration was supplemented with 1; 2 and 3% Artemisia absinthium L. powder in groups B and D, respectively, group A received amprolium: 60 ppm in drinking water, while groups E and F kept as infected un-medicated controls. First five groups were infected with Eimeria tenella sporulated ooccysts: 30.000/chick at the age of 20th. Maximum coccidiostatic effect was observed with Artemisia absinthium L. (3%) showing mild bloody diarrhea as compared to other infected groups receiving A. absinthium L. containing rations. Anticoccidial effect of used herb and coccidiostatic- amprolium, suggests that further studies should be carried out to determine the possible maximum safe levels with least toxic effects to be used as coccidiostat.
Key words: *Artemisia absinthium L., coccidiosis, amprolium, broilers*

INTRODUCTION

The genus Eimeria comprises a population of obligate intracellular protozoan species with a complex life-cycle including both asexual and sexual stages of development. Coccidiosis is the consequence of Eimeria infection of the intestine of the permissive host. This condition markedly reduces growth and feed utilization in poultry and livestock. Due to intensive breeding of poultry, coccidiosis is a lingering economical problem for poultry industries worldwide. Many anticoccidial drugs have been developed and introduced in the poultry industry all over the world. The increasing resistance of avian coccidia (protozoa) to anticoccidial drugs currently used by the poultry industry has stimulated the search for new methods of control. Therefore, there is need to find out the safe alternatives for the control of avian coccidiosis. In this context, a number of plants and herbal products have been found to be effective for a broad range of parasites such as protozoa, arthropods and helminates (Akhtar and Rifaat, 1985; Jiang et al., 1985; Klayman, 1985; Cooke et al., 1987; Quan, 1990). As part of this effort we have investigated *Artemisia absinthium* as a potential source of compounds with anticoccidial activity.

The genus Artemisia belongs to the family Compositae (*Asteraceae)* and has over 300 species spread worldwide. Plants from this family are a rich source of sesquiterpene lactones, a class of natural compounds with several proved medicinal effects, including anthelmintic effect. In the past 8-10 years, new medicinal benefits were reported for several *Artemisia* species (spp.) due to the anti-parasitic effects of some artemisinin-based compounds and the high antioxidant capacity of crude extracts of some plants of this genus. Besides artemisinin, *Artemisia* spp. are rich sources of sesquiterpene lactones and antioxidant compounds (flavonoids, phenolic acids, etc.) with potential benefits to human and animal health (Orav et al., 2006).

Information regarding anticoccidial activity of herbs and homeopathic products is very limited. Therefore, the present study was carried out to evaluate the anticoccidial effect of *Artemisia absinthium* in comparison with amprolium, a standard anticoccidial in broilers.

MATERIAL AND METHODS

Birds

The experimental protocol was approved by the local Ethics Committee; the principles of animal protection were strictly followed. Experiments under *in vivo* conditions were performed on ninethy broilers of the heavy line Arbor Acres, of both sexes. One –day-old broilers, randomly selected, were divided into six groups (A to F), each numbering 15 individuals. Bird fed a standard basal diet. All birds had free access to water and feed. Temperature and lighting regimens were in accordance with the recommenditation of the breeder. The initial room temperature 32-33º C was reduced weekly by 1ºC to a final temperature of 28ºC.

Parasite and dose

Coccidial oocysts of *Eimeria tenella* spp. were obtained from the guts of infected chicks and propagated in broiler chicks by giving oral infection. The oocysts were preserved in 2,5% potassium dichromate solution to induce sporulation and kept in a refrigerator (2-5ºC) until use. Each bird was challenged with 30.000 oocysts/chicken of *E. tenella* at the age of 20th day.

Experimental groups

There were six experimental groups and each was having 15 chicks. Different groups of chicks were assigned to various rations with different supplementations from day 1 till end of experiment. The infection was given on 20th day-of age to all the groups except group F, which served as uninfected un-medicated group. The medication with herbal powder and standard coccidiostatic was started according to the following schedule.

Group A: Amprolium (Kokciprol): 60 mg per 1 dm^3 of drinking water;
Group B: *Artemisia absinthium* crude powder: 1%;
Group C: *Artemisia absinthium* crude powder: 2%;
Group D: *Artemisia absinthium* crude powder: 3%;
Group E: Infected unmedicated control;
Group F: Uninfected unmedicated control.

Evaluation parameters

Efficacy of *Artemisia absinthium* powder and amprolium was evaluated on the basis of body weight gain, feed consuption, feed conversion rates, bloody diarrhea and oocyst counts. The body weight gain and feed conversion ratio was determined on weekly basis up to the end of experiment (six weeks). Bloody diarrhea was investigated from 4th to 6th day after the challenge. The extent of bloody diarrheal score was assigned one of the four degrees, from 0(-) to 3(+++). Zero was the normal status, whereas 1,2 and 3 corresponded to 33, 33-66, 66-99% blood in total feces, respectively. OPG (oocysts per gram of faeces) were counted from 6 to 13 days after infection with *E. tenella.*

Statistical analysis

The data of body weight gain, feed conversion rates and feed intake were analyzed statistically by repeated measures analysis of variance (Steel and Torrie, 1982).

RESULTS AND DISCUSSION

The mean values of body weight gain, feed consuption and feed conversion ratio in various groups at different weeks after the treatment are shown in table 1. During first three weeks, before inoculation of infection, the body weight gain, feed consuption and conversion ratio were not significantly different among the groups. At the end of experiment, the body weight gain in the groups treated with amprolium and 3% *Artemisia absinthium* powder (2316g and

2329g, respectively) were significantly higher than that of infected group (1991g). The body weight gain in the groups treated with rations supplemented with 1% and 2% *Artemisia absinthium* powder (2024g and 2059g, respectively) were relatively, but not significantly higher than that of infected group.

Table 1. Broiler production performance (0-6 weeks)

Groups	Average feed intake/bird (g)	Average wt gained/bird (g)	Feed conversion ratio
Amprolium (A)	4606[b]	2316[b]	2,05[a]
1% *Artemisia absinthium* powder (B)	4133[a]	2024[a]	2,26[b]
2% *Artemisia absinthium* powder (C)	4218[a]	2059[a]	2,24[b]
3% *Artemisia absinthium* powder (D)	4613[b]	2329[b]	2,01[a]
Infected control (E)	4121[a]	1991[a]	2,30[b]
Uninfected control (F)	4618[b]	2334[b]	1,98[a]

Means in each row lacking common superscript differ significantly (P<0.05)

The body weight gain, feed consuption and feed conversion rate of all the groups were investigated from 1st to 6th week. The body weight gain and feed consuption of all the infected groups were lower than that of uninfected control group. But, the body weight gain and feed consuption of groups supplemented with the rations containing amprolium and 3% turmeric powder were significantly greater than that of all other infected groups. Also, the body weight gain and feed consuption of groups supplemented with the rations containing 1% and 2% *Artemisia absinthium* powder were greater than that of infected group but that difference was not significant.

Bloody diarrhea of almost all experimental groups, with the exception of the uninfected control group, was observed from the 4th to 6th day after challenge with *E. tenella.* In the groups treated with rations supplemented with amprolium, and 2% and 3% *Artemisia absinthium* powder, the extent of bloody diarrhea was milder than that observed in various groups at different weeks after the treatment are shown in table 2*.*

Table 2. Bloods diarrhea of chickens treated with *Artemisia absinthium* powder and challenged with *Eimeria tenella.*

Groups	Blood in feces (days after infection)				
	3	4	5	6	7
Amprolium (A)	-	+	+	-	-
1% *Artemisia absinthium* powder (B)	-	+	++	+	-
2% *Artemisia absinthium* powder (C)	-	+	++	-	-
3% *Artemisia absinthium* powder (D)	-	+	+	-	-
Infected control (E)	-	+	+++	+	-
Uninfected control (F)	-	-	-	-	-

After challenge with *E. tenella*, the bloody diarrhea and excreted oocysts of feces were investigated during two weeks. Bloody diarrhea of all the experimental groups, except the uninfected control group were seen during 4-6 days after infection with *E. tenella.* But the extent of bloody diarrhea in the groups treated with ration supplemented with amprolium and 3% *Artemisia absinthium* powder was milder than that of other groups. Excreted oocysts in the groups treated with ration supplemented with 1% and 2% *Artemisia absinthium* powder were relatively lower than that of the infected control group. In the groups treated with ration supplemented with 3% *Artemisia absinthium* powder and amprolium, the peak excretion of oocysts was delayed about 1 or 2 days relative to the control infected group (table 3)*.*

Table 3. Oocyst excretions and mortality of chickens treated with *Artemisia absinthium* powder and challenged with *Eimeria tenella*

Groups	Average oocyst count g^{-1}		Mortality rate %
	Before treatmen	After treatmen	
Amprolium (A)	6500	1956	4(15)
1% *Artemisia absinthium* powder (B)	5500	19640	6(15)
2% *Artemisia absinthium* powder (C)	4300	15090	5(15)
3% *Artemisia absinthium* powder (D)	6000	2004	5(15)
Infected control (E)	4300	52200	6(15)
Uninfected control (F)	-	-	-

The oocysts out put and mortality rate were lower in all the treated groups as compared to infected un-medicated control group. However, among treated groups the birds treated with 3% *Artemisia absinthium* powder and amprolium showed better results in terms of oocyst count per gram of faeces and mortality rate as compared to those treated with 1% and 2% *Artemisia absinthium* powder. The counts were zero in uninfected groups.
The parasite was not completely suppressed by any of the treatment. The anticoccidial did not work in this case. The reason for this observation could be the resistance caused by anticoccidials (Butaye et al., 2000). Sluis (1998) also reported that severity of test exposure is important as resistant to anticoccidials was often effective with mild coccidiosis but ineffective at moderate or severe exposure. It has been reported that the diets supplemented with the different concentrations of the *Artemisia absinthium* were suppresive towards the development of coccidiosis in chickens. Furthermore, these diets were shown to increase the body weight gain, improve lesion scores and decrease oocysts out put.

CONCLUSIONS

It was concluded that the plant evaluated (*Artemisia absinthium)* in the study have anticoccidial activity.
Maximum coccidiostatic effect was observed with *Artemisia absinthium* (3%) showing mild bloody diarrhea as compared to other infected groups receiving *Artemisia absinthium* containing rations. Also, the weight gain in the group treated with 3% *Artemisia absinthium* was significantly higher ($p<0.05$) than that of infected control group.
It could be concluded that investigated plant (*Artemisia absinthium)* could be a potential source of protection against coccidiosis.

ABSTRACT: Goat's gastrointestinal helminths infection was of great importance to health status of goats and performances. This was parasitic infection caused by helminths from genus *Ostertagia, Trichostrongylus, Nematodirus, Chabertia, Haemonchus, Marshallagia, Skrjabinema* and *Oesophagostomum*. Goars infection had high prevalence, moderate morbidity and low mortality rate. Animals had abdominal pain, anemia, lost of appetite, dehydration, tenisms, weakens and lost of weight. Clinical signs are greenish or yellow diarrhea with smell, and some time is presented a blood. Young animals are depressive and inactive. Consequence is significant increase of kid accrescense, its weakens and less growth.
Key words: *gastrointestinal helminths, goats*

INTRODUCTION

During last decade goat production has started to play an important role in Serbia in providing animal protein for diet, especially for people living in villages. Goats reared in the area are of milk aptitude, but also constitute a meat supply for the consumers.
Goats gastrointestinal helminths infection was infection caused by helminths from genus *Ostertagia*, *Trichostrongylus*, *Nematodirus*, *Chabertia, Haemonchus, Marshallagia*, *Skrjabinema* and *Oesophagostomum* (Georgievski, 1989, Mishra, 1991). Goars infection had high prevalence, moderate morbidity and low mortality rate. Symptoms of acute greenish or yellow diarrhea with smell, and some time is presented a blood, and weight loss (Smith, 1990, Ilić, 1991).
No systematic studies had been previously made to determine the endoparasitic fauna of goats in Serbia. Examination of goat parasitoses has been sporadically performed and there are only a limited number of publications about it (Vujić and Bošković, 1981, Ilić, 1990, Vujić et al. 1991, Ilić et al. 1991, Pavlović et al. 1995).
In the present study we performed an extensive examination of parasitic fauna of goats at various parts of Serbia during a two year period (2010-2011) obtained during realization of project TR 31053.

MATERIAL AND METHODS

Our examination was performed in period 2010-2011. We examined 331 goat and sheep flock (usualy breed together) from 19 villages in the area of Belgrade. Total of 1450 faeces samples were examined using routine coprological methods (Zuriilski and Rusev, 1990). A total of 67 goats were slaughtered for post-mortem examination. Total differential worm counts were done on all the gastrointestinal tract and lungs using the technique described by Pavlović and Anđelić-Buzadžić (2010). Determination of adult and eggs of parasites were done by keys given by Euzeby (1981) and Pavlović and Anđelić-Buzadžić (2011).

RESULTS AND DISCUSSION

The faecal samples were obtained from a different source all together as they were collected from flocks in the field, and the results support the other findings. These counts were also of

value in providing some information on the peripartuirent egg rise. The number of guts and lungs examined in this survey thought small in number, but in combination with results of coprological examination, samples appeared to represent the population adequately.
In period 2009-2010 we found next helminth species: *Ostertagia circumcincta* (95,23%), *O.trifurcata* (91,53%), *Trichostrongylus axei* (100%), *T.colubriformis* (89,57%), *Nematodirus spathiger* (100%), *N. filicolis* (43,31%), *Haemonchus contortus* (88,95%), *Marshallagia marshalli* (23,77%), *Skrjabinema caprae* (13,28%), *Chabertia ovina* (64,14%) and *Oesophagostomum venulosum* (28,39%).
Most prevalent species of nematode were Trichostrongylus and Nematodirus species. Although most of the gastro-intestinal species appear to follow this general pattern of seasonal distribution, some variations in intensity and duration of these characteristics with different worm species occurred. Thus with *Trichostrongylus* and *Nematodirus* species infection at mature sheep the spring peak was more pronounced that the autumn infection. When we compared our results to the similar survey at mountain area of Serbia that have been done at Šara Mountain (Vujić and Bošković, 1981, Vujićet et al., 1991, Pavlović et al., 1995), and at East Serbia (Ilić,1990, Ilić et al.1991, Pavlović et al.,1991, 2003), we were concluded that dominant endoparasite species were *Trichostrongylus spp*. and *Nematodirus spp.* Same parasite species were diagnosed in other Balkan countries like Macedonia or Bulgaria (Georgievski,1989, Zurliiski and Rusev,1990).
Generally speaking the occured parasites represent a global problem. Way of breeding usualy at shepeng had prerequisite to a lot of infections including parasitoses. Pasture breeding make possible contact within sheep and eggs, larval stages and intermediate host of parasites. Those induce that there are no one goats without parasites. The countries of Magreb, Middle East and Northern Africa have also permanent problem with parasitic infections and losses ensued by them.
From these reasons both infection can be prevented by adding anthelmintic drugs to the goat's diet. With careful management and sound preventive measures, the losses associated with this disease can be reduced to minimal levels.

CONCLUSIONS

Goat’s gastrointestinal helminths infection was of great importance to health status of goats and performances. This was parasitic infection caused by helminths from genus *Ostertagia*, *Trichostrongylus*, *Nematodirus*, *Chabertia, Haemonchus, Marshallagia*, *Skrjabinema* and *Oesophagostomum*. Goars infection had high prevalence, moderate morbidity and low mortality rate. Consequence is significant increase of goats accrescense, its weakens and less growth
The best preventive measure a goat producer can take is to use a feed with anthelmintic drugs added. With careful management and sound preventive measures, the losses associated with this disease can be reduced to minimal levels.

ACKNOWLEDGEMENTS

Our work are part of results from project TR 31053, "Implementation of new biotechnological solutions in breeding of cattle, sheep and goats for the purpose of obtaining biologically valuable and safe food”, funded by the Ministry of Education and Science of the Republic of Serbia.

ABSTRACT: One of the most important parameters of feed quality is energy. Not all energy of feed (gross energy) will be utilized by the animal, but only its bio-available portion, i.e. metabolisable energy (ME). The accepted method for direct determination of ME of feeds is by *in vivo* trials. These are often time-consuming and expensive why there has been a need for *in vitro* methods for predicting the *in vivo* ME values of feeds. The aim of this study was to develop linear equations to predict the *in vivo* true metabolisable energy (TME) of poultry feeds based on digestibility of organic matter as determined by an *in vitro* method. Sixteen diets and fifty seven samples of feedstufs for poultry were used. *In vivo* determination of TME was based on digestibility of nutrients, by use of the adult rooster assay. Same feed samples were analysed by an enzyme incubation based laboratory procedure for estimating the enzymatic digestible organic matter (EDOM). Obtained EDOM values were regressed against the *in vivo* TME results, which generated the prediction equation TME = 0.191 x EDOM, with R^2 = 0.704 (RSD = 0.127). When other predictors were included, prediction was improved and the following equations and R^2 have been generated: TME = 0.177 x EDOM + 0.168 x Fat, with R^2 = 0.766 (RSD = 0.113) and TME = 0.191 x EDOM + 0.209 x Fat – 0.044 x Protein, with R^2 = 0.830 (RSD = 0.098). The conclusion was that *in vivo* ME of feeds for poultry can be sucessfully predicted by use of organic matter digestibility.
Key words: *Metabolisable energy, prediction, poultry, feeds, organic matter digestibility*

INTRODUCTION

One of the most important parameters of feed quality is its energy. Not all energy of the feed (gross energy) will be utilized by the animal, but only a bio-available portion called metabolisable energy (ME). This parameter serves as an accurate indicator of feed quality and can be reliably used for feed quality control. Metabolisable energy is directly proportional to digestibility of nutrients, as it directly affects their availability and absorption (Čolović et al., 2011).

The accepted method for direct determination of ME of feeds is by *in vivo* trials. These are often expensive and time-consuming. *In vitro* methods used for predicting ME are attractive because of rapidity and low cost (Farrel, 1999) and can be estimated directly from parameters accessible in the feeds (Noblet and Perez, 1993). Therefore, there has always been a need for reliable laboratory methods and related equations for prediction of the *in vivo* ME values of feeds, in order to implement an adequate system of quality control (Alvarenga et al., 2011). There has been a considerable and continuous interest to develop equations for rapid and accurate prediction of ME (Perai et al., 2010; Robbins and Firman, 2005; Zhang et al., 1994).

The aim of this study was to develop equations, using linear model, for predicting the *in vivo* ME of poultry feeds from the digestibility of organic matter, as determined by an *in vitro* method not used for poultry feeds.

MATERIALS AND METHODS

A total of 57 feedstuff samples and 16 commercial complete diets for poultry was used in this study.

Proximate analysis
Dry matter (DM), crude protein (Protein), crude fibre (CF), crude fat (Fat) and Ash were determined according to AOAC official methods (2000).

***In vitro* determination of enzyme digestible organic matter (EDOM)**
The three-step procedure of Boisen and Fernadez (1997) was modified to 2-step thus using incubation of feed sample with pepsin for 75 min, followed by incubation with pancreatin for 18 h. Solubilised protein was precipitated with sulphosalicylic acid. Insolubilised and precipitated materials were collected after filtration and then dried and finally ashed. Based on the results from determined dry matter and ash in the sample and residue, respectively, EDOM was calculated.

***In vivo* determination of true metabolisable energy (TME_n)**
The method used is a procedure for determining digestibility of nutrients (McNab and Fisher, 1982, 1984; Fisher and McNab, 1987). In this bioassay technique, 50 g of the test feed is introduced into the crop of an adult rooster by means of a stainless steel funnel and tube. Each test feed is replicated among six roosters. Excreta are collected during 48-h period. These are dried, weighed and analysed. Endogenous energy or amino acid losses are determined in roosters kept under the same conditions, but glucose is fed in place of the test ingredient. These endogenous losses are used to calculate the true digestibility of the test nutrient.

Statistical analysis
Using statistical package STATISTICA (Data Analysis Software System), v.8.0. (2008), obtained EDOM and proximate analysis values were regressed against the *in vivo* ME results, and 3D graphs and correlation plots were generated. Coefficient of determination (R^2) and root mean square (RMS) were used as parameters for assessment of model adequacy.

RESULTS AND DISCUSSION

Correlation between TME_n and EDOM is presented in Figure 1. For the prediction of TME_n simple linear model with one parameter was proposed. The single coefficient with value of 0.191 was significant ($p < 0.001$). Coefficient of determination (R^2) of proposed model had fair value of 0.704, while RSD value was 0.127. The proposed model could be used for fast prediction of TME_n value, as no additional chemical analysis is required.

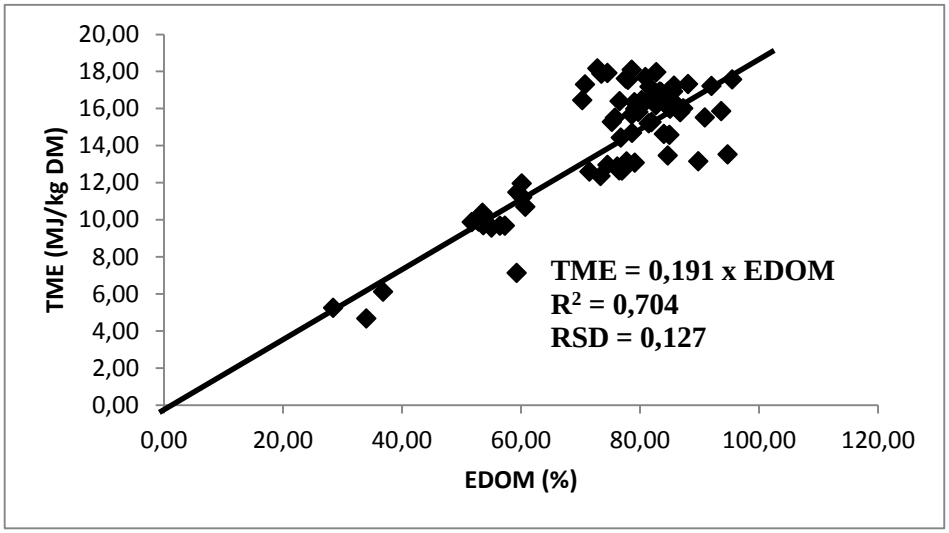

Figure 1. Correlation between TME_n and EDOM

In 3D graph (Figure 2) the correlation between TME_n and EDOM and fat is presented, i.e. linear model with two parameters was used for prediction of TME_n values. Both coefficients in model were significant ($p < 0.001$). Value of coefficient of determination (R^2) was 0.766, while value of RSD was 0.113.

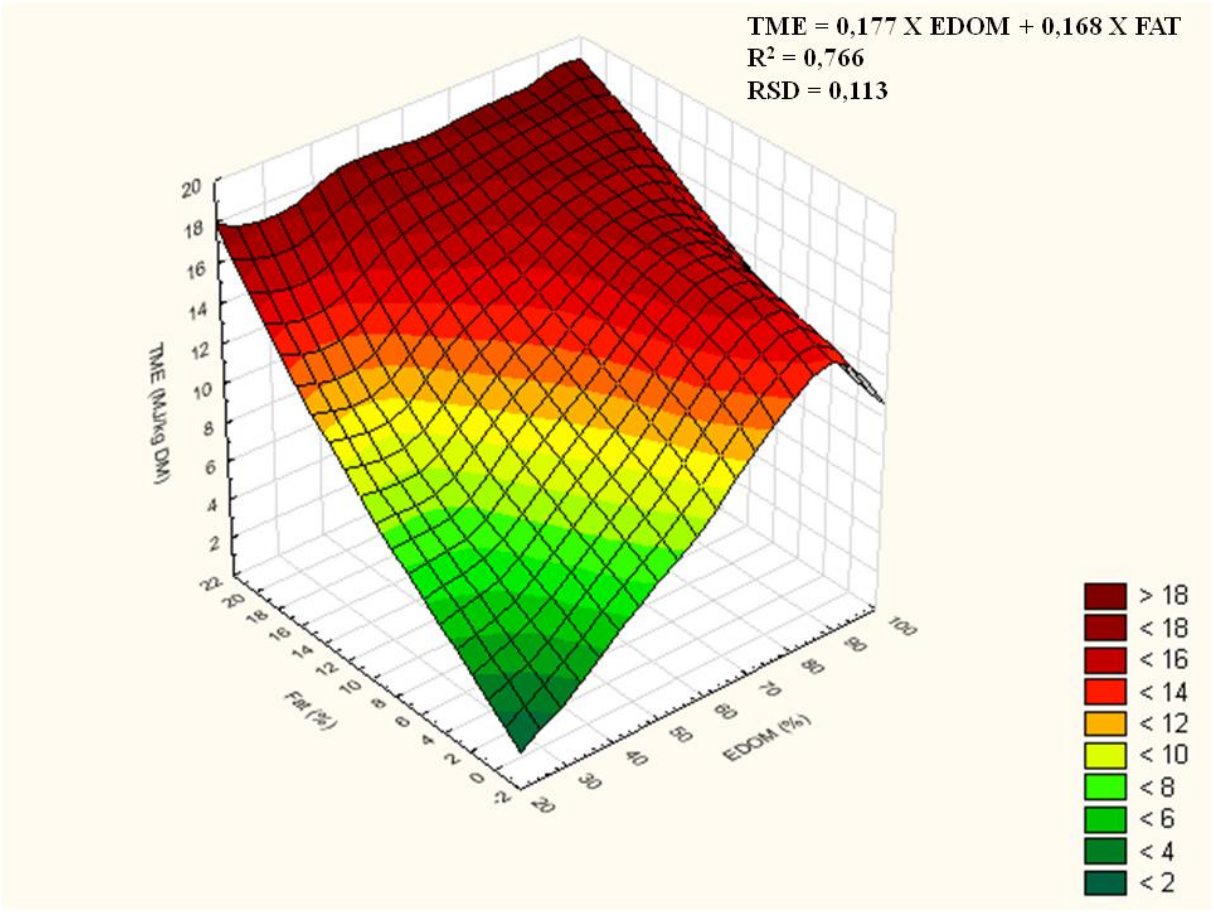

Figure 2. Correlation between TME_n and EDOM and TME_n and fat (3D graph)

Figure 3 presents correlation between TME and EDOM, fat and protein. Matrix graph was used for depicting validity of the proposed model. This graph is comprised of n x (n - 1) 2D graphs, where n is number of variables. Experimental values were presented with dots, while linear model was presented with linear trendline. All three coefficients in the model were significant ($p < 0.001$). Coefficient of determination (R^2) was 0.830, which according to Mayers and Montgomery (1995), can be considered as well fitting of data. RSD value of proposed model was 0.098.

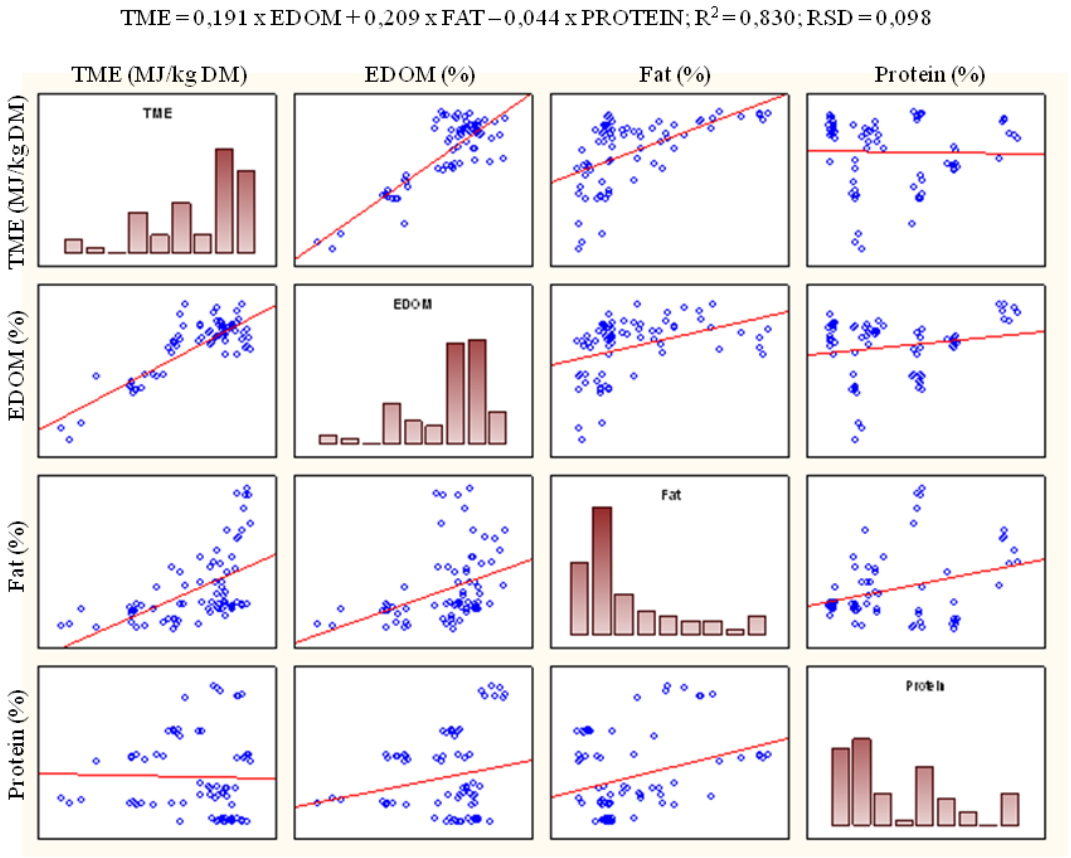

Figure 3. Correlation between TME_n and EDOM, fat and protein

Energy value of diets is of great importance for animal feed manufacturers and end users. The amount of available energy in feeds is described either by its metabolizable energy (ME) or by organic matter digestibility (OMD) (Pojić et al., 2008). Metabolisable energy is the most widely accepted value when expressing feed energy for poultry (Nwokolo, 1986; Farrell et al., 1991), however, its capability to estimate feed energy contents must be validated with *in vivo* determined values (Losanda et al., 2009, 2010).

In vitro methods used for predicting ME are rapid and not expensive (Farrel, 1999) as compared to *in vivo* determination of digestibility which is time-consuming and costly. Therefore, there has been a need for fast and reliable *in vitro* methods for determining nutrient digestibility in single feedstuffs for use in feed formulations and for control of complete diets (Boisen and Fernandez, 1997).

CONCLUSION

It can be concluded that the ME of feeds for poultry can be successfully predicted using the enzymatic procedure for determining the organic matter digestibility. Results of the statistical analysis showed that using only EDOM as a predictor is not as accurate as when the other variables from proximate analysis are included.

ACKNOWLEDGEMENT

The authors are grateful to the Ministry of Education and Science of Republic of Serbia for supporting this study through project III-46012, as well as to the Ministry of Science of Republic of South Africa for funding.

ABSTRACT: From January to June 2011 the content of iron and manganese in water, hay, complete feeds and muscular tissue, liver and kidneys of fattening bullocks after slaughtering was monitored with the aim of determining the correlation between the concentration of these elements in tissues and their quantity in water and complete feeds. The bullocks were bred on a mini farm in Kraljevo. Water and hay samples were collected on a fifteen-day basis. Ten samples of water, hay, complete feeds, muscular tissue, liver and kidneys were processed.
Apart from water, all the samples for the analysis were prepared by dry ashing and decomposition in a microwave oven (simultaneously), while Mn and Fe were determined by *atomic absorption spectroscopy* (AAS) (AOAC 1990) . The method of sample preparation did not affect the values of obtained results.
The average quantity of iron in water amounted 1.92 mg/L, 185.52 mg/kg in hay, 137.43 mg/kg in complete feeds, 38.87 mg/kg in muscular tissue, 67.60 mg/kg in liver and 78.83 mg/kg in kidneys. The average content of manganese was 1.57 x 10^{-2} mg/L in water, 76.01 mg/kg in hay, 12.64 mg/kg in complete feeds, 0.34 mg/kg in muscular tissue, 2.37 mg/kg in liver and 1.12 mg/kg in kidneys.
Our results showed that the intake of iron through water was significantly above MAC *(maximum allowable concentration)***,** whereas the quantity of manganese was substantially lower. The determined quantity of Fe in complete feeds was above minimal needs of bullocks as opposed to the quantity of Mn that did not comply with the proscribed limited quantity. The highest content of iron was determined in kidneys, and manganese had the highest value in bullocks liver.
Key words: *bullocks, feed, water, iron, manganese, tissues*

INTRODUCTION

When it comes to its content in animal organisms, iron is between micro and macro elements. A major part of iron can be found in blood hemoglobin and muscle myoglobin. The percentage of iron in hemoglobin is about 0.33%, while the remaining part of iron can be found in liver, spleen and kidneys. Iron in blood is an integral component of various important enzymes like hemoprotein enzymes (cytochromes) and flavonoid protein enzymes which have a very important role in oxidation processes of all cells. Iron is the key element in breathing process. As an integral part of hemoglobin, it enables transmission of oxygen and has the essential role in the reabsorption process.
Iron reabsorption takes place through intestine muscal which at the same time enables and controls its balance in organisms. Iron reabsorption in the digestion tract depends on the level of body reserves and the balance between the reabsorption process. The level of reserves is maintained. Some meal ingredients can affect the reabsorption process. It is believed that there is interdependence between the quantity of Ca, P and Fe and that reabsorption of one of them depends on its relative proportion in a meal. Fe reabsorption significantly decreases when the level of Ca is low and the quantity of phytic acid and P is high.
Fe excretion from organism is minimal and its quantity in serum is a typical indicator of the state of Fe enriched nutrition. The minimum Fe bullocks need from complete feeds is estimated to be about 20 mg/kg.
The first indicator of lack of Fe in food for animals is anemia. Anemia in bullocks occurs if they are solely fed with milk and no other food for a long time. As anemia problems in

humans are also related to the intake of Fe through beef, we found it important to determine the level of Fe in feed for bullocks, and in muscular tissue, liver and kidneys after slaughtering.
As opposed to other microelements, there is not much data available on the chemical composition of Mn or its combinations that can be found in animal organisms. Apart fromarginase in liver, which contains Mn as an essential component (Bach and Whitehouse, 1954) there is no metalloenzyme that contains a protein with a specifically determined quantity of Mn. However, Mn in vitro activates various enzyme systems, most commonly together with other divalent ions, magnesium in particular. The fact that Mn is concentrated in mitochondria implies that it is involved in partial regulation of oxidative phosphorylation. Manganese is not found in any specific organ or tissue, but its concentration in bones, liver, kidneys and pancreas is higher (1-3 mg/kg of fresh tissue) than in skeletal muscles (0.1-0.2 mg/kg).
Animal needs for Mn depend on animal species and the quantity of Ca and P in feeds. Estimation of Mn need is complicated because there is not much data on availability of Mn (in nutrition of poultry the availability is about 5 – 10 %), which means that fattening bullocks need at least 20 mg/kg of Mn. Copper has the key role in making use of iron, as Cu can be found in the enzyme ferroxidase which eases the process of iron release in mucous cells of intestines (Jovanovic et al., 2001). The quantity of Mn in hay is directly proportional to its content in soil, meaning that there are areas with deficit in Mn in hay because of its lack in soil. This is why Mn needs to be added to complete feeds for bullocks, taking care about its form. The most common additives are manganese oxide and manganese sulfate. If the relative biological utilization of manganese sulfate is 100%, then the utilization of manganese oxide is 60- 80%, manganese carbonate 25- 40% (Mc Dowell, 1992). Utilization of Mn from protein manganese or metionine Mn-chelate is, however, higher than that of manganese sulfate (Henry, 1995).

MATERIAL AND METHODS

The content of Fe and Mn in water, hay, complete feeds and muscular tissue, liver and kidneys after slaughtering of fattening bullocks was determined in this paper. The analysis included 10 samples of each of the examined parameters.
The samples of water, hay and complete feeds were taken from January to June 2011, on a fifteen-day basis, while the tissues were taken after slaughtering of cattle. The samples of water for the analysis were prepared by conservation (with nitrate acid) on the farm, and then they were concentrated in a laboratory. Hay samples were homogenized, chopped and burnt on a hot plate, and then calcinated in a calcinations oven at 550^{o}C. The residue after calcination was dissolved in HCl 1:1 and placed into 50ml vessels by redistilled water.
Complete feeds samples were homogenized in a homogenization mill “Cyclotec”, burnt on a hot plate and calcinated in a calcinations oven at 550^{o}C. The ash was dissolved in HCl 1:1, and determination of Fe and Mn in all the materials was performed by atomic absorption spectroscopy (AAS) method (Perkin Elmer 3300). These samples were destroyed in a microwave oven BEREGHOF - Speed (nitrate acid –hydrogen peroxide). Fe and Mn were determined in the same way with the aim to determine the impact of preparation method on the obtained result.

RESULTS AND DISCUSSION

The results of determination of Fe and Mn concentration in water, hay, complete feeds and tissues of fattening cattle are shown in tables 1 and table 2. The average quantity of Fe that cattle got through water amounted 1.92 mg/L with the interval of variation 0.47- 5.60 mg/l, while Mn amounted 1.57 x 10^{-2} mg/l. The current Rulebook on Hygienic Safety of Drinking Water does not limit the quantity of Fe, MAC for manganese is 0.050 mg/l. As the cattle farm is supplied with water from the Ibar alluvion, these results show that Mn quantity is almost

unchanged compared to determinations during 1987, 1988 and 1989. (Vukasinovic and Mihajlovic, 1990).
The results on Fe concentration in water for cattle were significantly higher than the results obtained by Vukasinovic and Mihajlovic R. (1990) who found that the concentration of Fe in the Ibar was 0.12 - 2.20 mg/l during 1987, 1988 and 1989. As the cattle farm and the town of Kraljevo are supplied from the Ibar alluvion, there is a significant increase of Fe level compared to the period ten years ago. Rajkovic et al. (2009) determined (indirectly, through aqueous lime scale) the presence of Fe and Mn in potable water in Belgrade. Their results show the presence of manganese in Vidikovac water supply network in the quantity of 0.040 mg/l, while the concentration of iron was 3.84 mg/l.

Table 1. Average concentration of Fe in water, hay and body tissues

Material	Measures of iron concentration variations (Fe)				
	n	x	Sd	Cv %	Iv (min-max)
Water (mg/l)	10	1.92	1.48	77.31	0.47-5.60
Hay (mg/kg)	10	185.52	83.25	44.87	66.44-302.41
Complete feeds (mg/kg)	10	137.43	18.073	13.15	103.32-158.87
Muscular tissue (mg/kg)	10	38.87	16.42	42.23	22.67-78.96
Liver (mg/kg)	10	67.60	13.10	19.38	45.27-88.37
Kidneys (mg/kg)	10	78.83	20.63	26.17	57.43-121.14

Average quantity of Fe in meadow hay from the Kraljevo area amounted 185.52 mg/kg with the variation interval of 66.44- 302.41 mg/kg of air dried hay. Sevkovic et al. examined the concentration of Fe (1989) in meadow hay from the Kraljevo area and they determined that it amounts 203.00 - 269.66 mg/kg of Fe, while the quantity of Fe in the hay from Pozega is insignificantly lower and it amounted 188.82- 247.28 mg/kg (Sevkovic et al.,1989). The average quantity of Mn in hay from Kraljevo amounts 76.01 mg/kg of air dried hay, with the variation interval of 32.08-100.16 mg/kg. The results we obtained are slightly higher that the results achieved by Sevkovic et al. (1989) who examined the concentration of Cu, Zn, Mn and Fe in meadow hay from Kraljevo and Pozega. They found that the concentration of Mn in meadow hay from Kraljevo amounted from 44.54 to 87.22 mg/kg, and that from Pozega was 68.42-143.95 mg/kg.
The average concentration of Fe in complete feeds for cattle amounted 137.43 mg/kg, with the variation interval of 103.32-158.87 mg/kg. The quantity of Fe was significantly above the quantity proscribed by the Rulebook on Animal feed Quality, which amounts 20.00 mg/kg. According to recommendations of NRC (2001), cattle need 2-3 mg of maganese per day and 10-20 mg of iron per day.

Table 2. Average concentration of Mn in water, feed and body tissues

Material	Measures of manganese concentration variations (Mn)				
	n	x	Sd	Cv %	Iv (min-max)
Water (mg/l)	10	1.57×10^{-2}	1.97×10^{-2}	125.15	0.002-0.070
Hay (mg/kg)	10	76.01	22.21	29.22	32.08-100.16
Complete feeds (mg/kg)	10	12.64	12.84	30.18	8.84-54.62
Muscular tissue (mg/kg)	10	0.34	9.70×10^{-2}	28.68	0.17-0.52
Liver (mg/kg)	10	2.37	0.32	13.69	1.81-2.86
Kidneys (mg/kg)	10	1.12	0.13	11.95	0.90-1.30

Average quantity of Mn in complete feeds amounted 12.64 mg/kg with variation interval of 8.84-54.62 mg/kg. The average concentration of Mn in complete feeds for the cattle was below the minimal needs stipulated by the Rulebook on Animal Feed Quality (“Official Gazette of the Republic of Serbia” number 4/10) in the amount of 20 mg/kg. As there is not much data on availability of manganese, it is difficult to determine the needs of cattle for manganese. There are few producers of complete feeds who use amino acid complexes as manganese source. Most of them use the salts of this element which are reabsorbed in small quantities (5-10%), while earlier research showed that organically chelated manganese is

reabsorbed better (80-90%) (McDowell, L.R.(1992). The reabsorption of manganese is increased by addition of EDTA to feed (Jovanovic et al., 2001).
Tables 1 and 2 show the results of examining the concentration of Fe and Mn in tissues of fattening cattle. The average concentration of Fe in muscular tissue amounted 38.87 mg/kg with variation interval of 22.67- 78.96 mg/kg, and Mn was 0.34 mg/kg with variation interval of 0.17-0.52 mg/kg. Livers of fattening cattle had the average concentration of 67.60 mg/kg of Fe with the variation interval of 45.27- 88.37, kidneys had 78.83 mg/kg with variation interval of 57.43- 121.14 mg/kg. The concentration of manganese in liver amounted 2.37 mg/kg with variation interval of 1.81-2.86 mg/kg, 1.12 mg/kg in kidney, with variation interval of 0.90-1.30 mg/kg. The determined quantity of Mn in liver was close to the quantity determined by Rogovski (1981), amounting 0.26 mg/100g.
Our results on the quantity of Fe in muscular tissue are higher than the results obtained by Rogovski (1981), finding the presence of Fe in the quantity of 3.00 mg/100g, while the concentration of Fe in liver determined by Rogovski was higher than our results (12.00 mg/100g). The concentration of Fe in kidneys was in accordance with the results obtained by Rogovski. The quantities of Fe determined by Djujic et al. (1981) in muscular tissue of cattle loin amounted 1.40 - 3.04 mg/kg, 1.22 - 2.56 mg/kg from flank and 1.42 - 3.57 in the meat from the head were significantly lower than the results we obtained.
According to the data on Fe and Mn concentrations in water, feed and tissues, we can conclude that the increase in concentration of examined minerals did not cause pathological changes that could result in impairment of general health of the examined cattle.

CONLUSIONS

Our examination provided the following results:
The samples of biological material for determination of Mn and Zn can be prepared from ash and by destruction in a microwave oven. The method of preparation does not affect the obtained results. The determined quantity of Fe in water for fattening cattle is significantly above the level determined by previous examinations, while the quantity of Mn did not exceed the MAC. The intake of Fe through complete feeds was significantly higher than the quantities proscribed by the current Rulebook, while the average quantity of Mn was below the minimum needs. The highest average quantity of Fe was determined in kidneys amounting 78.83 mg/kg, while the concentration of Mn in liver was 2.37 mg/kg.

ACKNOWLEDGEMENT

The work was realized within the project III 46012 co-financed by the Ministry of Education and Science, Gaverment of the Republic of Serbia.

ABSTRACT: This paper presents the analysis of amino acid composition of the diet for gilts from 9 farms in Vojvodina, with a goal to determine protein and amino acid content in mixtures for gilts. The aim of this study was presentation of the situation on the ground in terms of quality amino acid composition of gilt's diets. The work aroused unreasonably high protein content, as well as the essential and non-essential amino acids content in diets, which are economically unjustifiable and high above the recommendations for gilts. Protein content was ranged from 21.36% to 10.61%. Essential and nonessential amino acids were highly correlated with the level of protein, as expected. The highest correlation with the protein level was observed for arginine r = 0.92, and lowest in case of alanine r = 0.68, while for lysine was r = 0.75.
Key words: *amino acids, gilts, diet, liquid chromatography*

INTRODUCTION

It has been known for many years that when swine are fed by diets that are deficient in protein they do not grow or reproduce normally (Pond, 1973; Baker and Speer, 1983). Therefore, proteins were considered to be essential dietary constituents. It is now clearly recognized, however, that it is not proteins per se but their components, amino acids, that are the essential ingredients. Young pigs gain weight when fed by diets containing no protein, but an appropriate mixture of amino acids (Shelton et al., 1950; Beeson et al., 1951; Mertz et al., 1952; Eggert et al., 1955; Chung and Baker, 1991). Furthermore, sows are able to maintain a normal pregnancy during the last 84 days of gestation when fed by a diet that contains crystalline amino acids as the sole source of nitrogen (Easter and Baker, 1976).
Proteins differ considerably in their nutritional value. Some, such as milk proteins, are high in nutritional value; others, such as sesame meal, are low. It is well established that the nutritional value (quality) of a protein is primarily dependent on its amino acid composition, especially the content of essential amino acid, and on the availability of the amino acids. A protein that contains a perfect balance of amino acids, both among the essential amino acid and between essential and non-essential amino acid, has been described as an *ideal* protein. This concept has been discussed by numerous authors (Fuller and Wang, 1990; Cole and Van Lunen, 1994; Lewis, 1995; Baker, 1997).
Estimation of the proportions of amino acids in ideal protein for growing swine have been derived from an examination of various types of data, including the composition of pig tissue, the composition of sows' milk, and combinations of individual estimation of amino acid requirements. The validity of assuming that there is one set of ideal proportions among amino acids for all stages of growth has been questioned (Lewis et al., 1977) because it is clear that the ideal pattern for maintenance differs from the ideal pattern for synthesis of new tissue. Therefore, the overall ideal pattern will change as the proportions of maintenance and new tissue synthesis change. In addition, there are changes in the amino acid content of pig tissue as the pig grows from birth to market weight (Kyriazakis et al., 1993; Susenbeth, 1995; Mahan and Shields, 1998).
In theory, any deviation of the pattern of amino acids in ideal protein will lead to a reduction in animal performance, at least in terms of the efficiency of dietary protein utilization. In practice, however, swine seem to be relatively tolerant to quite wide variations in the pattern

of amino acids, as long as all amino acid requirements are met. Nevertheless, if the dietary amino acid pattern deviates too far from the ideal, swine performance will be reduced. The negative effects caused by the ingestion of disproportionate amounts of amino acids have been classified into three main types: *toxicity*, *imbalance*, and *antagonism* (Harper et al., 1970).

Toxicities, characterized by the consumption of a large excess of an individual amino acid, are rare in practical swine nutrition. It could be caused only by misinformation or errors in mixing of a diet that included crystalline amino acids. Unfortunately, out of four amino acids that are currently available in a feed-grade form for growing-finishing pigs (lysine, methionine, tryptophan, and threonine), two (methionine and tryptophan) have the highest relative toxicity of the essential amino acids. In rats, the addition of 3% methionine to the diet is severely toxic (Benevenga and Harper, 1967). The rat's requirement in sulfur amino acids is 0.60%; thus the margin of safety is rather small. Swine seem to be particularly sensitive to excess of methionine (Baker, 1977; Edmonds and Baker, 1987a; Edmonds et al., 1987). In contrast, excesses of lysine (Lewis et al., 1986; Edmonds and Baker, 1987b; Edmonds et al., 1987) and especially threonine (Edmonds and Baker, 1987a; Edmonds et al., 1987) are well tolerated by young pigs.

Imbalances are also caused by excessive intake(s) of (an) amino acid(s), but usually the extent of the disproportion is less and there are no clear toxic features that are specific for the amino acid(s) involved. Imbalances are caused by the exacerbation of the deficiency of the most limiting amino acid, and they can be corrected by the appropriate addition of that amino acid. In an experiment by Wahlstrom and Libal (1974), as little as 0.2% added methionine reduced the performance of growing-finishing pigs, but this effect was alleviated by the addition of 0.2% lysine (the First limiting amino acid). In general, amino acid imbalances reduce feed intake with little or no effect on the efficiency of utilization of the First limiting amino acid (D'Mello, 1993).

In most practical swine diets, the amino acid "disproportion" of greatest concern is simply a deficiency of one or more amino acids. Feedstuffs with high protein content are usually relatively expensive and thus there is a tendency to limit their inclusion in diets. When the dietary protein content is inadequate to meet the requirements for all essential amino acids, swine performance will be restricted. The amino acid that is present in the least amount relative to its requirement is said to be the *First-limiting amino acid*, and the extent to which it is adequate will determine animal performance. If the deficiency of this amino acid is corrected, then the amino acid next lowest in relation to its requirement (second-limiting) will dictate animal performance. Information about which amino acids are most limiting in natural feedstuffs is important in formulating swine diets (Austin J. et al., 2000).

MATERIAL AND METHODS

Material

Acetonitrile (LC grade) and methanol (LC grade were purchased from Sigma-Aldrich (St. Louis, MO). Borate buffer, OPA and FMOC reagents and amino acid mixture standard solutions (10, 25, 100, 250 and 1000 pmol μl^{-1}) were obtained from Agilent Technologies (Waldbronn, Germany). Hydrochloric acid, used for preparation of 6 M and 0.1 M HCl, was obtained by Lach-Ner (Neratovice, Czech Republic). Sodium phosphate monobasic was purchased from Acros Organics (New Jersey, USA). LC grade water was produced by Heming ID-3 system (Belgrade, Serbia), while cellulose membrane filters (pore size 0.22 µm) were purchased from Agilent Technologies (Waldbronn, Germany).

Equipment

Vacuum tubes for hydrolysis (19 x 100 mm) were purchased from Pierce (Rockfors, IL). Hydrolysis and evaporation of the sample was derived using the React-Therm™ (Thermo Scientific, USA).

The analysis was performed using the Agilent 1260 Infinity Liquid Chromatography System, equipped with µ-Degasser (G1379B), 1260 binary pump (G1312B), 1260 Standard

Autosampler (G1329B), 1260 unit thermostat (G1316), ZORBAX Eclipse-AAA column and 1260 DAD detector (G1315C).

Samples

Samples were collected from nine farms in Vojvodina, with a goal to determine protein and amino acid content in mixtures for gilts. Samples of mixtures for feeding gilts were milled in a laboratory mill with a sieve size of 0.5 mm. 0.1 to 1.0 g of sample was measured (equivalent to the nitrogen content of 10 mg) in a vacuum hydrolysis tube, and then hydrolyzed with 7 ml of 6M HCl. Hydrolysis was carried out with React-Therm^{TM} apparatus with constant stirring for 6 hours at 150 °C. After hydrolysis, samples were allowed to reach the room temperature and then evaporated to dryness using the React-Therm^{TM} at 70 °C in a stream of nitrogen. The residue was quantitatively transferred into a 50 ml volumetric flask with 0.1 M HCl. The solution was filtered through quantitative filter paper, and then additionally filtered using a cellulose membrane filter (pore size 0.22 µm).

Table 1. Injector programs

Injector program
Draw 2.5 µL from vial 1 (borate buffer)
Draw 0.5 µL from sample (position X)
Mix 3 µL .in air., max speed, 2x
Wait 0.5 min
Draw 0 µL from vial 2 (water, uncapped vial)
Draw 0.5 µL from vial 3 (OPA)
Mix 3.5 µL .in air., max speed, 6x
Draw 0 µL from vial 2 (water, uncapped vial)
Draw 0.5 µL from vial 4 (FMOC)
Mix 4 µL .in air., max speed, 6x
Draw 32 µL from vial 5 (water)
Mix 18 µL .in air., max speed, 2x
Inject

HPLC determination

Chromatography conditions were in accordance with the Agilent method (Henderson et al., 2000) with the exception of mobile phase A preparation where 5.678 g Na_2HPO_4 was dissolved in 1 L water and then adjusted with 6M HCl to pH 7.8. Hydrolyzed samples and standard mixtures of amino acids were automatically derivatized with OPA and FMOC reagents using the appropriate injector program (Table 1). After derivatization, an amount equivalent to 0.5 µl of sample or standard mixture was injected on ZORBAX Eclipse-AAA column (5 µm, 150 × 4.6 mm) at 40 °C, with detection at λ1 = 338 nm and λ2 = 262 nm. Mobile phase A was 40 mM Na2HPO4, adjusted with NaOH to pH 7.8, and mobile phase B acetonitrile / methanol / water (45:45:10 v:v:v). Separation was performed at a flow rate of 2 ml min^{-1} with a gradient program (Table 2) during the 26 min period of analysis.

All data were analyzed to test the correlation and for analysis Statistica 10 (Statasoft 2010) was used.

RESULTS AND DISCUSSION

The results of analysis of amino acids and protein in the diets for gilts from nine farms in Vojvodina are shown in Table 3. On the basis of shown values, it can be seen that only a mixture from farm no. 7 does not meet the criteria established by the "Regulations on the quality of feed". According to the "Regulations on the quality of feed" the minimum level of protein in the mixture should be 13%, and minimum level of lysine should be 0.55% (Pravilnik o kvalitetu hrane za životinje, 2010).

Table 3. Essential amino acids and protein content in diets for gilts from nine farms in Vojvodina

%	1	2	3	4	5	6	7	8	9
Protein	20.37	18.44	18.83	21.36	19.96	18.50	10.61	17.69	14.76
Lysine	1.173	1.130	1.131	1.575	2.262	1.212	0.503	1.020	0.769
Methionine	0.236	0.263	0.256	0.319	0.309	0.269	0.187	0.213	0.244
Threonine	0.675	0.589	0.567	0.729	0.916	0.614	0.341	0.531	0.434
Arginine	1.240	1.169	1.239	1.342	1.613	1.231	0.560	1.140	0.786
Histidine	0.610	0.592	0.645	0.600	0.952	0.538	0.205	0.577	0.391

Leucine	1.649	1.655	1.639	1.610	2.446	1.696	0.179	1.555	1.290
Phenylalanine	0.973	0.983	0.932	0.980	1.417	0.948	0.467	0.876	0.663
Valine	0.842	1.048	1.038	0.860	1.521	0.938	0.458	0.846	0.618

Results are given as mean, n = 3 samples; Farms were signed by numbers because of discretion policy not to publish the identity of the farm

In diet from farm no. 7, where was established the lowest level of protein, lysine content was 0.50 which is slightly lower than in the "Regulations on the quality of feed". Consequently, approximately 60 g of ileac digestible lysine/MJ of DE was required to optimize performance in gilts with high genetic potential for lean gain, irrespective of the feed intake level. In addition, a factorial model to estimate the lysine/energy requirements is proposed (Bikker et al., 1994).

Table 4. Non-essential amino acids content in diets for gilts from nine farms in Vojvodina

	1	2	3	4	5	6	7	8	9
Aspartic acid	1.797	1.720	1.632	1.877	2.611	1.811	0.806	1.581	1.183
Glutamic acid.	4.000	3.635	3.824	3.848	5.294	4.023	2.101	3.913	2.688
Serine	0.868	0.581	0.545	0.865	0.878	0.606	0.300	0.507	0.504
Glycine	0.811	0.846	0.911	0.913	1.243	0.874	0.433	0.830	0.553
Alanine	0.970	1.038	1.016	1.027	1.462	1.032	0.558	0.919	0.772
Tyrosine	0.493	0.373	0.388	0.476	0.595	0.495	0.224	0.399	0.338
Cysteine	0.114	0.056	0.057	0.128	0.076	0.072	0.038	0.067	0.058

Results are given as mean, n = 3 samples; Farms were signed by numbers because of discretion policy not to publish the identity of the farm

Results based on the feed intake observed in study, where the high-lean-growth gilt requires at least 22 g/d total lysine intake from 34 to 72.5 kg to maximize CP accretion (Hansen and Lewis, 1993).

The results of analysis of non-essential amino acids in diets for gilts, also with the nine most important farms in Vojvodina, are shown in Table 4. It is evident that the diet from farm no. 7 shows lower values than other farms, which was the case with the previous table in terms of protein levels and essential amino acids.

Correlation analysis (Table 5) between, protein and amino acid levels for a given farm indicates a significant difference ($p < 0.05$).

Table 5. Correlation between protein and essential amino acids

	Lys	Met	Thr	Arg	His	Ile	Leu	Phe	Val
Protein	0.75[a]	0.76 [a]	0.84 [a]	0.92 [a]	0.81 [a]	0.74 [a]	0.85 [a]	0.82 [a]	0.68 [a]

[a]*significant difference (p<0,05)*

Table 5, shows high correlation of protein levels and arginine r = 0.92, when it comes to the essential amino acids, and also a high degree of correlation was noted with almost all the essential acids (Table 5).

Table 6. Correlation between protein and non essential amino acids

	Asp	Glu	Ser	Gly	Ala	Tyr	Cys
Protein	0.83	0.83	0.87	0.82	0.78	0.85	0.75

[a]*significant difference (p<0,05)*

Also in Table 3 are evident unreasonably high values of protein content that reach up to 21.36%, as opposed to farm no. 4. If we notice the values for lysine, also shown in the same table, it can be seen that all values are unreasonably high, and some even more than double and reach up to 2.262% (sample of diet from farm 5), which is more than three times higher compared to the Regulations.
The values in Table 6 regarding the non-essential amino acids (p<0.05) were also highly correlated with the level of protein in the mixture, with many small mutual deviations.
The correlation between lysine and protein content (r = 0.75) is shown in Figure 1 and it indicates a significant but not very high correlation as it is the case with some other amino acids. Reasons for this may be related to the fact that the high level of synthetic lysine was added and that a good portion comes from soybeans.

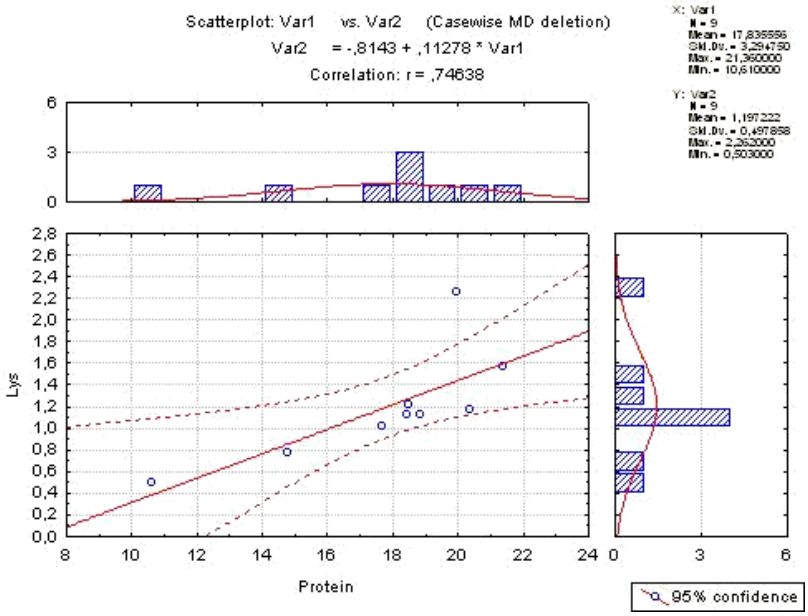

Figure 1. Correlation between lysine and protein content

CONCLUSIONS

Results of amino acid composition analysis of swine feed show less variation in terms of amino acid content which is primarily a consequence of the structure of the mixture. Since the First limiting amino acid in the diet of pigs is lysine, it is particularly necessary, in addition to other amino acids, to pay attention to its level in the diet.
Levels of protein in samples of analyzed diets for gilts on most farms are unjustifiable high. That level is higher than the level of requirements provided by the "Regulations on the quality of feed", compared to the level of protein and essential amino acids. From the point of meeting the requirements of the ideal protein diet, it is much more efficient to achieve with the levels of proteins that are closer to the needs of the given categories with the addition of synthetic amino acids.

One of the recommendations is that in the preparation of meals as a laboratory controlled mixtures, needs to be devoted more attention to amino acid composition and essential amino acids ratio than the protein content.

ABSTRACT: This paper investigates the effect of soybean oil, flax and rapeseed on production parameters and broilers carcass quality. At the beginning of fattening six groups of 40 one-day-old chick's hybrid Ross 308 were formed, with five replications. The control group was based on two levels of soybean oil, 4% and 8% and in the experimental groups were included 4% and 8% flax, or 4% and 8% rapeseed oil. Experiment lasted for 42 days. At the end of fattening period, 10 chickens from each group were sacrificed for the purpose of testing carcass quality. Including various types of oils in the diet did not result in statistically significant differences in body weight of chickens. At the end of the experiment, the control has achieved a body mass of 2704.0 g and 2695.0 g, experimental group with flax oil 2734.0 g and 2671.0 g and with rapeseed 2735.0 g and 2670.0 g. Feed conversion was the lowest in groups with rapeseed oil and the highest in groups with flaxseed oil. The difference in the carcass quality of control and experimental groups were not significant. The highest amount of abdominal fat (31,9g) was in the group with addition of 8% flax oil, and the lowest in the group with soy bean oil in same amount (22g) Treatments with 4% of oil, have almost the same amount of abdominal fat.
Key words: *nutrition, flax oil, rapeseed oil, soy oil, chicken, carcass quality*

INTRODUCTION

At the end of the last century the market was buying chickens with highest weight and highest efficiency for major body parts. Nowdays, there is a need for chicken meat with the altered structure of fat tissue rich in poliunsaturated omega-3 fatty acids, in order to reduce the number of people with cardiovascular illnesses. For that reason, the researchers are questioning the influence of the type and amount of oil on the growth intensity, feed utilization efficiency, carcass quality, and the chicken meat quality. Lopez-Ferrer et al., (2001) established that 2 and 4% flax oil in broilers mixtures, with addition of of 8% affects the fatty acid content of the tissue, while the production paremeters showed smoler diferences between treatments. Differences in yield of carcass mass between groups, were not significant ($P>0.05$). However, the results given by Bartos et al., (2004) show negative influence of the addition of 6% of flax oil in the mixture for broilers on the carcass quality. When the flaxseed meal was added in the amount of 5, 10 and 15% in the broilers chicken nutrition, during the first two weeks, growth depresion was not record. After that period differences in body mass are becoming more and more prominent so that at the end of the 6 week chickens were on the treatment of 15% of falxseed meal with recorded lower body mass for 8%, statistically significant ($P<0.05$) in accordance with the control group. Feed consumption was decreased, and conversion increased. The body mass was also decreased with the increase of participation of flaxseed meal, while the content of linoleic acid in red and white meat increased without the influence on sensor quality of meat (Mridula et al., 2011). The usage of the expeller of rapeseed meal in amount of 0 to 40% in the mixtures based on corn and soybean meal in broiler nutrition, did not significantlly ($P>0.05$) influence on the heart, kidney and thiroide gland mass, nor on the concentration of trijodthyronin and tetrajodthyronin, but it resulted in decreased growth and altered liver function (Woyengo et al., 2011). Using the oils with poliunsaturated fatty acids in broiler nutrition, to similar results

came Božić (1997), Antogovani et al., (2006), Azain (2004), Alparslan and Ozdogan (2006), Azman et al., (2005), Balevi and Coskun (2000), Bartos et al., (2004), Lopez-Ferrer et al., (1999), Stanaćev (2009), Talebali and Farzinpour (2005), Krasicka et al., (2000), Fouladi et al., (2008), Nelson (2005), Stanaćev et al., (2011). Having in mind the aforementioned, the aim of the research was to examine the productive parameteres and carcass quality of broilers chicken fed with different amounts of soy, flax and rapeseed oil.

MATERIAL AND METHODS

The researches conducted in productive conditions on the experimental farm »Pustara« in Temerin on the floor system of breeding. At the begining of fattenig period six groups with 40 one-day-old chicken of the hybride Cobb 500 were formed. The experiment is conducted in five repetitions, on the 200 chickens per treatment. Three mixttures with 21, 20 and 18% of protein where used for nutrition. First 14 days there was a preparation period for chickens, in which all groups were fed by starter mixture of standard content and quality. Then, for 21 days, grower mixtures with different source and oil amount were used. For the last 7 days, the chicken were fed by finisher mixtures with the same oil addition. The control group was fed with mixture based on 4 and 8% of soy oil, and in experimental groups there was 4 and 8% of flax and rapeseed oil (Table 1).Mixtures were izoprotein and izoenergetic. During the experimental period, that lasted for 42 days, the chickens were fed and watered *ad libitum*, and microclimatic conditions were regularly controlled. The control of body mass and the feed consumption was made every 7 days. At the end of the experiment, after 12 hours of starving, 10 chickens were taken from every group (5 females and 5 males) of avrerage body mass, marked with stamps and sacrificed for the needs of carcass quality research. After that there was debleeding, boiling, defeathering, taking out internal organs, and cooling. After that, clasically processed carcass was measured and cut on basic anatomic parts and measured (Regulations: Sl. List SFRJ, No.1/81 and 51/88). Marking was made based on yield and mass of certain parts of the carcass. For correct interpretation, given results were processed by the appropriate statistic methodes ANOVA (STATISTICA 9.1, StatSoft, Inc. 2010).

Group	**I**	**II**	**III**	**IV**	**V**	**VI**
	Control, Soy oil	Control, Soy oil	Flax oil	Flax oil	Rapeseed oil	Rapeseed oil
In grower	4%	8%	4%	8%	4%	8%
In finisher	4%	8%	4%	8%	4%	8%

RESULTS AND DISCUSSION

Based on the results given, it can be stated that introduction of different kinds and amounts of vegetable oil in nutrition of broilers did not affect the intensity of growth (Table 2). During the preparation period, the chickens had almost equal body mass per group. In the fifth week of the first experimental period it can be noticed that there is a very small depression in V group, on the treatment with 4% of rapeseed oil compered to control group. At the end of the experiment, the depression of growth is insignificantlly ($P>0.05$) marked in IV and VI group in the amount of 1.04 and 0.89%, while the III and V group more superior for 1.22 and 1.15% compared to the control group. With the analysis of variance and Duncan test, it is determinated that there are no statistically significant ($P>0.05$) differences among the groups.

CONCLUSIONS

Based on the resultes given above, it can be concluded that utilization of 4 and 8% of flax and rapeseed oil did not show significant differences concerned with productive parameters and carcass quqlity compared to control group that had a mass of 2703g and 2697g, and experimental groups in order 2736, 2669, 2734 i 2673g. Feed conversion was increased for 5.03% in III and 2.07% in IV group on the treatment of flax oil, whike the V and VI group on the treatment of rapeseed oil had more efficient utilization of feed for 0.52% and 2.69%.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR-31033 “Sustainable conventional and revitalized traditional production of poultry meat and eggs with added value”, financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT: Analysis of the fiber or cell wall present in forages is of major concern in ruminant nutrition because diets often contain large amounts of forage, and the fiber fraction affects both feed intake and animal performance. Research has revealed that plant genetics can affect the quality and digestibility of whole plant maize silage. All carbohydrates in plant feeds are grouped into: 1. Structural carbohydrates (carbohydrates of cell walls) including NDF (neutral detergent fibers-hemicellulose+cellulose+lignin), ADF (acid detergent fibers-cellulose+lignin), ADL (lignin), and 2. Non-structural carbohydrates-NFC (carbohydrates located inside the plant cell) made of starch, sugars and pectin. The aim of this present study was to observe quality parameters of ZP hybrids biomass with different genetic background for silage and to determine the relationship of these parameters, as well as, their effects on the digestibility of maize biomass dry matter. The contents of lignocelluloses fraction were determined by the modified Van Soest detergent method while *in vitro* digestibility of the whole plant was done by the Aufréré method. Obtained results showed that the NDF, ADF and ADL contents in the whole maize plant of the observed different ZP hybrids varied from 42.6% to 50.9%, 19.3% to 25.7%, and 1.6% to 2.5%, respectively. The difference in the digestibility of the dry matter of the whole plant between hybrids amounted to 10.4%. The differences in the contents of lignocelluloses fraction affected the differences in digestibility of dry matter.
Key words: *NFC, NDF, ADF, ADL, digestibility, maize hybrids*

INTRODUCTION

Maize is one of the most important naturally renewable carbohydrate raw materials. As a high-yielding carbohydrate plant, maize is very competitive in relation to other cereals (Radosavljevic et al., 2010). All carbohydrates in plant nutrients are grouped into: I structural carbohydrates (carbohydrates of cell walls), which include NDF (neutral detergent fibers - hemicellulose+cellulose+lignin), ADF (acid detergent fibers - cellulose+lignin), ADL (lignin) and II nonstructural carbohydrates - NFC (carbohydrates present in the plant cell content) that are made of starch, sugars and pectin (Jovanović et al., 1993). However, according Polakova et al. (2010) the NFC of substances comprises a diverse group of substances in terms of their composition and nutrient contents, excluding carbohydrates inherent to NDF. The NFC group of substances includes organic acids, monosaccharides, oligosaccharides, fructans, starch, pectin substances and □-glucans. There are numerous confirmations that the feeding ration with a high NFC content ferment and produce a great quantity of propionic acid in the rumen, which results in a higher insulin concentration in blood, i.e. in animal weight gain. Feeding rations rich in digestible fibers (hemicellulose and cellulose) produce acetic acid in the rumen and increase the growth hormone level in blood, which results in the increased milk production (Jovanović et al., 1993). Analysis of the fiber or cell wall present in forages is of major concern in ruminant nutrition because diets often contain large amounts of forage, and the fiber fraction affects both feed intake and animal performance. Research has revealed that plant genetics can affect the quality and digestibility of whole plant maize silage (Jung, 1997). Considering all stated, as well as, the fact that the digestibility does not depend on the energy concentration, the objective of this present study was to observe quality parameters of the whole plant of ZP hybrids with different genetic background for silage and to determine the relationship of these parameters, as well as, their effects on the digestibility of maize biomass dry matter.

MATERIALS AND METHODS

The hybrids of the FAO maturity group 100-700 (ZP 161, ZP 388, ZP 434, ZP 555, ZP 677, ZP 704) were used in this study. The two-replicate trail was set up according to the randomized complete-block design in the experimental plot of the Maize Research Institute, Zemun Polje. The experimental plot size amounted to 21m^2, while sowing density was 60,000 plants per hectare. Plants of each replicate were harvested in the full waxy maturity stage from the area of 7m^2 (two inner rows), and yields of fresh biomass of the whole plants, plants without ears and ears were estimated. Five average plants per replicate were selected for further tests. Samples of the whole plants were cut and dried at 60^{o}C for 48h. In order to determine the content of dry matter the whole plant samples were ground in the 1-mm mesh mill. Then, the analysis of the absolute dry matter was done on the oven dry basis (105^{o}C for 12 h) in order to estimate the total dry matter. Moreover, the analysis of the content of forage fibers (NDF, ADF, ADL, cellulose, hemicellulose) was performed by the modified Van Soest detergent method (Van Soest*,* 1963)*.* The method was modified by Mertens (1992). *In vitro* digestibility of the whole maize plant was done by the Aufréré method *(*Aufréré, 2006). This method is based on the hydrolysis of proteins of the whole plant in the pepsin acid solution (Merck 2000 FIP u/g Art 7190) at 40^{o}C for 24 h, and then on the hydrolysis of carbohydrates in the cellulase solution (cellulose Onozuka R10) in duration of 24 h. Methods applied in order to determine basic chemical content of the maize plant samples (contents of ash, protein and fat) were described in previously published paper (Radosacljević et al., 2000). The NFC content in the whole plant samples is calculated according to the formula: (%) NFC = 100%DM – ((%) crude protein + (%) NDF + (%) fat + (%) ash) (Polakova et al., 2010).

Statistical analysis of data

Data reported for quality parameters of ZP hybrids biomass was assessed by analyses of variance (ANOVA) and LSD multiple test was used for any significant differences at the P<0.05 level between the means. All the analyses were conducted using statistical software package STATISTICA 8.1. (StatSoft Inc. USA).

RESULTS AND DISCUSSION

Table 1 presents the NFC content of the whole plant and evaluation of significance of difference between the observed ZP maize hybrids. The results showed that the NFC content in the whole maize plant of the observed different ZP hybrids varied from 33.20% to 41.22%. The difference in the NFC content of the tested ZP hybrids was 8.02%. Differences in the contents of NFC were statistically significant between hybrids ZP 388, ZP 555, ZP 704, and between these and the ZP 161, ZP 434 and ZP 677. Differences in the contents of NFC were not statistically significant between the ZP 161, ZP 434 and ZP 677.

Table 1. Content of NFC of the whole plant of the ZP maize hybrids

Hybrids	NFC (%)
ZP 161	39.93^d
ZP 388	41.22^a
ZP 434	33.20^d
ZP 555	39.63^b
ZP 677	34.33^d
ZP 704	38.14^c
$LSD_{0.05}$	1.29

Means in the same column with different superscripts differ (p<0.05)

Data on the content of NDF, ADF, ADL, hemicellulose and cellulose are presented in Table 2. The results showed that the NDF, ADF, ADL, hemicellulose and cellulose contents in the whole maize plant of the observed different ZP hybrids varied from 42.57% to 50.84%,

19.32% to 25.74%, 1.63% to 2.51%, 23.26 to 26.07% and 17.69 to 23.62%, respectively. The differences in the content of NDF, ADF, ADL, hemicellulose and cellulose among observed ZP hybrids were 8.27%, 6.42%, 0.88%, 2.82% and 5.83%, respectively. Statistically significant differences in the NDF content of tested ZP hybrids were found, except between the ZP 434 and ZP 677, ZP 555 and ZP 704. Differences in ADF content were statistically significant except between hybrids ZP 161 and ZP 704. Statistically significant differences in the ADL case were found only between hybrids ZP 161 and ZP 555. The difference in ADL content was statistically significant only between hybrids ZP 161 and ZP 388. In other ZP hybrids these differences were not significant. Differences in hemicellulose content were not statistically significant between the ZP 161 and ZP 434 and ZP 677, and between ZP 388, ZP 555 and ZP 704. Statistically significant differences in cellulose content in the examined maize hybrids were found. The differences in cellulose content were not statistically significant between the ZP 161 and ZP 704.

Table 2. Content of forage fibres of the whole plant of the ZP maize hybrids

Hybrids	NDF (%)	ADF (%)	ADL (%)	Hemicellulose (%)	Cellulose (%)

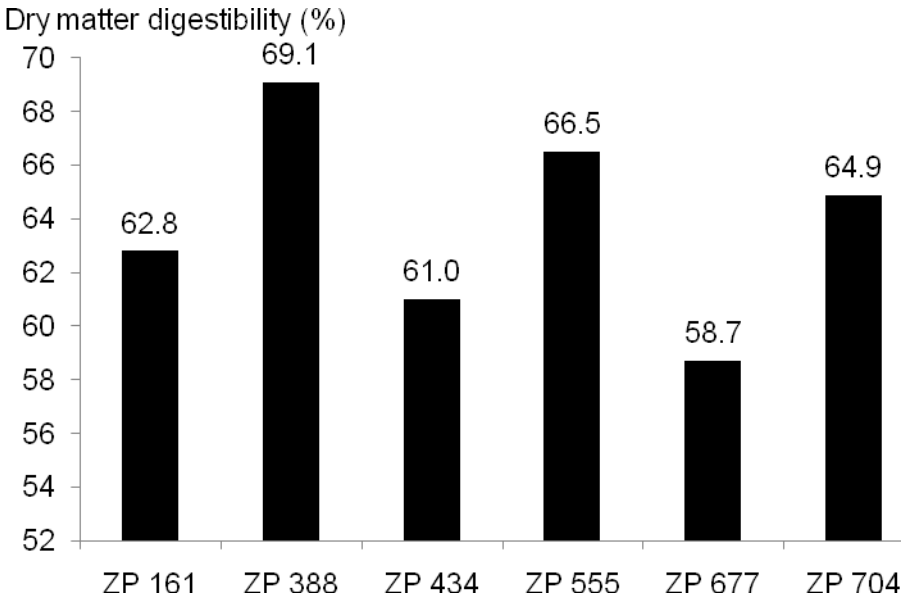
Considering the crucial effect of the NFC and forage fibers on the digestibility of the whole maize plant dry matter, the correlation dependence between the content of these components and the dry matter digestibility was observed (Table 3). A highly significant correlation between NFC content and dry matter digestibility of whole plant maize hybrids (r = 0.90), and a significant negative correlation between the content of NFC and the content of NDF, ADF, ADL, hemicellulose and cellulose were established (r = - 0.97, r = -0.90, r = -0.83, r = -0.96, r = -0.84). A very significant negative correlation was determined between the digestibility and NDF, ADF, hemicellulose and cellulose content (r=-0.96, r=-0.98, r=-0.79, r=-0.97), and significant negative correlation between the ADL content and the dry matter digestibility. Wermke (1986) ascertained a significant negative correlation (r=-0.67) between the digestibility and the ADF content, as well as, between the digestibility and lignin (r=-0.95). Burritt et al. (1985) studied three grass species and found high correlation dependence between the dry matter digestibility and the content of forage fibers. The coefficient of correlation between the digestibility and NDF, ADF, ADL and cellulose amounted to r=-0.84, r=-0.93, r=-0.91 and r=-0.86, respectively (Burritt et al., 1985). Very significant positive correlation was determined between the NDF content and content of ADF, ADL, hemicelluloses and cellulose amounted to (r=0.97, r=0.74, r=0.90, r=0.94). Significant positive correlation was determined between content of ADF and content of ADL and hemicellulose amounted to (r=0.66, r=0.77) and very significant positive correlation with cellulose content (r=0.99). Positive significant correlation was determined also between content of ADL and hemicellulose (r=0.76) and also between hemicellulose and cellulose content (r=0.72). Wermke (1986) established that there were maize hybrids with a low digestibility and a high content of stover cell wall constituents, as well as, there were hybrids with a high digestibility and a low content of cell wall constituents. These hybrids were defined as a dislocation type of hybrids. Hybrids with a high digestibility and a low NDF content of stover and a high NDF content of stover and a low ear digestibility are classified into types of hybrids with prolonged stover assimilation.

Table 3. Correlation dependence between digestibility, NFC and forage fibres of the whole plant of the ZP maize hybrids

	NFC	NDF	ADF	ADL	Hemicellulose	Cellulose
Digestibility	0.90**	-0.96**	-0.98**	-0.64*	-0.79**	-0.97**
NFC		-0.97**	-0.90**	-0.83**	-0.96**	-0.84**
NDF			0.97**	0.74**	0.90**	0.94**
ADF				0.66*	0.77*	0.99**
ADL					0.76**	0.55
Hemicellulose						0.72**
Cellulose						

The Figure 1 presents results of the digestibility of the whole ZP maize hybrid plant dry matter. The digestibility of the whole ZP maize hybrid plant dry matter ranged from 58.7% to 69.1%. The difference in the digestibility of the whole maize plant dry matter amounted to 10.4%. According to results obtained by Deinum et al. (1981) and Andreu et al. (1974) this difference varied from 2% to 3%, while Terzić (2006) and Terzić (2010) established the highest difference among observed hybrids of 11.52% and 8.56%, respectively. Differences in the digestibility of whole plant corn were statistically significant between the ZP hybrids.



$LSD_{0.05} = 1.07$
$LSD_{0.01} = 1.68$

Figure 1. Dry matter digestibility of the whole plant of the ZP maize hybrids

CONCLUSION

Obtained results showed that the NFC content in the whole maize plant of the observed different ZP hybrids varied from 33.20% to 41.22%. The difference in the NFC content of the tested ZP hybrids was 8.02%. The results also showed that the NDF, ADF, ADL, hemicellulose and cellulose contents in the whole maize plant of the observed different ZP hybrids varied from 42.57% to 50.84%, 19.32% to 25.74%, 1.63% to 2.51%, 23.26 to 26.07% and 17.69 to 23.62%, respectively. The digestibility of the whole ZP maize hybrid plant dry matter ranged from 58.7% to 69.1%. The difference in the digestibility of the dry matter of the whole plant between hybrids amounted to 10.4%. The differences in the contents of NFC and forage fibers affected the differences in digestibility of dry matter.

ABSTRACT: In this paper the influence of broken corn and extruded broken corn addition in broiler diet on carcass quality was investigated. The experiment was conducted on broiler hybrid ROSS (n = 720) divided in three groups. The first group (control - C) was fed with commercial broiler feed mixture, while second and third groups were fed with commercial mixtures where 25% of corn was substituted with broken corn (experimental group E1) or extruded broken corn (experimental groups E2). Broiler fattening lasted 35 days, and food and water were provided ad libitum in the floor fattening system.
The obtained results indicate that the substitution of corn with broken and extruded broken corn did not affect significantly ($P > 0.05$) on the mass of cold carcasses. Also, shares of carcass main parts (breast, whole legs, back portion and tail end and wings) showed no significant ($P > 0.05$) differences between all three groups. The only significant difference ($P < 0.05$) was determined for mass of abdominal fat between control C (14.4 g) and experimental group E2 (21.2 g). Differences of meat yield in breast and whole leg of broilers from different groups were not registered as significant ($P > 0.05$). Based on the results obtained in this study it can be concluded that the use of 25% of broken or extruded broken corn in broiler diet did not have significant influence on carcass quality.
Key words: *broiler, feeding, broken corn, extruded corn, carcass quality*

INTRODUCTION

Poultry meat quality is a complex and multivariate property, which is affected by multiple interacting factors including genetics, feeding, husbandry, pre-slaughter handling, stunning and slaughter procedures, chilling processing and storage conditions. However it is likely that the effects exerted by ante-mortem handling (feed withdrawal, catching, crating, transport and lairage) and slaughter (hanging, stunning, killing, scalding, plucking, evisceration, chilling and processing) conditions on final product quality may be greater than those attributable to variation in husbandry practises. Many problems may occur at these stages that potentially increase the rate of mortality, carcass downgrading and meat quality.
Feeding strategy is the management factor which is most actively used as a quality control tool in the production of meat and in relation to improvement and/or control of performance, animal welfare, safety, nutritional value, and eating and technological quality (Andersen et al., 2005).
In the domestic production of forage mixtures, the corn has the leading position compared to other cereals, because of high energy contents (16.2 MJ/kg), starch, comparably big contents of oil and low level of cellulose (Bekrić, 1999). Proper thermal process provides the reduction of thermo labile antinutrients contents, to an acceptable level, and increases digestibility of some nutrients (protein, oil, carbohydrates), as well as the improvement of sensory features and the microbiological quality of the final product (Kormanjoš et al., 2007). Parallel with the reduction of antinutrients contents it is necessary to preserve nutritionally valuable thermo labile components, so the thermal process requires a compromise between the two efforts.
New technologies used to increase the nutritional value of feed are: toasting, hydrothermal refinement, micronisation, microwave treatment, bielectrical heat treating (Marsman et al.,

1998). In Serbia the most often used process are extrusion and hydrothermal process (Sakač et al., 2001; Filipović et al., 2008).
With 30% influence on carcass and meat quality (Rede and Petrović, 1997; Čepin and Čepon, 2001; Džinić, 2005; Džinić et al., 2009) feeding is considered to be the dominant premortal factor. Quality can be assessed both objectively and subjectively. Objective assessment tends to predominate throughout the supply chain prior to consumption by the consumer where quality attributes can be measured scientifically. Determination of carcass quality includes two main parts the definition of indicators for expressing the individual characteristics of quality and quantification of the inherent characteristics in relation to the overall quality.
The objective of this study was to determine the effect of broken corn and extruded broken corn addition in broiler diet on carcass quality.

MATERIAL AND METHODS

The experiment was carried on 720 broilers, hybrid ROSS. Broilers were divided in three groups, control group (C) and experimental (E1) and (E2) groups and fed under the same conditions in the period of 35 days. Experimental groups were fed with commercial mixtures where 25% of corn was substituted with broken corn (experimental group E1) or extruded broken corn (experimental groups E2). During whole broiler growing period water and feed were ad libitum. After growing and 12h starving period, 9 broilers from each group were slaughtered and processed by bloodletting, scalding, plucking and evisceration and chilled. Then chickens carcasses "ready to grill" from each group were cut in the basic anatomical parts: (SFRY 1/81 and 51/88). Cutting and deboning of breast and whole leg were applied in order to determine the breast whole leg meat yield quality. Analysis of variance (Duncan test) was used to test the hypothesis about differences among obtained results. The software package STATISTICA 8.0 (STATISTICA 8.0, 2008) was used for analysis.

RESULTS AND DISCUSSION

Examination of carcass quality (Table 1) of control and experimental groups shown that greater weight (1352,7 g) of cold carcass "ready to grill" was in experimental group E1 comparing to control (1286.2g), and experimental group E2(1298.5g). The difference between the chilled carcases of groups were not significant ($P > 0.05$). Measured masses of chilled carcasses „ready to grill“ were smaller than the results of Petričević et al. (2011) and Džinić et al. (2011) for female chickens of Ross 308 hybrid line, what could be attributed to the prolonged fattening period of 49 days. Greater breast weight (489.4 g) and whole leg weight (389g), the most important parts of the carcass, were found in chickens of experimental group E1 (fed with broken corn).The differences between the breast and whole leg weight of control and experimental groups E1 and E2 were not significant ($P > 0.05$). Average values of back portion and tail end were lower in chicken carcasses from control group comparing to the experimental groups. Average values of wings in carcasses of control and experimental groups were in the range of 139.5g (E2) to 148.4g (E1). Mass of abdominal fat was the lowest (14.4 g) in control group and significantly lower ($P<0.05$) comparing to chicken carcasses of experimental group E2 (21.2g). Mass of abdominal fat in chicken carcasses of experimental group E1 was numerically lower 16.2 g but not significant ($P > 0.05$) then in experimental group E2. The results are consistent with the results of Milosevic et al. (2007), who found significantly lower content of the abdominal fat in carcasses of broilers not fed extruded corn flower. According to Ljubojević et al. (2011) extruded corn influenced the reduction of abdominal fat contents in carcass of male and female Ross broiler but this difference was not statistically significant.

Table 1. The results obtained by weighting (g) the main parts of chilled carcasses of control and experimental chicken groups (mean values ± standard deviation)

Group	Chilled carcass mass^{ns} (g)	Breast mass^{ns} (g)	Mass of whole leg^{ns} (g)	Mass of back portion and tail end^{ns} (g)	Mass of wings^{ns} (g)	Mass of abdominal fat (g)
C	1286.2 ± 75.1	478.1 ± 37.6	376.2 ± 23.7	278.2 ± 16.2	141.5 ± 10.8	14.4^{a} ± 6.0
E1	1352.7 ± 97.5	489.4 ± 54.6	389.0 ± 26.3	297.9 ± 17.5	148.4 ± 10.3	16.2^{ab} ± 6.7
E2	1298.5 ± 63.0	468.2 ± 56.7	380.9 ± 22.9	287.2 ± 24.9	139.5 ± 11.8	21.2^{b} ± 5.3

Table 2. Breast meat, bones and skin weight (g) and share (%) in total breast mass of control and experimental chicken groups (mean values ± standard deviation)

Group	Breast (g)			Breast (%)		
	Meat^{ns}	Bones^{ns}	Skin^{ns}	Meat^{ns}	Bones^{ns}	Skin^{ns}
C	375.4 ± 37.9	64.8 ± 7.4	33.6 ± 4.9	78.4 ± 2.2	13.7 ± 2.3	7.0 ± 0.9
E1	383.4 ± 51.9	65.7 ± 9.1	35.1 ± 4.7	78.2 ± 2.9	13.5 ± 2.1	7.2 ± 1.2
E2	360.1 ± 62.2	68.7 ± 9.6	33.5 ± 4.1	76.5 ± 4.3	14.9 ± 3.3	7.2 ± 1.0

Chicken breast (Table 2) from experimental group E1 had higher (383.4 g) meat (65.7g) bones and (35.1g) skin weight in chilled carcass, but not significant ($P > 0.05$) in comparison with control and experimental group E2.Share of meat in breast within groups was in the range from 78.4% to 76.5% and differences between groups were not significant ($P > 0.05$).

Whole leg (Table 3) from experimental group E1 had the highest meat weight (265.0 g) and share of meat (68.1 %) in whole leg, while the meat weight (254.6g) had the lowest whole leg control group C. Share of meat (68.1 %) in the whole leg in group E1 was higher but not significantly ($P > 0.05$) compared to group E2 (66.9 %) and C (67.7%). Share of skin in the whole leg was the lowest (8.97%) in group C and significantly lower ($P < 0.05$) comparing to experimental group E1 (10.1 %) and group E2 (10.6%).

Table 3. Whole leg meat, bones and skin weight (g) and share (%) in total whole leg mass of control and experimental chicken groups (mean values ± standard deviation)

Group	Whole leg (g)			Whole leg (%)		
	Meat^{ns}	Bones^{ns}	Skin^{ns}	Meat^{ns}	Bones^{ns}	Skin
C	254.6 ± 18.2	82.2 ± 7.2	33.8 ± 3.2	67.7 ± 1.7	21.9 ± 1.7	8.97^{b} ± 0.6
E1	265.0 ± 20.3	79.6 ± 8.8	39.3 ± 6.4	68.1 ± 1.5	20.5 ± 1.9	10.1^{a} ± 1.5
E2	254.8 ± 17.1	80.5 ± 7.3	40.5 ± 4.9	66.9 ± 1.5	21.2 ± 1.7	10.6^{a} ± 1.0

The results obtained in Table 4 showed that experimental group E1 had the highest breast meat, whole leg meat and total meat weight in chilled carcass comparing to the control and experimental group E2. Share of breast meat, whole leg meat and total meat in chilled carcass, between control and experimental groups were not significant ($P > 0.05$).

Table 4. Breast meat, whole leg meat and total meat weight (g) and share (%) in chilled carcass of control and experimental chicken groups (mean values ± standard deviation)

Group	Meat (g)			Meat (%)		
	Breast^{ns}	Whole leg^{ns}	Total^{ns}	Breast^{ns}	Whole leg^{ns}	Total^{ns}
C	375.4 ± 37.9	254.6 ± 18.2	629,9 ± 49,9	29.1	19.7	48.9
E1	383.4 ± 51.9	265.0 ± 20.3	648.4 ± 64.1	28.3	19.6	47.9
E2	360.1 ± 62.2	254.8 ± 17.1	614.9 ± 55.9	27.7	19.6	47.3

CONCLUSIONS

The diet with extruded corn did not affect significantly (P > 0.05) on mass of chilled carcass. Quality resulted in increased weight of carcass, higher share of breast meat in chilled carcass, higher protein and reduced free fat content in breast meat (P > 0.05), comparing to control group. Shares of carcass main parts (breast, whole legs, back portion and tail end and wings) showed numerically (P > 0.05) differences between control and experimental groups. Significant difference (P < 0.05) was determined for mass of abdominal fat between control C (14.4 g) and experimental group E2 (21.2 g). Experimental group E1 had the highest breast meat, whole leg meat and total meat (P > 0.05) weight in chilled carcass comparing to the control and experimental group E2.

ABSTRACT: Animal blood produced in slaughterhouses as a by-product of the meat industry represents serious biohazard. Transformation of wasted slaughterhouse blood to the highly valuable product(s) may partially solve the problem of disposing slaughterhouse blood wastes and at the same time, isolated heme concentrates can be used to fortify feed. The aim of this study was to optimize the isolation process of bovine hemoglobin from slaughterhouse blood by gradual hemolysis in a membrane bioreactor. 35 mM Na-phosphate/NaCl buffer solution of pH 7.2-7.4 was identified as the optimal external medium providing effective gradual osmotic hemolysis with an extent of hemolysis of 88%. The hemoglobin purity of >80% was confirmed by SDS-PAGE. Kinetic studies showed that maximal concentration of hemoglobin was reached after 40 min, but the process cycle at which recovery of 83% was achieved, lasted for 90 min. Methemoglobin levels remained below 2% with hemoglobin concentration of 4.8 ±0.5 gL^{-1} at the end of process. In order to produce ready-to-use feed additive for prevention of iron deficiency anemia in domestic animals, future studies should be oriented toward development of down-stream processes, such as tangential flow filtration and lyophilization.
Key words: *slaughterhouse blood, bovine hemoglobin, gradual hemolysis, membrane bioreactor*

INTRODUCTION

Iron deficiency is the most common and widespread nutritional disorder in the world. As well as affecting a large number of children and women in developing countries, it is the only nutrient deficiency which is also significantly prevalent in industrialized countries (http://www.who.int/nutrition/topics/ida/en/index.html). Besides, as the main cause of hypochromic anemia, iron deficiency represents a major problem in several segments of the livestock industry, whereas piglet anemia is the most wide-spread.

Food fortification is generally considered to be the best long-term strategy to combat iron deficiency (Cook and Reusser, 1983). Most of the supplements (for human or veterinary use) for prevention and treatment of hypochromic anemia existing on the market are based on non-heme iron (inorganic and organic iron salts). Another source of iron is heme iron, which is only found in myoglobin or hemoglobin. Compared to non-heme iron, the bioavailability of iron from heme iron sources may be 2- to 7-fold higher than that of iron from non-heme sources (Hurrell 1997; Seligman et al.; 2000; Quintero et al. 2008). Also it has shown that absorption of heme-iron is not dependent upon dietary composition (Conrad et al., 1966) and produces little side effects (Frykman et al., 1994).

In animal blood, hemoglobin accounts for more than half of the blood proteins and 90% of the cell fraction proteins. Animal blood produced in slaughterhouses represents the most problematic by-product of the meat industry due to the high volumes generated and very high pollutant load of this biohazard. At the same time it represents an inexpensive source of heme-iron. Transformation of one wasted slaughterhouse blood to the highly valuable product, such as hemoglobin may partially solve the problem of disposing slaughterhouse blood wastes, especially for developing countries. Hemoglobin has already been used with success for food fortification (Hertrampf et al., 1990; Walter et al., 1993). Its low iron content (0.35%) limits whole hemoglobin use as a food supplement in treatment of iron deficiency in humans, but it stands for suitable compound of common bulky feed for domestic animals.

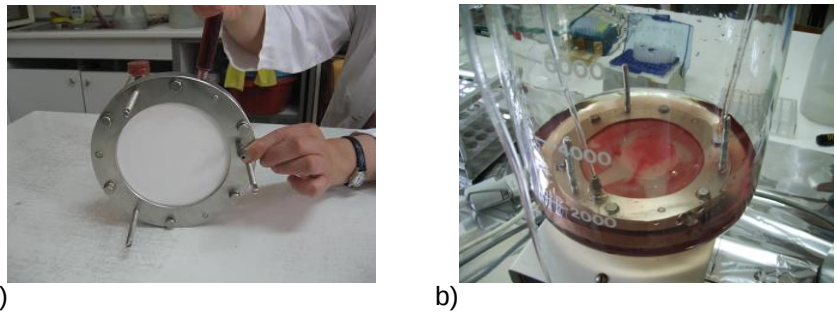
The isolation and purification of hemoglobin is the essential and first step in the heme iron production process. The aim of the investigation presented in this paper was to optimize the isolation process of bovine hemoglobin by gradual hemolysis in the originally designed membrane bioreactor (Bugarski et al., 2003), according to the osmotic properties of erythrocytes from bovine slaughterhouse blood. The process of gradual osmotic hemolysis is discussed in terms of extent of hemolysis, erythrocyte volume change, the time course of hemoglobin release, and morphological changes in red cells associated with osmotic swelling.

MATERIAL AND METHODS

Bovine blood (Slaughterhouse "Ambar", Surčin, Serbia) was taken from jugular vein of Holstein-Friesian calves and collected in a glass bottle containing 3.8% Na-citrate as an anticoagulant agent. Whole blood was centrifuged (2100 × g) at room temperature, and plasma proteins and leucocytes (buffy coat) were removed by vacuum aspiration. The three step washing with isotonic (0.9% w/v) saline solutions (Hemofarm, Vršac, Serbia), was sufficient to remove contaminating plasma proteins according to Andrade et al. (2004). After washing, erythrocytes were resuspended in isotonic (0.9% w/v) saline solutions at 40% of hematocrit. The cyanmethemoglobin method (Van Assendelft et al., 1984) was used for determination of hemoglobin concentration in erythrocyte suspension. The concentration of methemoglobin was determined by the method described by Palmer et al. (2008). Hematocrit was measured by the microhematocrit method (Sabine and Nickolai, 1952). Erythrocytes were counted on a Spenser hemocytometer. Osmotic fragility of bovine erythrocytes was determined by the method of Beutler (1983). The concentration of NaCl producing 50% of hemolysis (H_{50}) was calculated by the GraphPad Prism 3.0 software program. The osmotic swelling index and extent of hemolysis were determined according to methodology by Vitvitsky et al. (2000).

Membrane bioreactor

The main part of the membrane bioreactor is the module which was designed and constructed at the Department of Chemical Engineering, Faculty of Technology and Metallurgy, University of Belgrade, Serbia. It is composed of three stains-less still ring-like plates with an outside diameter of 16.6 cm and inside diameter of 11.5 cm, and two cellulose acetate membrane filters with 0.8 µm pores (Sartorius AG, Goettingen, Germany) placed between the rings (Fig. 1). The module has inside volume of 104 mL, while the total volume is 290 mL. The module is charged through an orifice placed at a lateral side of the device and closed with stainless still bolt. The module was placed in a 10 L glass vessel with an internal diameter of 22 cm.



a) b)

Figure 1. Membrane reactor: a) charging of module b) process of hemolysis

Gradual hemolysis in the membrane bioreactor

The module was charged with 100 mL of erythrocyte suspension (40% of hematocrit) and placed in the reactor vessel previously filled with 950 mL of isotonic saline solution. Hemolysis was performed by pumping hypotonic buffer solution at a flow rate of 900 mL/h using a peristaltic pump (IP610 Beomedicina, Belgrade, Serbia). The bioreactor was placed on an orbital shaker (Yellow line OS 5 basik (Ika Werbe GMBH & Co, Germany)) for continuous mixing at 320 rpm. Hemoglobin released from erythrocyte membranes diffused throughout the module, and accumulated in the external solution. The release of hemoglobin was followed by measuring optical density at 540 nm (OD_{540}) of the external solution by using UltroSpec 3300prp spectrophotometer (AmershamBioscience, Uppsala, Sweden); the aliquots of the external solution were withdrawn in 1 min time intervals for the first 15 min of hemolysis, in 3 min time intervals for the next 15 min, in time intervals of 5 min for the next 30 min and in the time intervals of 10 min by the end of the experiment. The samples were centrifuged and OD_{540} of the supernatant was measured as described above. The hemolytic process was stopped after 90 min.

The concentration of hemoglobin in hemolysates was determined by the cyanmethemoglobin method (Van Assendelft et al., 1984). Protein concentration in the suspension of erythrocyte ghosts was measured using BCA Protein Assay Kit (Pierce Biotechnology, IL, USA). Efficiency of the process was assessed in terms of recovery rates for hemoglobin (RR%).

The recovery rate was calculated according to the following equation:

$$RR\% = \frac{m_h}{m_i} \times 100\% \quad (1)$$

where m_i is the initial mass of hemoglobin in an erythrocyte suspension prior to hemolysis and m_h is the mass of hemoglobin in a hemolysate at the end of the process.

SDS electrophoresis

SDS polyacrylamide gel electrophoresis of hemolysate, obtained by gradual hemolysis (40 μg of hemoglobin) was carried out in SE 260 Mighty Small II Vertical Slab Electrophoresis Unit (GE HealthCare LifeScience, USA) in 12% gel according to the procedure of Laemmli (1970). Gels were stained in Coomassie blue R-250 and distained in an acetic-acid/methyl alcohol aqueous solution. Densitometric analysis was performed using ImageMaster TotalLab v1.1 software (GE HealthCare LifeScience, USA). PageRuler Prestained Protein Ladder (Fermentas) molecular size markers, with apparent molecular weight of 170, 130, 95, 72, 55, 43, 34, 26, 17, and 10 kDa, were used.

RESULTS AND DISCUSSION

Although the process of gradual osmotic hemolysis in the membrane bioreactor is already developed for isolation of human hemoglobin (Bugarski et al., 2003), it was necessary to adapt the process according to osmotic characteristics of bovine erythrocytes.

Since many properties (such as cell diameter, volume and shape, membrane lipid composition, ionic composition, etc.) differ between human and bovine erythrocytes which may affect the osmotic properties of erythrocytes, the first aim of this study was to investigate osmotic fragility (OF) of bovine erythrocytes. Fig. 2 represent mean cumulative and derivative bovine erythrocyte osmotic fragility curves drawn from mean values for three experiments. Herein we found the H_{50} value of 106 ± 9 mM for Holstein-Friesian calves investigated in our study. Also, results showed that osmotic fragility of bovine erythrocytes from slaughterhouse blood taken with sodium citrate as an anticoagulant remained unaltered four days. Derivative curve revealed that bovine erythrocytes were lysed in buffer with molarity lower then 70 mM.

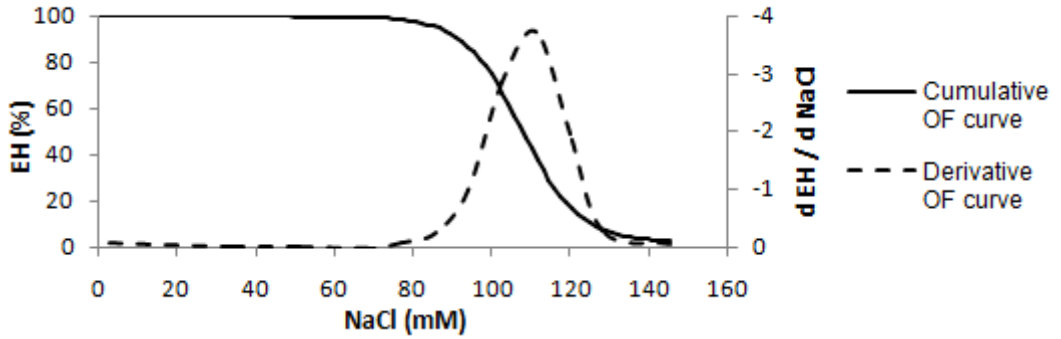


Figure 2. Mean cumulative and derivative osmotic fragility curves of bovine erythrocyte drawn from values for three experiments

The next step was to define the optimal concentration of Na-phosphate / NaCl solution at which gradual hemolysis will occur, giving hemoglobin in a high yield and preventing the rupture of cell membranes. Fig.3 demonstrates kinetics of changes in swelling index and extent of hemolysis induced in bovine blood samples by buffer solutions of decreasing molarities. We have defined the term "swelling index" equal to the relative volume change of erythrocytes. It is the difference between the hemolytic and isotonic volumes of a cell expressed as a relative value to the initial i.e. isotonic volume. A decrease in buffer molarities caused changes in the intracellular ion concentrations and an increase in cell volume and, consequently, decrease in the suspension hematocrit value; this was accompanied by appreciable hemolysis.

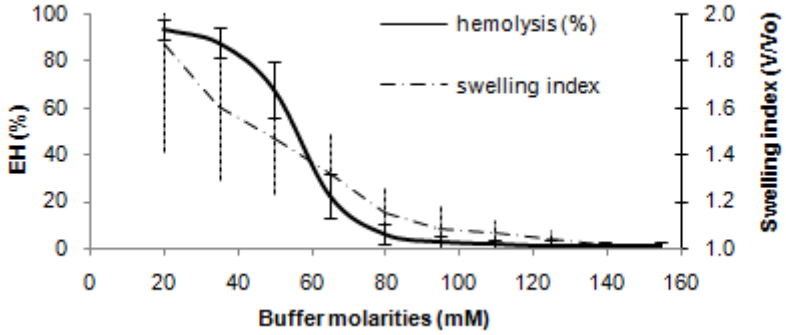

Figure 3. Extent of hemolysis and swelling index of bovine erythrocyte suspension as a function of Na-phosphate / NaCl buffer molarity. Results present mean ± SD values of five experiments.

The results show that ~90% of cells hemolyzed at ~35 mM solution. A 35 mM solution, caused a swelling of 1.84. on the average. With 35 mM solution, the residual hemoglobin in suspension of erythrocyte ghosts at the end of the process was 0.052 ± 0.002 (expressed as ratio of OD_{540} and hematocrit). For a sake of comparison, the same parameter was significantly higher (0.084 ± 0.016) after treatment of erythrocytes with 20 mM buffer solution. Considering all the facts named here 35 mM Na-phosphate / NaCl buffer pH 7.2-7.4 solution was identified as the optimal external medium permitting gradual osmotic hemolysis and isolation of hemoglobin in a high yield.

Further on, gradual hemolysis was performed in the membrane bioreactor with 35 mM Na-phosphate / NaCl buffer under a flow rate of 900 mL/h, during 90 min. The release of hemoglobin was followed by measuring OD_{540} of the external solution (Fig. 4). Maximal concentration of hemoglobin in the surrounding solution was reached after 40 min. The time interval needed to attain recovery rate of hemoglobin more than 80 % was 90 min and this period was set as duration of one process cycle in the membrane bioreactor. The concentration of hemoglobin at the end of the process cycle was 4.8±0.5 gL^{-1}.

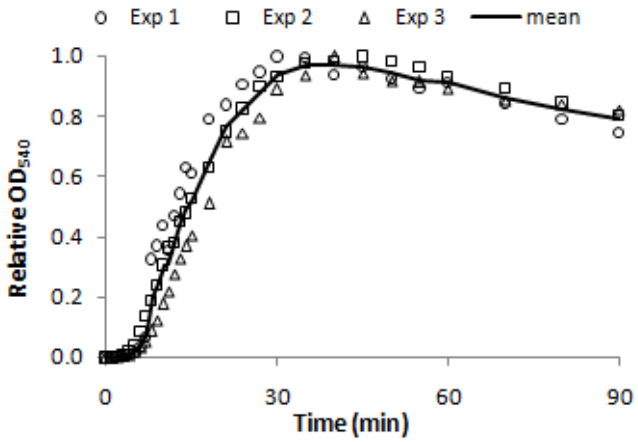

Figure 4. The time course of hemoglobin release during gradual hemolysis of bovine erythrocytes in the membrane reactor system. Results present three different experiments and its mean value.

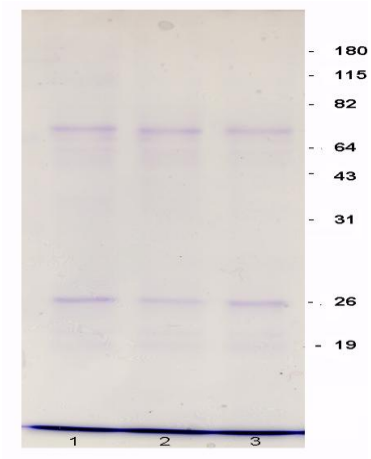

Figure 5. SDS-PAGE electrophoresis analyses for hemolysate samples obtained in three independent hemolysis cycles (Lines 1, 2 and 3)

The optimized process provided high yields of hemoglobin. For three experiments, the mean recovery rate of hemoglobin was 85 ± 11%. The fraction of methemoglobin was less than 2%. Absorption spectra of the isolated bovine hemoglobin from 250-800 nm confirm that isolation process yielded predominantly to oxyhemoglobin (figure not shown). The purity of hemoglobin solution was analyzed by SDS-PAGE (Fig. 5). Densitometric analysis showed that protein fraction which corresponds to globin chains (16 kDa) represented 84.90 ± 0.64% of the protein content. After process of gradual hemolysis is finished, empty, intact erythrocyte ghosts reside in the reactor chamber, while hemoglobin solution was separated by the membranes. Therefore, no additional steps were needed to collect lipid impurities. This is another advantage of the hypotonic dialysis in the membrane bioreactor as compared to most of isolation procedures described in literature which comprise methods like high speed centrifugation or filtration through glass wool for removing cell debris and membrane phospholipids (Sun and Palmer, 2008).

CONCLUSION

As a result of the optimized process of gradual hemolysis in membrane reactor described in this paper, pure bovine hemoglobin solution has been obtained from wasted slaughterhouse blood. With the aim to produce a dry powder from the obtained hemoglobin solution, which

could be used as the heme concentrate source in the fortification of feed, downstream processes such as tangential flow filtration and lyophilization merit further investigation.

ABSTRACT: The aim of examination in this work was: scientific determination of data about influence of phytase added into diets for fattening chickens, by lower level of mineral source of phosphorus to the finishing body weights had to some slaughtering traits of meat. Experimental examinations were done through the experiment of feeding fattening chickens of Arbor Acres strain. In the experiment were 220 chickens, divided into two groups, considering the different formulation of diets. K-control group (110 chickens), as the source of phoshorus gained by diet dicalcium-phosphate (DKF) at level 2%, O-I group gained by diet DKF-1% with addition of 0,1% enzyme of phytase. Standard fattening technology was applied in lasting period of 42 days. At the end of experiment, 14 head of animals were sacrificed (7 male and 7 female) out of each group. Necessory measuring were done: body weights before slaughtering; weight of dressed warm carcass; weight of the basic parts of carcass. Dressing percentages were calculated as well as yield and share of the basic parts considering dressed carcasses. Gained results show that the chickens of O-I group (DKF-1%+0,1% of phytase) gained better finishing body weights (2006,50gr) in comparison to K-group (DKF-2%)-1875,63gr ($P<0,05$). Also O-I group had better dressing percentages (65,66%), K-group (63,16%) ($P<0,05$). Further, yield of meat of the first category, by O-I group (771,56gr) and K-group (694,79gr) ($P<0,05$).
Key words: *chickens, mineral sources of phosphorus, phytase, production, meat quality*

INTRODUCTION

Application of mineral sources of phosphorus in animal diets takes risk to health of animal and human race. They are qualified as great canse of environmetal pollution (Otto,1998; Kies et al. 2001). They also have significant influence to the price on animal products, because they are expensive. Besides that, lately the new approach was established considering application of mineral sources of phosphorus. The ail of that is decreasing or complete leaving it out of animal diets. In these kinds of diets formulation, enzyme phytase has been added which with its hydrolisis effects, makes available phytinic sources of phosphorus from herbs diets for monogastric animals and poultry (Harter-Dennis, 2000). Diets which have additional phytase and have been used for feeding fattening chickens have positive influence to production traits and improvement of meat and bones quality.
The aim of these examinatins was to complete scientifical determination of data about the influence of phytase added into the diets for fattening chickens by lower level of mineral source of phosphorus to the finishing body weights and dressed carcass traits of meat.

MATERIAL AND METHODS

The experimental examinations were done while the period of feeding fattening chickens of Arbor Acres strain was in progress. There were 220 chickens in the experiment, which were divided into two groups: K-control (110 chickens) and the experimental group (110 chickens). The demand of the experiment was to divide chickens into two boxes considering the different source formulation of phosphorus. During the experimental period K-group gained per diet dicalcium-phosphate (DKF) at level of 0,2%, while O-I group gained per diet 0,1% with addition of 0,1% phytase. The fattening chickens were fed with the compositon made of same raw materials.

The experiment of feeding has lasted for the period 42 days. At the end of the experiment, 14 chickens from each group were sacrificed (7 male and 7 female). The body weight, weight of hot dressed carcass as well as the weight of the basic parts of dressed carcass were measured before the slaughtering.
Dressing percentages were calculated as well as yield and share of the basic parts in dressed carcass (per each chicken) – (measuring was done with precision balance ±0,1gr.

RESULTS AND DISCUSSION

Considering that the yield of dressed carcass, dressing percentages as well as yield and share of some meat categories of dressed chickens carcass, very important fact of quality, influence of food tretments to the mentioned traits was also observed.
The results of examinations (table 1 and 2, figure 1 and 2) show that: the chickens of O-group (1% DKF+0,1% phytase) gained better average finishing body weights (2006,5g) in comparison to K-group (2% DKF) (1875,63g) (P<0,05). Also, O-group had better percentages (65,66%) K-group (63,16%) (P<0,05). Further, yield of meat of the first category, by O-I group (771,56gr) and K-group (694,79gr) (P<0,05).

Diference		+8,68	+11,05	
			*P<0,05	

As for as the finishing body weights of the chickens, significant differences among groups were observed, considering the group which gained by diet DKF (K) and the group which gained lower level of DKF with addition of phytase 0,1% (O-I group). This difference in finishing body weights had direct influence to the dressing percentages, and also to the yield the basic parts of carcass (breast, drumstick, thigh). These results are in comrehension with the results of many authors, who clainred that the different variation diets formulations, could increase adsorption of phytinic phosphorus and other digestable consist of feeding mixtures (Sebastian et al. 1998, Radović i sar. 2011).

CONCLUSIONS

Considering the results of the examination gained by the experiment of feeding fattening chickens, we came to the conclusion that: addition of phytase into diets for fattening chickens, at the lower level of mineral source of phosphorus, had the positive effect to the observed traits in our examination. So that means, that phytase had its influence to the improvement of production and slaughtering traits of chickens. Further on, diets with phytase, fulfill ecological demands, considering decrasing of environmental pollution.

ABSTRACT: The paper presents the results of a trial conducted for 8 weeks on 90 Lohmann Brown layers (43-51 weeks of layer age) assigned to 3 groups (3 layers per cage). The control group (C) received a basal corn (53.35%), corn gluten (1%) and soybean meal (26%) diet. The diets for the experimental groups (E1 and E2) has the same basal diet as C group but included flax seeds (7%), buckthorn oil (1%) and antioxidants, as follows: 250 ppm vitamin E (E1), and 250 ml/kg marigold extract (E2). Feed intake and egg production were monitored throughout the experiment. Egg samples (15 eggs/group) were collected on weeks 2, 5 and 8. Average samples (3 eggs/sample) were formed from the collected eggs for each variant and assayed for the gross chemical composition and yolk cholesterol. There are different results ($p \leq 0.05$) regarding feed intake (105,616±1,085 g) for group E1 compared with C group (111,198±1,037g) and E2 (110,769±0.924). Also, are different results ($p \leq 0.05$) regarding the egg weight (63,109±0,527 g) for group E1 compared with C group (62,027±0,209037g) end E2 (61,744±0,104 g). The yolk cholesterol decreased throughout the experimental period (43-51 weeks of layer age) in all groups, which shows that this fact was not related to the diet. Thus, the decrease was 18.27% for C group (0.559 ± 0.13 g col/fresh yolk in the end of the experiment, compared to 0.684 ± 0.048 g col / fresh yolk, initial value), 7.15% for E1 (0.519 ± 0.053 g col / fresh yolk in the end of the experiment, compared to 0.559 ± 0.07 g col/fresh yolk, the initial value) and 8.45 % for E2 (0.520 ± 0.034 g col / fresh yolk in the end of the experiment, compared to 0.568 ± 0.042 g col/fresh yolk, initial value).

INTRODUCTION

The increasing concerns for human health, its relation with the structure and quality of animal feeds and the association of trace dietary ingredients (essential fatty acids, vitamins and minerals) to positive effects on human health, explain the drive of nutritionists towards finding rich sources of such nutrients. The hen egg is a basic natural food for humans. The egg has large amounts of protein (it has all the 9 essential amino acids) and other essential nutrients such as polyunsaturated fatty acids, vitamins, minerals etc. The only worrying issue for the consumers is the cholesterol level. Many physicians consider that the egg is the main source of dietary cholesterol and therefore the decrease of yolk cholesterol is a subject of top interest for layer feeding. Presently, there is plenty of documentation proving that the fatty acids profile can be changed by feeding, decreasing the ratio of ω:6 to ω:3 fatty acids as well as the ratio of the saturated to unsaturated fatty acids. The use of feeds rich in ω:3 fatty acids in layer feeding increases directly proportional the concentration of these acids in the yolk. These eggs rich in:3 fatty acids are alternatives to fish or to other foods from oleaginous seeds, also rich in ω:3. The change of the fatty acids profile and the decrease of the cholesterol level is done almost entirely through feeding. The specific feeding way is to enrich layer diets in omega 3 polyunsaturated fatty acids (Alvarez et al., 2005). Besides the addition of raw ingredients rich in fatty acids with double bonds, the nutritionists must also provide the proper amounts of antioxidants which will remove the unpleasant effects of self-

oxidation (rancidity) of the dietary lipids. The first signs are the unpleasant smell and the spoiled taste. Therefore, it is very important that the modification of the dietary composition doesn't affect the quality and the functional properties of the eggs. Vitamin E is the most often used antioxidant which is added to the compound feeds through the vitamin premix. Monounsaturated and polyunsaturated fatty acids were patented for their capacity to lower egg cholesterol. The decreased of yolk cholesterol is preceded by the decrease of the serum cholesterol, which is precursor of yolk cholesterol. Other methods to decrease the yolk cholesterol include the use of copper and chrome (Balevi and Coskun, 2004; Guruprasad et al, 2006). Recently, several teams of researchers focused on the use of phytoadditives to reduce the cholesterol level. Akhtar et al. (2003) used Nigella sativa seeds in layer diets, which inhibit cholesterol synthesis and stimulate the secretion of bile acids, both processes decreasing egg cholesterol.
The purpose of the paper was to study the effect of the diets rich in polyunsaturated fatty acids supplemented with (natural or synthetic) antioxidants on the cholesterol level of the hen eggs.

MATERIAL AND METHODS

The experiment was conducted on 90 Lohmann Brown laying hens (43-51 weeks) for 8 weeks. Birds were grouped taking into consideration body weight, being divided into 3 groups (30 birds / group) and housed in cages structured on three levels, according with modern and in accord with European standards. The structure of cages has allowed the registration of daily intake and excreta. Batteries were placed in a hall whose ambient temperature was 25°C during the experiment. Incandescent lighting throughout the experimental period was performed by a scheme with up to 16 hours daily light. Food and water were administrated *ad libitum*. During all 8 weeks, all experimental parameters were ensured on the specific microclimate according to growth technology and age of birds. The control group (C), it was used a ratio based on corn, corn gluten, soybean meal and raw materials rich in polyunsaturated fatty acids (PUFA) - flaxseed (7%), sea buckthorn oil (1%). Experimental groups diets (E1 and E2) differed from control by using two antioxidants, a synthetic antioxidant (vitamin E) and a natural antioxidant (marigold extract) (Table 1). Group E1 diet received the antioxidant supplement of 250 mg / kg vitamin E, and group E2 diet received 250 ml natural antioxidant extract of marigold / 100 kg CN. In terms of energy-protein, all three structures were isocaloric and izoproteic diets (Table 1). During the experiment, daily, were monitorized and recorded production parameters on feed consumption, and productivity of laying and eggs weight. Every two weeks samples were taken from eggs (15 eggs / serial / group). From collected eggs, medium samples were formed (3 eggs / sample) for each version in order to determine the gross chemical composition and cholesterol content in egg yolk. Physical parameters of eggs parameters (egg weight, yolk color index and the degree of freshness Haugh) were measured using the device: Egg Analyzer (Sanovo Engineering A / S, Denmark). Feed samples were taken at the beginning of the experiment, and were analyzed for nutrients content; dry matter, crude protein, fat, crude fiber and ash were estimated according to the ISO methods (The Romanian Standardized Association (ASRO)). For fatty acid analysis, and cholesterol from yolk, were extracted by the methanol-hexane procedure. The samples were analyzed by using a Perkin Elmer gas chromatograph (Clarus 500, USA). One way ANOVA analysis was performed to investigate the statistical differences between groups for all parameters analysed. Further differences between means were determined by the least square difference Fisher procedure. Values of $P< 0.05$ were considered significant.

Table 1. Ingredient of the feed mixture, %

RESULTS AND DISCUSSION

In Table 2 zootechnical performances are presented throughout the experimental period. There were significant differences ($P \leq 0.05$) on average daily consumption recorded, a 5.01% decrease from E1 compare to group C and 4.6% compare to group E2. Instead, the group E1 egg weight was significantly ($P \leq 0.05$) compared with the other two groups (C and E2). As expected, the lowest feed efficiency was registered in group E1 (1.961 kg CN / kg egg), differentiated significantly ($P \leq 0.05$) by E2 group. Laying intensity was 6.12% higher in group C compared to E1 and 4.33% higher than E2 (Table 2), but was not affected.

Table 2. Performances

Specification	C	E 1	E2
Average daily intake, g/zi	111,198±1,037 ^{b}	105,616±1,085 ^{a,c}	110,769±0,924 ^{b}
Feed efficiency, kgNC/kg ou	1,972±0,028 ^{c}	1,961±0,028 ^{c}	2,07±0,033 ^{a,b}
Laying intensity, %	91,63±1,103 ^{b,c}	86,021±0,86 ^{a}	87,661±1,205 ^{a}
Egg weight/period, g	62,027±0,209 ^{b}	63,109±0,527 ^{a,c}	61,744±0,104 ^{b}

Note: a = significantly diffrent ($p \leq 0,05$) compare to C ; b = significantly diffrent ($p \leq 0,05$) compare to E1; c = significantly diffrent ($p \leq 0,05$) compare to E 2;

Figure 1 presents egg components weights. Eggs collected from experimental groups had a higher weight, but insignificant (p> 0.5) from group C.

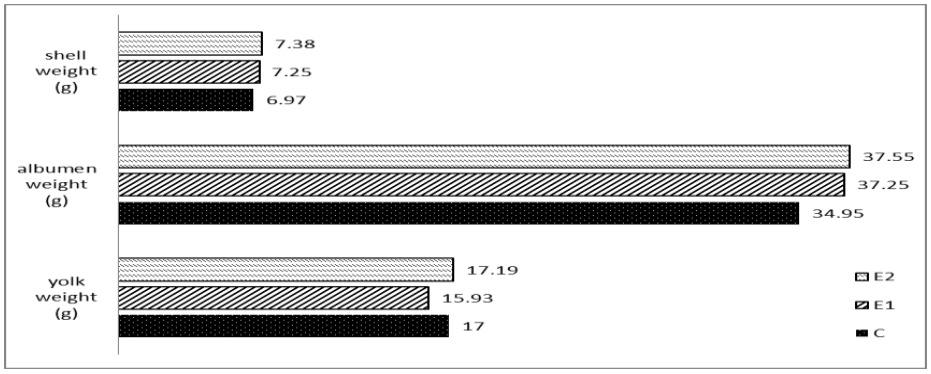

Figure 1. Egg components weights throughout the experiment

Due to the use of feed sources rich in fat, a major requirement is suggested concerning for feed quality while temporally preserving and consequently the eggs obtained during this experiment. To assess the temporally feed quality keeping, feed samples were taken from which were determined indices of fat degradation: acidity, peroxide index KREISS reaction (for fats oxidation evaluation), initially, at 14 days and 28 days. Evolution of the peroxide (Table 3) shows that at 28 days in group C appeared the phenomenon of degradation of fat. Confirmed, also, by Kreiss reaction (positive). Acidity, also, was consistently higher in this group, due to the insufficient level of vitamin E in the ration. The two experimental groups recorded lower values in terms of fat acidity index and peroxide. The results presented in Table 3 show that using a high-fat feed rations is strongly conditioned by the inclusion of antioxidant sources. For experimental groups, was given both the antioxidant effect of vitamin E supplementation (intake group E1) and the extract of marigold (intake group E2).

Table 3. Evolution of odder fat indices degradation

Specification	C	E 1	E2
Peroxid index (ml thiosulfat 0.1 N/g Gr)			
- initial	1.33	1.13	1.04
- 14 days from manufacturing	1.51	1.36	1.24
- 28 days from manufacturing	1.85	1.22	1.63
Fat acidity (mg KOH / g grasime)			
- initial	27.14	15.08	13.24
- 14 days from manufacturing	29.15	17.43	16.52
- 28 days from manufacturing	31.73	19.82	17.18
KREISS reaction			
- initial	Negative	Negative	Negative
- 14 days from manufacturing	Suspicious	Negative	Negative
- 28 days from manufacturing	Pozitive	Positive	Pozitive

During the experiment 15 eggs / group were collected randomly (at weeks 0, 2, 4, 6 and 8) of which medium samples were formed to establish physical and chemical parameters of egg yolk (Table 4). Egg samples collected were analyzed chemically, on the levels of protein, fat, ash and dry, and content in fatty acids, vitamin E and cholesterol.

Table 4. Egg yolk physica parameters (average values / group)

Specification	C	E1	E2
pH-whites	8,995±0,008	9±0,008	9,002±0,008
pH-yolk	5,998±0,006	6,008±0,005	6,008±0,005
Colour intensity	5,9±0,233	5,909±0,251	5,692±0,208
Vitamin E, mg%yolk	1,677±0,75 $^{b.c}$	4,757±0,164 ^{a,c}	1,075±0,105 ^{a,b}
H units	70,5±2,525	65,836±3,968	64,969±2,495

Note: a = significantly diffrent ($p \leq 0,05$) compare to C ; b = significantly diffrent ($p \leq 0,05$) compare to E1; c = significantly diffrent ($p \leq 0,05$) compare to E 2;

In Table 4, the physical parameters of egg yolk are presented. There were no significant differences between groups for pH whites values, pH yolk values and yolk color intensity. In terms of vitamin E concentration in egg yolk, the data presented previously an increase in concentration of vitamin E in group E1. This is due to increasing dose of vitamin E / kg CN group E1. Out of the total fatty acids determined in egg yolk, in Figure 2, changes are presented regarding concentrations of polyunsaturated fatty acids: linoleic (ω: 6) and linolenic (ω: 3) which are of major importance for the body. (Calvani and Benatti, 2003, Barlow and Pike, 1991; Mantzioris, 2000; Simopoulos, 2000; Kralik et al.(2005);

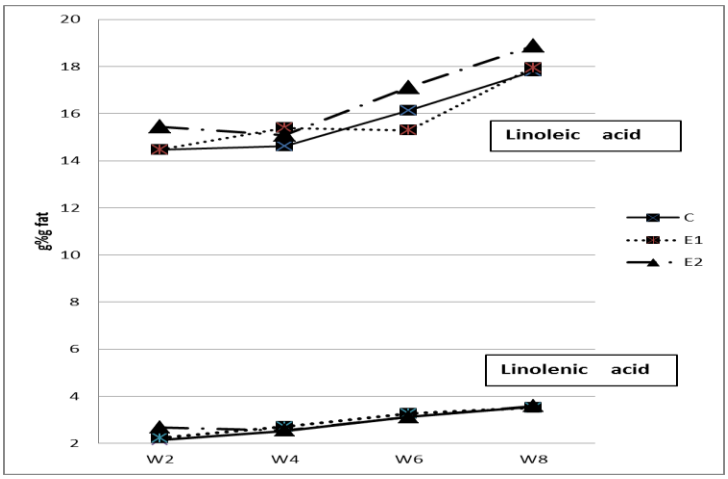

Figure 2. Temporally evolution of polyunsaturated fatty acids (linoleic and linolenic)

Figure 2 shows the values determined for the two presented acids ($p \leq 0.05$) higher at the end of the experiment compare to the beginning of the experiment for all three groups studied. Concentrations obtained in eight experimental weeks were significantly higher ($p \leq 0.05$) for group E2 compare to C for linoleic acid. For linolenic acid, there were significant differences between groups at the end of the experiment. Polyunsaturated fatty acid concentration was significantly higher in group received additional marigold, compared to group C. In terms of polyunsaturated fatty acids ratio ω 3 / ω: 6, values were comparable for the three studied groups.

Table 5. Ratio of mono-and polyunsaturated fatty acids in egg yolk

Specification	C	E 1	E2
PUFA	25,09	25,56	26,60
SFA/UFA	0,47	0,49	0,47
PUFA			
ω:3 / ω:6	0,180	0,177	0,173

There were no significant differences in terms of concentrations of polyunsaturated fatty acids, a result considered normal, taking into consideration that diets did not have a different structure from this point of view.
Processing analytical data obtained statistically to determine the concentration of cholesterol in egg yolk (mg col / 100 g fresh yolk) were obtained differences supported statistically between the three groups (Table 6).

Table 6. Cholesterol concentration (mg col /100 g fresh yolk)

Collection	C	E1	E2
BL	0,570±0,053	0,570±0,053	0,570±0,053
Week 2	0,684±0,048	0,559±0,07	0,568±0,042
Week 8	0,559±0,13	0,519±0,053	0,520±0,034

Determinations of cholesterol content from eggs collected in the 2-nd week of the experiment differed between C group and the two experimental variants, but were not supported statistically. At the end of the experiment, data showed that in group C cholesterol concentration was significantly ($p \leq 0.05$) higher than in other groups. The results in Table 6 indicate that during experimental period cholesterol from collected eggs decreased in all groups but not as the result of given supplements administrated to the experimental groups (Poltowicz and Wezyk, 2006). This decrease was 18.27% for group C, 7.15% for group E1 and 8.45% for group E2. To explain this differentiation of yolk cholesterol concentration in the

two experimental groups compare to C group, we quote Qureshi et al. (1986). These authors demonstrated that tocotrienols (found especially in seeds) have hypocholesterolemic action. Marigold Oily Extract, made from flowers, has a certain content of tocotrienols.

CONCLUSIONS

Concerning zootechnical parameters were significant differences ($P \leq 0.05$) in terms of: average daily consumption of combined fodder, specific consumption of combined fodder/ kg egg weight, number of eggs and egg weight of group E1 compare to E2 and C. In terms of temporally feed preservation, there was a slower decay for the two experimental groups given feed that contained antioxidants (vitamin E to E1, respectively, marigold extract to E2. There were no significant differences in the concentrations of PUFA in egg yolk, taking into consideration that the diets did not have a different structure from this point of view. During the 8 experimental weeks cholesterol from eggs collected from laying hens (age 43-51 weeks) declined in all groups studied, but more pronounced in those experimentals groups.

ACKNOWLEDGEMENTS

ABSTRACT: The general composition, plant cell walls fiber components content, in vitro digestibility and general feeding characteristics in forage quality evaluation of green mass of forage pea (*Pisum sativum* L.) spring forms in field trial – competitive variety testing, carried out at the Institute of Forage Crops – Pleven, Bulgaria (2009-2011) were studied. Four new introduced Ukrainian high productive varieties Kamerton, Glyans, Modus, Svit and Bulgarian standard variety Pleven 4 were harvested at the three vegetative stages – budding, flowering and full pod formation. Forage quality of the whole pea plants was evaluated by the parameters of general composition, plant cell walls fiber components content, digestibility, protein and energy feeding value. The standard variety Pleven 4 characterized by highest forage quality – highest protein content 18,0%, highest digestibility 74,9% and lowest plant cell walls fiber components content: NDF 36,4%, ADF 29,02%, ADL 4,57%. The new introduced Ukrainian varieties, Glyans and Kamerton show higher forage quality: higher protein content 13,3% , lower fiber content: crude fiber 23%, NDF 42-41%; ADF 30-31,5%; ADL 5,2-5,4%, respectively and digestibility 71% in comparison with varieties Svit and Modus. Energy feeding value of standard variety Pleven 4 is highest but in the group of Ukrainian varieties the highest energy value characterized Modus and Kamerton. The standard Pleven 4 distinguish highest protein feeding value: mean values for three stages – TDP 135 g kg^{-1}, PDIN 113,2 g kg^{-1}, PDIE 101,2 g kg^{-1}, and for Ukrainian varieties – variety Kamerton: TDP 89,4 g kg^{-1}, PDIN 83,4 g kg^{-1}, PDIE 89,6 g kg^{-1}, followed by variety Glyans and variety Svit.
Key words: *Pisum sativum L., varieties, protein, fiber, digestibility, energy and protein feeding value*

INTRODUCTION

The stable tendencies in planet climate require tolerate varieties to biotic and abiotic environment factors. The introduction of new varieties, the exact area distribution and effective growing management contribute to increase biological diversity, increasing yield and quality of forage pea production. The forage pea is fed as hay, silage and haylage alone or in diets. The forage pea is high nutritive source of protein and energy in animal especially ruminant nutrition (Ellwood 1998). It is fed as hay, silage, haylage alone or in mixtures with cereals in diets. The pea crop is significant in resolving the protein problem. The green mass contain 17-20 % crude protein of dry matter, minerals, sugars (Pavlov 1996). Pea grain has high protein content: 22-34% crude protein, but straw 6-9% (Kostov&Pavlov 1999). The chemical composition, protein feeding value, plant cell walls fiber components content determining energy feeding value and forage digestibility were studied in Bulgarian and some introduced forage pea varieties in breeding and management experiments (Naydenova and Todorova, 2009; Naydenova et al., 2008a, 2010b; Kirilov et al., 2010; Naydenova et al., 2010c, 2011d; Georgieva et al., 2011).
The aim of the study was evaluation the general composition, plant cell walls fiber components content, *in vitro* digestibility and estimation of potential protein and potential energy feeding value of pea forage of new introduced Ukrainian varieties in comparison with the standard Bulgarian variety Pleven 4.

MATERIAL AND METHODS

The plant material in the investigation is whole plant spring sown forms of forage pea (*Pisum sativum* L.). The field competitive variety trial in three replications of 10 m^2 plots with sown rate 120 numbers of germinating seeds was carried out at the Second experimental field of the Institute of Forage Crops, Pleven, Bulgaria, situated in the central part of the Danube hilly plain in the period 2009-2011. The soil type is leached chernozem with the followed characteristics: pH $_{(KCl)}$ – 4,78; pH $_{(H2O)}$ – 6,45; humus – 2,85% and total N content – 0,226 mg/1000 g soil, P_20_5 – 3,32 mg/100 g soil and K_20 – 30,2 mg/100 g soil. Four new Ukrainian varieties of forage pea: Kamerton, Modus, Glyans, Svit in three phenological stages in the vegetation (1. budding stage; 2. flowering stage; 3. full pod formation stage) are studied. The standard variety used is Standard Bulgarian variety Pleven 4 of forage pea, officially acknowledged by the State variety commission in Bulgaria. The forage pea is grown by approbate technology of the Institute of Forage Crops, Pleven.
The general composition of forage pea is determined as crude protein (CP) by Kjeldahl method (N x 6,25) and crude fiber (CF) by Weende system (AOAC 2001). The plant cell walls components content in energy feeding value are determined as NDF (Neutral-detergent fiber), ADF (Acid-detergent fiber) and ADL (Acid-detergent lignin) in percent of dry matter, by systematic detergent analysis of Goering and Van Soest. Enzymatic digestibility *in vitro* of organic and dry matter (IVDMD, %) is performed by two stage pepsin-cellulase method of Aufrere (Todorov et al. 2010).
The potential energy feeding value is estimated by French system UFL-UFV (INRA 1988), on the basis of equations for legumes, according experimental values of crude protein, crude fibers and digestibility of organic matter, calculated in Bulgarian (FUM-FUG), Feed units for milk, Feed units for growth by coefficients pointed from Todorov (1997). The coefficient of digestibility of organic matter dMO *in vivo* was determined by Andrieu&Demarquilly (1989), after dependence used *in vitro* digestibility of organic matter, determined experimentally. The additional comparative characteristics were estimated energy feeding value by Dutch system (VEM-VEVI). The protein feeding value (PDIN=PDIA+PDIMN and PDIE=PDIA+PDIME) was estimated by French system (INRA 1988) by the parameters: TDP/PBD-Total Digestible Protein/Protein Brute Digestible, PDIN-Protein digestible dans l'intestine in dependence of nitrogen and PDIE–Protein digestible dans l'intestine in dependence of energy. In comparative analysis at the three development stages were evaluated individual and mean values for each pea variety and the degree of variation of the parameters for forage feeding value, according their significance for the forage quality.

RESULTS AND DISCUSSION

Forage pea chemical analysis in establishing the general composition verify highest protein and lowest fiber composition content of Bulgarian standard variety Pleven 4 (Rang 1) with the follows parameters, mean for the three development stages: crude protein 18,03%, crude fiber 21,03% and *in vitro* dry matter digestibility 74,93%, i.e. that is the highest forage quality variety, grown in Bulgarian soil and climatic conditions (Table 1). In the group of the new introduced Ukrainian varieties the variety Kamerton distinguishes the highest protein content – mean value of the three development stages 13,29% of dry matter, in difference to the others three varieties contained from 10,0 to 11,7%. Crude fiber in lowest content belongs to the varieties Glyans and Kamerton – 23%, while the other two Ukrainian varieties demonstrate closed fiber content, but 2,0% of dry matter lower – almost 25,0%. The higher forage *in vitro* dry matter digestibility of Ukrainian varieties belong to variety Modus – 72,74% (Rang 2) and variety Kamerton – 71,15% (Rang 3) (Table 3). The character trait is that there is not exact corresponding in general composition – crude protein, crude fiber and digestibility in the group of new introduced Ukrainian varieties (Table 1; Table 3).
The plant cell walls fiber components (polyosides) content is presented in Table 2 and Table 3.

ADL – Acid-detergent lignin; % of dry matter; IVDMD - *in vitro* dry matter digestibility, %; R – Rang

The significant rang in forage quality evaluation is decreasing in fiber components content, determined as NDF, ADF, ADL and increasing *in vitro* digestibility of dry matter. The structural polyosides in forage plants present from 300 to 800 g kg^{-1} (30-80 %) of forage dry matter and they are the general source of nutritional energy for ruminants, but less than 50% of them are digestible and utilized (Fahey&Hussein, 1999). The Neutral detergent fiber present the total content of plant cell walls fiber components of lignin, cellulose, hemicellulose and are laboratory parameter for prediction of forage intake by ruminants. That's why they are selection criteria in evaluation of forage crops (Casler&Vogel, 1999). The Acid detergent fiber is the fraction, contained plant cell walls lignin and cellulose which determine forage digestibility. The mean ADF content is 9-10% units lower than those of NDF and in the vegetation process follows decreasing tendency. The acid detergent lignin in

forage pea, spring forms demonstrate low values (4,57 – 6,12%), which is important premise the pea stem be flat-tened. The degree of variation of plant cell walls fiber fractions, significant in forage quality evaluation in ruminant nutrition, is high (ADL: CV 11,2–18,0%; NDF: CV 6,3-9,6%; ADF: CV 5,2-13,5), because they may be utilized as selection criteria (Table 2, 3). The highest is the coefficient of variation in budding stage.

The plant cell walls fiber components fractions as a forage quality characteristics and energy source demonstrate adequate correspondence of fiber composition and digestibility of Bulgarian standard variety as well as in the group of new introduced Ukrainian varieties. Lowest fiber components content for all type of fractions – NDF, ADF, ADL and Cellulose belong to standard variety Pleven 4 (Rang 1) (Table 2, 3). In the group of Ukrainian varieties, the lowest fiber components content demonstrate varieties Glyans and Kamerton (Rang 2 and 3) as follow by mean values: NDF 42-41%; ADF 30-31,5%; ADL 5,2-5,4%; Cellulose 25-26%, respectively. The others two varieties Svit and Modus show higher fiber composition content (Rang 4 and 5 respectively), mean by 2% of forage dry matter, as follow by mean values NDF 43-44,5%; ADF 33-34%; ADL 5,9-6,2%; Cellulose 27-28%, respectively. The mentioned two varieties show higher content of undigestible fiber component lignin (Table 3).

The basic criteria, effectuated new evaluation in forage quality is *in vitro* digestibility by enzymes, characterized by rapidity, reproducibility and heredity, small sample quantity and direct correlation by *in vivo* ruminant digestibility (Fahey&Hussein 1999). The variation range of *in vitro* digestibility usually is 100 g kg $^{-1}$ dry matter. The breeding process for high protein content led to increased *in vitro* digestibility. Long-period breeding programs for increased protein content combined with decreasing the ADF (lignocellulose) content. The combined genetic changes may increase digestibility by 16 g kg^{-1} (2,1 %). It is proved that the genetic changes in *in vitro* digestibily were due to genetic changes in plant development. The digestibility of forage pea investigated is high in all development stages (69,5 – 72,0 %) and vary slowly CV 4,2%.

The forage feeding value estimation on the basis of chemical composition and enzymatic *in vitro* digestibility is suitable method for forage quality variety evaluation when it is not possible to effectuate *in vivo* digestible trials by animals (Fahey&Hussein 1999). The forage quality evaluation by composition and digestibility corresponds with the energy feeding value estimation (Table 4). Energy feeding value of standard variety Pleven 4 is highest (Rang 1). In the group of new introduced Ukrainian varieties the highest energy feeding value demonstrates variety Modus, followed by variety Kamerton.

In comparative forage quality analysis of composition and protein feeding value between varieties, the individual and referent values, standard deviations and the degree of parameter variation are presented in Table 5, 6, 7. The Bulgarian standard variety Pleven 4 distinguish by highest protein feeding value – Rang 1: mean values from the three development stages – Total digestible protein 135 g kg^{-1}, PDIN 113,2 g kg^{-1}, PDIE 101,2 g kg^{-1}, and in the group of new introduced Ukrainian varieties – variety Kamerton (Rang 2): Total digestible protein 89,4 g kg^{-1}, PDIN 83,4 g kg^{-1}, PDIE 89,6 g kg^{-1}, followed by variety Glyans and variety Svit – both evaluated by Rang 3. The variety Modus characterized lowest protein feeding value, which unsatisfactory distinguished to those of preceded two varieties.

CONCLUSSIONS

- The Bulgarian standard variety Pleven 4 (Rang 1) characterized by highest forage quality – highest protein content 18,03%, highest digestibility of dry matter 74,93% and lowest plant cell walls fiber components content: crude fiber 21,01%, NDF 36,4%, ADF 29,02%, ADL 4,57%.
- In the group of new introduced Ukrainian varieties, Glyans and Kamerton (Rang 2 and 3) show higher forage quality: higher protein content 13,3% , lower fiber content: crude fiber 23%, NDF 42-41%; ADF 30-31,5%; ADL 5,2-5,4%; Cellulose 25-26%, respectively and digestibility 71% in comparison to varieties Svit and Modus.

- The forage quality evaluation by composition and digestibility corresponds with the energy feeding value estimation Energy feeding value of standard variety Pleven 4 is highest (Rang 1). In the group of new introduced Ukrainian varieties the highest energy feeding value characterized variety Modus, followed by variety Kamerton.
- The Bulgarian standard variety Pleven 4 distinguish by highest protein feeding value – Rang 1: mean values from the three development stages – Total digestible protein 135 g kg^{-1}, PDIN 113,2 g kg^{-1}, PDIE 101,2 g kg^{-1}, and in the group of new introduced Ukrainian varieties – variety Kamerton (Rang 2): Total digestible protein 89,4 g kg^{-1}, PDIN 83,4 g kg^{-1}, PDIE 89,6 g kg^{-1}, followed by variety Glyans and variety Svit – both evaluated by Rang 3. The variety Modus characterized lowest protein feeding value, which unsatisfactory distinguish to those of preceded two varieties.

ABSTRACT: Research has included four breeds (Landrace and Yorkshire as fertile) and (Pietrain and Duroc as a terminal) pigs. Selection criteria are significantly different due to the negative genetic correlation between milk yield and meatiness and positive heads between capacity and production capabilities. The test involved 558 animals of both sexes who are descended from the 43 father and 282 mothers. Carcass quality tests were performed on 144 animals, also of both sexes. The average weight of animals at the end of the fattening period was 103 kg and a standard deviation of 2.6 kg. Bones density did not differ significantly between Landrace, Yorkshire and Duroc. Pietrain bones were significantly easier. This demonstrates the viability of lower growth in this race compared to the other and longer feeding for 24 to 32 days. When it comes to the only growth was significantly lower in Pietrain animals were compared to their peers of other races. The content of meat in the carcass was approximately 57.6% in fertile breeds and Duroc 58.9%. It was not significantly different. Pietrain had 62.1% of meat in the carcass which is significantly higher than in other races. Intramuscular fat content was: 0.8% of Pietrain, Duroc 2.6% 2.0% Landrace and Yorkshire 1.8%. The level of protein as the most important parameter of meat quality was the lowest in Pietrain (20.1%), Landrace and Yorkshire were 21.8% and 22.5% and 22.9% Duroc. Selection criteria relate to the last eight generations of selection and the effects show the expected trends.
Key words: *pigs, growth traits, carcass and meat quality*

INTRODUCTION

In pig production, the most important traits from economical point of view can be as follow: *number of weaned piglets per sow per year, feed conversion, growth and meat content in carcass then protein level in meat*. To provide optimal selection effect for each of them it is important to determine genetic correlation between them and size of heritability as well. According to knowledge of negative genetic correlations between fertility or milk yield and meat content in carcass it is necessarily to developed different selection criteria or better says specialized breeds.

Since of purpose of selection effects on farm production in analysis we separate due to selection criteria two groups of breed, e.g.: fertility and milking breeds – Landrace and Yorkshire and terminal breeds, e.g.: Duroc and Pietrain. Following literature sources we can accept some trend which can depends from selection criteria, farm, year and season effect of management on the farm too.

The research was defined to analyzed selection effects during more years of selection on farms. Selection criteria were different for terminal breeds (Duroc and Pietrain) compare Landrace and Yorkshire where selection has been concentrate on litter size and milk yeald.

MATERIAL AND METHODS

The experiment has been done at 4 farms since 2000 up to 2011. We included 4 breeds, L, Y as mother line and D and P as terminal one. The following pictures give different selection criteria that were used. Average alive weight at slaughter of all animals was 103 kg and standard deviation of 2,6 kg.

Table 1. Breed structure and number of animals in trial

Breed	Sire	Dam	Progeny	No. carcasses
Landrace	11	80	196	36
Yorkshire	12	74	182	36
Duroc	10	66	102	36
Pietrain	10	62	80	36

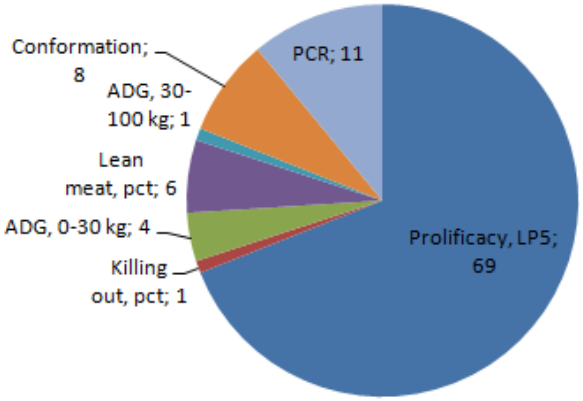

Figure 1. Used selection criteria for mother breeds: - Landrace and Yorkshire

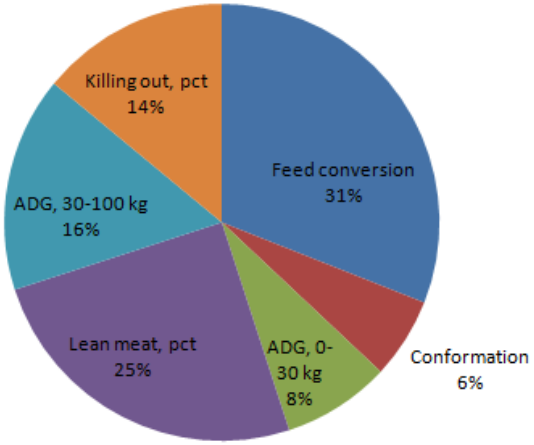

Figure 2. Selection criteria used for terminal breeds: – Duroc and Pietrain

Following MME LS model has been used to analyze influences of FYS (Farm, Year and Season) then Breed as fixed effect and Sire as random one (Vidović 2011a).

$$Y_{ijkl} = \mu + HYS_i + B_{ij} + S_{ijk} + E_{ijkl}$$

Y_{ijkl} - Number of observations hierarchically distributed;
μ - General mean of observations;
HYS_i - Fixed effect of farm, year and season;
B_{ij} - Fixed effect of different breeds;
S_{ijk} - Random sire effect;
E_{ijkl} - Residual.

RESULT AND DISCUSSION

Fattening days and feed conversion. The line (Figure 3) showed expected tendency. It means the selection criteria for most economically important traits have been well defined. Selection intensity was controlled by number of doses per jump. In case of feed conversion (FC) improvement were 90 kg per head. Most fast improvement was at first 5 years. Since that FC is average heritage there are new possibilities to continue with selection effect, e.g. to decrease FC, reduce cost and increase profit per kg of gain. Similar trend has been showed by Brascamp 1985., Rotschild 1990., Park at al. 1986., Bergsma at al. 2010., Vidović et. al. 2011a; 2011b.

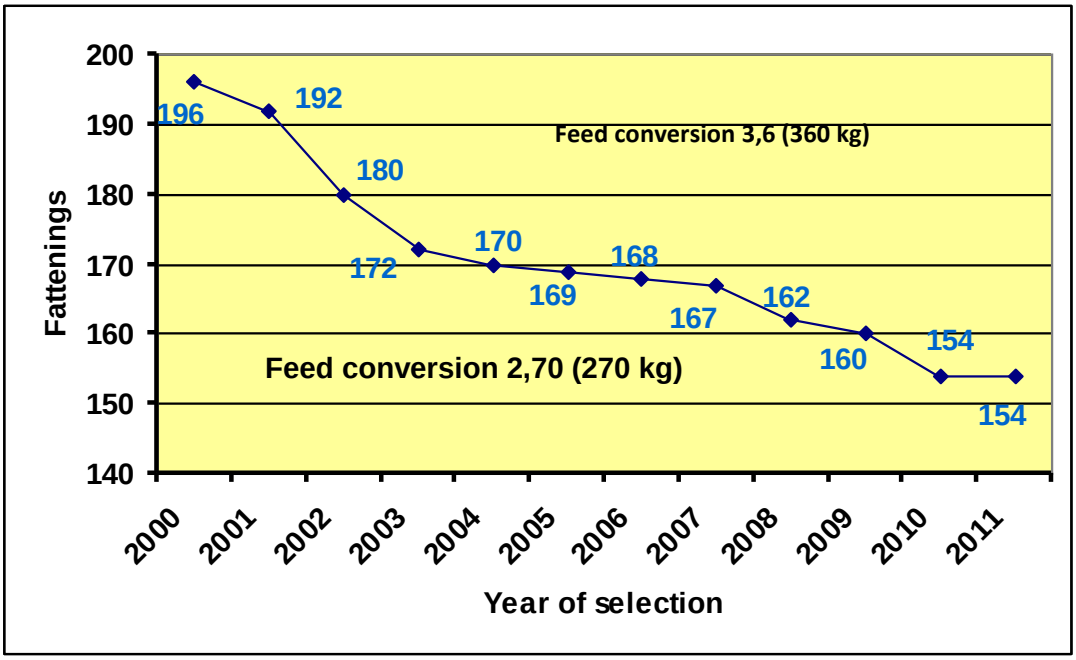

Figure 3. Effect of selection on age at slaughter (indirectly on growth) and feed conversion for Landrace, Yorkshire and Duroc

Effects:

1. Less of feed : 90 kg
2. Less fattening days : 42

Notes: There are no selection differences between Landrace, Yorkshire and Duroc. Pietrain had significantly less daily gain and age at slaughter compare to three other breeds.
According to fattening period we can recognize improvement of 42 days. Economicaly it is iprovement of about 20 euro per pig.
Comparison of age and FC between Duroc and Pietrain differences is present. Duroc had 32 days shorter period to the certain commercial weight and used 88 kg less food. Feed cost in Duroc are 19 euro less.(Figure 4). These rezult are similar to Vidović and Šubara 2010., Vidović et al. 2011c., Višnjić et. al. 2012.

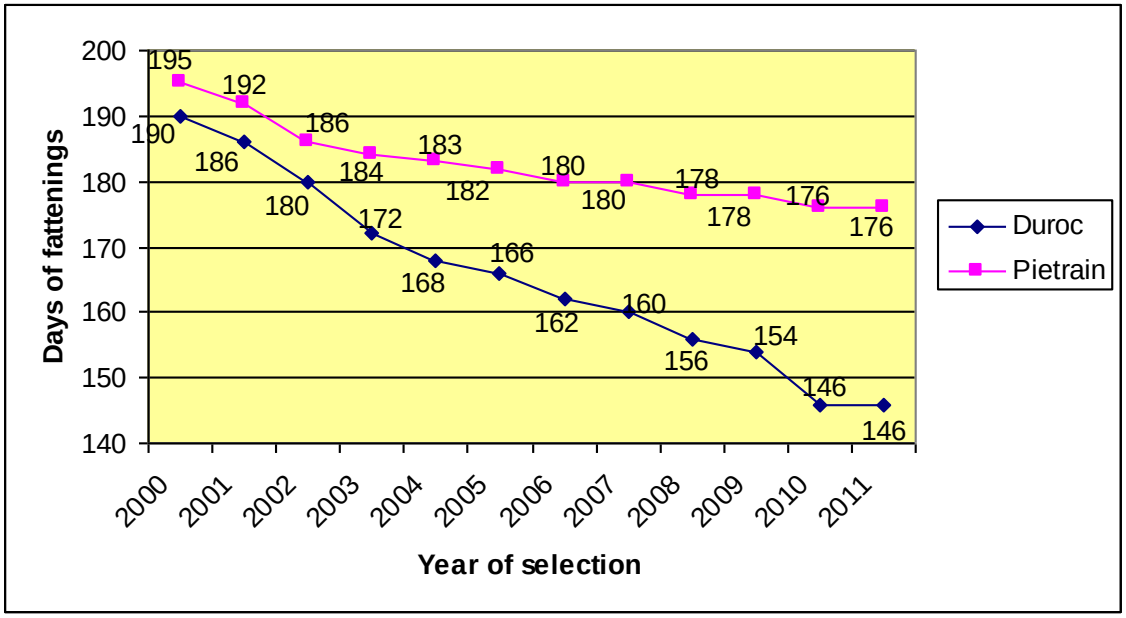

Figure 4. The differences in feed use and age at slaughter between Duroc and Pietrain in test production

The differences: Age: 32 days
Feed: 88 kg

Carcass quality. Meat content in Landrace and Yorkshire has no statistical differences even they showed optimal trend. Since those to breed are treated as dam line to provide heterosis effect at F_1 daughters selection criteria were concentrate more on fertility traits. Expected trend were very close to realized one. It is going to back fat between 16- 20 mm at that age. Later on these animals if they are going to be parents mast has some reserve to produce progeny (Figure 5).

Bones density did not differ significantly between Landrace, Yorkshire and Duroc. Pietrain bones were significantly easier. This demonstrates the viability of lower growth in this race compared to the other and longer feeding for 24 to 32 days. When it comes to the only growth was significantly lower in Pietrain animals were compared to their peers of other races. The content of meat in the carcass was approximately 57.6% in fertile breeds and Duroc 58.9%. It was not significantly different. Pietrain had 62.1% of meat in the carcass which is significantly higher than in other races. Intramuscular fat content was: 0.8% of Pietrain, Duroc 2.6% 2.0% Landrace and Yorkshire 1.8%. The level of protein as the most important parameter of meat quality was the lowest in Pietrain (20.1%), Landrace and Yorkshire were 21.8% and 22.5% and 22.9% Duroc. Selection criteria relate to the last eight generations of selection and the effects show the expected trends.

Just to remind case of present negative genetic correlations between milk yield and meat content in carcass mean that breeders have to optimize selection criteria and use specialized sire and dam lines in breeding program. In our experiment we divided into two different groups: L and Y as mother line and used totally different selection criteria compare to terminal sire lines: D and P. After 11 years of selection or 8 generations result were present (Figure 5 and 6).

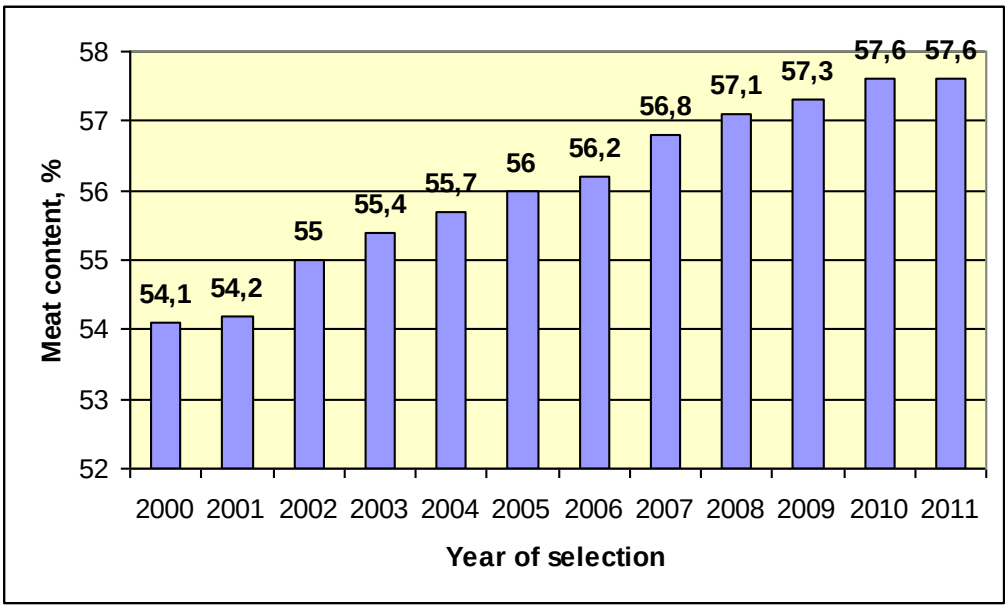

Figure 5. The trend of selection for percentage of meat content for Landrace and Yorkshire

At graph. 6 can be recognized the differences between Duroc and Pietrain even they have the same selection criteria. The only differences were at the beginning of start trial. In conclusion we can say the trend were more or les the same as selection effect. The differences of 3,4% of meat content or raptly 2,5 kg meat between them provide about 8 euro more profit in fewer to P. But in total D made about 14 euro more profit including FC and fattening period as well. Similar conclusion were defined by Gama at al 1990., Rotschild 2010., Bergsma at al. 2010., Vidović et. al. 2011c,d,e.,Višnjić et. al. 2012.

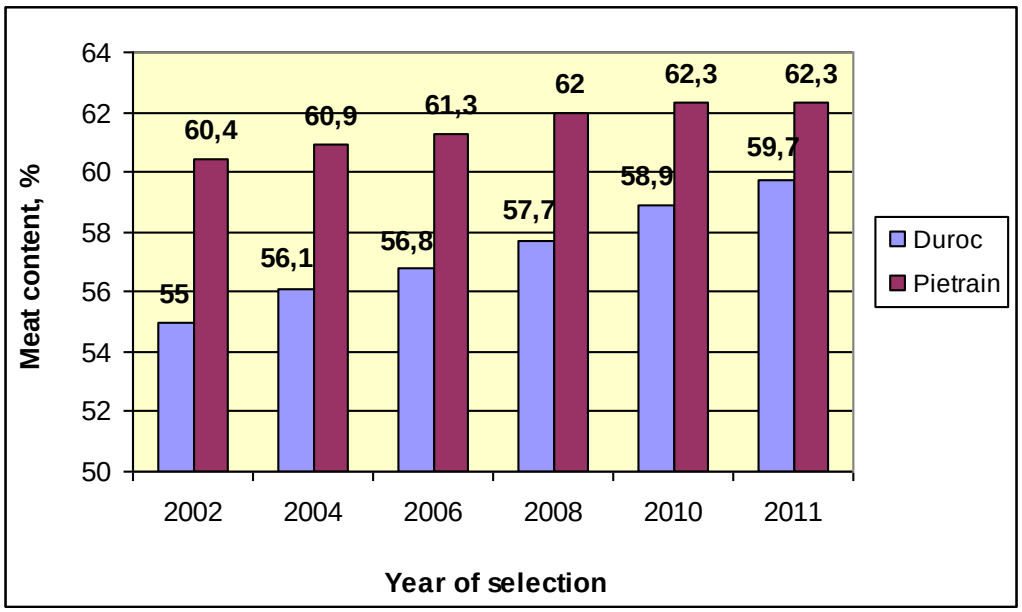

Figure 6. The effects of selection for meat content of Duroc and Pietrain

The effects in meat content, %: - Duroc: 3,9
- Pietrain: 1,9

CONCLUSION

Selection criteria for certain traits have been optimal. It showed clear genetic trend for certain traits.
There have no been selection differences for gain and age at slaughtered Y, L and D. Pietrain showed significantly les gain and needed longer period to reach certain weight. So that means more cost and less profit in case of P.
Also selection on meat content had positive trend. Selection efficiency were higher at D compare with P. Pietrain it self still have 3,4% more meat in carcass but much longer period of fattening. Intramuscular fat was much lover at P (0,5%) compare to D (2,5%). This has negative effect on meat quality in case of P.

ABSTRACT: Capa casein genotyping was performed on 36 cows, bull dams, and based on the analysis of DNA from blood using PCR – REFL techniques. Served for the identification of allelesand genotypes capa casein. Using the identified allels (A and B) and genotypes (AA, AB and BB) capa casein evaluated their frequency in the examined population of cows. Frequency capa casein genotype were: 0,450 AA +0,494 AB + 0,056 BB = 1,00. Furthermore, the frequency of allels A and B which is derived from frequencies of genotypes was 0,66 for allele A and 0,34 for allele B. This reletionship expresses the preliminary information about presence of different genotypes capa casein in Holstein. The contribution capa casein and total casein genotype on milk coagulation rate, determined by LS method, model 1, the coagulation of milk was highly significant. Using model 2, the coagulation of milk, the amount of calcium present in milk had a high impact significantly and lactation order significant impact on the speed of milk coagulation. Physical and chemical composition of fresh milk casein genotypes of different hats, meets the current criteria for the quality of fresh milk. Acceptable rennet – coagulation properties of k-BB groups are reflected in a shortetime of coagulation of milk with rennet. In particular it is a significant relatioship that manifests increased content of casein and total protein in milk. The analysis showed that reflect the time making chesse milk k-BB group was almost three times faster than k-AA milk about 2 times faster than k-AB milk.
Key words: *genetic, polymorphsiam, capa-casein, quality of milk*

INTRODUCTION

Studies of polymorphic protein systems are increasingly directed toward establishing a possible connection between the genes controlling protein polymorphisms - with other genes, desirable or undesirable, which control polygenic traits related to the productive traits of domestic animals. Determination this connection would have, undoubtedly, a great economic importance in the selection and increase productivity in livestock. Genetic variants of individual caseins differ by their structure and physico-chemical properties, of which, to a large extent on the technological properties of milk. The quality of milk has a significant effect on yield and quality of cheese, or the yield of cheese produced depends on the composition of milk. Milk must be normal to renneting curds and gives cund good features. This is possible if there are sufficient of casein and calcium, because they affect the speed of coagulation of milk under the action of rennet and the curds cund. The aim this paper was to examine the quality of milk for processing against frequency k-casein genotypes of black-white Holstein Friesian cattle. Milk proteins are expressed polymorphic nature, the application of molecular genetics techniques to identify genetic variants of these proteins. Thus, the DNA samples obtained from the blood, regardless of sex and age of the animal can be done to identify which greatly contributes to faster and more efficient selection cattle. The speed of coagulation of milk is influenced by k-casein genotype and the contents of total casein in milk, lactation number, calving season, stage of lactation, and the amount of calcium present in milk. Identification of k-casein genotype of Holstein bulls (males) has performed Pinder et al. (1991). Ng-Kwai-Hang et al. (1991) have proved that genetic forms of k-casein have to do with the speed of coagulation of milk rennet. Results Antunac et al. (1991) speaks about the impact of protein polymorphisms on milk coagulation properties, synthesis cheese cund and yield cheese. According to in-Schaar (1984) in terms of

coagulation properties, milk of BB genotype k-casein is attributed to the favourable influence. Genetic improvement of quantitative traits is relatively slow, since some productive traits can be determined only at one sex (Vidović i Lukač, 2010). Also, some can be determined only in adult animals, this is achieved by increasing the generation interval and the decrease of genetic progress by year (Vidović, 2009). For this reason, knowledge of qualitative traits, these as polymorphism of blood groups, enzymes, proteins, blood serum or different types of milk protein milk (Vidović i Stupar, 2010) provides the ability to increase the precision in assessing the genetic value of bulls and cows and selection procedures

MATERIAL AND METHODS

Kappa - casein genotyping was performed on 36 cows, of bull dams, based on analysis of DNA from blood using PCR - REPL techniques. Served for the identification of alleles and genotypes of kappa casein. In order to determine individual factors on the rate of coagulation of milk the analysis of physical - chemical composition according to the methods Carić et al., 2002. and examined the rate of coagulation under the action of rennet. The influence different factors on the rate of coagulation testing using the least squares LSMLMW, Harvey 1990.

1. Model - includes the effect of k-casein genotype, total casein, lactation number, calving season, stage of lactation and the effect of calcium present in milk coagulation rate.

$$\mathbf{Y_{ijklmn} = \mu + K - K_i + L_j + S_k + SL_l + Ca_m + e_{ijklmn}}$$

$\mathbf{Y_{ijklmno}}$ - phenotypic value of the observed trait (speed coagulation)
μ - general mean value
K – K_i – influence k-casein
L_j – influence lactation order
S_k – influence season calving
SL_l – influence stage lactation
Ca_m – influence calcium
e_{ijklmn} – random error

2. Model – include the effect of all these factors in Model 1 but without the influence of casein

$$\mathbf{Y_{ijklmno} = \mu + K - K_i + L_j + S_k + SL_l + Ca_m + b\ (X - \bar{X}) + e_{ijklmn}}$$

$\mathbf{Y_{ijklmno}}$ - phenotypic value of the observed trait (speed coagulation)
μ - general mean value
K – K_i – influence k-casein
L_j – influence lactation order
S_k – influence season calving
SL_l – influence stage lactation
Ca_m – influence calcium
b $(X - \bar{X})$ – linear regression The influence of casein
$e_{ijklmno}$ – random error

RESULTS AND DISCUSSION

DNA isolation was performed according to standard protocol using proteinase K in the presence of detergents. Clean the DNA in all samples satisfactory because the ratio of absorption at 260 nm and 280 nm ranged between 1.8 and 2.0. Table 1 shows the distribution of k-casein genotypes were of the analyzed for 36 bull dams.

Table 1. k-kasein typing DNA of bull dams

Number	Genotype	Number	Genotype	GENOTYPING	
1	AA	19	AA		
2	AA	20	AA		
3	AA	21	AA		
4	AB	22	AB		
5	AB	23	AA		
6	AB	24	AB		
7	AA	25	AB		
8	AB	26	AB		
9	AB	27	BB	AA–16	16
10		28		AB–18	18
11		29		BB–2	2
12		30		Total	36
13		31			
14		32			
15		33			
16		34			
17		35			
18		36			

During the analysis of the 16 samples genotyped with the k-casein AA genotype, 18 samples with genotype AB, and two samples as a k-casein BB genotype. The frequencies of genotypes were 0.450 +0.494 AA AB BB + 0.056 = 1.00. Frequencies of alleles A and B, which is derived from the frequency of genotypes was 0.66 for allele A and 0.34 for allele B. This ratio expresses the preliminary information about the presence of different genotypes of kappa casein in black- white Holstein cows in our population.

Table 2. Phisico-chemical composition of milk of different k-casein genotype

Genotype	pH	°SH	*Proteins* (%)	*Casein* (%)	Ca (%)	*Coagulation time* (min)
AA	6,73	6,5	2,83	2,76	0,18	8
AB	6,76	6,6	3,32	3,24	0,18	5
BB	6,76	6,5	3,93	3,84	0,19	2
Aggregate of milk	6,75	6,6	3,24	3,16	0,18	5

Based on the results shown in Table 2 can be seen that the milk cows k-casein BB genotype is characterized by a higher content of total protein or casein. Bovenhuis et al. (1992) point out that the cows k-casein BB genotype produced milk containing 0.08% higher protein content of cows genotype AA. In terms of coagulation properties, milk obtained from cows k-casein BB genotype is attributable to the favorable impact is reflected in the time of renneting milk with rennet(Table 2). Schaar et al. (1984) also concluded that the time renneting milk casein group B was 2-3 times shorter than the time renneting kasein A milk.

Table 3. F-value in determining the impact of certain factors on speed of coagulation

Trait	Model	F-value					
		k-casein genotype	Total casein	Lactation on order	Season calving	Stage lactation	Quatity of Ca
Speed of coagulation	1	34,264**	11,234**	1,134	1,117	1,277	1,135
	2	86,453	-	3,677*	1,856	2,044	5,712**

P<0,01**; P<0,05* ; P>0,05^{nz}

As seen from Table 3, using model 1, k-casein genotype and total casein have the greatest influence, and highly significant impact on the speed of coagulation of milk, while the effect of other factors, no significant influence. On the basis of model 2, which excludes the influence

of total casein in milk coagulation rate, and includes the effects of other factors studied, it can be concluded that the amount of calcium in the milk had a highly significant impact on the speed of coagulation of milk, lactation in order a significant, while other factors are not had a significant influence on the observed trait.

CONCLUSIONS

Estimated frequency of alleles A and B can be given preliminary information on the presence of different genotypes of k-casein in the studied population. Genetic variant of k-casein BB in terms of coagulation characteristics preferable to k-casein AA because it is associated with increased content of casein, k-casein and total protein in milk. Favorable rennet coagulation properties of milk k-BB groups are reflected in a shorter time of coagulation of milk rennet. Time renneting milk k-BB group was about 2 times faster than other k-casein group. So, preferably increase the frequency of type B k-casein, as it directly favors the selection. In particular, rapid progress can be made in the selection of bulls maintain homozygous k-casein B gene.

ABSTRACT: The aim of this study was to determine differences in the distribution of certain tissues (muscle and adipose tissue and bone) in carcasses of male and female animals. The paper included two fertile breeds: Yorkshire and Landrace and Hampshire breeds as terminal. Carcass dissection was performed by model EU 1992. During dissection data was collected about: weight of animals at slaughter, weight hot and cold carcass, less valuable parts, weight and proportion of the back, the neck, thigh, belly, shoulders the carcass, and the share certain tissues (muscle, fat and bone) on the carcass. Carcass weight in male animals was 40.66 kg with fat thickness on the back of 24.54 mm and 30.58 mm on the ramp, while in the female animal carcass weight was 40.37 kg, the thickness of fat on the back 21.49 mm and 26.71 mm on the ramp. Comparing the proportion of muscle tissue in the carcass of male and female animals was statistically significant difference ($P < 0.05$). Comparing within the breed, no statistically significant differences ($P > 0.05$) in the percentage of meat between two fertile breeds (Landrace and Yorkshire), while there is a statistically significant difference ($P < 0.05$) between the two fertile breeds and terminal (Hampshire). The share of meat in the carcass of female animals was 56.94%, while the males had a lower percentage of meat, 54.82. Sex and breeds have highly significant effect on the amount of meat on the carcass.
Key words*: pigs, sex, quality carcasses*

INTRODUCTION

One the most important trait from economical point in pig production is meat content in carcass. A good quality carcass regardless of breed or sex characterized high proportion of muscle tissue in the carcass. Differences between the sexes in pigs are of special importance, because sex influences the composition of pig carcasses, and the quality properties of muscle tissue (Evans and Kempster, 1979., Petričević et al. 2000., Kušec et al., 2002.). Many studies indicate that there may be some differences between the populations of pigs (resulting from the use of different selection criteria and in accordance with the objectives of the market) in relation to carcass composition and tissue distribution (Evans and Kempster, 1979., Vidović,1987.,Planella and Cook, 1991., Gu et al., 1992., Engel and Walstra, 1993., Daumas and Dhorne, 1997.) According to market demands, pork carcass must be accompanied by a higher proportion of muscle tissue of satisfactory quality, and a smaller proportion of fat. Evaluation meatiness and classing of carcasses of slaughtered pigs is based on the determination of carcass composition (ratio of tissue in them) and some that are significant for commercial value. Given the importance of meatiness in pig carcasses, the aim of this study was to determine differences in the distribution of certain tissues (muscle and adipose tissue and bone) in carcasses of male and female animals.

MATERIALS AND METHODS

This paper included two fertile breeds (Landrace and Yorkshire) and a terminal breed (Hampshire). Carcass dissection was performed on the model of EU 1992. The study involved 327 randomly chosen pig carcasses classified by breed and sex: 191 (93 males and

98 females) breed Landrace, 59 (30 males and 29 females), breed Yorkshire and 77 carcasses (27 male and 50 female) breed Hampshire. During dissection data was collected about: weight of animals at slaughter, weight hot and cold carcass, less valuable parts, weight and proportion of the back, the neck, thigh, belly, shoulders the carcass, and the share certain tissues (muscle, fat and bone) on the carcass. The measured length of the carcass, the average value of backfat thickness measured at the middle of the back and of the ramp. Average slaughter weights of female animals were 102.20 kg and 103.22 kg male.
Statistical analysis was performed using the software Statistic 10. To determine the difference between the average values of individual groups the Duncan test was used. To determine the influence of sex and breed to the observed properties the ANOVA was used.

RESULTS AND DISCUSSION

Values of the quality of pig carcasses are shown in table 1. We can see that the average warm carcass weight, carcass length and backfat thickness measured at the back and ramp. With the average carcass weight in male animals from 40.66 kg in back fat thickness was 24.54 mm and 30.58 mm ramp, while in the female animal carcass weight was 40.37 kg, with the thickness of fat on the back 21, 49 mm and ramp 26.71. Males animals had greater fat thickness (3.87 mm) on the back and ramp in relation to female, both within breed and between breed. Female animals were on average had longer carcasses (0.63 cm) in all three breeds compared to males. Also, backfat thickness was greater in males of 3.87 mm compared to the females.
Comparing the proportion of muscle tissue in the carcass of male and female animals was statistically significant difference (P <0.05) (table 2).Comparing within the breed, no statistically significant differences (P> 0.05) in the percentage of meat between two fertile breeds (Landrace and Yorkshire), while there is a statistically significant difference (P <0.05) between the two races and terminal fertile Hampshire (table 3). To the same results came Kušec et al. (2002, Petricevic et al. (2000.) who were found a statistically significant difference between the breeds and between sexes within a breed.

Proportion of muscle and backfor tissue, bone and less valuable parts are shown in table 4. The results showed that the proportion of meat in the carcasses of females animals 56.94%, 26.73% fat, bone, 9.53% and less valuable parts of 6.80%. Unlike female animals, males had a lower percentage of meat in the carcass (54.82%), higher percentage of fat tissue (29.15%), percentage of bone was 9.25% and less valuable parts of 6.78%. The share of fat and bones were no significant differences between the sexes. To the same results came and Petricevic et al. (2000), who were also found no statistically significant difference between male and female animals in the proportion fat and bone.

The influence of sex and breed on the amount of meat in pig carcasses are shown in table 5. We see that all the factors (sex and breed) have a highly significant impact on the amount of meat on the carcass. To the same results came Kušec et al. (2008.), Latorre et al. (2004.), Ball et al.(1996), Evans and Kempster (1979.).

Table 5. Influence of sex and breed on the amount of meat on the carcass

Source of variation	DF	SS	MS	F	P
Sex	1	73,5	36,8	11,66	0,0000**
Breed	2	40,6	12,89	12,89	0,0003**

P < 0,01** – highly significant; DF – degree of freedom; SS – sum of squares; MS – middle of the squares;
F – value; P - probability

The share of the more important parts of pig carcasses originating from male and female animals are shown in table 6. It can be seen that between the sexes within breed and between the breeds there were no significant differences in cold carcass weight and percentage of representation of certain parts of the carcasses. The same conclusions are there Kušec et al. (2008.), Ball et al.(1996). These results coincide with the results of Latorre et al. (2004.), who did not identify statistically significant differences in cold carcasses weight in male and female animals. The largest and most important share in the carcasses, but it ham with a share of 29.10% in males and 29.51% in female animals. To similar data arrived and Kušec et al. (2008.), Vidović et al., (1994. 2011.) where the share of ham in carcass was been 25.15% for males and 25.00% in female animals.

CONCLUSIONS

From the results, can be seen that the average carcass weight in male animals was 40.66 kg with fat thickness on the back of 24.54 mm and 30.58 mm on the ramp, while in the female animals carcass weight was 40.37 kg, the thickness of fat on the back 21.49 mm and 26.71 mm on the ramp. Fat thickness was greater in males of 3.87 mm. Comparing the proportion of muscle tissue in the carcass of male and female animals was statistically significant difference ($P<0.05$). Comparing within the breed, no statistically significant differences ($P>0.05$) in the percentage of meat between two fertile breeds (Landrace and Yorkshire), while there is a statistically significant difference ($P<0.05$) between the two fertile breeds and

terminal (Hampshire). This is so because the selection criteria are different. The share of meat in the carcass of females animals was 56.94%, while the males had a lower percentage of meat, 54.82%. At the share fat and bones were no significant differences between the the sexes. Between the sexes within breeds and the between breeds there was no significant difference in cold carcass weight and percentage of representation of certain parts. Sex and breeds have highly significant effect on the amount of meat on the carcass. The capacity of animals is of particular importance how at fertile so that terminal breeds. Quality rating of pigs and forming of prices at slaughter line is a prerequisite for the establishment of trust between farmers and butcher. The motive of these relationships is the profit because farmers by performing a selection on meatiness (it is known that when the pig growth in the kg meat must consumed about 1.7 kg of concentrate while in the example growth in kg of fat consumed about 7.0 kg) to earn more money to save in the food while butcher buy animals with more optimum meat quality.

ABSTRACT: The main objectives of study were to evaluate the impact of milk polymorphism significantly protein, k-casein, and to investigate whether it is possible to use this influence to improve milk production. The purpose were to examine how technology and in terms of milk processing can take advantage of these impact. The k-casein genotyping was performed in 18 cows. Isolation of DNA was performed in all blood samples. Determination of k-casein polymorphism in Red and White Holstin cattle based on analysis DNA using PCR-RFLP methods. We have analyzed the chemical composition and physical properties of milk obtained from cows of different k-casein genotypes (AA, AB, BB) and the aggregate of milk for production of cheese. Genotyping of cows has been identified 8 animals with AA, 9 with AB and 1 BB k-casein genotype. The frequencies of genotypes were: 0,44 AA + 0,500 AB + 0,056 BB = 1. Frequency of allels A and B were estimated from frequencies of genotypes, so the frequency of allel A was 0,69 and the frequency of allel B 0,31. It was found that the physicochemical composition of fresh milk that was used to produce trappist according to the criteria for the quality of milk. There were significant differences in milk fat content that are over the values for milk fat used to produce cheese. In neither sample of milk or aggregate milk not found the remains of mycotoxins and antibiotics, or *E. Coli*. The total number of microorganisms and somatic cells satisfying our standards.
Key words: *polymorphism k-casein, technological quality of milk, Trappist cheese*

INTRODUCTION

Over the last several decades have gained important knowledge about the polymorphic properties of a large number of proteins of body fluids. Thanks primarily electrophoretic studies, it was found that the most important constituents of casein: α-casein, β-casein and k-casein, exhibit characteristics of polymorphic proteins. The study of genetic polymorphism of milk proteins has, in addition to the general biological, genetic and biochemical importance, also, the importance of technology for animal and milk production. Polymorphism of k-casein studied Woychik (1964), Leeson et al. (1988), Bech and Kristiansen Rotvig (1990), Pinder et al. (1991). The main objective of this study was to determine the most advantageous genetic variants of k-casein milk from which it is possible to improve the quality and milk production traits for the production of Trappist cheese. Possessing pleiotropic effects of milk protein genes (Vidović i Lukač, 2010; Vidović i Stupar, 2010) affect the technological properties, primarily on the properties related to the production of cheese. The relationship between polymorphism of milk proteins and cheese yield were studied Marziale and Ng-Kwai-Hang (1987). Making of Trappist cheese is not well balanced yet and there is great variability in organoleptic and chemical properties (Herczegh and Fenyves, 2001). However, no matter, we can say that here is a Trappist cheese, which are typical and optimal organoleptic and chemical properties of partially and clearly defined by the quality of milk Rules.

MATERIAL AND METHODS

Kappa casein genotyping was performed in 18 cows (bull dams). DNA isolation is the first step in the analysis and manipulation of DNA. The insulation is made from all 18 blood samples, with 14 samples isolated using standard procedures (Sambrook et al., 1989), and 4 samples with off-the DNA kit. Determination of k-casein polymorphism in red and white Friesian cattle based on analysis of DNA (from blood) using PCR-RFLP method. Amplified DNA products were analyzed by electrophoresis. On the basis of identified alleles and genotypes was a calculated frequency of alleles and genotypes in examined population. In order to study the effect of different k-casein genotypes on the technological quality of milk for the production of Trappist cheese, fresh milk (different k-casein genotypes and aggregate milk) used for this purpose should meet the current criteria for the quality of fresh milk, according to the quality of milk Rules. When analyzing the chemical composition and physical properties of milk obtained from different k-casein genotypes (AA, AB, BB) and cumulative milk following parameters were determined: dry matter, milk fat, ash, total protein, titration acidity (original or natural acidity), casein, content non casein nitrogen, lactose, calcium, volumetric weight, cholesterol content, phosphorus, sodium, somatic cells, the total number of microorganisms, the identification of *E. coli*, antibiotics and mycotoxins.

RESULTS AND DISCUSSION

Isolation of DNA was performed according to standard protocol using proteinase K in the presence of detergents. Clean DNA in all samples is satisfactory because the ratio of absorption at 260 nm and 280 nm was between 1.8 and 2.0. Using amplification of DNA fragments of 453 bp by PCR-RFLP method was performed to identify alleles A and B, k-casein. Table 1 shows the distribution of k-casein genotypes for 18 bull dams analyzed by PCR-RFLP method. During the screening analysis genotyping the 8 samples with k-casein AA genotype, 9 samples with AB and 1 sample as k-casein genotype BB. The frequencies of genotypes were 0.444 AA + 0.500 AB + 0.056 BB = 1 The frequencies of alleles A and B were estimated from genotype frequencies, so that the frequency of allele A was 0.69 and the frequency of allele B 0.31. Considering the relatively small number of samples, however, these data can provide preliminary information on the presence of different genotypes of k-casein in red and white Holstein cows.

Test results of physicochemical composition of milk from cows of different k-casein genotypes used for the production of Trappist cheese are shown in Tables 2 and 3.

Table 2. Chemical composition and physical properties of milk for the production of Trappist cheese

The parameters	Aggregate of milk	Milk AA k-casein genotype	Milk AB k-casein genotype	Milk BB k-casein genotype
Dry matter (%)	13,10	13,11	13,32	11,90
Milk fat (%)	3,95	4,28	4,32	3,61
Specific gravity (˚LD)	1,030	1,032	1,032	1,031
Acidity (˚SH)	6,70	6,50	6,20	6,60
pH	6,73	6,80	6,83	6,78
Proteins (%)	3,13	2,91	3,01	3,17
Lactose (%)	4,85	4,50	4,67	4,43
Casein (%)	2,58	2,55	2,57	2,64
Dry matter fat free (%)	9,15	8,83	9,00	8,29
Ash (%)	0,79	0,71	0,79	0,75
Ca (%)	0,19	0,17	0,19	0,18
Na (%)	0,058	0,06	0,07	0,06
P (%)	0,11	0,10	0,095	0,11
Fe (mg/kg)	0,41	0,45	0,40	0,43

Table 3. Parameters of importance to the technological quality of milk for the production of Trappist cheese

The parameters	Aggregate of milk	Milk AA k-casein genotype	Milk AB k-casein genotype	Milk BB k-casein genotype
Tests of antibiotic	Without antibiotic	Without antibiotic	Without antibiotic	Without antibiotic
Cheese fermentation tests	Compact curd	Compact curd	Compact curd	Compact curd
Cholesterol (mg/g)	2,52	3,07	3,12	1,71
Mycotoxins	Without mycotoxins	Without mycotoxins	Without mycotoxins	Without mycotoxins
Total bacterial	0,5 x 10	1,0 x 10	1,0 x 10	0,8 x 10
Escherichia coli	Not found	Not found	Not found	Not found
Somatic cells	164.000	340.000	227.500	155.000

From the results of determining the basic indicators of physical and chemical composition of crude milk used to produce Trappist, it is evident that the milk fat content in milk AA and AB genotype k-casein is above the value used for the production of Trappist cheese (According to the Regulations up to 4% milk fat) and due to the use of milk obtained from the evening milking when milk fat content is higher than the content of the morning milk. The dry matter content of fat-free AA and AB k-casein genotype was within permitted limits, while the value of k-casein BB genotype were below the prescribed value. (Regulation 2002 at least 8.50). Milk casein genotype BB cap is characterized by a higher protein content compared to the AA and AB genotype. Beskorovajni et al. (2002) found that milk BB-type k-casein containing 0,13% milk protein than AA type. Lactose content was within the limits of known values. Minerals are very important for the technological properties of milk and its behaviour during the treatment and processing. In this regard the most important are calcium and phosphorus. One of the calcium is bound to the casein (calcium caseinate), the second part is related to the form of phosphoric acid and phosphate insoluble absorbed from casein, while only 31% of the total amount of calcium are insoluble salts. This percentage increases with increasing acidity of milk. An average sample of milk of all genotypes and aggregate milk contained the value of minerals and acidity within the allowed limits. The examination of certain parameters that are relevant to making quality of milk obtained from cows of different k-casein genotypes (AA, AB and BB) and aggregate milk that is used in the production of Trappist cheese was found that in any sample of milk have not found the remains of mycotoxins and antibiotics, or E. Coli. This suggests that the milk produced in hygienic conditions and that it is a milk of healthy cows. Microbiological status of milk is very important for the technological quality of

milk for cheese (Popović et al., 2009). The total number of bacteria in all samples meets the standards of regulation. Bacteriological status of milk indicates that milk used to produce Trappist cheese made with respect to hygiene during milking, transport and treatment of milk. It also shows that the milk is properly cooled after milking; the milk is cooled to low temperatures slow down or stops the activity of microorganisms. Milk casein genotypes (AA, AB and BB) and aggregate milk with rennet form a compact and sturdy curd. The number of somatic cells in 1 ml of milk in accordance with the Rules, which suggests that milk is a healthy cow. Based on these results, can see that the cholesterol content was significantly increased in samples of milk AA and AB k-casein genotypes, which is consistent with the content of milk fat in the same samples. Been recorded from the given tables that the milk BB k-casein genotype used to produce Trappist better technological quality in terms of protein and casein in milk compared to the AA and AB k-casein genotype.

CONCLUSIONS

Genotyping of the cow k-casein has been identified as two k-casein alleles: A and B, using PCR-RFLP method. K-casein DNA typing 18 bull dams identified 8 individuals with AA, 9 AB and 1 with BB k-casein genotype. The frequency of alleles A and B were estimated from the frequencies of genotypes, so the frequency of allele A was 0.69 and the frequency of allele B 0.31. These results may provide preliminary information on the presence of different genotypes of k-casein in red and white Holstein cattle. Physical and chemical composition of fresh milk that is used to produce Trappist cheese meets the criteria for the quality of fresh milk. However, there were significant differences in milk fat content as they were above values used for the production of Trappist cheese. Not one sample of milk or aggregate milk not found the remains of mycotoxins and antibiotics, or *E. Coli*. This shows that the milk produced in hygienic conditions and that it is a milk of healthy cows. The total number of microorganisms and somatic cells satisfies our standard. Milk k- milk casein BB genotype were used to produce Trappist is better in terms of technological quality protein and casein in milk compared to the AA and AB k-casein genotype.

ABSTRACT: Control of microbiological safety of animal feed is regulated by a law. The regulation is based on methodological standards for estimation of feed quality. Those methods are permanently amended and with a strive for continuous improvement of microbiological safety of feed. The question remains whether the presence or absence of some bacterial species is sufficient for proper assessment of feed safety. The answer to this question can be found not only in the examination of the number of bacteria in animal feed, but also in qualitative analyzes of the isolated microorganisms. The sensitivity of bacteria from animal feed to antimicrobials is one of the qualitative characteristics of microorganisms that can affect food safety even if the feed meets the standards and is within the maximum permitted level. The subject of our work was to determinate the presence of bacteria in animal feed with a purpose to examine if they possess lower sensibility to antibiotics. For testing antibiotic sensitivity the isolates from routine microbiological feed control were used. The animal feed was analyzed by the standard methods for the isolation and identification of bacteria and determination of susceptibility was done using disc diffusion method according to CLSI. The following bacteria were detected: *Escherichia coli*, *Enterobacter* sp., *Staphylococcus* sp., *Micrococcus* sp., *Bacillus cereus*, *Bacillus* sp. The results showed that some isolates have reduced susceptibility to certain antimicrobial drugs. This finding gives a reason for further examination of certain characteristics of the bacteria found in animal feed and detect their possible influence on ecology.
Key words: *animal feed, bacteria, antimicrobial drugs*

INTRODUCTION

Different types of microorganisms can be found in feed. The microorganisms can be transmitted in different ways from the ground: by wind, rain and insects or by mechanical treatment (K.G. Maciorowski et al., 2007). Since the feed is the first critical point in the food production chain, it is necessary permanently to control the feed in terms of its safety. A detailed microbiological control of feed is described in the current legislation (“Official Gazette” SFRJ 25/1980). This implies also to the methods of testing the number of microorganisms. In this way an entry of certain pathogens and zoonotic microorganisms in the feed is prevented. In an indirect way, this ensures the microbiological safety of food of animal origin which can become a potential source of human infection. The standard methods for feed control and allowed limits in terms of number of saprophytic microorganisms are available.

The number of saprophytic microorganisms permitted by regulation is different depending on the type of feed and the animal category for which the feed is intended. Legal acts determine only the quantity of saprophytic bacteria but the qualitative characteristics of saprophytes can be overlooked. On the other hand, saprophytes are living organisms that can posses some undesirable properties. They can also transfer some of their properties to microorganisms in the digestive tract of animals. A qualitative analysis of saprophytic bacteria can contribute in preventing the transfer of undesirable features. An example is the transfer of resistance genes to microbes that reside in animals. The increased selection of the resistant bacteria in animals and humans and the spread of genes that carry these characteristics may affect ecosystem (Leila Soufi et al., 2011). For these reasons, the subject of our research was

related to monitoring the presence of bacteria in animal feed in order to determine whether the isolated bacteria posses the decreased sensitivity to antibiotics.

MATERIAL AND METHODS

Animal feed was analyzed for six months in the second half of 2011. The examined samples originated from feed mills that regularly check their products. A total of 26 samples was examined for different animal categories. Total mix used in poultry fattening and growing breeding hens (starter, grower, finisher), as well as the mix for calves and food supplements (vitamin and mineral, vitamin and protein) were examined. The samples were processed according to the methodology described in the Ordinance on the methods of performing microbiological analysis and super nutritional support life ("Official Gazette" SFRJ 25/1980). The samples were homogenized and weighed to 20 g in the Erlenmeyer flask bottle. A A sterile physiological saline solution was added to the volume of 180 mL to obtain a basic dilution 10^{-1}. From this dilution 1 ml was taken and placed directly on blood agar (agar with 5% defibrinated sheep blood) and McConkey agar. Identification of bacterial isolates was done after Gram stain and microscopic examination was performed by determining the physiological characteristics of bacteria through a series of biochemical tests (Quinn et al., 2002).
The sensitivity of isolated strains was done as recommended by CLSI (2006). We used antibiotic disks Tetracycline (30 μg), ampicilline (10 μg), streptomycin (10 μg), Ceftriaxone (30 μg), Trimethoprim + sulfamethoxazole (25 μg (trimetoprim 1,25 μg + sulamethox-azole 23.75 mg)), chloramphenicol (30 μg), lincomycin (2 μg), enrofloxacin (5μg), amoxicillin (30 μg (amoxiciline 20 μg + 10 μg clavulonic acid)) (produced by Bioanalyse) while Lincospectin (109 μg (lincomycin 9 μg + Spektinomicin100 μg) discs were from the producer Oxoid.

RESULTS AND DISCUSSION

From a total of 26 processed materials 62 isolates were detected. Within the total number of isolated bacteria six different bacterial species were confirmed. Our study is limited to the obtained isolates and the sensitivity to antimicrobial drugs is given in Table 1.
Among *Enterobacteriacae* most frequently *Escherichia coli* and *Enterobacter sp* were found. These microorganisms were represented with 62.85% of total isolates. *Bacillus sp., Staphylococcus sp.* and *Micrococcus sp.* are microorganisms that are widespread in nature and are part of the saprophytic microbiota of humans, animals and the external environment. *Flavobacter sp*. belongs to a group of microorganisms that are found as commensals in the soil and their findings may indicate that the feed is contaminated and has been, directly or indirectly, in contact with bacteria of the soil.
The results showed that *E. coli* and *Enterobacter sp*. as the predominant microorganisms, contaminating feed, carry a high resistance to certain antimicrobial drugs. These two species showed complete resistance to lincomycin. This can be due to the long use of antimicrobial products as growth promoters or in prophylactic purposes (Frank M. Aarestrup, Henrik C. Wegener 1999., Torrence E. Mary 2001). An extraordinary high resistance (75-100%) to lincomycin and the fact that 50% or more isolates were resistant to ampicillin, amoxicillin and lincospectin is surprising since it is obvious that the strains isolated from food animals were in contact with the antimicrobial drugs long enough to develop resistance. Equally important would be to determine the sources of microorganisms from animal feed because of their characteristic high resistance to certain antimicrobial drugs that can occur only in contact with these agents or through horizontal transfer of the genome responsible for resistance (K.G. Maciorowski et al., 2007, Velhner Maja et al. 2010). The data obtained are similar to the study from Portugal (Paulo Martins da Costa et al., 2007) where the resistance in *E. coli* was relatively low (29.9% ampicillin, tetracycline 27.7%) or absent for amoxiclav. The study also shows that the resistance to three and more antibiotics was present in 18.1% of isolates.

S – Sensitive, I – Intermediate, R - Resistant

Microflora of the digestive tract contains hundreds of bacterial species (S. Steve Yan, Jeffrey M. Gilbert, 2004). The vertical transfer of resistance determinants can occur via plasmids, prophages, transposons and integrons (S. Steve Yan, Jeffrey M. Gilbert 2004, Velhner M. et al., 2010), especially among Gram negative bacteria. Subsequently drug-resistant strains can be transmitted from animals to humans. The presence of bacteria from the family *Enterobacteriacae*, such as *E. coli* and *Enterobacter sp*. in animal feed may contribute to the spread of resistance genes through horizontal or vertical transfer. This is why bacteria carrying resistance genes, become part of the microflora of the digestive tract (S. Steve Yan, Jeffrey M. Gilbert 2004). Also, resistance to some antimicrobial drugs can occur in herds that were not in contact with drugs during their lifetime.
The presence of resistant strains of *Flavobacter sp*. in animal feeds confirms the possibility of transfer of soil bacteria to feed (K.G. Maciorowski et al., 2007). Also the observed resistance to some antimicrobials may indicate that the antibiotic preparations came to the soil where they caused the resistance. On the other hand it is possible that the emergence of resistance occurred as a result of the spread of bacteria among which the horizontal resistance gene transfer may happen.

CONCLUSION

Control of feed in respect to quantitative microbiological examination meets the standards that provide the limits of permissible and impermissible microorganisms. Our study has shown that the qualitative analysis of bacterial isolates contributed to a higher degree of food safety since it can provide information about the reduced sensitivity of bacteria to antimicrobial agents, a possible elimination from the food chain which leads to improvement of ecology.

ABSTRACT: The article presents the analysis of work of feed mills, which use a portioned grinding. It is shown that the components such as extraction cakes of olive cultures and limestone contain a significant amount of mealy fractions, which don't require grinding. The scheme of technological process suggests the preliminary sifting of the portions of components that are directed on grinding with the aim of separation the mealy fraction. The use of an additional mixer is justified to obtain a preliminary mixture of microcomponents that improves the uniformity of their distribution in the mixed feeds.
Key words: *technology of production of the mixed feed, feedmills, chart of technological process, efficiency*

INTRODUCTION

The end of last century was marked by the beginning of building of feed mills of IV generation for which characteristic feature is portioned grinding of components (Kersten et al., 2003; Iegorov, 2011). In the European Union, the USA, Indonesia, Brazil, Argentina and China dozen of such feed mills were constructed for last 20 years. Today in Ukraine 7 feed mills of IV generation are exploited. Such schemes are typical for variety of such leading machine-building companies as Buhler AG (Switzerland), Andritz Feeds and Biofuel (Denmark), VanAarsen (Netherlands), Awila anlagenbau GmbH (Germany), Wynveen International (Netherlands) and allows to make loose and the pelleted mixed feed. According to the scheme a portion of the weighed components (grain, extraction cakes of olive cultures, limestone) arrives into portioned grinding knot which represents the overgrinding bunker, hammer grinder and the filter-cyclone established on the special bunker. The grinded portion of components is submitted to the main mixer with the help of the conveyor. Portion of the weighed protein components can also just be submitted to the main mixer, and can be sent to the portioned grinding knot (in case, if the size of particles of these raw materials exceed the allowable limit for the produced mixed feed limits). As a result of such technological operations the performance of the feedmill is significantly reduced.
Microcomponents such as premixes, amino acids, enzymes, adsorbents, etc. are unpacked manually to the bunkers of the technological line of microdosing. Microcomponents are weighed in turn in accordance with the prescription of mixed feed and sent to the main mixer. As a result of mixing we get loose mixed feeds According to the information of the manufacturers of the process equipment, used mixers provide the uniform distribution for microcomponents in the composition of mixed feeds in the ratio of 1:100000 (Charlton et al., 2007). However as research has shown in practice, dosages for microcomponents may reach the minimum values (up to 0,05 %) of the mass of the recipe feed which questioned the possibility of uniform distribution of such component in the mixture (McEllhiney, 1994). In addition in most cases vegetable oil is put to the technological line of the main mixing, which complicates the process of obtaining highly uniform mixture. Receiving of results of non-uniform mixed feed can become the reason of decrease in productive action.
Technologies of the IV generation are characterized by the high flexibility of the technological process, the low specific energy consumption for production of mixed feed, the high quality and productive effect of mixed feed. Further improvement of the technology of production of

the mixed feed requires the theoretical foundation and practical confirmation of the proposed solutions. Primarily the technological process of grinding portions of the mixed feed requires the improvement as some of them contains fractions that does not require grinding. As the result, there is an overgrinding of components such as soybean extraction cakes or limestone.
The experience of the industrial operation of the constructed feed mills in combination with the analysis of the peculiarities of the raw material base and the differences in the organization of production and the results of new researches allows us to formulate a number of suggestions to improve the efficiency of production of mixed feed.

MATERIAL AND METHODS

Assessment of the efficiency of grinding of mixed feed components was carried by the method of particle size analysis of the particles.
Cost of energy for production of mixed feed was determined by relating the installed power to the performance and stability of the technological process, and it was evaluated by the index of stability, which is defined as the ratio of the minimum and maximum variance of the distribution of controlled quality index.
Content of the mealy fraction was determined in soybean extraction cakes and limestone. Energy consumption on the grinding portions of feed components and on the production of one ton of the ready-mixed feed was also determined.

RESULTS AND DISCUSSION

Primarily the technology of portion grinding requires improvement as oilcakes, extraction cakes of olive cultures and limestone consists are in the portion. They contain a considerable amount of mealy fractions (Figure 1).

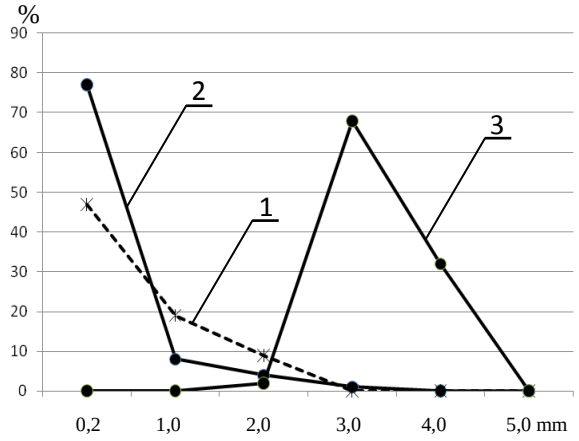

Figure 1. Granulometric composition of
limestone (1), soybean extraction cake (2) and

Their overgrinding leads to waste energy and reduce operational durability of the basic working elements of hammer grinders. The investigated limestone (Zakupansk deposit, Ukraine) contains 77,4 % of the particles of size less than 0,56 mm and soybean extraction cakes - 43,25 % of the particles of size less than 0,56 mm. It is reasonable to use preliminary sifting of the portions of the weighed components before sending them to the portioned grinding knot. Such a decision is consistent with the findings obtained in the course of the research, conducted by Nasi and Calini (1997).
The question of the uniform distribution of the portion of microcomponents in the loose mixed feed rises acutely. It is necessary to provide the installation of a paddle mixer to obtain a preliminary mixture of such components as products of synthetic amino acids, adsorbents,

acidifiers and other biologically active substances which are included in mixed feed in extremely small dosages (about 0,05 %). The necessity of this step is justified in the work of Iegorov (2011). In addition, installation of the additional mixer enables to receive highly concentrated vitamin and mineral premixes (blend) and pre-mixes for the subsequent manufacture of mixed feed.

The question of application of technological systems of microspraying liquid preparations of biologically active substances, first of all enzymes, again requires scientific-practical substantiation because their application had previously been justified by the use of heat-labile dry biologically active substances. At the present time their thermal stability has increased substantially due to the introduction of nanotechnology production of matrix microcapsuled enzyme preparations. The use of technological processes of steam-conditioning and expansion of mixed feed before granulation is not in doubt as sanitary purity of the components of mixed feed is worse in recent times.

Thus you can submit an improved scheme of technological process of production of the mixed feed of IV generation (Figure 2) by realizing the above suggestions. The proposed scheme allows making the following kinds of products: loose mixed feed, pelleted mixed feed, grits mixed feed, expanded grits mixed feed, protein-vitamin additives and pre-mixtures of microcomponents.

The maximum productivity is 20-60 t/h of pelleted mixed feeds. During the production of protein-vitamin additives and pre-mixtures productivity is reduced in relation to the chosen prescription.

Grain raw material comes by railway and motor transport. It is cleaned and placed in storage as a rule in the existing elevator. Oilcakes and extraction cakes may come loose and be placed in storage in the warehouse floor-type and in silos. Wheat bran can be received from the mill with the help of pneumatic transport.

Limestone (grits, flour) is in the big-bags and in a bulk form and it can be unloaded by use of the receiver from rail transport. Storage is provided in the floor type warehouse. Feed to the production is carried out by loader with the help of the receiving device. It is advisable to use a separate system to download the limestone in silos 59-70.

Protein components (meat, meat and bone, fish flour, fodder yeast) are also placed on the storage in the warehouse floor storage and fed to the production with the help of a separate receiver to the overweighing bunkers. It is possible to feed the limestone to some of these bunkers.

Packed raw materials (premixes, amino acids, enzymes, adsorbents, etc.) are placed on the storage also in the floor type warehouse and fed to the production with the help of the freight elevator to the overweighing bunkers of the micro-dosing line.

Liquid preparations of enzymes are fed to the production also with the help of the freight elevator on the floor where microspraying system is located.

Grain components, oilcakes, extraction cakes and limestone are weighed with the help of a multi-component weighing batcher. First the weighted portion is fed to the first operational bunker, and then it is fed to the second operational bunker. The presence of two operational bunkers allows providing stable work of management system of the portion grinding. It is recommended to sift components before grinding. This provides separation of mealy fraction which is sent to the bunker under the hammer grinder. A large fraction comes to the hammer grinding and a small fraction goes to the undergrinding bunker. It is expedient to install a rotary shutter before undergrinding bunker in order to avoid violations of the trajectory of the material flow of the products of the grinding process in undergrinding bunker and dusting.

Preliminary sifting allows substantially (for 25-50 %) improving the productivity of hammer grinder, to reduce the unit cost of electricity for grinding and to increase the operation life of the kit hammers. Grinded portion of the components is sent with the help of transporter 5 to the mixer 1. Protein raw materials located in the overdosing bunkers are dosed in accordance with the recipe and also with the help of transporter 5 are sent to the mixer 1.

If these components require grinding, they are immediately placed in these bunkers or sent to the line of portioned grinding with the help of transporter 3. The plant's capacity can be significantly reduced.

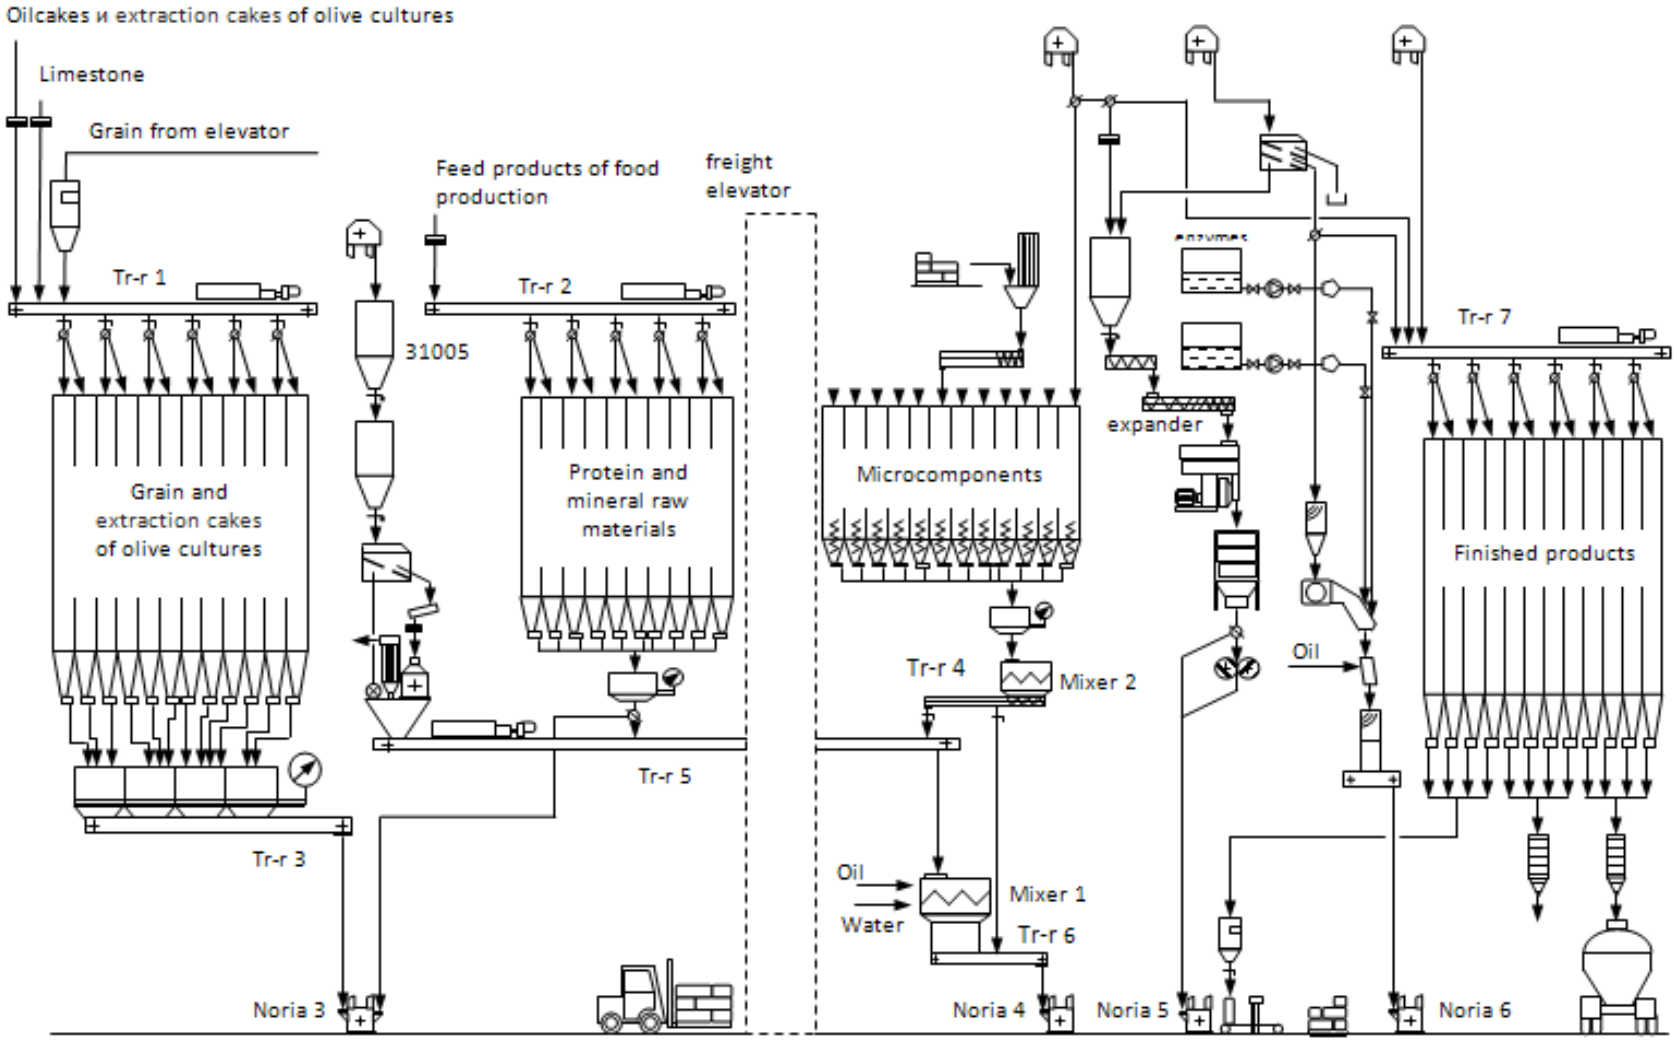

Figure 2. Improved scheme of the technological process of production of the mixed feed of the fourth generation

On the line of micro-dosing weghing for microcomponents is located in the overdosing bunkers with a capacity of 500-1000 litre each of them. Limestone or any other component of animal feed (soybean or sunflower extraction cake, fodder chalk, etc.) can be used as filler. The weighted portion of microcomponents is directed to the mixer 2 and to a mixer 1 using a transporter 4 and 5 after the reception of a homogeneous mix.
After mixing, feed is sent by transporter 6 and noria 4, in the bunkers of finished products 61-70 or on the line of pelleting. In the case of production of pre-mixes there is the possibility of feeding mixture from mixer 1 to the separate bunker for microdosing line which allows bringing highly concentrated form of feed products to the required concentration by a subsequent mixing with the filling.
Mixed feed is sent to the expander before pelleting which allows improving the hygiene quality, digestibility of nutrients, efficiency of the process of pelleting and increasing the operation life of the pellet press. It is possible to obtain whole pellets or crumbles by crumbling granules in the rolling grinder and the subsequent sifting. It is possible to apply of liquid preparations of heat-labile enzymes on the surface of granules or crumbles. The scheme provides the possibility of production of mixed feed in packaged form.
The scheme is enhanced by magnetic protection to improve the quality of finished products and to avoid sparking because mounted in the hammer grinders and pelletisers magnetic separators are not clearly sufficient in the production of mixed feed from a contaminated fodder raw materials.
During the construction of the new feed mills it is necessary to take into account a number of factors specific to each country. For example, the level of development of transport infrastructure, logistics and information support essentially influence on the determination of optimal terms of storage of raw materials and finished products, which in turn largely determine the cost of the project.
As a result of studying of possibilities of Ukrainian suppliers of fodder raw materials and efficiency of functioning of the national transport infrastructure we determine the expected timing of storage of some types of raw materials and finished products. For example, it is assumed to have a supply of grain up to 2500- 5000 tons to feed mill with capacity of 20 tons per hour. The storage time of bran wheat should not exceed 2 days. Coming from the mill bran wheat have a humidity of about 15,0-15,5 %, that causes threat of sticking of raw materials in silos. It is necessary to provide an opportunity to move the bran from one silo to another.
The expected storage periods of oilcakes and extraction cakes of olive cultures are: the oilcakes - from 5 to 14 days, the extraction cakes - from 14 to 30 days on storage in silos. The expected dates for storage of fodder products of food and biochemical industries are from 10 to 14 days.
Limestone and feed chalk can come by the motor transport (in big-bags of 1 ton or bulk) and with a railway transportation in big bags or in bulk. Salt comes in polypropylene bags with capacity of 25 to 50 kg. The expected storage periods are: limestone - from 5 to 14 days (in winter), feed chalk - from 5 to 14 days, phosphates - from 7 to 30 days, salt sodium - from 5 to 14 days.
The expected storage periods of premixes and other microcomponents are from 7 to 14 days.

Liquid types of raw materials. It is supposed to use sunflower oil and soya oil and liquid concentrate of biologically active substances with the installation of the micro-spraying line. The expected storage periods are from 7 to 30 days.

Finished products. It is supposed to manufacture loose or pelleted mixed feed (in bulk or packed form in four-layer paper craft-bags or woven polypropylene bags weighing 5, 10, 20 and 40 kg). The expected dates of storage of mixed feed in silos up to 70% of the capacity of the plant are 3 days and the expected dates of storage of packed mixed feed are up to 30 days. It is proposed to use warehouse floor storage with area 1200m^2 for their placement, storage and delivery.

A characteristic of Ukrainian feed mills is redistribution of the production capacity. About 30-50 % of the production capacity is provided for the production of mixed feed for their own needs because virtually all new factories are included in the composition of agro-holdings. The remaining production capacity is used for the production of mixed feed for sale for a small wholesale and retail for small farmers. Regarding this it is expedient to set up two pelletisers on the line of feed pelleting. For example, it is advisable to install one of the pelletisers with a capacity of 15 t/h and the second - with a capacity 5-8 t/h when the capacity of the feed mill is 20 t/h. Such step is profitable because you can acquire a larger number of dies of different sizes to press a lesser productivity that allows meeting consumer demand for a wide range of pelleted feeds, without frequent replacement of matrix at the main pelletiser.

CONCLUSIONS

Improved scheme of technological process has been implemented in the construction of a feed mill in Rozdelnaya (Odessa region, Ukraine). In the course of the conducted research, it is advisable to install sieve separators before hammer grinder for separation of mealy fraction of portions of the components that require on grinding. As a result, the energy consumption for production of mixed feed can be reduced by 10-15 % and the stability of the technological process increases from 0,85...0,90 to 0.95...0,97. Three year experience of operation of the feed mill showed high efficiency of proposed technical and technological solutions which can be used in the construction of new feed mills.

ABSTRACT: Mycotoxins are secondary metabolites of fungi that can contaminate animal feeds at all stages of food production chain. Consumption of feed contaminated with mycotoxins may result in immunosuppresion, which represent a factor predisposing livestock to infectious diseases. From the epidemiological point of view, it is important to note that mycotoxins may cause breakdown of active immunity and occurence of disease even in properly vaccinated animals. The aim of the paper was to evaluate the influence of mycotoxins on the health status of piglets. The material for this research included the samples from five swine farms, where health disorders in suckling and weaned piglets were detected. Depending on the specificity of each evaluated case and available material, the applied research methods included: epidemiological and clinical evaluation, pathomorphological examination, standard laboratory testing for detection the precence of aerobic and anaerobic bacteria, virological testing and microbiological feed testing, in order to examine the presence of fungi and mycotoxins by the method of thin layer chromatography. In our research the persistant presence of various infections, which react poorly or do not react on the applied antimicrobial therapy was discovered. The presence of mycotoxin in feed can be directly connected to the detected health disturbances in piglets on the examined swine farms (vulvovaginitis, pneumonia, gastroenteritis).
Key words: *mycotoxins, swine feed, piglets diseases*

INTRODUCTION

Mycotoxins are secondary metabolites of mould, and so far, approximately 400 secondary metabolites with toxigenic potential produced by more than 100 moulds have been reported (Kabak et al., 2006). At the global level, it is considered that 25% of the world crop production is contaminated by mycotoxins, which may be a risk factor affecting human and animal health (Bouhet and Oswald, 2005). The issue of mycotoxins and mycotoxicoses in veterinary medicine is directly connected to the usage of mouldy and adversely storage of diffent types of grains (corn, wheat, barley) in animals feed (Osweiler, 2006).
In swine production in our geographic region, the most common are mycotoxicosis caused by zearalenon (F-2 toxin, ZEA), but also aflatoxins (AF), ochratoxin (OCT) and trichothecenes. (Gonzales and Rodriguez, 2008). The clinical and patomorphological picture of mycotoxicoses in swine depend on the age and category (breeding animals, suckling and weaned piglets, fatteners) (Prodanov et al., 2009). The young animals are much more sensitive to the effects of mycotoxins comparing to adults. Mycotoxins have hepatotoxic, nephrotoxic and immunosuppressive effects (Kabak et al., 2006), which can further complicate clinical and pathomorphological picture and diagnosis of mycotoxicosis in swine. The biggest challenge with mycotoxicoses is the non-specific nature of symptoms in the affected animals. Consequently, the health disorders due to mycotoxins in the feed are difficult to diagnose (Osweiler, 2006; Prodanov et al, 2009). It has been recognised by veterinary clinicians that marked immunosuppression is observed in livestock ingesting mycotoxins at levels below those that cause overt toxicity (Oswald et al., 2005). Immunosuppressive effects of mycotoxins are of special interest and may have significant influence on the occurence of infective diseases of pigs (Obremski et al., 2008; Prodanov-Radulović et al., 2011).

The aim of the paper was to evaluate the influence of mycotoxins on the health status of suckling and weaned piglets.

MATERIAL AND METHODS

The material for this research included the samples from five swine farms, where health disorders in suckling and weaned piglets were detected. Depending on the specificity of each evaluated case and available material, the applied research methods included: epidemiological and clinical evaluation, pathomorphological examination, standard laboratory testing for detection the precence of aerobic and anaerobic bacteria, virological testing and microbiological feed testing, in order to examine the presence of fungi and mycotoxins by the method of thin layer chromatography.

RESULTS AND DISCUSSION

In the first examined farm, the health disturbances in suckling piglets and weaners were registrated. Clinically, the diarrhoea in suckling piglets already in the first 3 days of life after farrowing were detected. After supervision of the farm records several facts were discovered: diarrhoea occurs in the piglets of normal birth body weight, the percent of mortality is higher in animals in good body condition and on the weaning there is 30% of small piglets. Therapeutic treatment of piglets by oral and parenteral antibiotics aplication did not improve health problems. On the farm dams are twice vaccinated during gestation with the aim to prevent disease in piglets (diarrhoea) in the first days of life. By clinical examination the certain number of suckling piglets the clinical sign of vulvovaginitis (swelling and reddening of the vulva) were dicovered. Carriyng health control in the weaned piglets the diarrhoea and signs of pneumonia (cough, nasal secretion) were detected. The pathomorphological examination of the dead suckling piglets revealed lesions dominantly on the mucosal surface of the digestive tract (*Haemorrhagiae mucosae ventriculi, Enteritis catharralis acuta*). In dead weaners beside lesions in the digestive tract, the prominent pathological changes in lungs were discovered (*Pneumonia fibrinosa in statu hepatisationis rubrae et griseae*). By bacteriological testing on tissue samples deriving from dead animals the following bacteria was detected: *Escherichia coli haemolytica, Streptoccocus alfa haemolyticus, Pasteurella sp*. Having in mind the clinical and pathological symptoms observed, especially the signs of vulvovaginitis in just farrowed piglets, a justified suspicion on the presence of mycotoxins in feed was made. Microbiological first feed for piglets testing detected 3-fold increase in the number of fungi genera *Fusarium sp, Penicillium, Aspergillus, Rhisopus sp*. as compared to the level set by the regulation. Applying further laboratory testing increase of the total number of fungi in the large number of examinated feeds was discovered: corn ($887x10^3$ *Aspergillus, Rhisopus*), piglets second feed ($319x10^3$ *Aspergillus, Mucor, Rhisopus*), feed for pregnant sows ($123x10^3$ *Penicillium, Fusarium*) and feed for lactating sows ($526x10^3$ *Aspergillus, Penicillium, Mucor*). The presence of mycotoxins was detected: zearalenon (ZEA) in the feed for pregnant sows (0.72 mg/kg), aflatoxin (AF) B1 in the piglets first feed (0,018 mg/kg) and ochratoxin (OCT) A in the piglets second feed (0.12 mg/kg).

On the second examined swine farm the health problems included increased incidence of clinical and pathomorphological signs of infective diseases. Analysing the existing data on the farm, the high mortality in piglets 7 days before weaning was noticed, which do not decrease after medical treatment. With the aim to overcome the problem, the measure of medical treatmet of piglets 3 days before weaning was introduced, but again with no result. In the weaned piglets the disease was clinically characterised with the signs of severe yellowish diarrhoea, dehidratation, huddling, roughly hair and sporadically coughing. Therapeutic treatment of the diseased animals was multiple: the antibiotics were given through feed, water and parenterally. Appying pathomorphological examination on the dead weaned piglets, the prominant changes on the digestive and respiratory tract were detected (*Gastroenterotyphlitis haemorrhagica, Poliserositis fibrinosa massiva, Pneumonia complex*).

By bacteriological testing on tissue samples from dead piglets the following bacteria were isolated: *Escherichia coli haemolytica, Pasteurella sp, Streptococcus uberis*. By laboratory feed testing i. e. the available first feed for piglets the presence of OCT (0.5 mg/kg) and ZEA (4 mg/kg) was discovered.

The presence of mycotoxin in feed for pregnant sows have influence on the occurence of decreased immunological defence in piglets (Prodanov et al., 2009). As a consequence of immunosuppresive action of mycotoxins, clinical and pathological lesions correspond to the infective diseases of different ethiology (Kabak et al., 2006; Obremski et al., 2008). Combinations of several mycotoxins may potentiate the action of one other, or at least exert an additive effect (Osweiler, 2006). Nutritional effects associated with feed refusal may also contribute to observed decreased efficacy of therapeutic treatments and vaccination (Oswald et al., 2005). In the second evaluted case, the presence of OCT and ZEA in the swine feed was detected. Consequently, on the farm an evident decrease in the swine immunity against infective diseases was noticed and there was no positive respond on the applied antibiotic therapy. Also, the occurence of diarrhoea and increased percent of waste piglets can be connected with presence the mycotoxins in the feed, because the piglets display clinically feed refusal. The gastrointestinal tract represents the first barrier against ingested food contaminants and natural toxins. Following ingestion of mycotoxin contaminated feed, intestinal epithelial cells could be exposed to a high concentration of toxin (Bouhet and Oswald, 2007). From a public haelth perspective, increased infections in animals may result in increased animal-to-human transmission of pathogens and/or increased antibiotic concentrations in meat, as a consequence of animal treatment (Oswald et al., 2005).

The complex health problems on the third swine farm were noticed. Applying control of the anamnestic data, lately the frequent periods when sows delivery mummified piglets, stillbirths and decreased litter size were observed. Beside this, just farrowed piglets are nonviable and despite the medical treatment, they live only 3-4 days after birth. In the pregnant dams the immunoprophylaxis is carring out with the aim to prevent the outbreak of disease in suckling pihglets. Beside this, the antibiotics are added in the sows feed 7 days before and 7 days after farrowing. Sporadically, the occurence of severe yellowish diarrhoea in piglets and apparent clinical signs of vulvovaginitis in just born piglets were evident. In the weaners the clinical signs of diarrhoea and pneumonia are sporadically noticed. The pathomorphological examination of the dead weaners revealed lesions on the organs of respiratory (*Pleuropneumonia actinobacillosa, Pneumonia interstitialis*) and digestive tract (*Gastroenterotyphlitis haemorrhagica acuta*). Applying bacteriological examination on the tissue samples deriving from dead piglets the following bacteria were isolated: *Escherichia coli haemolytica, Pasteurella sp, Actinobacillus suis*. After laboratory testing of swine feed samples the simultaneous presence of several mycotoxins was established: ZEA (6.4 mg/kg), AF (0.0064 mg/kg), OCT-A (0.032 mg/kg).

For the known mycotoxins of clinical importance for swine production, the response is usually subacute or chronic and the presenting signs are often subtle and vague (Gonzales and Rodriguez, 2008). The continuos intake of small amounts of mycotoxins leads to chronic intoxication which is clinically characterized by the loss of weight, insufficient weight gain and increased susceptibility for infectious diseases (Osweiler, 2006). Ingestion of low doses of mycotoxins can increase intestinal colonization by opportunistic pathogenic bacteria in piglets (Oswald et al., 2005; Taranu et al., 2005). Mycotoxins mixtures i.e. the combinations of several micotoxis are likely to occur naturally and they may influence on the immunity in an additive or synergistic manner. Economic losses that occur as a consequence of interaction of several mycotoxins are still unknown because in low concentrations several mycotoxins may interact in way that is difficult to detect. Combinations of several and more moderate concentrations of different mycotoxins, which individually may appear to be too low in level to be a concern, can cause cumulative toxicosis, which affect the ability of the pigs organism to fight diseases (Diekman and Green, 1992; Osweiler, 2006).

On the fourth examined farm, clinically in suckling piglets the sings of severe distrurbance of the central nervous system (wide open eyes, paddling, trembling, ataxia, paresis and paralysis) were detected. In some cases the whole litter of piglets died within 48 hours.

Despite the fact that the piglets were therapeutically treated, there was no evident respond to applied medication. The pathomorphological changes that were detected in dead sucklings indicated the lesions characteristic for *Morbus Aujeszky* infection (MA) (*Necroses miliares hepatis, Haemorrhagiae corticis renis, Tonsillitis diphtheroides necroticans*). By microbiological testing in feed for lactating sows the precence of fungi (*Fusarium sp., Mucor*) and AF (0.02 mg/kg) were detected. Applying virological testing (viral isolation on the susceptible cell culture) from the tissues deriving from dead piglets the MA virus was isolated.

Aflatoxins (B1, B2, G1, G2) are recognized as immunomodulatore agents, and when AFB1 is metabolised by mammals occurs in milk as M1. It is assumed that AFB1 is the most toxic fraction (Osweiler, 2006; Živkov-Baloš et al., 2008). In the case where the outbreak of MA on the farm were examined, mycotoxin (AF) in the feed can be connected with the possible reactivation of chronioc (latent) infection. It has been discovered that aflatoxins decrease resistance to bacterial, fungal, viral and parasitic diseases in swine. Subsequently, vaccinations against various infective diseases may be less effective in animals exposed to mycotoxins (Diekman and Green, 1992). Even when is present in low doses, AF alters the immune response and this may predispose pigs to infectious diseases. From the epidemiological point of view, it is important that mycotoxins may cause breakdown of active immunity and occurence of disease even in properly vaccinated animals (Marin et al., 2002; Oswald et al., 2005; Taranu et al., 2005).

In the last examined case, in suckling piglets the occurence of neonatal diaorhea already in the first 3 days of life after farrowing were detected. These health problems did not improve after the medical treatmant with antibiotics. In great number of just farrowed piglets the most prominent clinical sign was vulvovaginitis (swelling and reddening of the vulva). Beside this, a large number of small, weak and splayleg piglets were noticed. The newborn piglets were weak, nonviable, with diarrhoea. The diseased piglets lived only for 4 days after birth. They probably died due to hypoglicemia, because sows did not have enough milk or the piglets were too weak and did not have enough strenght for milk suckling. Applying patomorphological examination on the dead suckling piglets the prominent changes on mucosal surfaces of the digestive tract (*Gastroenteritis haemorrhagica*), less number of pale kidneys, necrotic and distrophic processes on liver tissue were detected. By laboratory testing of the available swine feed grains, the presence of ZEA in different concentrations was detected (from 0.72 to 6.4 mg/kg). The ZEA mycotoxicosis in weaned piglets was clinically characterised with signs of pneumonia, slow growth, vulvovaginitis and necrosis of the tails, sporadically with diarrhoea and rectal prolapses. The patomorphological examination of the dead weaners revealed the following lesions: bleeding on the mucosal surface of the digestive tract, pleuropneumonia and pneumonia, hepatomegalia, focal nephritis and rectal prolapses. Ethiologically the pneumonia was caused by *Actinobacillus pleuropneumoniae, Haemophilus suis, and Mycoplasma hyopneumoniae.* Also the problem that was frequently observed was digestive infection with enteropathogenic *Escherichia coli*, which can be potentiated with the detected mycotoxin (ZEA 0.8 mg/kg) and a high number of different fungi species in weaners feed (*Fusarium, Penicillium, Aspergillus, Rhisopus).*

Zearalenone is a mycotoxin which as an estrogen binds competitively to estrogen receptors of the uterus, mammary gland, liver and hypothalamus (Gajecki, 2002). Pigs are the most prone to the presence and negative effects of ZEA (Diekman and Green, 1992; Obremski et al., 2003). In our research, the perinatal hyperestrogenic syndrome was a constant clinical sign in suckling piglets. This is certainly the consequence of mycotoxins presence in feed for sows, e.i. during the pregnancy and the presence of its excreted metabolite in milk of the exposed sows.

CONCLUSIONS

The influence of mycotoxins on immune system is of special interest in swine industry. The technology on swine farms demands frequent vaccinations, especially in piglets and sows which may be a problem in the case of immunocompromised animal. From the obtained

results an example of immunosuppresive effect can be presented i.e. the occurence of enteroxemia in piglets, despite the fact that dams were vaccinated twice during gestation. The enterotoxemia is caused by pathogenic bacterial strains and occurs frequently as a cause of mortality in the young categories. It can be provoked with the feed quality i. e. the presence of mycotoxins.

The presence of mycotoxins in feed can be directly connected to the detected health disturbances of the examined piglets. In our research we discovered the persistant presence of various infections, which react poorly or do not react on the applied antimicrobial therapy (gastroenteritis, pneumonia). Also, the chronic disturbances, for instance slow growth, malnutrition, vulvovaginitis suggest on the potential presence of mycotoxins.

ACKNOWLEDGEMENTS

FA0802: THE HUB FOR FEED FOOD AND HEALTH

Luciano Pinotti*

Università di Milano, Italy

**Feed for health Action Chair*

ABSTRACT: The COST Action Feed for Health has addressed several scientific topics during the last three years. From a practical point of view three main scientific fields can be identified: feed-and animal nutrition; food of animal origin (FOA) quality and functionality and consumers' perception. In this context a general scientific output of the Action is that not all FOA are the same. Milk, as a functional food has been investigated in more depth than meat and eggs. The network activities have been based on the premise that the feed selected to produce FOA on the farm determines the concentration and composition of bioactive molecules in the final product, and hence the effect on human health. FA0802 provides a unique opportunity for linking animal science with social science. From this point of view It is generally accepted that consumers prefer animal products from livestock systems that used animal feed safe for consumers, friendly to the environment and the animals. Furthermore health and sustainability are issues that show both similarities and overlap with regard to products, consumer segments and consumer behaviour, imposing to the scientific community multidisciplinary approach.

INTRODUCTION

Food of animal origin (FoA) contributes significantly to the total nutrients in the current EU diet. The latest review of livestock production and trade (FEFAC, 2010) indicates that more than 45 million tonnes of meat, and more than 135 million tonnes of milk and 7 million tonnes of eggs were produced in the EU in 2010. To sustain this scale of livestock production, about 470 million tonnes of feedstuffs are required each year within the EU-27. Clearly, ensuring such high outputs of these traded products conform to adequate quality standards is a major undertaking and it is fair to say that the EU has made significant progress in defining standards and promoting legislation in this area. As a consequence the explicit and detailed formulation of the concepts of food/feed safety and food/feed quality, has given rise, within the EU, to legislation on the traceability, control and labelling of both feed and food. However nowadays both feeds/and foods must be considered not only in terms of their nutritional properties but also in terms of their ability to promote health and protect against disease. As a consequence, the role of animal nutrition in designing foods closer to the optimum composition for long-term human health are becoming increasingly important (Feed for health MoU, 2008). Starting from these assumptions an integrated and collaborative network of research groups focused on: (i) the roles of feed and animal nutrition in improving animal health and also the quality, safety and wholesomeness of human foods of animal origin; (ii) the perception of consumers as regards the effects of feed production processes on animal health and on the quality and safety of the resulting food products, has been set up. During its lifespan the COST Action FA0802 promoted the acquisition and facilitated the dissemination of knowledge in these areas and encouraged cooperation between various research fields. Accordingly the aim of this paper is to provide an overview of the topic addressed by the Action FEED for HEALTH (www.feedforhealth.org/) using some specific examples.

NUTRITION AND HEALTH

In the field of feed-and animal nutrition the FA0802 Action provided the opportunity for addressing the impact of animal nutrition on animal health, and how to produce quality products that enhance human health whilst at the same time improving animal health. In this

context feed additives are extremely important. They contribute in general to health and welfare of the animals and provide by this a certain standard of quality of food of animal origin. Some of the nutritional additives and sensory additives have an influence on both animal wellbeing and characteristics and composition of food for human consumption, even if their formulation, dose and mode of administration can differ affecting the effectiveness (Gropp, 2010). Vitamins, vitamin-like compounds, essential fatty acids as well as probiotics and nutraceuticals are under investigation by different groups in order to evaluate their effectiveness in the animal (animal health, metabolic health, animal production efficiency) and on the quality of FoA. An example in this context is choline for dairy ruminants. Choline has been classified as vitamin-like compound, and although its requirement of dairy cows is still unknown, higher choline availability (by feeding rumen-protected choline, RPC) can have a favourable effect on milk production, especially at the onset of lactation, when choline has been proposed as limiting nutrient. Findings in transition and early lactating dairy cows in fact, suggest that greater choline availability can improve not only milk production, but also lipid, methyl group metabolism and choline secretion in milk (Pinotti et al., 2010). From a metabolic and hephatic point of view, since choline is a lipotropic factor, it may be particularly beneficial at this time in view of the adipose and liver metabolism changes that occur during the transition from late pregnancy to early lactation. Choline at this stage may optimize the balance between fat retained and fat metabolized by the liver, thereby improving lipid metabolism in general (metabolic health optimisation). Milk production response is often a consequence of these metabolic improvements.

With regard to FoA quality and functionality, the case of trace elements has been addressed in different species. For instance, as reviewed by Juniper and Bertin (2011), selenium (Se), is an essential trace element in the diets of both animals and humans; severe deficiencies have been associated with cardiomyopathies, whereas less pronounced shortfalls, although not manifesting themselves as clinical symptoms, result in sub-optimal expression of a number of Se dependent enzymes that are important for normal function and antioxidant status. Throughout much of Europe human Se intakes are well below levels needed to optimize the expression of Se dependant enzymes. A number of methods can be adopted to address this shortfall; these include the use of dietary supplements, the use of Se enhanced fertilizers or the use of dietary supplements in food producing animals diets. Animal feed supplements can contain either inorganic (sodium selenite) or organic (selenoyeast) Se. Organic sources are significantly less toxic and more bio-available than inorganic sources, principally because of differences in uptake and subsequent incorporation into animal proteins predominantly as selenomethionine (SeMet). SeMet in the body is not distinguished from methionine and is therefore actively transported across gut epithelial tissue by methionine transporter mechanisms and is either used for selenoprotein synthesis, via the selenide pathway, or incorporated non-specifically into body proteins in place of methionine. Conversely, the transport of inorganic Se across the gut epithelia is predominantly by diffusion and is then either utilised by the selenide pathway for selenoprotein synthesis or methylated and excreted. The rapid incorporation of organic Se into animal products can be demonstrated quite clearly in food producing animals, particularly in tissues and fluids that have comparatively high rates of protein inclusion or turnover such as muscle, liver and milk. In north America end in Europe milk products contribute to 25% of total selenium intake. With respect of this latter, analysis of estimates of Se intake and Se appearance in milk indicated that efficiency coefficients of transfer were greater in Selenium Yeast (SY) supplemented animals when compared to sodium selenite (SS). Furthermore, coefficients of transfer were consistent between doses in SY supplemented animals (approximately 18%) but were markedly lower in higher dose SS supplemented animals (11.3 vs. 8.1%), indicating that as SS dose increases the efficiency of total Se transfer decreases. Regression analysis of the transfer efficiency of SeMet from feed to milk indicated that changes in milk total Se concentrations appear to be more a function of the SeMet content of the animals diet rather than total Se content. It is concluded that the use of higher doses of Se supplements that have comparatively low SeMet contents would result in greater levels of Se being excreted from the animal into the environment whilst conferring little additional benefit, with respect to

shortfalls in Se intakes, to the consumers of these animal derived products (Juniper and Bertin, 2011). By contrast organic selenium administration can be useful strategy for increase its content in milk and dairy products. Similar approaches have been developd for other farm animals including fish (Moran, 2010).

In addition to the role of specific feed additives, diet formulation and in some case diet distribution can also affect quality and functionality of animal products. The case of fatty acids profile of milk and dairy products originated by cattle on pasture versus harvest forage is a further example. Milk lipids are the group of compounds which has attracted the greatest interest in research in order to change in desired directions. Further fatty acid (FA) content and composition, as well as the fat soluble vitamins are some of the compounds that are easiest to manipulate through feeding and through selection of animal breed. Main focus with respect to FA has been to increase the content of polyunsaturated fatty acids (PUFA) on expense of saturated FA. Metabolism of FA in the rumen and their transfer to milk is dependent on a great variety of factors, including accessibility of the lipid in the feed matrix, the extent of biohydrogenation in the rumen, absorption in the small intestine and transformation and utilization in the body. FA with chain length longer than C18 cannot be synthesized by the cow, therefore the occurrence and composition of these FA is highly dependent on the feed source. Typically, strategies based on lipid supplementation of high-concentrate diets are the most effective for altering milk FA composition, but these also result in significant increases in milk trans FA content. Forage based strategies, though less effective in absolute terms, have potential as a low-cost sustainable alternative, avoiding substantial increases in milk trans FA content. Thus, a detailed knowledge to the mechanisms involved in the metabolism and transference of feed lipid, metabolism in the rumen and their transference into milk as well as their interactions is of utmost importance in order to understand and control how the lipid composition of milk can be manipulated through the feeding. Likewise content of fat soluble vitamins is an important quality parameter in the milk both with respect to nutritional value and as simple antioxidants in order to protect PUFA (Savoini, 2010; Fievez, 2010; Jansen et al., 2011).

The research in dairy science has also yielded knowledge on how milk composition can be tailored to specific requirements, e.g. products targeted at risk groups, and milk for isolation and production of different bioactive molecules. Both areas are of large strategic importance for the ability of the dairy and food industry to develop novel, competitive, health-promoting products (Sejrsen personal communication). Development of nutritional strategies to improve milk composition through sustainable means can be considered as an integral component of this overall strategy. In fact, because of the wide variety of available milk products and their high consumption, these products appear as an excellent matrix for new and functional products whose consumption may have a significant impact in public health (Baldi and Pinotti, 2008).

The FA0802 Action however provides the evidence that in addition to milk, meat (McAfee, 2011) and eggs (Griffin, 2011) can contribute in designing a healthy diet. It is well established that nutritional composition of chicken feed affects the nutritional value and quality of the chicken meat and may affect chicken health. The most pronounced relationship regards fatty acids and microminerals. When the feed content of ω-3 fatty acid α-linolenic acid from oils such as linseed- and rapeseed oil is increased, the meat is enriched in these fatty acids, and a conversion towards the long ω-3 fatty acids EPA, DPA and DHA also takes place. Supplementation of organic selenium to the feed can give a meat product with a selenium concentration as high as in fish (Krogdahl, 2011). Among poultry production, it has been proven that vitamin E, carotenoids and Se are efficiently transferred to the eggs and therefore they can be easily enriched with vitamin E, Se and natural carotenoids to provide with a single egg a daily requirement in vitamin E (15 mg), 50 % RDA in Se (30-35 µg) and substantial amount of natural carotenoids (mainly lutein and zeaxanthin) (Surai, 2011).

In beef production, modern livestock breeding, production and butchery techniques have reduced the levels of fat in red meat and both livestock feeding and breed can affect the fatty acids in red meat. Industry led studies have been carried out to assess the fatty acid content of red meat, to evaluate the manipulation of fatty acid profiles in a commercial setting, to

explore breed differences and to assess consumers views on the key attributes of red meat (Maltin, 2011).
The main advantage of increasing these micro-constituents of FoA by animal nutrition rather than by postharvest fortification is that they can also safeguard the health of the animal, and this is a primary factor determining the quality, safety and wholesomeness of foods of animal origin for human consumption. Furthermore, this 'feed-to-food' approach makes it possible to reposition animal products as key foods for the delivery of important nutrients into the human diet (Baldi and Pinotti, 2008).

CONSUMERS PROSPECTIVES

Cost Action FA0802 has provided a unique opportunity for linking animal science with social science, working in the consumers perception area (figure 1).

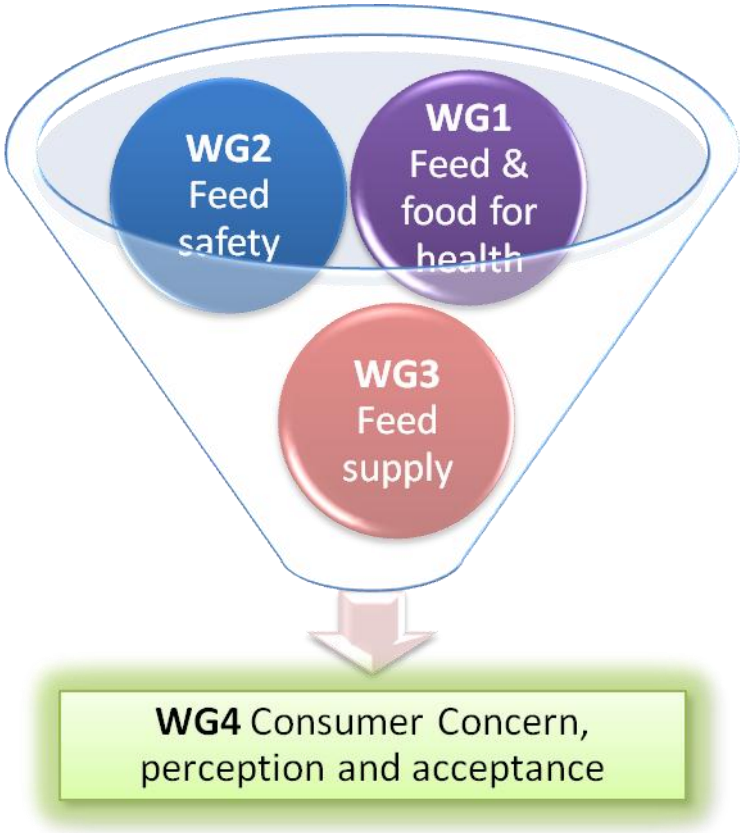

Figure 1.Feed for health Working groups

In order to address consumer expectations and concerns, it is necessary to investigate what determines consumers' food choice. Motive and value fulfilment are in general major antecedents for consumer food decision-making, and the achievement of desired consequences, such as a nice, enjoyable meal or the expected health benefits achieved by eating specific foods, are important drivers for food choices (Brunsø, 2009). However, examine the perception of consumers as regards the effects of feed production processes on animal health and on the quality and safety of the resulting food products - that consumers will be willing to purchase- is different. It is generally accepted that consumers prefer animal products from livestock systems that used animal feed safe for consumers, friendly to the environment and the animals. They also like to know that there is a traceable link of the animal feed industry to all regulations related to food safety and quality. In animal production systems, the animal feed was perceived to be particularly vulnerable to contamination, with subsequent negative impacts for the whole chain. Traceability was considered by consumers

as a useful tool that offers the potential to improve consumer confidence in food safety. Based on the consumers, the optimal livestock production is the one that would decrease feed costs, increase growth and add nutritional and ethical value. More realistically, they would prefer a balance between acceptable price and welfare conditions, with all detailed information available, but not directly to them, so as on the packaging (Luten and *Altintzoglou*, 2009; *Frewer*, 2009; *Verbeke, 2009*). All these features should match with taste. In fact, as very well addressed by Almli (2011) at the 3rd feed for health conference in Denmark, consumers do not compromise on taste for health benefits. This was the first conclusion from these studies: (i) well-accepted innovations do not alter the need for acceptable sensory properties of the product: consumers do not compromise on taste for health benefits. Furthermore (ii), from a consumer perspective, healthy innovations are highly product specific (e.g. omega-3 is not suitable for incorporation into all products), context specific (e.g. innovations of healthy character are more suitable for everyday use than for special occasion product consumption) and segment specific (e.g. rejection of pasteurisation of traditional cheese by a consumer segment in France). Finally (iii), healthy innovations may favourably be supported by appropriate consumer communication (Almli, 2011).
Thus social sciences studies suggest that public interest in livestock production practices has increased while individual perceptions have worsened following consecutive food safety crises during the last decades, combined with a growing alienation from agriculture and farming. Issues of seemingly growing concern among the broader public pertain to the environmental impact, sustainability, and animal friendliness of livestock production, as well as the intrinsic quality and safety of the resulting end products. This evolution contrasts with the actual quality of practice in contemporary livestock production in Europe (*Verbeke, 2009)*.

EMERGING ISSUES

In the COST Action feed for health we tried to address the consumers prospective about the animal production chain by involving also keynote representatives from a large retailer (e.g. Marks & Spencer plc) and food chain stake holders (e.g. Quality Meats Scotland). From their point of view feeding for health is an important topic, but its extensive application depends on efficiency, consumers demand and in turn their acceptance to pay for a premium product. Scientific and market contributions from these stakeholders to the Action has however also provided the opportunity to start a discussion about a “relatively new” topic i.e. sustainability of livestock production. Although, demand for FoA in the future could be heavily moderated by socio-economic factors, such as human health concerns and changing socio-cultural values, the global demand for livestock products is expected to double during the first half of this century, as a result of the growing human population, and its growing affluence. Over the same period, we expect big changes in the climate globally. In light of this animal production will increasingly be affected by competition for natural resources, particularly land and water, competition between food and feed and by the need to operate in a carbon-constrained economy (Thornton, 2010). For example, food, feed and fuel demand have accelerated the trend demand growth for agriculture commodities (Pinotti and Dell’Orto 2011). Among these the dramatic expansion of crop production for biofuels is already impacting on the resources available globally for food production, and hence on food supply and cost (BSAS, 2012). Moreover, the entire European food supply chain, from plant breeding, feed crop production and feed formulation, to the production of meat, dairy products, eggs, and aquaculture products, is experiencing challenges created by competition from low production cost countries and restrictions imposed by national and EU regulations on environmental impact, animal welfare and traceability. There is considerable uncertainty as to how these factors will play out in different regions of the world in the coming decades. This scenario is likely to generate new trends in the feed sector and in the feed supply chain, as recently addressed by Pinotti and Dell’Orto (2011). For example, above the competition between sectors for raw materials, the availability of by-products from bio-fuels plants, such as distillers grains and crude glycerin for use in feed, is likely to increase in the near future. This is the reason for which by-products use in animal diets formulation is matter of research worldwide, in order to

asses, above economics and marketing issues, also nutritional and safety facts and effects. One example in this field is represented by glycerol (Holtenius, 2011). It is an energy-rich byproduct from bio-diesel production that may be used as additive to diets fed to cattle. Absorbed glycerol is efficiently converted to glucose via the gluconeogenesis. Apart from the properties related to energy- and glucose metabolism glycerol also acts as substrate for *Lactobacillus reuteri* a bacterial strain with probiotic properties. Furthermore glycerol may alleviate dehydration. Glycerol of varying quality is available on the market. Crude glycerol, containing 80-90 % glycerol but also water, mineral salts and methanol, appears to currently be the quality that is most commonly used in farm animal feeding. However, diets have also been supplemented with refined glycerol, containing >99% glycerol, which is more expensive. Results from an experiment with cows in an early stage of lactation consuming crude or refined glycerol indicated that glycerol quality did not affect total dry matter intake. Obviously the bad taste and foul smell of crude glycerol did not affect the feed intake. However, intake of refined glycerol increased milk yield and the protein content in milk increased (Holtenius, 2011). Accordingly, it would be essential not only to integrate and collate knowledge on feed ingredients quality (including safety- see Feed for Health 2011 http://www.feedforhealth.org/default.asp?ZNT=S0T1O-1P58) and feed ingredients supply (market), but also to promote the acquisition and facilitate the dissemination and sharing of information between research institutions, industry, farmers and consumer organizations about feedingstuffs. Proper production and use of these by- and co-products as feed ingredients have the potential to provide both the opportunity to formulate least-cost feed, and increase significantly their value.

A different situation exists in the case of seafood. It is generally acknowledged that fish is an important part of a healthy and balanced diet. A high level of interest among European consumers in health and healthy eating, higher living standards and a good overall image of fish have yielded an increase in fish consumption. In view of that, the importance of safety and quality of fish feed, as well how consumers think about the origin of fish and aquaculture production, were key issues for the action. Aquaculture is one of the livestock sector which is growing at high rates. While most agree that fish from aquaculture is beneficial for human nutrition, concern are raised about sustainability of the raw materials used for producing fish feed (Koppe, 2010).This implies that feed supply and availability of raw materials for aqua-feed is another important issue in term of choosing sustainable and safe ingredients. The main ingredients of feeds for farmed carnivorous fish species are fish meal (FM) and fish oil (FO), at inclusion levels of about 25% and 30%, respectively. These two ingredients supply essential amino acids and fatty acids required by the fish for normal growth. Although the inclusion rates of FM nad FO in aqua-feed have been progressively reduced in the recent past (in 1985 the inclusion rate was 60% for FM, and in 2005 the level of oil was 35-40%), at present over 50% of fish meal and over 80% of fish oil produced around the world are used in aquaculture. World annual production of fishmeal and fish oil is about 6.5 million tonnes and 1.0 million tonnes, respectively from 33 million tonnes of whole fish and trimmings. Furthermore recently, small quantities of FM and FO (3-5% and 1-3%, respectively) have been included in feeds for omnivorous and herbivorous fish (Koeleman, 2009). In light of this, one of the most-frequently cited issues with the sustainable development of aquaculture is the capture of other fish as raw material to be used as fish feed in the form of fish meal and fish oil. The source of these ingredients (manufactured from wild-caught, small, bony/oily marine fish which are usually deemed not suitable for direct human consumption) in fact, are expected to remain static, or even decrease, making the supply of alternative proteins and fat sources for aqua-feed quite urgent. In this situation new development in fish nutrition find progressive role of amino acids especially taurine with conclusion that it promotes growth development and health of aquatic animals. It is believed that dietary supplementations with taurine may be beneficial for (i) increasing the chemo-attractive properties and nutritional value of aqua feeds with low fish meal inclusion. (ii) Improving fillet taste and texture (iii) enhancing immunity and tolerance to environmental stress and many more (Gupta, personal comunication). Higher doses of taurine in feed provides higher taurine contents in fish, and this can contribute to human healthy diets.

SUMMARY

Scientific results obtained across Europe in the frame of the COST Action feed for health have suggested that in general, nutritional interventions in farm animal and fish may positively affect animal health and in several cases the quality, the safety and the functionality of food of animal origin. This 'feed-to-food' approach makes it possible to reposition animal products as key foods for the delivery of important nutrients into the human diet, even though there are some distinguish between traditional and innovative food. Farther aspects addressed by the Cost action feed for heath are that health and sustainability (linked to environment and greenhouse gas emissions from farm animals) are issues that show both similarities and overlap with regard to products, consumer segments and consumer behaviour. It has been shown that consumer segments typically identified as more involved with the issue of health also tend to buy 'sustainably indicating a strong link between the two issues (Aschemann-Witzel, 2011). All these areas are of large strategic importance for the food industry to develop innovative, competitive, health-promoting products.

ABSTRACT: In innovative society as European strives to be, entrepreneurship based on innovations originating from academic research gains permanently in importance. One of the possibilities for achievement of this goal is initiation of start-ups and spin-offs by the representatives of the research community itself. Attitudes, personalities, cultural characteristics, knowledge and skills are only some of the personal features related to the probability and potential of initiation of entrepreneurial projects by representatives of academic community. The research based on the questionnaire targeted to collecting of data related to mentioned characteristics among academics involved in agro-food research was conducted was conducted in academic Institutions in Serbia. The relations among potential features of researchers and probability of initiation of enterprise ware analyzed and the most influential factors supporting entrepreneurship among academics were detected. Based on conducted research recommendations for improvement of potential for entrepreneurship among academics are provided.
Key words: *entrepreneurship, academic institutions, academics, intentions*

INTRODUCTION

In knowledge based economy universities are responsible not only for education and research process but for overall economic and social development. This new mission is transforming the traditional university into an entrepreneurial university (Lopez et al 2009). Louis et.al (1989) in pioneer research on this topic distinguished five types of academic entrepreneurship: (1) engaging in large-scale science (externally funded research), (2) earning supplemental income, (3) gaining industry support for university research, (4) obtaining patents or generating trade secrets, and (5) commercialization—forming or holding equity in private companies based on a faculty member's own research. Nowadays two commonly utilized organizational forms are recognized in relation to university engagement in entrepreneurial activities: the spin-off and the technology license agreement (Wood, 2009). According to statement of Van Burg et al. (2008) academic entrepreneurship by means of university spin-offs commercializes technological breakthroughs, which may otherwise remain unexploited. In order to foster initiation of spin offs from the universities numerous research activities in this direction have been recently realized. It has been found by Coduras et al. (2008) that entrepreneurial intention is statistically related with universities support and thus different structures have arisen in universities in order to stimulate innovation and entrepreneurial activities including spin-off companies. (Almeida 2008, Botelho and Almeida 2010) including university incubators actively established by many public universities (Todorovic and Suntorphitung 2008). It has been shown by Nossela and Grimaldi (2009) that the number of people dedicated to technology transfer activities and finally support services provided by universities have a significant influence in fostering the generation of new ventures.
Conducted research activities also prove that attitudes, knowledge, skills and expectations of academics as potential entrepreneurs play significant role for development of entrepreneurial universities. The need for the development of entrepreneurial spirit among the educated youth has been immensely recognized in developing countries and education system is

considered as a powerful tool in developing it (Jiothy, 2009) and consequently entrepreneurship programs and courses are offered by many business schools to support students and academics who aspire to start and operate own businesses.(Levenburg et al. 2006). Findings of Pilegaard et.al (2010) illustrate the importance of bridging innovation using twin skills to balance research and commercial goals, while Styhre and Lind (2010) suggest that rather than representing something radically new, the entrepreneurial university is a domain wherein traditional academic research interests and industry objectives are continuously negotiated and mutually adjusted.
Research presented in this paper was conducted with the objective to characterize the intentions towards entrepreneurship among academics from Serbia in relation to a number of personal features which can be considered as potentials or limitations for entrepreneurial ventures from academia in Serbia.

MATERIAL AND METHODS

The on line application of the questionnaire including question about intention of respondents towards entrepreneurship on one hand and questions reflecting respondents basic data, education and skills, experiences, position, incomes and personality on the other, was developed with automatic placement of data obtained from respondents into an excel data base. The questionnaire was anonymous. From the population of researchers in Serbia consisting of about 10.000 researchers the researchers who perform research which is directly or indirectly related to the agro-food sector were targeted. In order to compose the list of the researchers to be invited to fill in the questionnaire the list of research institutions accredited for research by Serbian Ministry of Education and Science and involved in national project under agro-industry and biotechnology research direction was. The list of e-mails of the researchers employed in all selected institutions was composed based on the data available on institutional web pages. Respondents were invited to fill in the questionnaire by e-mail. Limited, five day period was announced as the time during which the questionnaire is available.
The variable describing respondents intentions and attitude towards entrepreneurship was tested for independence against other collected respondents feature. Testing was performed by application of cross tabulation followed by Pearson Chi Square test of goodness of fit. Statistical software StatSoft, Inc. (2011). STATISTICA (data analysis software system), version 10. www.statsoft.com was used.

RESULTS AND DISCUSSION

Results are presented by groups of respondents' personal features including basic data and title, management experience and language skills, research area and interdisciplinary, personality and status and attitudes concerning incomes. The results are expressed as shares of respondents heaving no intentions towards entrepreneurship (inexistent intention), have been or are considering the possibility to become entrepreneurs (existent intention) or already have their own companies (realized intentions) under every examined personal feature. Results are presented in tables 1, 2, 3, 4 and 5 respectively. For each examined feature the value of p value is also presented in the tables, reflecting the probability of independence of intentions towards entrepreneurship from examined parameter.
According to the results presented in table 1 it can be stated that entrepreneurship intentions are dependent upon all examined features: gender, age and academic title with probability higher than 99%. Obtained results indicate that males are more entrepreneurship inclined confirming the findings of Rosa and Dawson (2006) and that older generation are either more entrepreneurship averse or already have their own companies, while among representatives of younger generations the share of academics who consider starting of their own companies is higher. The same observation can be applied in the case of academic title: professors and

scientist are either more entrepreneurship averse or already have their own companies, while assistants and researchers in more cases consider starting of their own companies.

Table 1. Dependence of intentions of academics towards entrepreneurship of basic personal traits

		Intentions towards entrepreneurship		
		Inexistent	Existent	Realized
Gender p=,00731	Male	35,00%	50,00%	15,00%
	Female	54,46%	40,18%	5,36%
Age p=,00146	<30	31,25%	68,75%	0,00%
	30-45	46,22%	47,90%	5,88%
	45-60	52,17%	26,09%	21,74%
	>60	46,67%	26,67%	26,67%
Title p=,00011	Professor/scientist	53,60%	31,20%	15,20%
	Assistant/researcher	38,89%	61,11%	0,00%
	Other	31,88%	65,22%	2,90%

The results presented in table 2 point out that intentions towards entrepreneurship with probability higher than 99% depend on experience in both organization and project management as well as on level of English language skills.

Table 2. Dependence of intentions of academics towards entrepreneurship of management experience and language abilities

		Intentions towards entrepreneurship		
		Inexistent	Existent	Realized
Organization management p=,00062	none	46,72%	48,91%	4,38%
	short	15,38%	53,85%	30,77%
	medium	33,33%	44,44%	22,22%
	long	60,00%	25,71%	14,29%
Project management p=,00303	none	43,94%	51,52%	4,55%
	short	25,00%	66,67%	8,33%
	medium	44,12%	29,41%	26,47%
	long	58,82%	26,47%	14,71%
English p=,00420	low	56,25%	18,75%	25,00%
	medium	65,79%	28,95%	5,26%
	high	41,61%	49,68%	8,71%

The share of academics that have no intentions towards entrepreneurship is the highest among those with long lasting experience in organization or project management. Academics with short to medium experience in organization or project management are characterized with higher share of those who already have their own companies, while academics with short management experience in most cases consider starting of the own entrepreneurial venture. Very interesting observation concerns the fact that the most academics already having their own companies have low level of English language skills, while the share of academics stating existence of intentions towards entrepreneurship increases with increase of level of English language skills.

Results presented in table 3 indicate that intentions towards entrepreneurship among academics are not dependant on the research field in which the academics are involved. The only parameter on which the dependence of intention towards entrepreneurship can be stated, with probability higher that 95 %, is the interdisciplinary orientation of the academics which includes combination of technical background (food technology, agriculture or mechanical sciences) and management or economy. Among academics with such profile the share of those without entrepreneurship intentions is the lowest while the share of those which already realized entrepreneurial ventures is the highest.

Table 3. Dependence of intentions of academics towards entrepreneurship of research area and interdisciplinary

			Intentions towards entrepreneurship		
			Inexistent	Existent	Realized
Research field	Agriculture	p=,05027	65,00%	25,00%	10,00%
	Food	p=,44572	41,35%	46,62%	12,03%
	Mechanics	p=,21217	30,61%	57,14%	12,24%
	Economy	p=,05294	39,39%	42,42%	18,18%
	Management	p=,06653	25,71%	62,86%	11,43%
	Natural	p=,60547	53,19%	36,17%	10,64%
Interdisciplinary	Technical+Economy and/or management	p=,04797	28,57%	42,86%	28,57%
	Technical + fundamental	p=,30252	50,00%	50,00%	0,00%

Table 4. Dependence of intentions of academics towards entrepreneurship of personality

		Intentions towards entrepreneurship		
		Inexistent	Existent	Realized
Imaginative p=,17749	low	72,22%	22,22%	5,56%
	average	56,60%	39,62%	3,77%
	high	38,85%	48,16%	12,99%
Creative p=,33147	low	80,00%	20,00%	0,00%
	average	56,76%	35,14%	8,11%
	high	41,40%	47,54%	11,06%
Organizer p=,62475	low	87,50%	12,50%	0,00%
	average	50,94%	41,51%	7,55%
	high	41,28%	47,16%	11,57%
Pro-active p=,01463	low	90,91%	4,55%	4,55%
	average	47,46%	50,85%	1,69%
	high	40,40%	45,97%	13,63%
Self confident p=,17764	low	58,55%	38,82%	2,63%
	average	53,13%	39,06%	7,81%
	high	37,59%	48,40%	14,00%
Communicative p=,36599	low	62,50%	31,25%	6,25%
	average	48,57%	45,71%	5,71%
	high	46,53%	42,86%	10,61%
Risk declined p=,07210	low	62,50%	31,82%	5,68%
	average	48,10%	43,04%	8,86%
	high	28,44%	56,87%	14,69%

According to the results presented in table 4 the only personality trait on which the intentions towards entrepreneurship are dependent is the the pro-active personality as already stated by Yang et al. (2006). Academics scoring this trait for themselves low in more than 90% have no intentions towards entrepreneurship.

Table 5. Dependence of intentions of academics towards entrepreneurship of attitude and position concerning personal incomes

Incomes		Intentions towards entrepreneurship		
		Inexistent	Existent	Realized
Contentment with incomes p=,12940	not at all	42,31%	34,62%	23,08%
	partly	45,61%	46,49%	7,89%
	complete	45,83%	45,83%	8,33%
Sufficiency of incomes p=,59914	much lower than needs	72,73%	18,18%	9,09%
	insufficient	39,39%	50,00%	10,61%
	sufficient	45,53%	43,90%	10,57%
	more than sufficient	50,00%	50,00%	0,00%
Willingness to increase incomes p=,25027	un conditional	40,00%	48,18%	11,82%
	conditional	52,00%	40,00%	8,00%
	inexistent	0,00%	100,00%	0,00%

In spite of expectations that the intentions towards entrepreneurship will depend upon the sufficiency, intentions and satisfaction of respondents with their incomes, obtained results, presented in table 5, indicated no dependence.

CONCLUSIONS

Based on conducted research it can be concluded that intentions towards entrepreneurial activities among academics directly or indirectly involved in agro-food related research in Serbia are more expressed under male population and among younger researchers while females and older scientists seem to be more averse towards entrepreneurship. Experience in either organization or projects management and existence of management skills especially in combination with technical skills are supportive factors regarding the intention of academics towards entrepreneurship. Satisfaction with, sufficiency off and willingness to increase incomes were not proven to influence the entrepreneurial intentions of the academics.

ACKNOWLEDGEMENT

This paper is a result of the research within the project III46001 Development and utilization of novel and traditional technologies in production of competitive food products with added value for national and global market - CREATING WEALTH FROM THE WEALTH OF SERBIA, financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: In addition to the traditional use and a range of benefits they have for local communities, non-wood forest products (NWFP) occupy a significant place in the market, particularly given the expansion of organic production and consumption. The wealth of natural diversity of Vojvodina creates an exceptional foundation for the development of entrepreneurship based on the purchase, processing and marketing of NWFP. Regardless of company size, adequately organized organizational structure, in relation to market conditions and general environment, makes one of the key determinants of efficient and effective operations. The goal pursued in this paper is to examine and analyze the organizational leadership of an enterprise system for processing and marketing of medicinal plants, primarily from the marketing aspect. Focusing on the leading companies in the industry, in Vojvodina, the research is conducted with the purpose of gaining insight into the functioning of organizational structures and ways of organizing marketing activities in it. The subject of this study was to go from the moment of purchase of raw material base and distribution of finished products. As a research technique, it is used a survey that included questions about how to organize the department in the company, personnel structure and other internal features of the company. On that basis it is formed a SWOT matrix, in which are confronted by the weak and strong companies with external opportunities and threats. The maximum capacity utilization of the developed distribution network and price competitiveness, contribute to the leading position of the surveyed company.
Key words: *organization, entrepreneurs, marketing, non-wood forest products, leader, Vojvodina*

INTRODUCTION

In recent years, domestic and international demand for non-wood forest products (NWFPs) is increasing and the forest sector gains a new awareness of their importance. NWFPs, in the broadest context, include all the biological material from forests, other than wood. In some regions they may provide a higher income in rural communities than from wood production and other traditional forest activities (2011/a). The most effective companies for processing of non-wood forest products are small, with low overheads (Nicholson et al., 2006). Majority companies in the forestry sector are small family enterprises, which is often classified as micro enterprises.[1]

One of primary determinants of effective and efficient business operations, regardless of their size is adequate organizational form compatible with the environment and the conditions prevailing in the market. According to the marketing concept, all the elements that make up the enterprise environment, external factors are considered as business for the company to provide an objective (Vasiljev et al., 2002, Vasiljev, 2005). For understanding the organization's operations, it has been interviewed the company for processing of medicinal plants which is located in Vojvodina (Figure 1).

[1] Today there are about 3000 small and medium enterprises and their jobs are based on the forest as a resource. Even 98% of all enterprises that their jobs are based on forest as resource are small enterprises (2011/b).

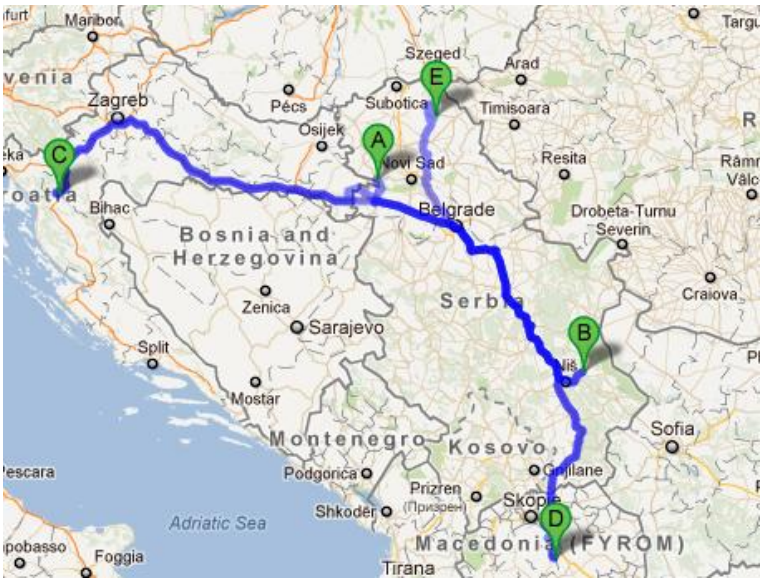

Figure 1. Map with locality of enterprise and purchase stations (Source: original)

The company is the leader in processing and marketing of medicinal plants in Vojvodina. The main **objective** of the article is analysis of the organizational structure of enterprise for the purchase, processing and placement of NWFPs. The purpose of article is analysis of functioning of organizational forms in order to consider optimal marketing strategy. The case study was the organization of company, primarily in terms of marketing activities, obtaining raw materials and distribution of final goods.

MATERIAL AND METHODS

In order to evaluate the organizational structure, which has its primary activity based on the purchase, processing and further marketing of medicinal and aromatic plants we used the survey as well as basic research techniques (2011/b). The survey includes questions about the organization sectors, particularly of marketing, the staff structure and other internal features of the company. According to the image formed on the functioning of enterprises, we created conditions for the analysis, primarily from the organizational aspects. Mutual comparison of the elements related to marketing, resulted in the constructed SWOT matrix. In that way were established strengths and weaknesses in the company, which were put in relation with external opportunities and threats. The results have created a basis for analysis, and market environment in which it operates (Schmithüsen et al., 2006).

RESULTS AND DISCUSSION

The company, which was the subject of research by the nature of the organizational type is in the company capital, in the form of joint stock company and limited liability company. The company currently has 48 permanent employees, making it, taking into account only the number of personnel by classification in the category of small enterprises. The organizational structure is based on the principle of departments, which are characteristic form of organization for small businesses. The three main divisions of the company are: procurement, sales and marketing (Diagram 1).

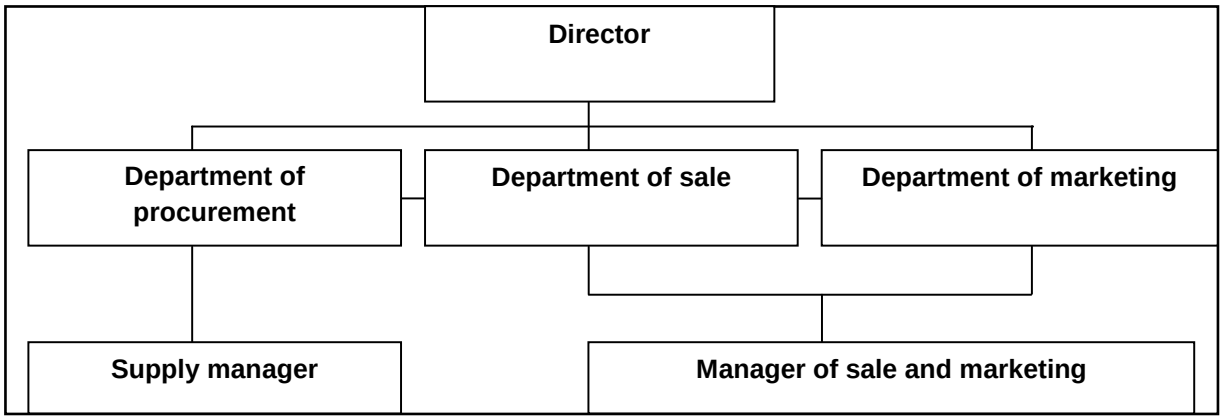

Diagram 1. The organizational structure of the company (Source: original)

Main activity of the enterprise is buying, processing and sale of medicinal plants and the company is one of the leaders in the industry. There is an active export orientation toward Western Europe and America, as well as significant coverage of domestic market with their product range. The company is a private and established in 2001. in Bačka Palanka, its activity is based on processing of medicinal plants, then their packaging and placing on the market. Oriented and to contract farming, organized the purchase of raw materials, followed by their processing and packaging operations and at the end of the final products. Their product range includes different varieties of teas in bulk and filter bags and capsules made from extracts of dried herbs. Since 2007 introduced a new technological process of production of tea in the form of granules, which is relatively innovative in this sector. The company is basically a marketing-oriented, because of its business is based on the needs and demands of consumers. In this sense, the products and the production process itself is based on the latest regulations and standards. Quality management system complies with ISO 9001:2008 and system risk analysis and control points for HACCP system. In addition, the present high level of automation in the production and application of modern technologies in the processing, packaging and finished products. Quality control of raw material base is done by accredited institutions and internally within the company.

Processing facilities for processing and packaging are part of the company and any segment is not dislocated. Supply of raw materials is carried out organized purchase of the previously agreed production. In this way, the company has security in terms of continuous supply of required quantity of raw material base suitable quality. Suppliers of raw materials are located in Svrljig and Padej, while some if it is imported from Croatia and Macedonia (Figure 2).

Transport of raw materials to processing plants is done by contract, by truck or own vans. Funds for the transport of raw materials are in accordance with the HACCP system, the part referring to the conditions to be fulfilled by means of transport for the transport of plant materials.

In the domestic market, the wholesale distribution is done independently, while sales to wholesalers, independent pharmacies and retail stores, performed by the intermediary company. Sales network is spread all over Serbia, but also present in the exporting country's environment and the Western European market. Products are completely placed to the final consumers by the intermediaries.

For activities related to procurement of raw materials in charge is manager of procurement, while business sales and marketing is managed by a person who is both a function of the manager for sales and marketing. Since the company has not fully developed the marketing department, as an independent entity, the key decisions in this field involved the entire management, through the agreement achieved at internal meetings.

The collection and sorting submitted bids is present in the marketing department. In the department actively has been coordinated with agencies for market research. Therefore, the production program of the enterprise adequately has been accommodated to the demands of

the market and consumers. In addition, there is constant cooperation with the Department of Marketing designers for making advertising and promotional materials.

Figure 3. SWOT analysis of the enterprise

S *(strengths)*	**W *(weaknesses)***
- High product quality and price competitiveness (domestic markets)	- Strong competition in the narrow area, and insufficiently aggressive promotional activities
- A wide range of products	- Poor collection of products
- Maximum utilization of installed capacity	- Import of raw materials, causing higher costs for the company and the final products more expensive
- Accepted ISO 9001:2008 and HACCP standards	- The lack of e-business
- Wide distribution network and its own means of transport	- Lack of stuff engaged in marketing activities
- High degree of automation of production	- Department of Marketing is not fully independent
O *(opportunities)*	**T *(threats)***
- Innovative products	- Competition (with domestic and foreign markets) and the variability of prices of raw materials
-Natural Resources	
- Orientation to foreign markets	- Cheaper products of lower quality
- Expansion of processing capacities	- Low customer payment capacity
- Market presence in the "Srboflora" cluster	- Economic Crisis
- Adoption of standards and product certification	- Illiquid market
- Subsidized exports	- Influence of natural factors to the yield of medical plants

Source: original

The company promotes activities throughout magazines about healthy food, official website, and performance at various fairs and gatherings of entrepreneurs from related economic activities. Actually, the entire organization for trade shows and other events of similar type, in order to promote the product, but the whole company, was entrusted to the department of marketing. Based on the SWOT analysis (Figure 3) revealed that the company has significant internal resources. The maximum capacity utilization, with a wide range of high quality and high degree of automation in manufacturing, are its most important internalassets. Potential for development, are the innovations that are introduced into the product line, joining the National Association "Srboflora" and the increasing orientation to foreign markets. But on the other hand, there are threats which have very bad influence on the enterprise like: unfair competition and insolvent market.

According to Hegedűs et all. there is great potential around Europe for improving the market and the commercialization of NDSP, which means that in this sector there are many business opportunities in the short and long-time (Hegedus, 2007). In support of this conclusion is the fact that there is the growing demand for this group of products globally. For companies involved in purchasing, processing and marketing of NWFPs starting point is the choice of adequate suppliers, which will supply the raw materials of adequate quality at affordable prices and convenient form of payment. According to Bauch and Sills, the most obvious factor in the selection of suppliers is the price, assuming that the manufacturers choose to purchase NWFPs as raw state from manufacturers, creating a potentially higher transport costs, and potentially lower prices (Bauch and Sills, 2007). In the first case there is the case when two suppliers on the basis of purchased large amounts realized in the form of volume discount rebates. Donovan argues that SMEs in the forestry sector must overcome a number of internal weaknesses that limit their competitiveness in the globalized market. Precisely, this is a policy that is managed by a company that was the subject of the survey, because of its competitive environment exist several medium-sized companies and in this respect, emphasizing price competitiveness. Generally speaking, all companies operate on their own special system, regardless of company size or activity they are involved (Ahmetagić, 1998, Ahmetagić and Harmath, 2000).

In the studied company organizational structure is formulated in the form of classes and sectors. However, there is considerable flexibility in terms of tasks and mobility of staff within the organizational unit. The way the company is promoting its products and performs communication with the market and direct users to a large extent determines the sale itself (Vujković, 2005, Schmithüsen et al., 2006). Company as the main form of promotion uses: web site, various types of printed promotional material and active participation in trade fairs that bring together entrepreneurs from the industry. Export markets require products that are the processing procedures and comply with quality standards that are included in food products. Standardization implies a range of activities on the preparation and adoption of standards, norms and regulations. In accordance with export orientation, which is the company adopted the ISO 9001:2008[2] and HACCP[3] standards.

Because of exceptional natural predisposition of the company in terms of quality and accessibility of raw materials, in the future it will seek to expand the capacity of processing and enrichment of the product range, in line with changing market demands.

CONCLUSIONS

The company has quality raw material bases that are characteristic for organic production. All organizational units exist within their office and no segment is dislocated, which greatly contributes to more efficient operations. Export-oriented and most important quantities of

[2] The main idea and goal of ISO 9000 series of standards is to define a single system, enabling the supplier always sure that products and services meet market demands and customer needs (Acin-Sigulinski, 2002).

[3] The use of HACCP system has become a legal requirement and in Serbia under the Veterinary Act (Official Gazette RS no. 91/2005) and Law on Safety (Official Gazette RS no. 41/2009).

final products are carried in the markets of Western Europe. Products and manufacturing processes comply with ISO 9001:2008 and HACCP standards. Problems encountered in business, primarily related to competition and difficulty collecting payments due to the relatively illiquid markets and low purchasing power of consumers. Most important instruments in promoting both companies are web-sites with information and presentations for their production, printed advertising messages, advertising in magazines about healthy food and active participation in thematic exhibitions that bring together companies from segment processing of medicinal plants and other related activities. Lack of enterprise is the non-existence of an independent sector, where the required number of qualified stuff performs marketing activities. The problems faced in business, primarily related to the weak financial strength of the market. Based on the results of the SWOT matrix, the recommended alternative strategy would be **SO** (Maximum - Maximum), in which a firm should seek maximum use of internal forces, using the opportunities in the region.
