Contemporary machine-technological solution for the biomass briquette plant is a complete solution that comprises following processes: collection, transportation, drying, grinding, briquetting, and storing and product delivery. Process of transferring biomass into briquettes has a significant positive contribution to environment protection.
Key words: *briquetting, waste biomass, environment protection*

INTRODUCTION

Briquetting technology is the process by which the chopped or grinded material under a high pressure is converting into a compact form attributed with high bulk density. According to Zubac et al. (1988) to be able to convert biomass to briquettes raw material should meet following criteria: moisture content should be in the range 10-18%, particle size not greater than 10 mm and briquetting temperature of 70-90^{o}C (Zubac, 1988). The most common practice is that biomass should undergo extra drying and volume is reduced by 7-12 times. Due to the diversities of raw material mainly consisting of wheat, barley, oat or rye straw, cornstalks, hay crops, residue of sunflower stalks and husks, pruning fruit and vineyards, forest biomass, wood waste in wood processing etc., a complex machine technological procedure is involved in briquette making (Brkić and Janić, 2008).

MATERIAL AND METHODS

The importance of briquette making, in particular, has increased in recent days, when there has been experienced the increased shortage and price increase of oil and gas as conventional fuels. At the beginning, bio briquettes were mainly experienced for solving problems of waist surplus in some production areas like wood processing and others. Those industries used briquettes as energy sources. Today, biomass is increasingly used not only as an important indigenous energy source for production, but also as a commercial energy substitute for numerous users including consumer goods (Brkić and Janić, 2005, Martinov et al., 2011).
Following characteristics can be stated for this technology and its products:

1. Existence of huge source of renewable raw materials,
2. Average bulk density of briquettes range from 900 and 1100 kg/m3 and the possibility of a suitable packaging (foil, boxes, etc.) allows easy manipulation without contaminating the environment and the staff at work (Brkić and Janić, 2008),

3. Caloric value of briquettes, depending on sorts of raw material and moisture content, is ranging from 14,000 to 18,000 kJ/kg pointing to be similar to a good type of brown coal (Brkić and Janić, 2008),
4. Briquette combustion is very good, practically without smoke and no sulphur emissions, accompanied with low ash content, 2-3%,
5. Waste from the food industries (brewing spent grains, sediment sludge from oilseed processing, waste from the milling industry, withdrawn bread etc.) is an convenient raw material for briquette production for animal feed (Filipović et al., 1996, Filipovića et al., 1997, Filipović et al., 1995, Nježić et al., 2010).
6. In plants for separation of waste after separation, organic waste comprise over 60% in the morphological composition therefore it can be used in briquetting process (Nježić et al., 2006),
7. Existing combusting plants (various types of furnaces in households, smaller systems for heating buildings and manufacturing plants, etc.) enable the broadest application and use of briquettes as a source of heat,
8. Technological and technical concept simultaneously resolves: collection transportation, preparation, drying, briquetting and packaging of final products,
9. Market demand provide opportunities for practically unlimited amount of briquettes on both domestic and foreign markets and achieved sales prices provide a good cost-effectiveness of production and also a positive accumulation.

Due to the nutritional value of biomass consisting of: wheat, barley, oat, rye straw, maize, oilseed straw, sunflower stalks and remnants of the shell, waste from the milling industry, withdrawn bread, etc., it is necessary that the analysis of raw materials meet the requirements hygiene and health safety, microbiological and toxicological analysis by the Regulation on maximum permissible harmful substances, Off. SRJ 5/92, 11/92 and 32/2002, or meets the Regulation of the maximum amount of ingredients in animal feeds (sl. list SFRJ No. 2/90 and 27/90). Then biomass is used to produce animal feed, and otherwise in the process of briquetting as fuel. Parameters are examined according to table 1.

Table 1. Content of mycotoxin and heavy metals (Regulation on maximum permissible harmful substances, 2002, Regulation of the maximum amount of ingredients in animal feeds, 1990)

mycotoxin content (ELISA)	µg/kg
Aflatoxins B1+G1+B2+G2	<3
Ochratoxin	<10
Zearalenon	<1
Content of heavy metals (AAS)	mg/kg
Pb	0,4
Cd	0,005
As	0,5
Hg	0,03

For briquette making the production facility in Vršac was used. Briquettes were made from cereal straw, pruning branches of fruit trees and wood processing waste. Prior briquetting, moisture content in these raw materials was determined according standard AOAC procedure (1984).

There is no uniform standard in Europe, it‘s established by the European EPC pallet center standards in the report CEN/TS14961, so our country uses German DIN 51731. In table 2 is shown acceptable limits for content of heavy metals and ash by a European CEN/TS14961 report and DIN 51731/DIN plus standard.

Table 2. Content of heavy metals, ash (CEN/TS14961, DIN 51731)

Content	mg/kg

As	<0,8
Hg	<0,05
Cu	<5
S	<0,08%
N	<0,3%
ash	<3%

RESULTS AND DISCUSSION

Production of briquettes as a technical-technological process that aims to compress bulky material, i.e. to increase his bulk density. Is the tool for briquettes making, due to physical and chemical processes that are occurring, particles are tightly linked in a compact aggregates – briquettes. To be able to convert biomass to form briquettes following conditions must be ensured:

- moisture content of raw material must range from 10 to 12%
- particle size must not be greater than 5 mm

To ensure above mentioned technological requirements in most cases biomass should be grinded (chopped) and dried. After these preparations, raw material is brought into briquetting press where the briquetting form is made and than packed in appropriate packaging. Briquettes are usually circular or rectangular in cross section, minimum length of 50 mm. Biomass briquettes can be packaged in cardboard or plastic packaging.

Briquetting line capacity is up to 1,0 t/h at a moisture content of raw material not greater than 10%.

Briquetting plant consists of three technological lines:

1. Line for raw material preparation
2. Line for drying
3. Line for briquetting

For all types of raw materials and their combinations the optimal parameters were determined regarding: moisture, grain size, temperature, shape and size of the briquettes.

1. In straw briquetting trial work has not been used extra drying because the straw had 16% moisture. Straw briquettes were rectangular, measuring 270x100x50 mm, weight 1737 g. Analysis of the quality of briquettes is in acceptable limits according toTable 2.
2. In briquetting twigs the we used dryer as starting humidity was 45%. We have reduced the moisture to 16%. Briquettes of twigs were cylindrical with a diameter of 90 mm and length of 220mm, weight 1470 g. Analysis of the quality of briquettes is in acceptable limits according to Table 2.
3. In briquetting chaff extra drying was not used because the humidity was 14%. Briquettes of chaff were rectangular, measuring 270x100x50 mm, weight 1573 g. Results of analysis of briquettes are given in Table 3.

Table 3. Content of heavy metals, ash

Content	mg/kg
Pb	<10
Cd	<0,1
As	<0,2
Hg	<0,05
Cu	2,75
S	<0,08%
N	1,25%
ash	9 %

Results of analysis of briquettes from the chaff showed that it has 9% ash, 1.25% nitrogen, which exceeds acceptable limits, therefore mixing was done with sawdust in order to improve quality and meet the allowable value. Both raw materials were reduced to 15% moisture, and are mixed in ratio 50% chaff and 50% sawdust.

4. Briquettes from 50% chaff and 50% sawdust. Results of analysis of briquettes are given in Table 4.

Table 4. Content of heavy metals, ash

Content	mg/kg
Pb	<10
Cd	<0,5
As	<0,8
Hg	<0,05
Cu	1,47
S	<0,08%
N	0,25%
ash	1,36%

This briquette meets all established criteria, as briquettes for export to the EU. Moisture in all briquettes obtained were below 10%.

CONCLUSION

Moisture and granulation of raw material are crucial parameters for processes of collecting, transportation and briquettes processing. The production of briquettes from biomass originated from various raw materials attributed with different moisture content and granulation is completely solved in the production facility with automatic process regulation in Vršac. These briquettes are intended for domestic market and the European Union while meeting high standards of bio briquette quality in European Union. The presence of heavy metals is extremely dangerous because they accumulate in the body and when critical limits are reached they threaten the health of the population. The use of herbicides based on heavy metals and their quantity must be strictly controlled. To reduce the amount of heavy metals in the finished product, raw materials should be mixed with other materials that do not have heavy metals. Thus, it is necessary to make appropriate recipes from different types of raw materials.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project III046012 – “Study of modern biotechnological procedures in the production of animal feed in order to increase competitiveness, quality and safety of the feed”, financially supported by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: Osmotic dehydration is an alternative method for reducing postharvest quality losses of vegetables, and a common process for producing dried vegetables which can be directly consumed or used as an ingredient in bread, cakes, pastries and many products of other food industries. The objective of the present study was to investigate the effect of using sugar beet molasses as an osmotic agent in the dehydration of carrot and to evaluate chemical characteristics of osmotically dehydrated products as compared to the *in natura* vegetables. Sugar beet molasses is an excellent medium for osmotic dehydration, primarily due to the high dry matter (80%) and specific nutrient composition. The paper describes the effects of different concentrations of sugar beet molasses (80, 60 and 40%) and immersion times (1, 3 and 5h) on osmotic dehydration/impregnation of carrot cubes. Osmotic dehydration process was conducted at constant temperature of 55℃ and under atmospheric pressure. During the process the solution to carrot ratio was 8:1. Analyses of variance (ANOVA) was used in order to find significant effects of solution concentration and immersion time on water loss, solid gain, dry matter, carbohydrates and minerals content. It was found that, both process variables had statistically significant effects ($p< 0.05$) on all examined responses, with the exception of sodium content ($p<0.10$). Immersion time was found to be more significant factor affecting water loss, dry matter content, carbohydrates and minerals content, while the effect of concentration was more evident on solid gain and magnesium content (significant at $p<0.05$).
Key words: *osmotic dehydration, carrot, sugar beet molasses*

INTRODUCTION

It is known that fresh fruit and vegetables constitute an important source of valuable and essential nutrient substances such as vitamins, minerals, cellulose and others. Unfortunately, fresh fruit and vegetables cannot be stored for a long time. High moisture content (for fruit and vegetables often higher than 80%) and water activity are conducive to developing of germs and putrefactive bacteria, which are responsible for decaying processes. For this reason fruit and vegetables are processed to extend their shelf life *(Kowalski and Mierzwa, 2011).*

Drying, especially hot air drying, is one of the most often applied industrial methods of preserving post harvested fruit and vegetables. This process stabilizes and prolongs the shelf life of fruit and vegetables and enables their longer storage and further utilization. High temperature and long time drying often change the shape, color, taste, aroma and nutrient properties of fruit and vegetables *(Mujumdar and Law, 2010).* Besides, drying is also one of the most energy-intensive unit operations in food processing industry. It was stated that drying easily accounts for up to 15 % of all industrial energy usage *(Chua et al., 2001; Kudra, 2004).* Therefore, alternative methods of drying or dehydration of products before drying are sought to minimize energy consumption and to improve the final product quality *(Min et al., 2010)*. The osmotic dehydration (OD) is one of these methods *(Shi & Maguer, 2010).*

Osmotic dehydration is a water removal process, based on soaking foods (fruit, vegetable, meat and fish) in a hypertonic solution. Water removal in liquid form, usage of mild temperatures and osmotic solution reusing are main advantages of osmotic dehydration process in comparison with other drying treatments *(Madamba, 2003).*

Osmotic dehydration as a pretreatment to many processes improves nutritional, sensorial and functional properties of food without changing its integrity *(Matusek and Merész, 2003).* In this way even 50 % of water, initially present, in the material can be removed at a relatively low expenditure of energy *(Kowalski and Mierzwa, 2011).* The literature contains earlier findings that state *(Lewicki and Lenart, 2006)* convective drying needs about 5 MJ per kilogram of evaporated water, compared to 0.1-2.4 MJ per kilogram of water removed in osmotic dehydration. The type of osmotic solution also plays an important role in the process, with salt solutions used for vegetables and sugar solution and syrups used for fruits *(Lewicki and Lenart, 2006*). Sugar beet molasses, as a by-product of sugar refining, is cheap and excellent medium for osmotic dehydration, primarily due to the high dry matter (80%) and specific nutrient content. It is also a significant source of numerous micronutrients (vitamins and minerals), especially K, Ca, Na and Mg *(Šušić and Sinobad, 1989)*. In this study, the effect of nutrients, present in the sugar beet molasses on the quality of osmodehydrated carrot was analysed.

MATERIAL AND METHODS

Carrot samples were purchased in a local market in Novi Sad (Serbia) and stored at 4º*C* until use. Initial moisture content, $X_{o,}$ was 89.65 ± 0.48 %. As osmotic agent, pure sugar beet molasses (around 80% solid content) and sugar beet molasses solutions (with 40% and 60% solid content) were used. Solutions were made by mixing pure molasses with distilled water. Sugar beet molasses was obtained from sugar factory in Pećinci, Serbia. Initial dry matter content in sugar beet molasses was 83.68%.

Carrots were washed thoroughly and peeled manually (using a stainless kitchen peeler). The peeled carrots were manually sliced into cubes, dimension 1x1x1 cm using a kitchen slicer. The amount of 100 g of sliced carrot cubes samples were prepared for each treatment. In all experiments, a weight ratio of solution to carrot samples of 8:1 (w/w) was used. The experiments were conducted under atmospheric pressure at solution temperature of 55º*C,* in an apparatus for osmotic dehydration, installed in the laboratory at the Faculty of Technology, Novi Sad.

The immersion lasted for 1, 3 and 5 hours. After osmotic dehydration, the samples were washed with water and gently blotted to remove excessive water from the surface. The next step was measuring the mass and determining of dry matter content, content of sucrose (S), total reducing sugar (TRS), invert sugar (IS) and some minerals (K, Na, Ca and Mg) in the fresh and dehydrated samples. The samples were kept in an oven (Instrumentaria Sutjeska, Serbia) at 105 ℃ for 24h, until constant weight was attained. Solid content of osmotic solutions was determined refractometrically *(Milić et al., 1992).* All analytical measurements were carried out in accordance to *AOAC (2000).*

Evaluation of mass exchange between the solution and the sample during osmotic dehydration was made by using the parameters such as final dry matter content (*DM)*, water loss (*WL)* and solid gain (*SG)* according to the equations presented in *Eren and Kaymak-Ertekin, 2006.*

Descriptive statistical analyses for calculating the means and the standard error of the mean, analysis of variance (ANOVA) and Tukey's post HOC tests, and Responce surface method (RSM) were performed using *StatSoft Statistica,* for *Windows, ver. 10* program. All obtained results were expressed as the mean ± standard deviation (SD).

RESULTS AND DISCUSSION

The osmotic process was studied in terms of WL, SG and DM content. An initial high rate of water removal (and solid uptake) followed by slower removal (and uptake) in the latter stages was observed. Rapid loss of water (and solid gain) in the beginning is apparently due to the large osmotic driving force between the fresh carrot cubes and the surrounding hypertonic

medium (sugar beet molasses). Figure 1 shows WL, SG and final DM content with respective standard deviation of experimental data, at the different osmotic dehydration conditions.

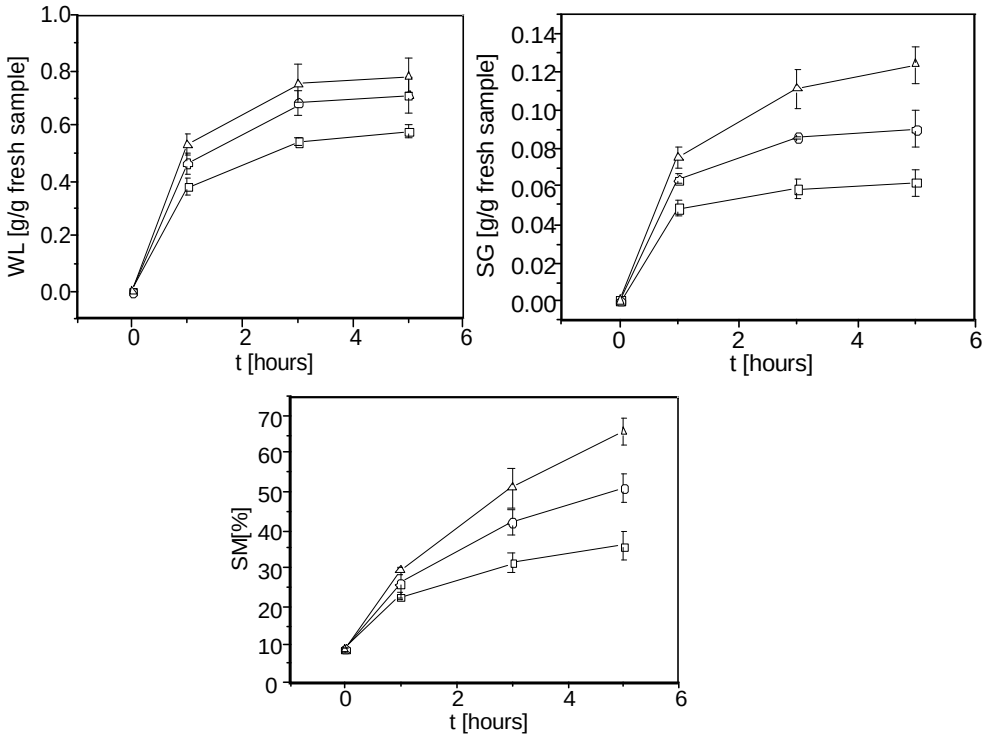

Figure 1. Changes in WL, SG and DM, during osmotic dehydration of carrot in different concentrations (40% □, 60% ○, and 80% △) of sugar beet molasses solutions

The initial values of WL and SG were set to zero, and the initial dry material content was 9.16±0.42%. The highest enlargement of WL (0.78 $g/g_{fresh\ sample}$), SG(0.12 $g/g_{fresh\ sample}$) and DM (65.82%) contents were observed after 5 hours of osmotic treatment in 80% sugar beet molasses concentration. Approximate values of corresponding parameters were obtained after 3h in 80% molasses solution (WL was 0,76 $g/g_{fresh\ sample}$, SG was 0,11 $g/g_{fresh\ sample}$ a DM was 51,1%). In the last stage of the process (last two hours) upward trend of kinetics parameters values is very small so it would be desirable to shorten the process to 3h and use 80% molasses solution, from economically aspect, considering the possibility of process expences reduction, and decreasing the energy consumption for heating.

The independent variables were osmotic time (X_1) of 1, 3 and 5h and molasses concentrations (X_2) of 40, 60 and 80% (by weight). The dependent variables observed were the response: water loss, *WL* (Y_1), solid gain *SG* (Y_2) and dry matter, *DM* (Y_3).The following second order polynomial (SOP) model was fitted to the data (*Montgomery, 1984*):

$$Y_k = \beta_0 + \sum_{i=1}^{2} \beta_i X_i + \sum_{i=1}^{2} \beta_{ii} X_i^2 + \sum_{i=1}^{2} \sum_{j=i+1}^{2} \beta_{ij} X_i X_j, \quad (1)$$

where: β_{kn} are constant regression coefficients; Y, either DM (Y_1), WL (Y_2), or SG (Y_3); X_1 treatment time and X_2, solution concentration.

The ANOVA for kinetic terms (Table 1) reveals the significant effects of independent variables, dehydration time and sugar beet molasses concentration to the kinetics terms (WL, SG and DM). The SOP models for all variables were found to be statistically significant and the response surfaces were fitted to these models. The linear terms of SOP model were found significant, at 99% confidence level, and their influence were found most important in model calculation. DM was significantly affected by all process variables, at 99% confidence level. WL was also significantly affected by all process variables, at the same confidence

level. Each of these kinetics terms was most affected by treatment time. SG was significantly affected by treatment time and molasses concentration, but SG showed more sensitivity to the changes in molasses concentration. Table 1 shows that all kinetics SOP models had insignificant lack of fit tests, which mean that all the models represented the data satisfactorily.

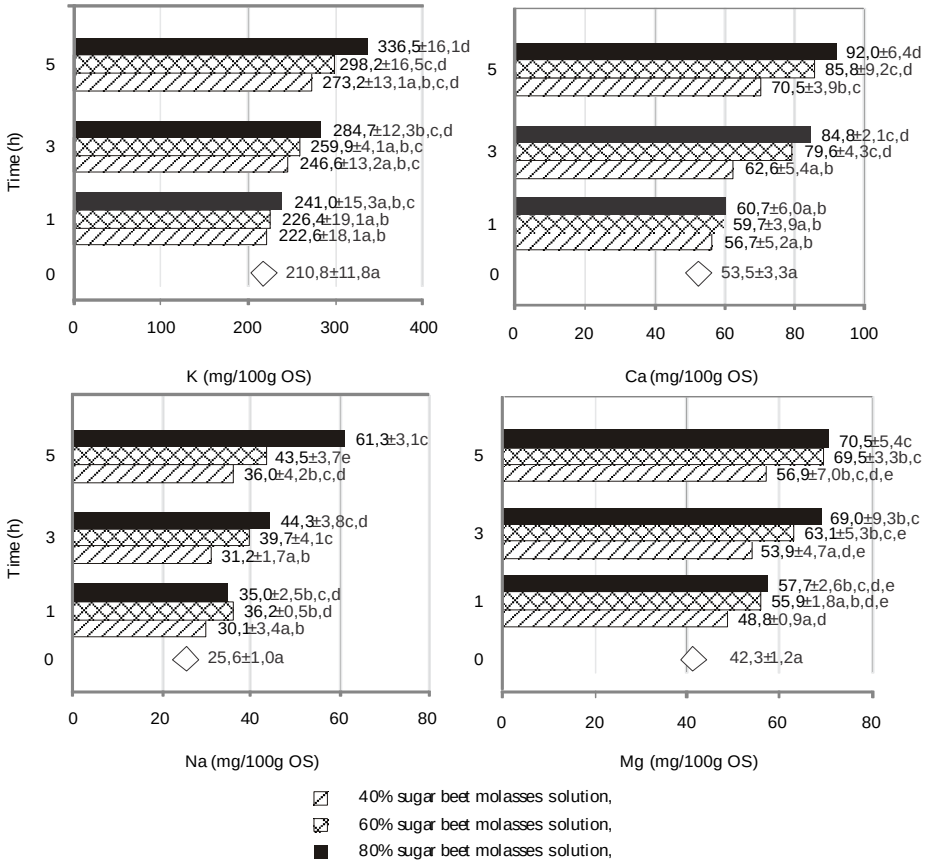
Figure 2 represents changes in content of examined minerals, during osmotic dehydration in different concentration of sugar beet molasses solutions. The initial values of K, Ca, Na and Mg contents were 210.8±11.8 mg/100g, 53.5±3.3 mg/100g, 25.6±1.0 mg/100g and 42.3±1.2 mg/100g, respectively.



^{a,b,c,d,e} different letters printed within the same raw show significantly different means of observed data ($p<0.05$).

Figure 2. Changes in minerals content in carrot, during osmotic dehydration in sugar bet molasses solutions (mineral content expressed per 100 g sample).

The highest increase of mineral content was observed after 5 hours of osmotic treatment in 80% sugar beet molasses concentration (K was 336.5±16.1 mg/100g, Ca was 92.0±6.4

mg/100g, Na 61.3±3.1 mg/100g, and Mg 70.5±5.4 mg/100g). A statistically significant increase ($p < 0.05$) in content of the studied minerals, occurred after 3h of dehydration in 80% molasses solution. From the economic aspect it is cost effective to shorten the process duration to 3h during which the content of K, Ca, Na, and Mg increased to 284.7 ±12.3mg/100g, 84.8 ±2.1mg/100g, 44.3 ±3.8mg/100gand 69.0±9.3mg/100g and, respectively.

The SOP model (Eq. 1) was used to fit the minerals content data (K, Ca, Na and Mg). The SOP models (Table 2) for all variables were found to be statistically significant and the response surfaces were fitted to these models. The linear terms of osmotic time were found significant, at 95% confidence level, and their influence were found most important in model calculation. The sugar beet molasses concentration affects Mg content at 95% confidence level, while Na content is affected at 90% level of confidence. All mineral content in SOP models had insignificant lack of fit tests, which means that all the models represented the data satisfactorily.

The initial values of TRS, S and IS contents were 5.8±0.5g/100g, 4.0±0.2g/100g and 1.6±0.2 g/100g, respectively. The greatest increase was observed after 5 hours of osmotic treatment in 80% sugar beet molasses concentration (TRS 21.8±0.3 mg/100g, S 19.0±2.6 mg/100g, and IS 3.4±0.3 mg/100g). Since the aim of dehydration was not candying of fruits, it was necessary to minimize the penetration of sugar components in the samples of carrot. In this sense it is desirable to shorten the duration of the process at 3 h, whereas the content of S, IS, and TRS increased to 15.8 ± 0.8, 3.2 ± 0.1 and 17.0± 1.9 g/100g, respectively.

The SOP model (Eq. 1) was used to fit TRS, S, IS content data (Table 3). The SOP models for all variables were found to be statistically significant and the response surfaces were fitted to these models.

Table 4. ANOVA for sugar content in carrots during osmotic dehydration in sugar beet molasses

Term	Factor	df	Sum of squares		
			TRS	S	IS
Linear	Time	1	79.081^{+}	61.391^{+}	0.875^{+}
	Concentration	1	4.378*	6.748*	0.050^{+}
Quadratic	Time	1	0.247^{ns}	0.036^{ns}	0.094^{+}
	Concentration	1	0.008^{ns}	0.112^{ns}	0.003^{ns}
Cross-product	Time x Conc.	1	0.576^{ns}	0.663^{ns}	0.001^{ns}
Lack of fit	Error	3	0.651	1.874	0.003
	r^2		99.444	98.557	99.770

$^{+}$Significant at 99% confidence level, *Significant at 95% confidence level,**Significant at 90% confidence level, ^{ns} Not significant

The linear terms of osmotic time were found significant, at 99% confidence level, and its influence was found most important in model calculation. The sugar beet molasses concentration affects TRS and S content at 95% confidence level, while IS content is affected at 99% level of confidence. All sugars content SOP models had insignificant lack of fit tests, which means that all the models represented the data satisfactorily

ACKNOWLEDGMENT
This paper is a result of the research within the project III046005, TR – 31055, financed by the Ministry of Science and Technological Development, Republic of Serbia.

CONCLUSION

Both investigated parameters (immersion time, concentration) had statistically significant influence on WL, SG, DM, minerals and carbohydrates content, during osmotic dehydration of carrot cubes in sugar beet molasses. The ANOVA and RSM were successfully used for determination of the system responses, all input variables were found statistically significant while predicted and observed responses correspond very well. Process time, in comparison with solutions concentration, had more statistically significant effect on all tested variables, with exception of SG. Increase of valuable bioactive components in dehydrated carrots contributes to improving theirs nutritional quality. Some increase in sugar content, combined with reduced moisture content, contributing to sustainability of this semi-final product. According to the results, it can be concluded that proposed process conditions for improving product quality were found to be: osmotic time of 3h and sugar beet molasses concentration of 80%. Considering the shorter immersion time and thus lower energy consumption in heating system, the proposed conditions are also acceptable from economic aspects of production.

ABSTRACT: In the past few decades there has been a cosiderable intrest in consumption of ancient wheat. Spelta wheat is growing without the use of pesticides in harsh ecological conditions and marginal areas of cultivation. It is believed that primitive wheat species are more disease-resistant and can produce healthier foods than those made from modern varieties. Spelta wheat is suitable raw material for production organic food like of pasta, specialty type of bread and other products of altered nutritional characteristics compared to conventional wheat products. In determining the purity of products spelta aleuron layer plays a key role. This paper investigates the technological quality and dough rheology of wholemeal spelta flour as a raw material for pasta. Technological quality of wholemeal spelta is defined by basic chemical analyses (protein, starch, fat, cellulose, ash and reducing sugars) and metal content of Ca, Zn, Cu, Mn, and Fe. Rheology of wholemeal spelta is defined by gluten characteristics, farinogram and alveogram. Activity of amylases is defined by Falling number and amylograph. Beside chemical and rheological properties the convenience of spelta wholemeal flour for pasta is evaluated on the data concerning cooked pasta quality. Data point at good indicators of technological quality and sensor characteristics of spelta pasta. Pasta obtained from wholemeal spelta flour may be a new organic safe product at the market.
Key words: *wholemeal spelta flour, quality of spelta pasta, pasta color*

INTRODUCTION

Spelta wheat (*Triticum aestivum* subsp. *spelta*) is an old European crop. In the past few decades there has been a cosiderable intrest in consumption of ancient wheat. Spelta wheat is growing without the use of pesticides in harsh ecological conditions and marginal areas of cultivation. It is believed that primitive wheat species are more disease-resristant and can produce healthier foods than those made from modern varieties (Bonafaccia at all 2000, Abdel-Aal & Rabalski 2008).

The nutritive value of spelta wheat is high and contains all the basic components which are necessary for human beings such as starch and nonstarch carbohydrates, proteins, lipids, vitamins and minerals. Spelta wheat is reported to have higher protein content (16-17%) than *Tr. Aestivum* due to higher protein of aleuron layer (Bojanski and Frančakova, 2002). Spelta varieties have shown potential in various food applications, including bread, pasta, breakfast cereal and other products of altered nutritional characteristics compared to conventional wheat products. With so much interest in organic foods, organically-grown spelta finds its way to the food market (Marconi at all 2002, Abdel-Aal & Rabalski 2008).

This paper investigates the technological quality and dough rheology of wholemeal spelta flour as a raw material for pasta. Technological quality of wholemeal spelta is defined by basic chemical analyses (protein, starch, fat, fiber, ash, moisture and reducing sugars) and metal content of Ca, Zn, Cu, Mn, Fe. Rheology of wholemeal spelta is defined by gluten characteristics, farinogram and alveogram. Activity of amylases is defined by Falling number and amylograph. Beside chemical and rheological properties the convenience of spelta wholemeal flour for pasta is evaluated on the data concerning cooked pasta quality

MATERIALS AND METHODS

Wholemeal flour of two spelta varieties (Nirvana and Eco 10) is tested.
Basic chemical analyses (protein, starch, fat, cellulose, ash) of wholemeal spelta flour are defined according to the Regulations on the physical and chemical methods of analysis for quality control of grain, milling and bakery products, pasta and deep frozen dough (1988),
Falling number according to ICC Standard No 107/1, gluten index and gluten index after 1h at 30 ℃ according to ICC Standard No 155 , reducing sugars content according to Kaluđerski and Filipović 1998 and metal content (Ca, Zn, Cu, Mn and Fe) ,according to methods practiced in accredited FINS Laboratory 2011. Rheology of wholemeal spelta is defined by farinogram *(*Kaluđerski and Filipović, 1998*)* and alveogram (AACC, 1994*)*
Pasta is made on the device "La Parmigiana D45" MAC 60, LaParmigana Italy. Moisture content of the dough is adjusted to 31,5%, mixing time was 15 min. Quality of cooked pasta was determined on the behaviour of pasta during cooking according to the method described by Kaluđerski and Filipović (1998).

RESULTS AND DISCUSSION

Quality of wholemeal Spelta flour of two different varieties is presented in Table 1. Moisture and ash content of both wholemeal varieties are fairly consistent, but the ash content is significantly higher than the ash content of flour from wholemeal vulgare wheat (Kaluđerski, Filipović 1998). The high ash content is a consequence of the characteristics of spelta grain anatomy, i.e. high ratio of bran layer, deep crease, lower endosperm content and different distribution of minerals within the grain in comparison to bread wheat grains and the statement is consistent with data of Ruibal-Mendieta et al., (2005). Investigated spelta varieties are characterized by high protein content (Table 1) which qualifies this raw material as a suitable for pasta production. In addition to the high total protein content, gluten proteins are attributed with good quality. Gluten index (Table 1) was significantly lower in Eco variety in relation to the Nirvana, indicating increased activity of proteolytic enzymes which is confirmed by extremely low value of gluten index after 1h. Regarding variety Nirvana an increased activity of proteolytic enzymes is indicated by gluten index after 1h. The content of starch, fat and fiber have are relatively uniform in both varieties. It is worth emphasizing that spelta contains more fiber than the bread wheat varieties in which the average value is round 2.0% (Vukobratovic, Dozet 1992). Data concerning content of individual elements vary depending on the variety with the greatest difference in Fe content. The high mineral content experienced in spelta varieties point at the improved bioavailability of those elements, due to low phytic acid content reported by and Ruibal-Mendieta et al. (2005).

Table 1. Parameters of quality of wholemeal spelta flour

Parameters of quality	Nirvana	Eco 10
Moisture content (%)	13.25	12.82
Ash content (% d.m.)	2.36	2.37
Crude protein content (% d.m.)	18.17	16.02
Cellulose content (% d.m.)	2.29	2.16
Starch content (% d.m.)	57.59	57.3
Fat content (% d.m.)	2.20	2.23
Gluten index	95	68
Gluten index (after 1h at 30°)	57	50
Ca content (mg/kg)	245.38	299.95
Zn content (mg/kg)	30.0	33.38
Cu content (mg/kg)	4.89	3.98
Mn content (mg/kg)	43.76	46.45
Fe content (mg/kg)	41.19	37.9

Based on farinograph data. (Table 2) water absorption. dough development and stability are quite uniform and can be considered optimal for bread making but not for making pasta. A variety of eco 10 has an extremely high 15 min drop indicating a high proteolytic enzyme activity and thus classified as a quality class C1. Alveograph data: tenacity, length of curve, dough extensibility and baking strength depend on the variety characteristics, while the value of P/L is even (Table 2).

Table 2. Rheology of wholemeal spleta flour

Farinogram	Nirvana	Eco 10
Water absorption (%)	63	64.1
Dough development (min)	3.5	3
Dough stability (min)	0.5	0.5
15 min drop (FU)	80	150
Number of quality /quality class	59.4 / B 1	41.2 / C 1
Alveogram		
Tenacity (mm)	75	55
Length of curve (mm)	25	18
Dough extensibility G (ml)	11.1	9.4
Baking strength W (10^{-1}J/kg)	74	40
Configuration ratio P/L	3.0	3.06

A slightly higher content of reducing sugars is experienced with Eco 10 than with Nirvana variety. Both values are considerably higher than that average values for vulgare wheat (Vukobratovic and Dozet 1992) (Table 3). Falling number and amylograph data of Nirvana are within the optimum range for baking contrary to Eco 10 where they indicate an increased activity of alfa amylase (Table 3). Concerning the quality for pasta, both varieties could be considered as inconvenient due to increased amylase activity.

Table 3.. Activity amylolitic enzymes of wholemeal spelt

Characteristics	Nirvana	Eco 10
Falling number (s)	261	225
Content of reducing sugars (% d.m.)	4.15	4.62
Amilograph maximum viscosity (AU)	370	120

Table 4. shows that pasta Eco 10 is attributed with significantly higher percentage of water absorption compared to the Nirvana pasta, resulting in an increased volume of cooked pasta. Increased cooked pasta volume indicates the possibility of starch swelling and this property is in both cases in the optimal range. Higher residue in cooking water is attributing Eko 10 pasta compared to Nirvana, probably due to lower protein content and high activity of proteolytic enzymes (Table 1). In addition to above pasta features. for consumers is a very important impression when chewing. Properly cooked pasta should provide resistance to the bite and not to give the impression of creamy products. Eco 10 pasta is attributed with high stickiness contrary to Nirvana pasta (Table 4). On the whole, pasta made of wholemeal spelta has good sensor characteristics and much improved nutritive characteristics in comparison to commercial pasta that is at our market.

Table 4. Quality characteristics of spelt pasta

Quality of pasta cooking	Nirvana	Eco 10
Water absorption (ml/100g)	144.0	153.5
Cooked pasta volume increase (α)	2.8	2.9
Residue in cooking water (% d.m..)	6.8	7.4
Stickiness (max -0. min 10)	8	5

CONCLUSIONS

Based on the investigation concerning convenience of spelt varieties Nirvana and Eco 10 for whole meal pasta it can be concluded:

- The protein and gluten content of both spelt varieties reach values greater than the values commonly achived for bread wheat and these values approache the values of durum wheat protein and gluten content.
- Rheology data point at increased activity of proteolytic and amylolitic enzymes, particularly for Eco 10.
- Beside the unfavorable rheological properties spelta wholemeal flour proved to be convenient for pasta.
- Data of spelta pasta quality point at good technological quality and sensor characteristics of spelta pasta. Pasta obtained from wholemeal spelta flour may be a new organic safe product on the market.

ABSTRACT: The drying kinetics of raspberry in a laboratory dryer was studied. Fresh, untreated raspberries were dried at selected temperatures of 50 ^{o}C with a constant air velocity of 1.2 m/s. The drying rate curves showed that drying process took place only in the falling rate period. Thin-layer drying models of Newton-Lewis, Henderson and Pabis, logarithmic, Page, Wang and Singh evaluated based on coefficient of determination (R^2), reduced chi-square (χ^2) and root means error (RMSE). The logarithmic model was found to be the best model for describing the characteristics of raspberry. The changes of color on raspberry's surface were determined by original approach, combining digital camera, computer and graphic software. Pearson correlation coefficients and triplicate sample paired t-test on R (red) colour index frequency were calculated during the experiment. A mathematical model to predict the shrinking of geometrical bodies was proposed, assuming unidirectional drying and two-dimensional shrinkage. The model was numerically solved by finite differences, taking into account a convective term in the mass balance equation, which appears as a consequence of non-unidirectional shrinkage. Thermal analysis, by means of differential scanning calorimetry (DSC) and thermogravimetry (TGA) of fresh and dried raspberries have been studied. From results obtained differences in thermal stability of fresh and dried raspberries were shown.

INTRODUCTION

Drying of moist materials is a complicated process which involving simultaneous, combined heat and mass transfer phenomena, which occur in the material being dried (Yilbas, et. al 2003). One of the most widely used methods of food (fruit and vegetable) preservation is convective drying process, which finds its principal purpose in removing of water in the solid material, up to certain level, at which microbial spoilage and deterioration chemical reaction are greatly minimized (Krokida, et. al 2003). The quality of products is considerably improved, by understanding the heat and mass transfer in the product, and also the drying process parameters. Drying process activity is influenced by a number of internal parameters, which characterize the material, such as density, permeability, porosity, sorption-desorption characteristics and their physical properties, and also external parameters, related to drying process, like drying temperature, drying air velocity, sample dimensions and relative humidity of the drying medium). In most drying processes water is removed by convective evaporation in which heat is supplied by hot air.
Mathematical modeling is widely used in developing kinetics models to predict the mass transfer of drying process at atmospheric pressure. However, it is very difficult to develop a mathematical model capable to incorporate all above mentioned factors (both internal and external) involved in the process (Kaya, et. al, 2007, Lewicki et. al., 2004, Sacilik, et. al. 2006, Srikiatden, et. al. 2005, Uretir, et. al. 1996, Velić, et. al. 2004).
The main objective of this study was to determine the effects of process parameters like drying air temperature, air velocity and sample surface on the diffusion model coefficients and the values of moisture diffusivity and heat transfer coefficients by using multiple

regression analysis, and to test the most appropriate drying model for understanding the drying behavior of raspberry.

MATERIALS AND METHODS

The laboratory convective dryer, consisted of an electric 5000 W heater placed inside the heating chamber. In the measurements of temperatures, J type iron–constantan thermocouples were used with a manually controlled 10-channel automatic digital thermometer (Omega, MDS Si8-TC-C4EI-AL, USA), with reading accuracy of ±0.1 ^{o}C. A thermo hygrometer (Vaisala HMT330) was used to measure humidity at various locations of the system. Moisture loss was recorded at approximately 5 min intervals during drying process for determination of drying curves by a digital balance (Napco, JA3000S, China), with measurement range of 0–3000 g and an accuracy of ±0.01 g. The raspberries were thoroughly washed before drying process. Samples were selected from the lot for uniformity using the specific gravity of the fruits.The tray was loaded as thin layer, and the initial weight of the raspberries on each tray was approximately 35 g. The raspberries (aver. diameter 11.4 mm, and aver. weight 2.9 g for single fruit), were carefully and orderly placed on the trays, which were not perforated. The initial and final moisture contents of the products were determined at 105 ^{o}C by using an Infrared Moisture Analyzer (METTLER, LJ16, Switzerland). After the dryer is reached at steady state conditions for operation temperatures, the samples are put on the tray of dryer and dried there During the experimental drying, raspberries of average initial moisture content 85.7% (wb), were dried, at temperatures of 50^{o}C, relative air humidity 50-55%, in atmospheric convective dryer, at the velocities of drying air of 1.2 m/s. The final moisture contents represent moisture equilibrium between the sample and drying air under dryer conditions, beyond which any changes in the mass of sample could not occur.

Color images of raspberries during drying process were captured in triplicate, by a Canon PowerShot A550 CCD camera, which is a common digital cammera for home use. All the acquired images were 24 bit RGB (16.8 millions of colors) with a 1024 x 768 spatial resolution. The macro function of the digital camera has been used, to cover a scene area of approximately Ø10 cm. Each sample was chosen to be at the approximately constant thickness of 5 mm and to an area sufficient to cover completely the image scene, in order to avoid the presence of background in the image. Then, it was placed on a white paper napkin set on a flat white painted surface, 15 cm below the digital camera. Paper napkins were used in order to absorb the excess of oil and therefore to avoid undesired reflection effects. With this setup, it was possible to capture images with negligible shadows and without specular reflections. The acquired RGB images were transferred to a computer in the form of .jpeg compressed image files. The size of the imported jpeg images ranged from 900 to 1250 KB for the 9 x 22 = 198 images of the data set. For the elaboration of the images, every image file is imported in the originally developed computer program.

The dimensions of raspberries were measured by a digital micrometer.

The kinetics models were selected with the correlation coefficient (R^2)., the reduced chi-square (χ^2), mean bias error (MBE) and root mean square error (RMSE) were used to determine the quality of that fitting function (Akpinar, 2006; Midilli et al., 2002, Mujumdar, et. al., 1995).

These commonly used parameters can be calculated as follows:

$$\chi^2 = \frac{\sum_{i=1}^{N}(MR_{\exp,i} - MR_{pre,i})^2}{N-n},\ RMSE = \left[\frac{1}{N}\cdot\sum_{i=1}^{N}(MR_{pre,i} - MR_{\exp,i})^2\right]^{1/2},$$

$$MBE = \frac{1}{N}\cdot\sum_{i=1}^{N}(MR_{pre,i} - MR_{\exp,i}) \quad (1)$$

where $x_{exp,i}$ stands for the experimental values and $x_{pre,i}$ are the predicted values by calculating from the model for these measurements. N and n are the number of observations

and constants, respectively. For quality fit, R^2 value should be higher, and χ^2, MBE, RMSE and values should be lower (Yaldiz, et. al 2001; Ertekin, et. al 2004).
Analysis of variance (ANOVA) were performed using StatSoft Statistica, for Windows, ver. 10 program. The model was obtained for each dependent variable where factors were rejected when their significance level was less than 95%.
Differential scanning calorimetry (DSC) and thermogravimetry (TGA) of fresh and dried raspberries have been performed on TA Instruments DSC Q 1000, differential scanning calorimeter and TGA measurements on TA Instruments TGA Q 500 thermogravimetric analyzer under N_2 purge flow of 50ml/min and 60ml/min respectively. DSC scans were conducted in temperature range from -90ºC to 400ºC, with heating rate Hr=5Cº/min, and TGA scans were performed in temperature range of 25ºC to 900ºC with heating rate Hr=5Cº/min.

RESULTS AND DISCUSSION

Kinetics study

The moisture content data at the given drying conditions fitting computations with the drying time were carried on the several drying models evaluated by the previous workers (see Table 1). The moisture ratio (MR), as well as the R color index and overall fruit diameter changes during the drying experiment are presented on Fig. 1.

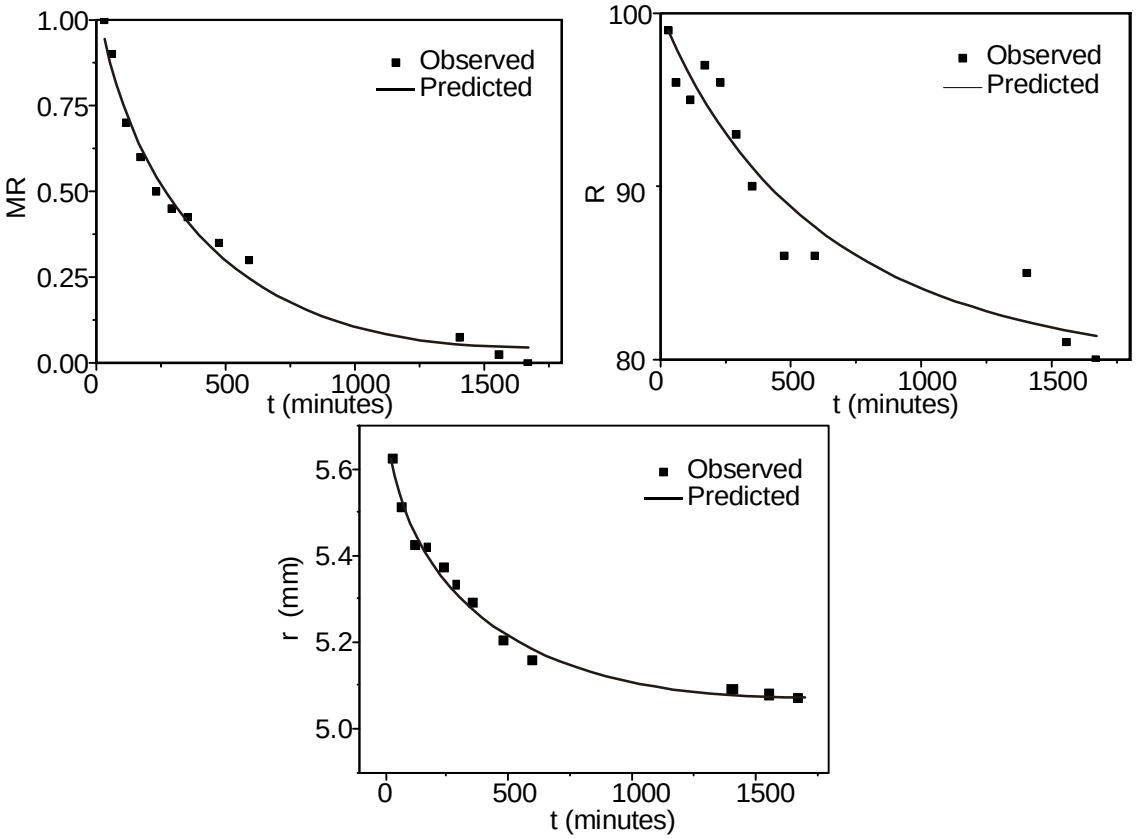

Figure 1.Raspberry moisture ratio MR, R color index and fruit radius during drying process at temperature of 50 °C, atmospheric pressure, 1.2 m/s air flow velocity

The statistical analyses results applied to the common mathematical models of drying process at 50°C air temperature and 1.2 m/s air velocity are given in Table 1. The best model describing the thin layer-drying characteristic was chosen as the one with the highest r-value and the lowest χ^2, MBE and RMSE values. From Table 1, it was determined that the

best fitting results were obtained with logarithmic model (estimated coefficients were: *a*=0.989; *k*=0.003; *c*=0.034).

Table 1. Thin layer drying curve models

Model name	Model	R^2	χ^2	MBE	RMSE
Newton-Lewis	$MR = \exp(-k \cdot t)$	0.918	8.94E-02	-1.82E-01	3.15E-01
Page	$MR = \exp(-k \cdot t^n)$	0.863	4.82E-02	-2.70E-02	4.68E-02
Henderson and Pabis	$MR = a \cdot \exp(-k \cdot t)$	0.924	2.63E-02	-1.06E-03	1.83E-03
Logarithmic	$MR = a \cdot \exp(-k \cdot t) + c$	0.937	2.22E-02	-1.33E-03	2.31E-03
Wang and Singh	$MR = 1 + a \cdot t + b \cdot t^2$	0.875	8.33E-02	-1.44E-01	2.50E-01

Table 2 shows the results of the statistical analyses results applied to the common mathematical models of color changes during the drying process. The best model describing the color changes characteristic was logarithmic model (coefficients were: *a*=19.402; *k*=0.002; *c*=80.494).

Table 2. Red color index changes models

Model name	Model	R^2	χ^2	MBE	RMSE
Newton-Lewis	$R = \exp(-k \cdot t)$	0.914	1.58E-02	-6.88E-02	1.19E-01
Page	$R = \exp(-k \cdot t^n)$	0.945	5.11E-03	4.09E-03	7.08E-03
Henderson and Pabis	$R = a \cdot \exp(-k \cdot t)$	0.912	7.96E-03	8.86E-05	1.53E-04
Logarithmic	$R = a \cdot \exp(-k \cdot t) + c$	0.958	3.93E-03	-3.36E-08	5.81E-08
Wang and Singh	$R = 1 + a \cdot t + b \cdot t^2$	0.951	4.64E-03	-8.25E-03	1.43E-02

For a mixture of components with constant specific volumes, the mass conservation equation can be written as (Viollaz, et. al. 2002),:

$$\frac{\partial \rho_A}{\partial t} = D \frac{\partial^2 \rho_A}{\partial^2 x} - v \frac{\partial \rho_A}{\partial x} \tag{2}$$

where: ρ_A is mass concentration of drying material (kg water/m^3 of total volume), t - time (s), D is mutual diffusion coefficient (m^2/s), x - coordinate, (m), v - volume average velocity in direction x (m).

Eqn. (2) will be solved numerically using the following assumptions: the partial specific volumes of water and dry solid are constant; moisture diffusivity is constant; drying is unidirectional; shrinkage is three-dimensional.

By expressing the change of volume with time as the product of velocity times area, the volume average velocity at the position x due to the change of the lateral area can be obtained (Viollaz, et. al. 2002):

$$v = -\frac{x}{A}\frac{dA}{dt} \tag{3}$$

Eqs. (2) and (3) were solved numerically using the following initial and boundary conditions:

$$t = 0; \quad \rho_A = \rho_{A0}; \quad x = 0; \quad \frac{\partial \rho_A}{\partial x} = 0; \quad x = L; \quad \rho_A = \rho_{A\infty} \tag{4}$$

Evalutive procedure starts with the average raspberry fruit radius of 5.6 mm. Diffusion coefficient for long drying periods, can be simplified to first term of the series, and moisture ratio can

be expressed as M/M_0, due to relatively small value of M_e compared to M or M_i, written in the logarithmic form:

$$\ln\frac{M}{M_e} = \ln\frac{6}{\pi^2} - \left(\pi^2 \cdot \frac{D_{eff} \cdot t}{r^2}\right), D_{eff} = D_0 \cdot \exp\left(-\frac{E_a}{T \cdot R}\right), \quad (5)$$

where the effect of temperature on effective diffusivity is expressed using Arrehnius type relationship. E_a is the activation energy of moisture diffusion (kJ mol^{-1}), D_0 is the diffusivity value for infinite moisture content, and R represent universal gas constant (kJ mol^{-1}). T is absolute drying air temperature (K). Calculated effective diffusion coefficient was 3.2E-10m^2/s, and activation energy of 20 to 40 kJ/mol, which were in accordance to literature values (Lewicki, et. al. 2004).

The obtained results for prediction of fruit radius corresponds very well to those achieved by experimental measurement. The obtained statistical parameters are, as follows: R^2=0.934; χ^2=1.78E-02; MBE=4.12E-03; RMSE=8.18E-03.

Thermal analysis

Obtained DSC and TGA curves of fresh and dried raspberries, (Fig 2.) show differences of thermal stability between fresh and dried fruits caused by water loss during drying process (Syamaladevi et. al, 2009). On Fig 2a DSC curves for fresh (dashed curve) and dried (solid curve) fruits are presented. From DSC curve for fresh raspberries it can be seen that phase trasition of ice melting and water evaporation are dominant thermal events, as the sample water content is high. High water content (85.7%) is also observed from corresponding TGA curve of fresh raspberries (solid curve Fig 2b). DSC curve of the dried sample, Fig 2a (dashed curve) is characterized by three edothermal peaks with maximums at T_{m1}=-40.7ºC, T_{m2}= -20.23 ºC and T_{m3}=114.0ºC respectively and one glass transition T_g= 42.3 ºC. Results are in agreement with Syamaladevi et. al, 2009, who showed that glass transition temperatures of raspberries are influenced by water content, and Shyam et al 2010, Kim et. al, 2001, as it was found that dried food material has similar thermal properties of semicrystalline polymers. Water content of dried sample obtained from TGA curve, Fig 2, dashed curve was 19.3%.

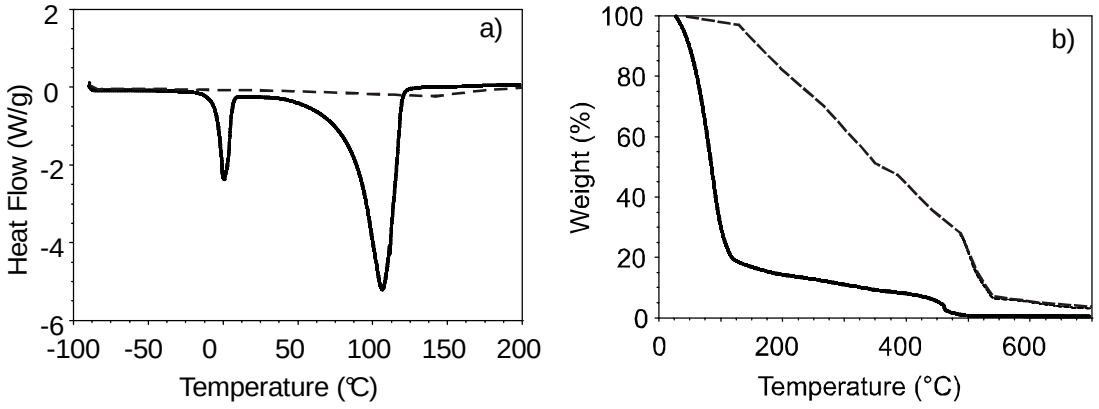

Figure 2. a) DSC curves of dried (dashed curve) and fresh (solid curve) raspberries and b) TGA curves of dried (dashed curve) and fresh (solid curve) raspberries

CONCLUSION

In order to explain the drying behavior and develop the mathematical modeling of raspberry convective drying process, several models, were applied, upon the changes in raspberry moisture ratio. The best model (logarithmic) adequately describe the drying behavior of raspberry fruit in the drying process, with gained r^2 of 0.937 and χ^2 of 2.22E-02.

Also, a few mathematical model of browning process during drying were developed and tested. Statistical analysis, including comparison tests, showed that logarithmic model adequately represent the browning process, showing r^2=0.958 and χ^2=3.93E-03.
Finally, a mathematical model to predict the shrinking of geometrical spherical bodies was proposed, assuming unidirectional drying and two-dimensional shrinkage. This model showed good results, also, with r^2=0.934 and χ^2=1.78E-02.
Thermal analysis shows differences of thermal stability between fresh and dried fruits caused by water loss during process of drying.

ABSTRACT: Dough mixing is very important stage in the bread making process. The mixing process promotes numerous physical, chemical and physic-chemical modifications that conduct to dough development. The aim of this work was to investigate the mixing time and temperature influence on volatile compounds in dough made from flour blend (triticale, hull-less barley, rye, rice, and corn flour). Dough was made from flour blend, sugar, salt, yeast and water, according to the recipe and technology used in wheat bread making. An investigation of volatile compounds was done using solid-phase microextraction (SPME) and gas-chromatography mass-spectrometry (GC-MS). Volatile compounds were analyzed during dough mixing after 6, 8, 10 and 15 minutes at dough temperature 20, 25 and 32 °C. The optimal parameters for qualitative dough making (appropriate elasticity) could be: time 6 min and temperature 32 °C, time – 8 and 10 min and temperature 25 °C. There were detected 13 volatile compounds in the mixing process. Identified volatile compounds belong to alcohols, aldehydes, carboxylic acids and terpens. Part of identified volatile compounds such as hexanal, D-limonene, 1-hexanol, 1-octen-3-ol and heptanol detected in dough originate from flour blend. Some compounds were released from dough due to physical and chemical changes taking place in the dough mixing process. Total peak area of volatile compounds increased extending dough mixing time and temperature.
Key words: *mixing, triticale, volatile compounds, solid-phase microextraction*.

INTRODUCTION

In production of bread and pastry various grinds of wheat and rye flour traditionally are used, though new possibilities for expanding of the assortment are sought. Researchers worldwide have been studying use of triticale, hull-less barley, maize and rice in bread and pastry production (Taketa *et al*., 2004; Ozola et al., 2011).
Triticale (*Triticosecale wittmack*) is the first man-made cereal produced by crossing wheat (*Triticum spp.*) and rye (*Secale ceral L.*). The nutritional value of triticale is close to that of wheat and rye, and although some triticale-based food can be purchased at health food stores. (Salmon et al., 2002; Hosseinian and Mazza, 2009). Triticale is mainly used as an ingredient in animal feeding, but also on a smaller scale as a food ingredient, for example in bread making or as replacement for soft wheat in biscuits, cakes and cookies (Sabovics et al., 2010; Rakha et al., 2011).
Bread making is basically a temperature-dependent two-step process, consisting of fermentation, in which CO_2 production associated with yeast activity is manifested in a dough volume expansion, and baking, in which yeast activity is terminated and the bread structure is finalized (Bajd and Serša, 2011).
The first step in a baking process is dough mixing. How the mixing is performed and the ingredients are incorporated and dispersed largely determine the quality of the baked product (Gras et al., 2000; Aamodt et al., 2003). The mixing process promotes numerous physical, chemical and physic-chemical modifications that conduct to the dough development (Aït Kaddour et al., 2008). Mixing contributes three main functions in structure formation of dough: homogenization, it blends the ingredients into a macroscopically homogeneous mass; air inclusion which will form nuclei for gas bubbles that grow during dough fermentation and gluten development via mechanical energy input (Peighambardoust et al., 2010; Koeler et al., 2010). In dough mixing, the distribution of dough ingredients and the hydration phase

occur concomitantly with the mechanical energy input (Peighambardoust et al., 2010). The dough must be mixed for a specific time identified as an optimum dough development to ensure optimal loaf volume and bread texture (Aït Kaddour et al., 2008).
The aim of this work was to investigate the influence of the mixing time and temperature on volatile compounds in dough made from triticale, hull-less barley, rye, rice and maize flour.

MATERIALS AND METHODS

Experiments were carried out at the Faculty of Food Technology, Latvia University of Agriculture. The data are reported as means of measurements made in triplicate, where each sample was obtained from a separately prepared batch of dough for each formulation.

Materials

Triticale, rye and hull-less barley crops of 2011 cultivated at the Priekuli Plant Breeding Institute (Latvia) were used in the current study. Triticale, rye and hull-less barley used for study were ground in a laboratory mill Hawos (Hawos Kornmühlen GmbH, Germany) obtaining whole grain fine flour. Rice and maize flour was purchased from Joint Stock Company Ustukiu Malunas (Lithuania). For this research there was used flour blend that contains 60% - whole grain triticale, 15% - whole grain hull-less barley, 15% - whole grain rye, 5% - rice and 5% - maize flour. Ingredients, such as sugar, salt, water and yeast are included in dough formulation in order to improve sensory properties and keep quality of bakery products.

Sample preparation

All flour samples were mixed together in one flour blend. For dough sample preparation there was used flour blend (250g), dried yeast (7.8 g), sugar (4.5 g), salt (3.8 g) and water (170 ml). Water temperature was calculated from formula (1) and it was adjusted accordingly before adding to flour blend. The preparation of samples and experiment scheme are shown in Figure 1.

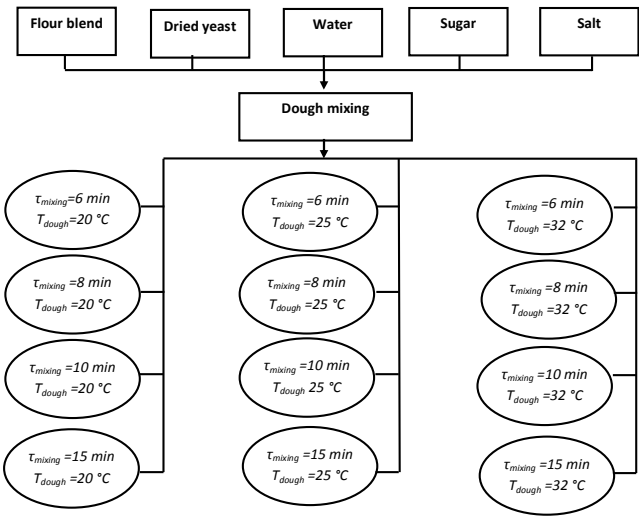

Figure 1. The preparation of samples and experiment scheme

The following abbreviations of the samples in the article are used:

- 6-20, 6-25, 6-32;
- 8-20, 8-25, 8-32;
- 10-20, 10-25, 10-32;
- 15-20, 15-25, 15-32.

Where the first number in the sample code: 6, 8, 10 and 15 – means dough mixing time in the experiment, but the second number 20, 25 and 32 – corresponds dough temperature.

Dough temperature
To obtain the required temperature of the dough the following calculation formula was used:

$$T_{water} = (2 \times T_{dough}) - T_{flour\ blend} \quad (1)$$

where:
T_{water} – temperature of the water, ºC;
T_{dough} – required dough temperature, ºC;
$T_{flour\ blend}$ – temperature of the flour blend, ºC.

Detection and identification of volatile aroma compounds
Volatile compounds were determined from flour blend dough samples using solid-phase microextraction (SPME) in a combination with gas chromatography/mass spectrometry. The SPME fibre was coated with a thin polymer film – Carboxen/Polydimethylsiloxane (CAR/PDMS). The film thickness is 85 μm with bipolar polarity (Supelco, Inc., USA). Volatile compounds were absorbed from dough to fibre in a closed mixer container in the mixing process at various temperatures for various duration according to the experimental design. Volatile compounds from fibre were thermally desorbed in the injector of a gas chromatograph-mass spectrometer '*Clarus 500 GC/MS'* (PerkinElmer, Inc., USA). The SPME extraction time was done for different duration of dough mixing: the first - extraction time is 6 min at dough temperature 20±2 °C without pre-incubation, the second – 6 min at 25±2 °C and the third – 6 min at 32±2 °C. Other samples were mixed for 8, 10 or 15 min at the above mentioned temperature.
Separation of volatiles was carried out in the Elite-Wax (PerkinElmer, Inc., USA) capillary column (60 m x 0.25 mm i.d., DF 0.25 μm). The details of the program used in GC–MS analysis are following: the initial temperature was 40 ºC, held for 7 min, then ramped from 40 °C to 160 °C at a rate of 6 °C min^{-1} and from 160 ºC to 210 °C at a rate of 10 °C min^{-1} with a hold time for 15 min. The total run time was 47 min for a sample. Mass spectrometer in Electron impact Ionization mode was set on 70 eV as the electron energies, while the ion source temperature was set to 250 °C and inlet line temperature was set to 250 °C. Injections were performed in splitless mode and helium (He) was used as carrier gas at a constant flow of 1 ml min^{-1}. Acquisition parameters in full scan mode: scanned m/z 40-300. Compounds were identified by comparison of their mass spectra with mass spectral library Nist98.

RESULTS AND DISCUSSION

It is an important factor in breadmaking that dough temperature should be kept under control during dough mixing (Li and Walker, 1992). To make dough in mixing process with required temperature (20±2, 25±2 and 32±2 °C) water temperature should be around 14, 21 and 42 °C, respectively. Temperatures of added water and mixed dough are shown in Table 1.
The calculated water temperature can be used at all times when the same mixer and the same weight of dough are used, for desired temperature of the dough in mixing process. Temperature deviations can influence the forming of volatile compounds in dough mixing time.

Table 1. Temperatures of added water and mixed dough

Sample code	Required dough temperature, °C	Added water temperature, °C	Mixed dough temperature, °C
6-20	20	14.00±0.26	21.43±0.25
6-25	25	22.10±0.26	25.07±0.40
6-32	32	43.17±0.23	32.10±0.36
8-20	20	12.60±0.26	22.00±0.44
8-25	25	21.47±0.06	25.50±0.20
8-32	32	42.00±0.00	31.57±0.21
10-20	20	12.77±0.06	21.80±0.26
10-25	25	20.77±0.21	26.23±0.49
10-32	32	42.17±0.15	32.30±0.26
15-20	20	12.77±0.06	21.80±0.26
15-25	25	20.77±0.21	26.23±0.49
15-32	32	42.17±0.15	32.30±0.26

Results are given as mean ± standard deviation (n = 3)

Cereal grains contain important flavour precursors, such as amino acids, fatty acids and phenolic compounds, which produce various flavours during processing – mixing, fermenting and baking (Hansen and Schieberle, 2005). All volatile compounds that were found in 6, 8, 10 and 15 minutes of dough mixing at various temperatures are shown in Table 2.

Table 2. Composition of volatile compounds in mixed flour blend dough

Compounds	Peak area ($\times 10^6$) depending on dough mixing time and temperature											
	6-20	8-20	10-20	15-20	6-25	8-25	10-25	15-25	6-32	8-32	10-32	15-32

n.d. – not detected
Results are given as mean (n = 3)

Analysing the collected data, in all dough samples there were indentified 8 alcohols, 2 carboxylic acids, 2 terpenes and 1 aldehyde. In all samples there were found 10 common volatile compounds (4-penten-2-ol, hexanal, D-limonene, 3-methyl-1-butanol, 1-hexanol, 1-octen-3-ol, heptanol, acetic acid, 2-methylpropanoic acid and carvone). Three of volatile compounds found in flour blend were D-limonene (value of volatile compound peak area – 28.17×10^6), 1-hexanol (77.84×10^6) and heptanol (5.84×10^6). And these volatile compounds were found in mixed dough, too. D-limonene, 1-hexanol and heptanol in mixed dough show smaller volatile compounds peak areas comparing to peak areas detected in flour blend samples.

The peak areas of detected 13 volatile compounds increased in dough mixing process, when the mixing time and dough temperature increased. The added raw materials and their amount can effect aroma formation in bakery products, too (Theile et al., 2002). The volatile

compound peak area of D-limonene increased slightly. This could be explained by the fact, that the D-limonene can oxidize easily in moist air to produce carveol, carvone, and limonene oxide (Karlberg et al., 1992). In the mixed dough there was identified a volatile compound – carvone, where the peak area increased in mixing process from 6 min (0.35×10^6) to 15 min (1.40×10^6), by 1.05×10^6. Alcohol 2-methyl-1-propanol was detected in the sample 6-32, but 1-penten-3-ol was detected only in the sample 8-25 (Table 2). The grain itself contains certain flavour – active volatile compounds, such as aldehydes, alcohols and ketones, of course they contain important flour precursors, too, such as amino acids, fatty acids and phenolic compounds, which produce various flavours during processing (Hansen and Schieberle, 2005). The highest value of peak area (29.95×10^6) among all detected volatile compounds had 4-penten-2-ol (alcohol) indentified after 15 min of dough mixing at temperature 32 °C.

Most of these compounds are well known to affect bread flavour and their origin is either associated with yeast, or they can be produced in dough mixing, fermentation and baking process. All of the detected volatile compounds can produce dough aroma: 3-methyl-1-butanol can be formed in yeast secondary metabolism, which gives malty flavour to dough, 2-methyl-1-propanol produces whiskey odour, 4-penten-2-ol – fruity, 1-hexanol – freshly mown grass, D-limonene and carvone – caraway odour (Schieberle, 1996; Kulp et al., 2003; Sabovics et al., 2011).

CONCLUSIONS

Solid-phase microextraction in combination with GC/MS can be used for detection of volatile compounds in mixed dough, changing mixing times and temperatures.

To make dough in mixing process with required temperature (20±2, 25±2 and 32±2 ºC) the water temperature should be around 14, 21 and 42 ºC, respectively. The calculated water temperature can be used at all times when the same mixer and the same weight of dough are used.

In all mixed dough samples totally 13 volatile compounds were detected, among them 10 volatile compounds were common for all samples: 4-penten-2-ol, hexanal, D-limonene, 3-methyl-1-butanol, 1-hexanol, 1-octen-3-ol, heptanol, acetic acid, carvone and 2-methylpropanoic acid.

Volatile compounds detected in mixed dough did not significantly differ at the same temperature, changing mixing times (6, 8, 10 and 15 min), but they significantly differ at the same mixing times, changing dough temperatures (20, 25 and 32 °C), except D-limonene, which did not significantly differ in both cases.

ABSTRACT: The objective of this research was to determine influence of different concentration of sugar beet molasses and the duration of the process of osmotic dehydration of carrot on apparent diffusion coefficients of water (D_w). Carrot samples were cut into cubes and immersed in different concentrations of sugar beet molasses (40.0%, 60.0% and 80.0% dry matter) during maximim process time of 5 hours. After each sampling time (60, 180 and 300 min) the carrot samples were weighed and analyzed for dry matter content. Solution concentration and immersion time had a significant influence on the D_w ($p<0.05$) at 95% confidence limit. Proposed equation that describes dependence of the concentration of osmotic solution and the time of osmotic dehydration on the apparent diffusion coefficient, can be successfully used for modeling process of osmotic dehydration of carrots in molasses solutions.
Key words: *osmotic dehydration, water apparent diffusivity coefficient, carrot, sugar beet molasses*

INTRODUCTION

Either fresh or processed, carrot *(Daucus carota)* is one of the most often used vegetable in human nutrition, primarily due to its nutrient, vitamin and dietetic value. Drying of carrot is very common way of its preservation. Dried carrot is a component of different mixed spices, instant soups, and already prepared meals. Pulverized dried are used as a supplement to various bakery products and cakes (Filipčev et al., 2010).
Osmotic dehydration (OD) is a mild process, which starts to be interesting because of the low processing temperature and energy requirements. OD is governed by osmotic pressure difference between the food material (hypotonic medium) and concentrated osmotic solution (hypertonic medium). The diffusion of water is accompanied by the simultaneous counter diffusion of solute from the osmotic solution into the tissue. Since the membrane responsible for osmotic transport is not perfectly selective, other solutes present in the cells can also be leached into the osmotic solution (Rastogi and Raghavarao, 2004). The rate and dewatering degree of the material and changes in its chemical composition depend on the type of the osmotic solution used, the kind and the size of raw material, as well as the ratio of material to osmotic solution, temperature, duration of dehydration, agitation of liquid solution and type of apparatus. Rate of OD is the highest at the beginning of the process. It results from the largest difference of osmotic pressure between the osmotic solution and the cell sap of the material and small mass transfer resistance at this stage of the process (Moreira and Sereno, 2003).
For fruits and vegetables dehydration, the most commonly used osmotic agents are sucrose and sodium chloride and their combination. Glucose, fructose, maltodextrin and sorbitol also can be used for osmotic dehydration (Ispir and Togrul, 2009). Recent research has shown that use of sugar beet molasses as hypertonic solution improves OD processes (Koprivica et al., 2009; Lević et al., 2007).
The Response Surface Methodology (RSM) equations describe effects of the test variables on the observed responses, determine test variables interrelationships and represent the combined effect of all test variables in the observed responses, enabling the experimenter to make efficient exploration of the process (Mišljenović et al., in press).

The objective of this paper is to determine the influence of different concentration of sugar beet molasses and the duration of the process of OD of carrot on apparent diffusion coefficients of water, calculated by the method for determination of the apparent diffusion coefficients proposed by Azuara et al., 1992.

MATERIAL AND METHODS

Carrot samples were purchased at a local market in Novi Sad (Serbia) and stored at 4ºC until use. Initial moisture content, $X_{0,}$ was 89.94 %. Prior to the treatment, the carrots were thoroughly washed and cut into cubes, dimension 1x1x1 cm. The amount of 100 g of carrot cubes samples were prepared for each treatment. Different concentrations of sugar beet molasses (40.0%, 60.0% and 80.0% dry matter) were used as osmotic solution. Sugar beet molasses was obtained from the sugar factory Pećinci, Serbia. Initial dry matter content in sugar beet molasses was 82.23%. For the dilution of sugar beet molasses distilled water was used. In all experiments, a weight ratio of solution to carrot samples was 8:1, considered high enough to neglect concentration changes during the process. The carrot cubes were put in a glass jars with 800 g of molasses solution and the jars were placed in the heat chamber under atmospheric pressure at 55ºC and manually agitated at every 15 minutes.
Dehydration lasted 5 hours and samples were taken out of the osmotic solution at different times (60, 180, and 300 min). After removal, carrot samples were washed with water and gently blotted in order to remove the excessive water. The samples were weighed and analyzed for dry matter content. Dry matter content of the samples was determined by drying the material at 105ºC for 24h in a heat chamber (Instrumentaria Sutjeska, Serbia) and measuring the weight loss of the product, gravimetrically on a scale. The solid content of the osmotic solutions was determined by Abbe refractometer, Carl Zeis Jenna (AOAC, 2000).

Osmotic dehydration
In order to describe the mass transfer kinetics of the OD, experimental data from three key process variables are usually obtained: moisture content, change in weight and change in the soluble solids. Using these, dry matter content (DMC) and water loss (WL), were calculated for different solutions and processing times as described by Mišljenović et. al, (2010).

Apparent diffusion coefficient of water
Apparent diffusion coefficients of water (D) were determined from experimental results of WL (g of water/g initial sample weight (i.s.w.)) after period of time t. The time interval in which is used the proposed model was 300 minutes. The results of the WL from Table 1 were used for calculating time/water loss ratio. Values of D of WL during OD in three different concentrations of molasses solutions, and four different times of dehydration were calculated from the following equation:

$$D = \left(\frac{WL}{WL_{\infty}}\right)^2 \cdot \left(\frac{\pi \cdot r_e^2}{36 \cdot t}\right) \text{ [m}^2\text{/s]},$$

Equivalent radius of the samples r_e , is calculated for the cubical shapes where sample had dimensions of 1x1x1 cm, and the equivalent radius r_e was calculated to be 6.205 mm.

Response Surface Methodology
The RSM method was selected to estimate the main effect of the process variables on D, during the OD. The independent variables were osmotic time (X_2) and concentration of osmotic solution (X_1), and the dependent variables observed was the D. The experimental data used for the determination study were obtained using a custom design, with 9 runs. A model was fitted to the response surface generated by the experiment:

$$Y_1 = \beta_0 + \sum_{i=1}^{2} \beta_i X_i + \sum_{i=1}^{2} \beta_{ii} X_i^2 + \sum_{i=1}^{2} \sum_{j=i+1}^{2} \beta_{ij} X_i X_j, \quad (1)$$

where: β_{kn} are constant regression coefficients.

Statistical analysis

Analysis of variance (ANOVA) and response surface regression method (RSM) were performed using StatSoft Statistica, for Windows, ver. 10 program. The model was obtained for each dependent variable (or response) where factors were rejected when their significance level was less than 90%. The same program was used for generation of graphs and contour plots.

RESULTS AND DISCUSSION

The essence of the OD process is to obtain high DMC in the treated samples in order to increase microbiological and enzymatic stability. In the Table 1. values of DMC, WL, equilibrium water loss (WL_∞) and D for OD of carrot in all osmotic solutions are shown.

Table 1. Values of Dry matter content, Water loss, Equilibrium water loss and apparent diffusion coefficient for osmotic dehydration of carrot

	Concentration of molasses solutions (% dry matter)	Time of OD (s)	DMC (%)	WL (g of water/g i.s.w.)	WL_∞ (g of water/g of sample)	D (10^{10} m^2/s)
	X_1	X_2	Initial=10.06			Y_1
1	40	3600	22.49	0.3103	0.6353	2.24[a]
2		10800	30.34	0.4779		1.76[b]
3		18000	36.44	0.5325		1.31[c]
4	60	3600	25.36	0.4370	0.8764	2.32[a]
5		10800	43.96	0.6696		1.82[b]
6		18000	51.37	0.7254		1.28[c]
7	80	3600	27.03	0.5312	0.9461	2.94[d]
8		10800	53.30	0.7672		2.04[e]
9		18000	64.66	0.8174		1.39[c]

[abc] different letters in the superscript in the same column indicate significant statistical difference between the values, at level of significance $p<0.05$

The increase in concentration and immersion time during the OD resulted in higher content of dry matter in the samples. The highest value of DMC in carrot samples, after 5 hours, (64.66 %) was achieved when 80% solid content sugar beet molasses was used as the osmotic solution. With this relative simple food preservation method, low energy required and nutritionally favorable, DMC were increased several times, which implicate that osmodehydrated carrot can be used as a raw material in the different food processing or could be suitable pre-treatment for other preservation technique (convective drying, freeze drying…) (Pavkov et al., 2008). It was observed that concentration and dehydration time have important effect on the carrot dehydration rate. Rapid loss of water in the beginning is apparently due to the large osmotic driving force between the dilute sap of the fresh carrot and the surrounding hypertonic solution. Higher concentrations of molasses increased the osmotic pressure gradient and, hence, higher WL. The highest WL (0.8173 g/g of i.s.w.) was observed in the sample which was dehydrated in molasses with 80% solid content for 5 hours.

The highest values of D were calculated for the WL in the samples of carrot dehydrated in the most concentrated osmotic solution (80%) during the shortest period of time (60 minutes). With the extension of the time of OD, values of D has started to decline, so the

value of D at the time of osmotic dehydration of 300 minutes was only 47.28% of the value of D during the dehydration time of 60 minutes.
The value of D for WL at the time of the dehydration for 60 minutes in the osmotic solution with concentration of 40% of dry matter was 76.19% of the value of D at the same duration of dehydration in the osmotic solution with concentration of 80% of dry matter. These results can be explained by higher driving force for water diffusion due to the higher difference of osmotic pressure between more concentrated osmotic solution and sample of carrot than the gradient of osmotic pressure between less concentrated osmotic solution and sample of carrot.
ANOVA test was conducted by StatSoft Statistica, ver. 10 to show the significant effects of the independent variables to D, and also is it significantly affected by the varying treatment combinations (Table 1). D was found significantly affected by both process variables, treatment time and concentration, at 95% confidence level. The main influential variable seems to be the treatment time ($F=295.48$, $p<0.01$), concentration term is also very influential ($F=26.79$, $p<0.05$). Quadratic term for treatment time was not significant ($F=0.46$, $p>0.05$), while quadratic term for concentration were found significant at $p<0.10$ level ($F=5.61$). The interrelation term was found statistically significant, at 95% confidence level ($F=13.75$, $p<0.05$). A high r^2 (0.991) is indicative that the variation was accounted and that the data fitted satisfactorily to the proposed model, and it was found very satisfactory and showed the good fitting of the model to experimental results. Tab. 2 shows the ANOVA calculation for the response second order polynomial (SOP) models, eq. (1) of apparent diffusion coefficient, and Table 3 shows regression coefficients for D.

Table 2. ANOVA table for system responces, showing the variables as a linear, quadratic and cross terms on each response variable

Term	Source	Sum of Squares			
		df	*DMC*	*WL*	*D*

	Time	1	1003.368*	0,106*	2,065*
Quadratic	Conc (quad)	1	2.816^{ns}	0,003**	0,039**
	Time (quad)	1	43.090**	0,013*	0,003 ^{ns}
Crossproduct	Time Conc	1	140.186*	0,001 ^{ns}	0,096*
Error	Error	17	15.357	0,001	0,021
r^2			99.108	99.600	99.131

*Significant at 95% confidence level,**Significant at 90% confidence level,
^{ns}Not significant

Table 3. Regression coefficients of the SOP model for D

β_0	$\beta_1 \cdot 10^2$	$\beta_{11} \cdot 10^4$	$\beta_2 \cdot 10^5$	$\beta_{22} \cdot 10^9$	$\beta_{12} \cdot 10^6$
2.78± 0.55*	-2.15± 1.81 ^{ns}	3.50± 1.48**	-3.36± 3.05^{ns}	7.72± 11.41 ^{ns}	-1.08± 0.29 **

*Significant at 95% confidence level,**Significant at 90% confidence level,
^{ns}Not significant

The contour plots developed from the approximating SOP model is shown on Fig. 1. The contour plot for D showed a saddle point configuration, and its value raised to the lower right corner of the plot, with the increase of concentration, and with lowering the treatment time.

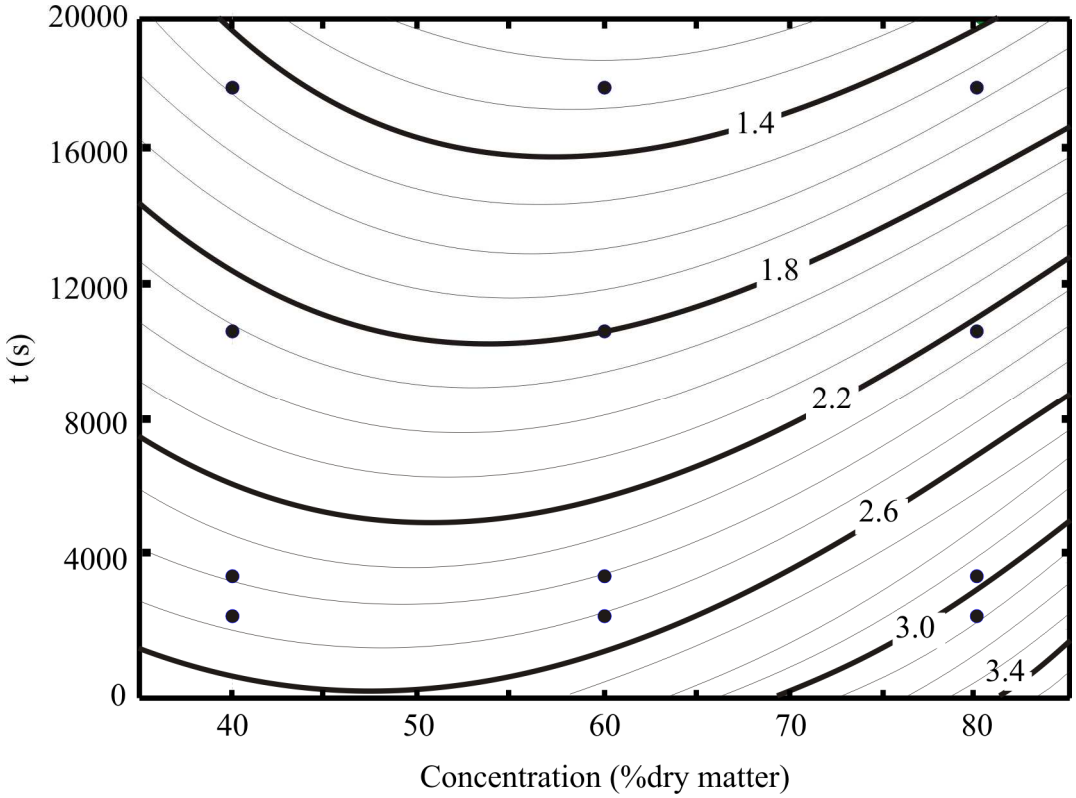

Figure 1. Contour plots for D e10 as a function of concentration of osmotic solution and treatment time time

CONCLUSION

The highest values of dry matter content (64.66 %) and water loss (0.8173 g/g of i.s.w.) were observed in the samples of carrot dehydrated in molasses with 80% solid content for 5 hours.
Values of the D of water from carrot in osmotic solutions of molasses ranged from $1.28 \cdot 10^{-10}$ m^2/s to $2.94 \cdot 10^{-10}$ m^2/s.
D was found significantly affected by all process variables, treatment time and concentration, at 95% confidence level.
Proposed equation that describes dependance of the concentration of osmotic solution and the time of osmotic dehydration on the apparent diffusion coefficient, due to the high coefficient of correlation can be successfully used for modeling process of osmotic dehydration of carrots in molasses solutions.
A new environmentally friendly value has been added to the molasses, wich is a by-product of sugar beet production, by extension of it's usage as a osmotic solution in a low energy required process of osmotic dehydration.

ABSTRACT: In accordance with the national strategy for sustainable development, the objective of our investigation is to develop innovative technology for a higher level of raspberries processing and to obtain products for the food and confectionery industries, as well as the active ingredients for the functional foods and dietary supplements. The concept of food engineering is applied in the development and scale up of processes from laboratory to semi-industrial level. Key entities of the product quality for medical application are verified by antioxidant capacity, anti-microbial and anti-cancer effects. Incremental innovation is achieved in the process development and additive innovation in the design of technical solutions. A preliminary economic feasibility shows positive effects in relation to the raspberries costs for the higher level of processing, domestic market capacity and sales prices of competitive products. The current level of innovative technology and estimated economic indicators provide the basis for the development of industrial technology, competitive production and international technology transfer through a business model based on partnership relations with the use of development funds, loans and grants.
Key words: *berry fruits, higher level processing, food engineering, innovation, economic indicators*

INTRODUCTION

Serbia has a large quantity of natural and acquired raw material resources available in agriculture and in food industry. The natural raw material resources are exported or used for lower phase of preparation. The acquired resources are mostly used as waste material. The existing, available technological equipment capacities of chemical, food and pharmaceutical industries (Hranisavljević, 2007), would be used for manufacturing bulk products for food and confectionery industries and the medical substances for functional foods and dietary supplements.

The fruit processing chain is at a low level within the current development and a food product range. Serbia exports fruit as frozen products, processed at the lowest level (Hranisavljević, 2010). In the case of the berry fruits (raspberries, blackberries, etc…) the products of a higher processing level are mostly imported.

On a global scale, raspberries are very important in many different fields, from food and confectionery to pharmaceutical and cosmetics products. Raspberries are a significant source of anthocyanins and quercetin, the powerful antioxidants. These decelerate the effects of aging, prevent cancer and may reduce the risk of heart disease. Quercetin also reduces the release of histamines, which may minimize allergic reaction. In addition, raspberries are a significant source of ellagic acid, a phenolic compound known to have potential anti-carcinogenic features (www.bremnerfoods.com). Raspberry seed oil has very important application. Red raspberry seed oil is a superb antioxidant. It contains 83% essential fatty acids, especially high levels of Omega-3 and Omega-6 acids, and exceptionally high levels of alpha and gamma tocopherols, Vitamin E. Thus, the red raspberry oil is known especially for the prevention of gingivitis rashes, eczema and other skin lesion and sun protection. It is useful in skin creams, bath oils and tooth paste (www.man-gmbh.com).

Domestic production of raspberry's products is poorly represented and is carried out according to traditional methods and with small production capacities. During 2010, Serbia exported about 80% of frozen and fresh raspberry, while the remaining stock was used for the production of jams, concentrates, juices, etc... Over the years, the production of jams, marmalades, purees and pastes has been increasing. Serbia exported about 53 tones of them in 2010 (www.trademap.org).
In accordance with the National strategy for sustainable development, the aim of the case study presented in this paper is a part of our investigation (Hranisavljević, 2011) to develop innovative technologies for a higher level of raspberries processing and to obtain bulk products for the food and confectionery industries (juice concentrate, natural aroma, natural colors), as well as active ingredients for functional foods and dietary supplements (seeds, pectin).

MATERIAL AND METHODS

The process engineering concept (Kolomejcova, 2001; Mahoney, 2006) is applied in the innovative development for higher level of raspberries preparation.
Incremental innovation is achieved in the key process development and additive innovation in the design of technical solutions.
Key entities of the product quality were dry material content and pectin concentration. In the case of medical application, the products quality will be verified by antioxidant capacity, anti-microbial and anti-cancer effects analysis (Hranisavljević, 2011-2015).
A preliminary economic effect was defined in relation to the raspberries costs for the higher level of processing, domestic market capacity and sales prices of competitive products.
The business model based on partnership between the research Institutes and the University is applied.

RESULTS AND DISCUSSION

The technologies are developed for a higher level of the raspberry processing with the aim of obtaining products of various profiles (Table 1)

Table 1. Product profiles of raspberries at the higher processing level

Product name	Product Category	Use of product
aroma concentrate	final semi-product	natural aroma juice concentrate with aroma
juice concentrate	final semi-product	natural colors no aroma juice concentrate with aroma
juice concentrate with Aroma	final semi-product	natural colors with aroma syrup
protopectin	semi-product	syrup, jam, jelly
seeds powder	final	dietary supplement

The eco-friendly technologies are developed. Thus, seeds and aroma are obtained as products and not treated as waste. Processes and technical solutions enable utilization of all the active ingredients from the raspberry fruit and integrated outcome of a several final products of processing (Figure 1).

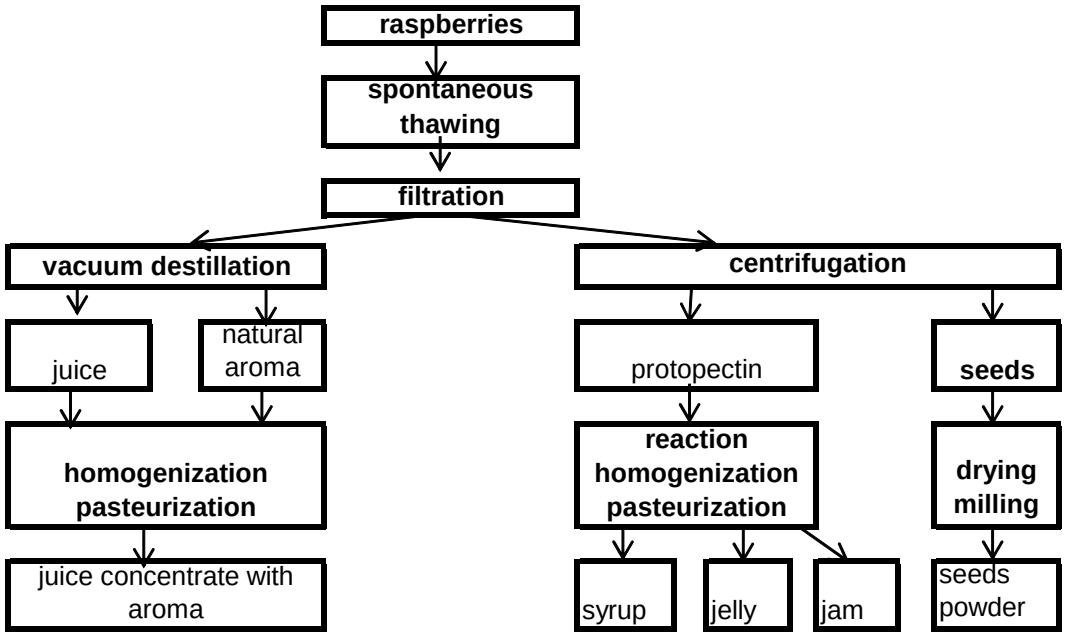

Figure 1. Flow diagram for the higher level of raspberries processing

Spontaneous thawing of raspberry as a critical process is performed at the temperature of t=20-30 ^{0} C with the absence of oxygen and light. During this step the tanning reactions (enzymatic and non enzymatic) are carried out at the temperature of t = 20-25^{0}C resulting in a greater concentration of coloring substances (flavonoides), increased antioxidant capacity and biological activities of the products obtained.

The protopectin is reactant in the hidrolysis to the pectin production The reaction was carrried out at the temperature t = 85^{0}C and pH 3,2-3,5. At the same time the homogenization and pasteurization are performed. The native ingredients in raspberries obtain a higher viscosity and degree of gelling depend on the pectin concentration.

In all technological stages the temperature is lower than t = 85^0 C, thus reducing the denaturation of biologically active substances in raspberries. Short retention time of material flows at the target temperatures creates conditions for the energy efficient technologies.

A technical solution for condensation the aroma is designed. The 2-stage vacuum destillation of aroma-water mixture evaporation is applied. The destillation was carried out at vaccum of 740 mmHg and temperature t = 20-25^{0}C. The technical solution being easier to use, more favorable in terms of energy efficiency and more acceptable in terms of investment, compared to the traditional process of rectification.

The concept of modular technology is applied. The modules are formed with standard processing equipment in accordance with the technology for obtaining a target final product. (Figure1). The concept allows for the efficient use of available production capacity in the domestic food and pharmaceutical industries, and the contents of modules can also be applied in processing other types of berries.

A preliminary economic feasibility shows positive effects in the application of the concept of integrated obtaining the products (Table 1, Figure 1). Based on the achieved material balance for the amount of final products and semi-products from 1kg of raspberries and the selling prices for the same amount of imported final products, the share of the raspberries purchase price in the aggregate selling price of the product is 1-3%.

CONCLUSIONS

Incremental innovation was achieved for the higher level of raspberries processing by using the integral concept at semi-industrial scale.
The modular technological concept was applied and additive innovation for existing technological equipment was achieved.
Non-waste and energy efficient technologies were developed, thus maintaining active ingredients of raspberries.
It is possible to develop a pilot-sample product at a higher level of the raspberry processing for investigating the domestic market with the aim of substituting the product import.
The final product for the food and confectionery industries (juice concentrate, natural aroma, natural colors), as well as the active substances for dietary supplements and functional food (seeds, pectine) were obtained.
Under the conditions of integrated output of the final products, the material balance achieved shows economically efficient participation of the raspberry price in the selling prices of imported products.
The achieved level of innovative technology and the preliminary economic indicators establish a basis for the industrial development of technologies and for competitive production.
Valorization of own knowledge could be possible via the development of technology export through the mechanisms of international technology transfers.
The innovation of a business model is possible through the strategic alliance and the cluster-based networking of the raspberry producers, small and medium-sized enterprises, as well as through the use of government and regional development funds, loans, and grants.

ABSTRACT: This study aimed at evaluating the textural properties of quince in fresh and after drying at different conditions. In parallel, colour was also measured to evaluate how the visual aspect of the product changed with drying. The experiments were done in a tunnel drier, at different temperatures, from 30 to 60ºC, and different air velocities, varying in the range 0.7 to 1.2 m/s. The colour coordinates of the fresh quince were: L* = 78.02±0.86, a* = - 1.27±0.32 and b* = 31.75±1.68. These values indicate that the samples were bright, because L* was closer to 100 than to 0. Furthermore, it can be seen that quince was greenish, although very slightly and strongly yellowish. With drying, the samples became darker and redness was intensified, as a result of browning. In relation to the textural properties in fresh, the values were: hardness = 48.46±6.47 (N), springiness = 74.86±5.17 (%), cohesiveness = 0.75±0.06, resilience = 0.47±0.08 and chewiness = 27.23±4.06 (N). Furthermore, it was observed that drying, regardless of the conditions, induced an important hardening, increasing hardness and diminishing springiness.
Key words: *quince, drying, texture, colour, hardness*

INTRODUCTION

Quince is characterized by many flavour compounds derived from oxidative degradation of carotenoids, with the majority of them belonging to the class of thirteen carbon (C_{13}) norisoprenoids (Lutz-Roder et al., 2002). In addition to their potent antioxidant activity, it has an anti-inflammatory effect of a non-toxic, cost-effective natural agent (Essafi-Benkhadir et al., 2012). The chemical composition of its fruits (*Cydonia oblonga* Miller) range from 11.5 to 14.7 ºBrix, with fructose and glucose as predominant sugars, malic acid (0.78 %) as the main organic acid, followed by tartaric (0.22 %) and citric acids (0.009–0.014 %), besides having a low fat content. Furthermore, quince also is a source of dietary fibre, mostly pectic and cellulosic polysaccharides, and consequently it has been used in production of fibre rich powders (Pla et al., 2010; Thomas et al., 2000, Rodríguez-Guisado, 2009).
Besides its nutritional properties and health benefits, quince is used mostly for cooking preparations such as cookies, jellies, jams or marmalades since it is relatively hard, bitter and astringent (Silva et al., 2006). However, as the drying allows softening the pulp of the fruits, dried quince appears as an alternative to its fresh consumption. Different methods of drying are used to dry fruits and vegetables but all of them have a potential impact on the quality of the dehydrated products, namely on colour and texture properties. Therefore, the evaluation of both characteristics after drying is a pivotal aspect, since there is a strong impact on acceptability by consumers. Many works in the literature have studied the impact of different drying methods on the quality and properties of different fruits and vegetables such as red pepper (Doymaz and Pala, 2002), blueberries (Shi et al., 2008), potato (Leeratanarak et al., 2006), banana (Prachayawarakorn et al., 2008), apple (Mandala et al., 2005), bell pepper and pumpkin (Guiné and Barroca, 2011, 2012), mushrooms and onions (Guiné and Barroca, 2011a). Even though there have been a few works on drying of quince (Kaya et al., 2007; Koç et al., 2008) none of them has analysed their quality attributes.
The present study aims to compare the colour and texture properties of the quince in fresh and after drying in a tunnel drier, at different temperatures, from 30 to 60 ºC, and different air velocities, varying in the range 0.7 to 1.2 m/s.

MATERIAL AND METHODS

Drying

Quince was washed and cut into slices which were placed in a tunnel drier (Tray Drier UOP-8, Armfield). Drying experiments were performed under different conditions, namely varying air velocity and temperature. The values tested for air velocity were 0.7, 0.9 and 1.2 m/s and the temperatures essayed were 40, 50 and 60 ºC.

Colour evaluation

The colour of the fresh and dried samples was measured using a handheld tristimulus colorimeter (Chroma Meter - CR-400, Konica Minolta). A CIE standard illuminant D65 was used for calibration and the colour coordinates L*a*b* of the CIELab colour space were determined. From the Cartesian coordinates (L*a*b*) the total colour difference (□E) was calculated by equation (1):

$$\Delta E = \sqrt{(L^*_0 - L^*)^2 + (a^*_0 - a^*)^2 + (b^*_0 - b^*)^2} \quad (1)$$

having the fresh product as reference, with coordinates L^*_0, a^*_0, b^*_0.

The Cartesian colour coordinates were then used to calculate the cylindrical coordinates, chroma and hue, by the following equations:

$$\text{Chroma} = \sqrt{a^{*2} + b^{*2}} \quad (2)$$

$$\text{Hue}\,(^o) = \text{atan}\left(\frac{b^*}{a^*}\right) \quad (3)$$

For the colour determinations twenty samples were analysed for each state (fresh and different dryings) and the mean values and standard deviations were calculated for each set.

Texture measurements

Texture profile analysis (TPA) to all the samples was performed using a Texture Analyser (model TA.XT.Plus from Stable Micro Systems). The texture profile analysis was carried out by two compression cycles between parallel plates performed using a flat 75 mm diameter plunger, with a 5 second period of time between cycles. A force load cell of 5 kg was used and the test speed was 0.5 mm/s. TPAs were performed in 20 samples for each state, and the textural properties: hardness, springiness, resilience, cohesiveness, and chewiness were calculated after the following equations (see Figure 1):

$$\text{Hardness (N)} = F_1 \quad (4)$$

$$\text{Springiness (\%)} = \square T_2/\square T_1 * 100 \quad (5)$$

$$\text{Resilience} = A_2/A_1 \quad (6)$$

$$\text{Cohesiveness} = A_3/(A_1+A_2) \quad (7)$$

$$\text{Chewiness (N)} = F_1 * \square T_2/\square T_1 * A_3/(A_1+A_2) \quad (8)$$

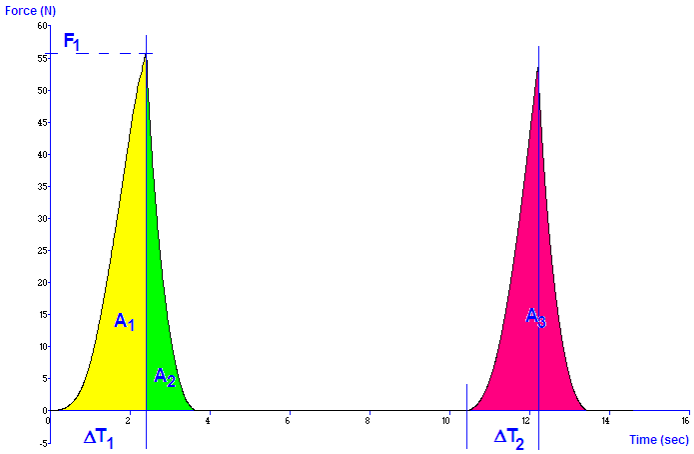

Figure 1. Example of a texture profile analysis.

RESULTS AND DISCUSSION

Figure 2 shows the variations through time of the experimental values measured for the Cartesian colour coordinates: L*, a* and b* for fresh and dried quince. The values of these coordinates indicate that the quince fresh pulp is clear (L* = 78.02±0.86), slightly green (a* = - 1.27±0.32), and very yellow (b* = 31.75±1.68). In general, drying produces a darker, redder and more yellow product when compared to the fresh product. Furthermore, it is possible to see that the increase in temperature from 40 ºC to 60 ºC had a small effect on the colour parameters since the brightness, L*, and the two opposing colour, a* and b*, ranged, respectively, from 74.41 to 71.80, 8.09 to 9.33 and 35.77 to 37.23.
For a temperature of 60 ºC, the increase in air velocity from 0.7 to 1.2 m/s also had a reduced effect on the colour parameters.

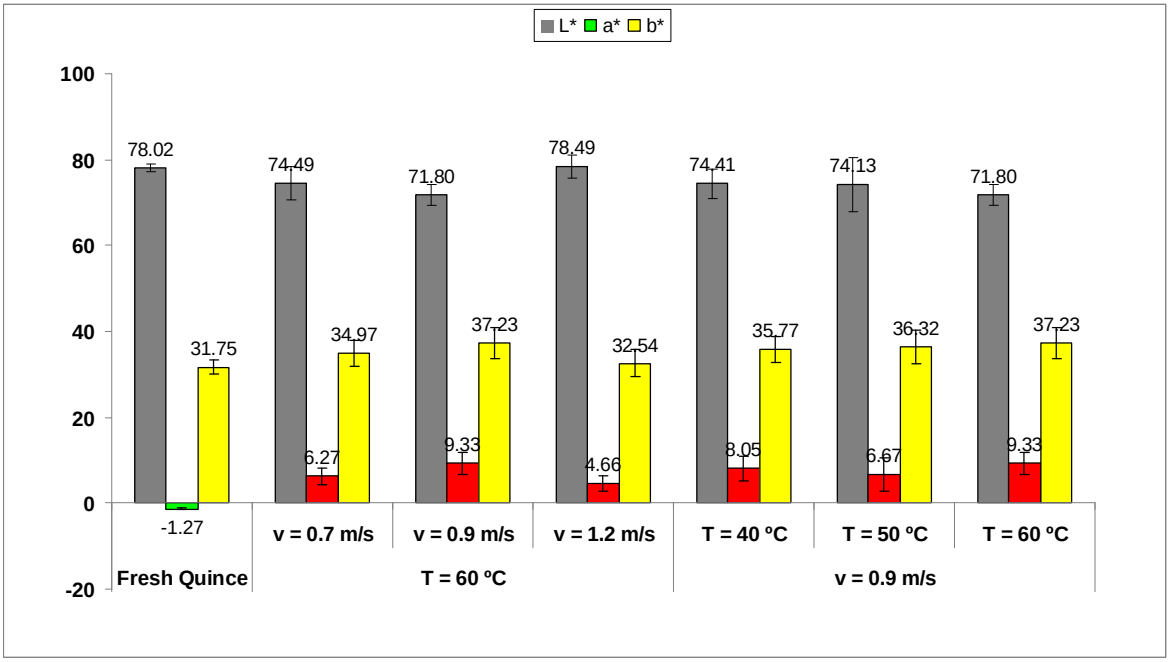

Figure 2. CIELab colour coordinates for fresh and dried quince.

Figure 3 reveals the total colour difference, which was calculated according to Equation (1), and quantifies the deviation of colour in relation to the reference colour. The range of temperatures and velocities studied induced a maximum colour difference of 13.45 in relation to the fresh quince, and this happened for the drying at 60 ºC and 0.9 m/s.

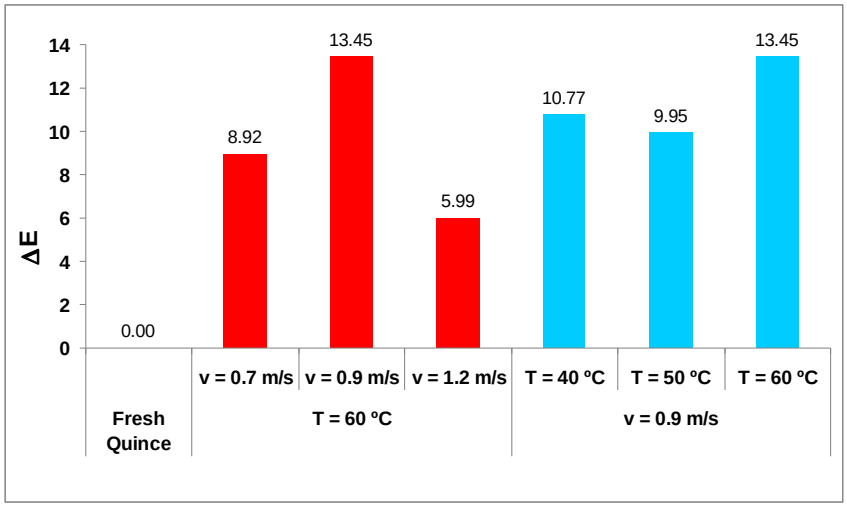

Figure 3. Total colour difference for dried quince samples.

Figure 4 presents the cylindrical coordinates, chroma and hue angle, calculated by Equations (2) and (3).The tunnel drying induces a small effect on intensification of colour (chroma), but moves the hue angle from the yellow colour to the red zone, although staying far from the fully red (0º), as compared with the fresh state. However, the operating factors temperature and air velocity had a slight effect on both cylindrical coordinates.

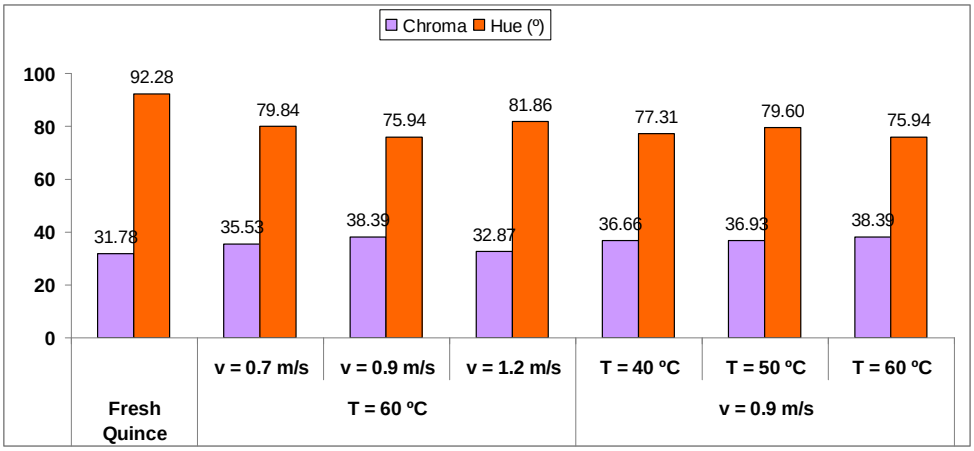

Figure 4. Cylindrical colour coordinates for fresh and dried quince.

Figure 5 highlights the results of hardness and chewiness obtained for the fresh and dried quince. It can be seen that the hardness of fresh quince is much lower than that of the dried state, independently of the operation conditions. This means that the drying intensifies the quince hardness and, consequently, the dried quince requires more energy than the fresh quince for the first bite. The hardness of fresh quince is 48.46 N against 87.26 N and 103.62 N, respectively, for 40 ºC with 0.9 m/s and 60 ºC with 1.2 m/s, which are the minimum and maximum values obtained after drying. However, the effect of drying on the energy required for chewing the quince until it is ready for swallowing, measured by the chewiness, is much less pronounced than in hardness.

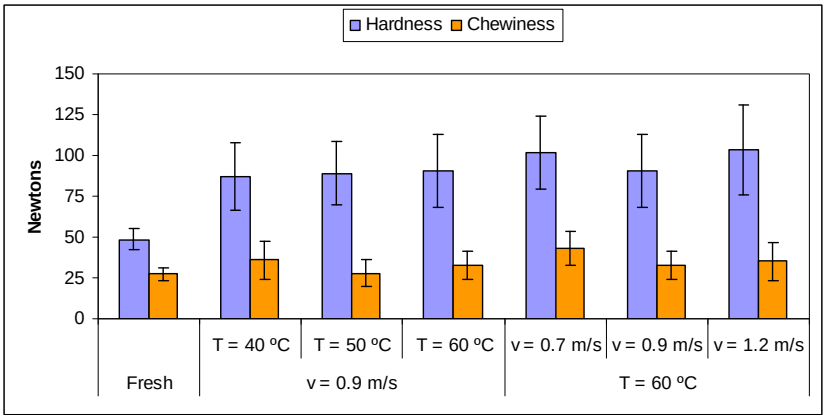

Figure 5. Hardness and chewiness of fresh and dried quince.

As seen in Figure 6, the drying has no visible effect on cohesiveness, which is related to the strength of the internal bonds of the sample neither on the capability of the sample to recover its size and shape after deformation (resilience).

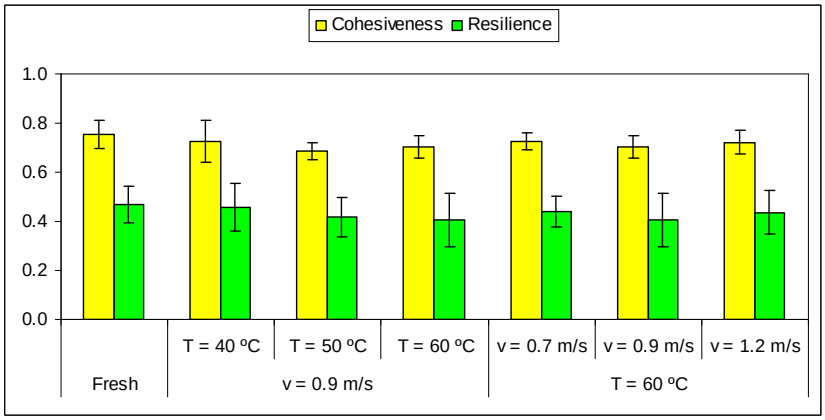

Figure 6. Cohesiveness and resilience of fresh and dried quince.

Figure 7 reveals that drying contributes to the reduction of the springiness of quince since the value of 74.86 % in fresh fruit is decreased to values near 50 % after drying.

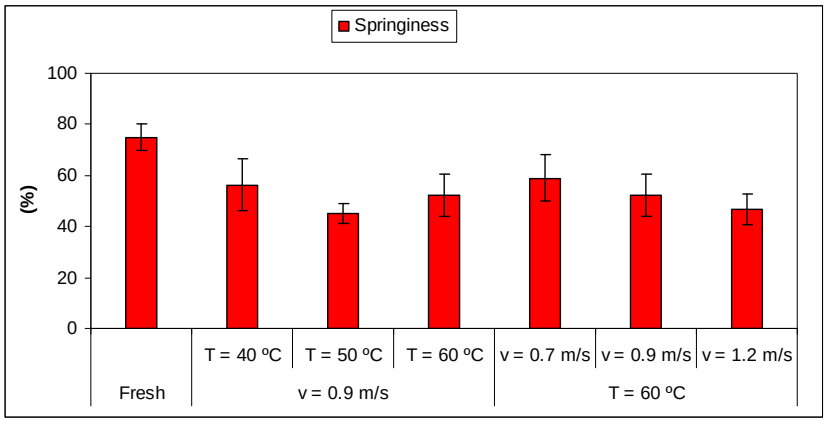

Figure 7. Springiness of fresh and dried quince.

CONCLUSIONS

Based on the results it was possible to conclude that tunnel drying produces a darker, redder and more yellow product, in relation to the fresh product, independently of the experimental conditions used. Besides that, the increase in temperature and air velocity had a slight effect on colour attributes (maximum colour difference, chroma and hue angle) in the range of temperatures and air velocities studied.

With respect to the textural attributes, it was observed that tunnel drying substantially influenced the hardness and springiness, regardless of the conditions, since induced an important increasing in hardness and a decreasing on springiness. The chewiness is another textural property that increases with drying, although not so strongly as hardness. The values of cohesiveness and resilience were not affected with drying, since the value in the fresh state is approximately the same as in the dried state, independently of the temperature and air velocity.

ABSTRACT: Pasteurized eggs exhibit better keeping quality and longer shelf life in comparison with un Pasteurized eggs. Also pasteurization guarantees the consumer's safety but thermal processing affects the egg proteins quality therefore in this study, microwave heating has been considered for white liquid egg pasteurization. White liquid was pasteurized by using electromagnetic method in two different frequencies (2950-4500 MHz) and both frequencies together for constant times of (3,5,6) second and two pulses (1,2), then with blank samples after different storage times (5, 15, 60, 180 and 360 days), the population of aerobic mesophilic bacteria, coliforms and molds & yeasts were measured. Results revealed that the effect of four variables include adding frequency, duration process, number of pulses and pasteurized product durability on reduction of total mesophilic aerobic count was statistically significant and the number of bacteria in the 360 th day in the pasteurized and blank specimens were $1/8\times10^4$ cfu/ml and $2/15\times10^6$ cfu/ml respectively. The number of coliforms in pasteurized samples were less than 10 pcs/mL and in the blank samples were $1/15\times10^4$ cfu/ml as the number of molds & yeasts in pasteurized samples were less than 30 pcs/mL while in the blank samples were $7/5\times10^3$ cfu / ml. According to Iranian National Standard, in electromagnetic method, liquid white shelf life has been defined 360 days which it is very ideal in comparison with thermal pasteurization (7d max) and blank sample (2d max).

INTRODUCTION

Eggs are one of the most commonly consumed food products e.g. Many of the dishes like Caesar salad, hollandaise or béarnaise sauce, mayonnaise, eggnog, ice creams, egg fortified beverages etc. (Mermelstein 2001). Eggs are potential hosts and carriers for pathogenic microbes like Salmonella enteritidis, because of their rich nutritive values therefore heat pasteurization is a best solution for controlling these pathogens. Egg is used as a vital ingredient in several foods, especially for its exceptional functional properties. These properties mainly depend on the egg proteins quality and because of proteins denaturation are severely affected by heating (Dev, 2007). Egg proteins are highly heat sensitive components which in turn high temperatures have an undesirable effect on their functional properties like whipability, foamability, foam stability etc. (Hank et al. 2001). Microwaves can be used to raise the temperature of in-shell eggs to the required pasteurization temperature in a few minutes. (Tajchakavit 1997). Microwaves are not ionising radiations but the dielectric properties of the microorganism (i.e. heat generated within the microorganism), itself enhance its destruction in a microwave environment. The microwave power distribution inside the shell eggs also seems to be well suited for uniform pasteurization (Datta et al, 2005).

There are very restricted researches on making microwave pasteurization viable for industrial use and limited literatures are available. Egg microwave pasteurization could make the process faster, continuous and the total operation could be completed in a few minutes. The shell egg appears ideally suited for pasteurization in a microwave environment (Fleischman 2004; Rehkopf 2005). This study examined the effect of cold pasteurization by electromagnetic waves (microwave) on liquid egg white and followed by comparing the population of total mesophilic aerobic bacteria, coliform and molds & yeasts after different storage times (5, 15, 60, 180 and 360 days).

MATERIAL AND METHODS

Sample preparation

Samples were selected from a fresh and healthy batch of egg and they were broken by egg breaker equipment, and were separated (yolk and white egg) then were filtered (to separate crust and small particles) and after that were homogenized. These were performed by selecting 190 samples of 100 g from 100kg liquid white randomly and they were filled in special poly ethylene bags automatically after filtering and were stored at 0 to 4ºC until experiments.

Instrumentals specifications

Electromagnetic pasteurizer which was able to work in variety of temperatures, times and frequencies, was used (model SCP150, Afra Sanat Kimia Mashhad co, Mashhad, Iran).

Methods

190 pcs of 100 g samples in accordance with those mentioned above were prepared and 60 samples randomly selected within the reservoir system was placed and the frequency of 2950 MHz as pasteurized in 10 samples in a pulse of 3 seconds -10 sample a pulse of 5 seconds -10 samples in a pulse of 6 seconds -10 sample two pulses 3 seconds (6 seconds) -10 of the two pulses 5 seconds (10 seconds) -10 of the two pulses 6 seconds (12 seconds) and Also randomly selected 60 samples exactly the same way and at a frequency of 4500 MHz was pasteurized. 60 samples with random acts of two frequencies were pasteurized and 10 samples as control samples (non-pasteurized) were selected. Furthermore the effect of storage times on samples microorganisms that were treated in the appropriate conditions (0-4℃) for a period of 5, 15, 60, 180, 360 days, were examined. At the designated time, 36 samples from 18 treatment of the (two repeats) and two control samples for microbial cultures transferred to the laboratory for cultivation with culture medium of plate count agar in 2 repeat, and cultivated in 30 ˚C for 72 hours according to national standard NO. 5272,13248, and Total Aerobic Mesophilic Count (TAMC) and with culture medium of violet red bile agar in 2 repeat, and cultivated in 37 ˚C for 24 hours according to national standard NO. 11166,13248, and Total coliforms and with culture medium of yeasts glucose agar in 2 repeat, and cultivated in 25 ˚C for 120 hours according to national standard NO. 10899, 13248 and molds & yeasts were determined.

Statistical analysis

Each treatment was analyzed as randomized complete block design with ten replications and the data were assessed by analysis of variance (ANOVA) and Duncan s multiple range test using MSTAT-C software program. Differences among treatments were tested with least significant difference (LSD) test ($P<0.05$). Besides, correlation analyses were preformed to clarify the relations among parameters considered in this study. Microsoft Excel 2007 was used to plot apparent.

RESULTS AND DISCUSSION

The effect of different frequency electromagnetic (microwave) and different times of the frequency on microorganisms

Microwave energy inactivates micro-organisms through thermal kill and also has enough potential to cause biological damages as well as alteration of the cell membrane and metabolic functions. This injurious effect on the vegetative cells and may induce additional lethality and impair the recovery during the subsequent time period of product storage (Huang, 1989). In this study, the two frequencies 2950, 4500 MHz and two (4500 +2950 MHz) with a pulse time of 3, 5, 6 and 2 pulses time 3.5, 6 seconds (6,10,12 seconds total times) on liquid egg white was investigated. Results showed that pasteurization with electromagnetic waves, the number of microorganisms which were present in the liquid egg white, were reduced to the convention. In the first test of the fifth day, the total mesophilic aerobic count in pasteurized and control samples were $2/05\times10^2$ and $7/2\times10^3$ cfu/ml, respectively and also coliforms and yeasts & molds were found in pasteurized samples (table 1). This indicates that in wave pasteurization, the number of total mesophilic aerobic bacteria, coliforms and yeasts & molds dropped to 1/55, 0/95 and 1/6 logarithmic cycles as high as the blank samples, respectively. The results confirmed the results of kozempel et al. (1999) which reported microwave energy has a significant effect on reduction of microbial population in egg yolk liquid (Kozempel *et al.,* 1999). The results also agreed with results of Dev et al. (2008) which has been considered microwave heating for in-shell egg pasteurization. First of all, the effects of temperature (0-62^{o}C) and frequency (200 MHz to 10 GHz) on the dielectric properties of egg components were investigated. Laboratory trials on microwave heating of in-shell eggs indicated that the heating rates of both albumen and yolk were similar. Therefore, microwave heating appeared perfectly suited for in-shell egg pasteurization (Dev *et al.,* 2008). According to results, that obtained from statistical analyzes, effect on adding frequency variants ($P<0.05$) and pasteurized product durability ($P<0.0001$) on reduction of total aerobic mesophilic count in white egg in α level of 0.05 (95% probability) and it was statistically significant, and interaction was observed between studied variants in cold pasteurization process. Storage time which was studied up to 360 days has a higher effect on total aerobic mesophilic count than various frequencies applied so the value of increasing TAMC was higher than reduction of it during white liquid pasteurization process by different electromagnetic waves. The results showed (Figure 1) the total of treatments, the frequency 4500 MHz with a total of two frequencies (4500 and 2950) was almost similar and the average number of bacteria in mesophilic aerobic was 3.6 cfu/ml log (4×10^3 cfu/ml), but the 2950 MHz frequency have poorer performance and aerobic mesophilic bacteria in the samples treated with the cfu/ml 9.3 log (8.3×10^3 cfu/ml), respectively. It showed that 2450 MHz frequency is better than 915 MHz frequency in pasteurization and sterilization, and higher frequencies will increase killing effects (Tang *et al.* 2002).

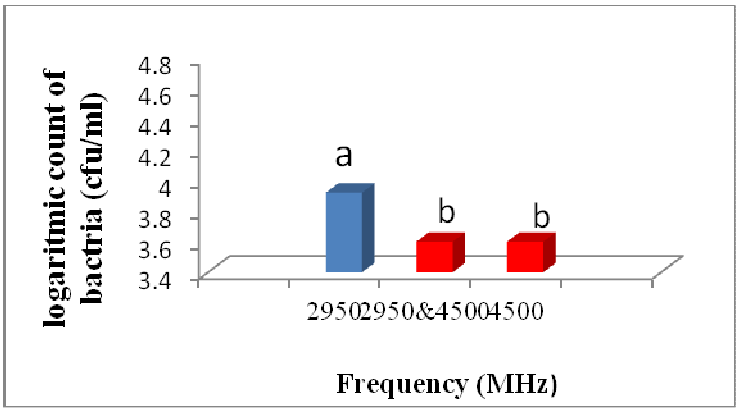

Figure 1.Effects of different frequencies on TAMC in liquid egg white cold pasteurization procedure

Effect of time process of the fatality of microorganisms and the short time pasteurization process and produce a higher quality product

Results also showed that the time process of the fatality rate is effective and often the higher frequency result in higher case fatality rate. The number of aerobic mesophilic bacteria at 3, 5, 6 respectively cfu/ml 3.63, 3.72, 3.83 is the logarithmic terms (Fig. 2). The higher pulse number dues to the higher fatality rate and lower total bacteria count (Fig. 3). Microwave sterilization can deliver products that taste good because microwaves are able to heat the product 3-5 times faster than conventional sterilization systems. The microwave-sterilized product is not temperature abused, so the food looks better, has better texture and better tastes than products processed by other available technologies (Harlfinger, 1992). There are significant reduction in process time which is important in results of other studies, also in this study confirmed total time of process is in most the time (time off and relax in two 6-second pulse) only 15 sec that it is very short comparing with 120 sec time of thermal pasteurization. And why do not adversely impact on the functional properties of egg white.

Tang and others (2010) Showed that it is possible to reduction packaged food pasteurization time from 1.1 to 1.4 in comparison with regular methods (Tang *et al.,* 2010). In comparison with regular methods for heating foodstuffs, pasteurization by microwave potentially could improve organoleptic properties, appearance and nutritional value. Ohlson (1987) reported that very short time length in microwave process causes to producing a product with very higher grade and quality comparing with products obtained from regular heating methods (Ohlson, 1987). Also David Reznik (1995) showed that there are many obstacles in egg pasteurization because of its unique properties. Because of these contortions and according to trading practical respects, yolk liquid thermal pasteurization is very difficult (Reznik, 1995). Results of this research showed that usage of both heat and waves could have stronger effect on lethal factor that it confirmed Kozmpel et al. which demonstrated that microwave energy may complete or strength thermal effects (Kozmpel *et al.,* 1999). Such that Sanvo co. (2010) used microwave method combine with 65°C heating and claimed that this methods very quickly and total time of operations is only a part of second and product heated to only coagulation and coacolation point and consequently the product was completely like fresh egg. This process decreases total amount of bacteria 10 times more than regular pasteurization methods. Studies showed that the method will protect egg functional properties 20% more than regular methods (Colavitti *et al.,* 2010). In different studies have severally referred to damages to egg yolk physical and functional properties in temperatures above 60 °C, for instance Wang et.al. (2009) showed that thermal denaturation was affected by dielectric properties and polar compounds in egg, and these changes (higher loss coefficient) occur in temperatures higher than 60°C which is effective on egg yolk

functional properties and results in losing some of this properties (Wang *et al.,*2009). In a similar study by Huang egg white-containing mixture was inoculated with Escherichia coli (ATCC #25922) at a concentration of 10 cfu per ml, and subjected to microwave heating to various product temperatures. The resultant samples were tested to determine bacterial survival and water soluble protein content. An Arrhenius plot of the inactivation rate vs. temperature (1/T) was then constructed. The rate of bacterial kill increased at a greater pace than that of the protein denaturation. Based upon the study results, it is believed that the advantage of having bacterial killed by increasing the processing temperature outweighs the drawback of losing some protein functionality (Huang, 1989).

Table 1 - Treated samples by electromagnetic waves of compared with blank samples in growth of microorganisms (cfu/ml) during storage of egg whit

Day/results	**Total count (cfu/ml)**		**Coliforms (cfu/ml)**		**Molds/yeats (cfu/ml)**

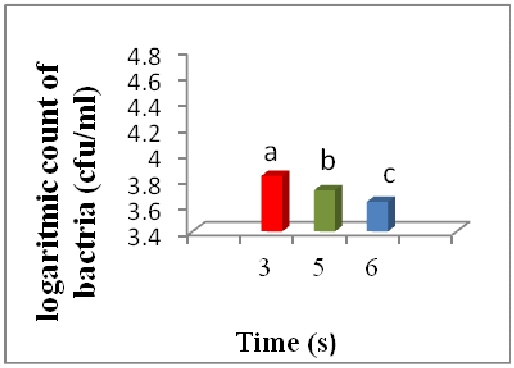

Figure 2**.**Effects of different time process on TAMC s6in liquid egg white cold pasteurization procedure

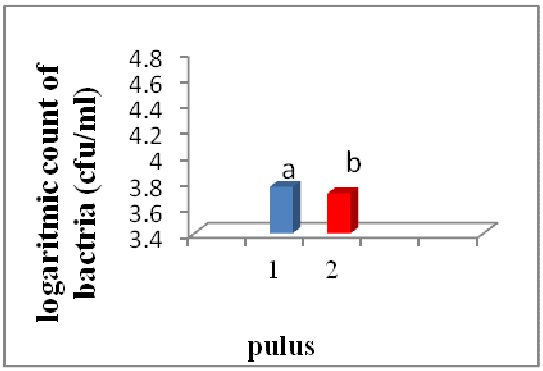

Figure 3**.**Effect of different pulses on TAMC

Determination pasteurized sample's storage time according to Iranian national standard limit

The number of aerobic mesophilic bacteria in pasteurized samples of the 2.31 log cfu / ml of the fifth day of 4.25 log cfu / ml in the 360 th day .This means that during the year, about 1/94 cycle logarithmic increase. Whereashe number of aerobic mesophilic bacteria in blank samples of the 3.86 log cfu / ml of the fifth day of 7.33

log cfu / ml in the 360 th day. This means that during the year, about 3.47 cycle logarithmic increase. Also the average number of coliforms count in the different treatments with pasteurized waves were less than 10 per ml and in blank samples wad the $1/15\times10^4$ cfu/ml in the 360 th day Also the average number of molds and yeasts count in the different treatments with pasteurized waves were less than 30 per ml and in blank samples wad the $7/5\times10^3$ cfu / ml in the 360 th day (table 1). Thus, according to Iran's national standard that limits the number of aerobic mesophilic bacteria in pasteurized products to conventional thermal ($3/0\times10^4$) and limits the number of coliforms (less than 10) per ml and limits the number of molds and yeats (less than 50) per ml and the products shelf life 7 days at(0-4 ℃) has been determined. Then concluded that pasteurized samples with wave after one year is still held. Therefore results of the study, confirmed Sanvo co. reports (2010) that invented commercial system for using waves in egg pasteurization, and announced that pasteurization by waves can increase eggs shelf life and protect its functional properties (Colavitti, 2010). Tang et al. (2002) in Washington university by similar studies on bean showed that the product was processed by microwave had better color and taste than those pasteurizing by regular method in cans and shelf life of sterile product by microwave will increase (Tang *et al.,* 2002).

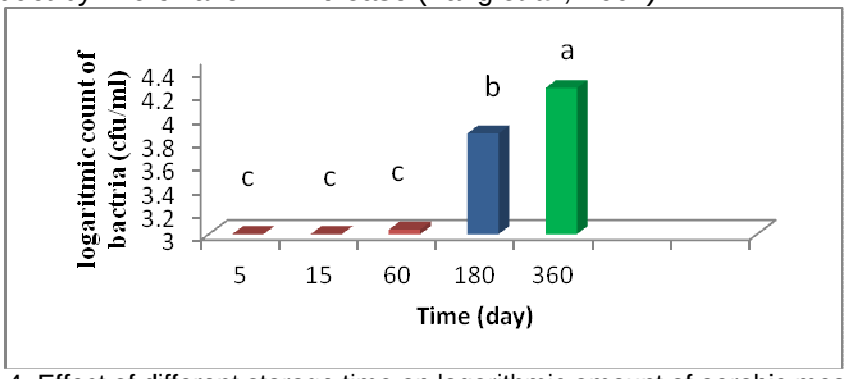

Figure 4. Effect of different storage time on logarithmic amount of aerobic mesophilic bacteria's in liquid egg white cold pasteurization procedure

CONCLUSIONS

Liquid egg white cold pasteurization significantly decreased total aerobic mesophilic count & other microorganism of samples. Therefore this method can be used in liquid egg yolk manufacturing industry. Because the egg whites are extremely sensitive to temperature and heating time on protein denaturation and loss of functional properties, it is very effective. So this method can be a safe and high quality product for use in food production. Shelf life of heat pasteurized liquid egg whites in the refrigerator temperature is a maximum of one month and In this new methods 12 times (about one year) increased then economic benefits of a reduction in production costs and maintenance and transportation for manufacturers and consumers have and less impact of price fluctuations are fresh eggs.

ABSTRACT: Deficit of food for population that grows every year, significantly makes the food production a very important problem the world and in Serbia. The solution to increase the feed and food production is in the usage of new technologies, technologies in biotechnology, actually in bioindustry. One of the main features of contemporary agriculture is production of feed of high nutritive value and microbiologically safe feed in sufficient quantities. The most important feedstuffs that are used in animal nutrition like cereals and other grain – soybean, rapeseed, corn, barley and sorghum, beside nutritive substances contain certain antinutritive substances, that represent limiting factor of their usage. Many antinutritive substances can be eliminated or significantly reduced with the usage of adequate heat treatments. The aim of this study was to collect, display and interpret the results, achievements and latest world science and technology trends trough application of contemporary technical and technological processes of feed processing. With the application of the latest heat treatment, such as extrusion, it comes to destruction of antinutritive substances and improvement of nutritive, hygienic, physical-chemical and other feed properties. The usage of processing technology such as extrusion is certainly one of the most important alternatives for feed and food production which by its high nutritive values can fulfill high demands of modern nutrition.
Key words: *feed, heat treatments, extrusion, animal nutrition.*

INTRODUCTION

Deficit of food for population, that grows every year, significantly makes the food production a very important problem the world and in Serbia. The solution to increase the feed and food production is in the usage of new technologies, technologies in biotechnology, actually in bioindustry. Numerous technological processes aimed at improving nutritional value of food and feed products intended for human and animal consumption and efficiently utilization of primary and processed agricultural and food byproducts have been developed worldwide (Filipović et al., 2010). Now days, huge numbers of various heat treatment processes are used all over the world for cereals and other grain processing, and among them is cooking, roasting, popping, steam flaking, toasting, conditioning, pelleting, micronization and extrusion (Marsman et al., 1998; Tsukamoto et al., 1995, Lević and Sredanović, 2010). According to the literature data, and practical experience, extrusion is the most commonly used process in Serbia for extruded products (Sakač et al., 2003; Sakač et al., 2006; Stanaćev et al., 2011; Puvača, 2011). Many raw materials in the basic form are not usable as feed for animals and nutritional value of certain raw materials is often lower than expected based on content of individual nutrients. Most often, the reason for

that are chemical and physical characteristics that reduce the biological value and digestibility of one or more ingredients. In order to enable the optimal use of nutrients, the technological processes in which the mixtures or raw materials for their production can be translated into usable, namely more usable forms of feed, are studied (Sredanović et al., 2005; Jovanović et al., 2006; Sredanović et al., 2007; Jovanović et al., 2009). Heat treatments have found a significant practical application among the most studied technological processes to improve the usable value of feed (Lević and Sredanović, 2010; Puvača, 2011). Properly applied heat treatment process has shown to reduce anti-nutritional factors to an acceptable level, enhance digestibility of some nutrients such as protein, oil, carbo hydrate, and improve sensory properties and microbiological quality of final product. Along with the antinutrient content reduction, thermolabile nutritive components must be preserved, therefore, process need to compromise these two demands (Jansen 1991; Vujković et al., 1993; Stanaćev et al., 2008; Filipović et al., 2010).
The aim of this study was to collect, display and interpret the results, achievements and latest world science and technology trends trough application of contemporary technical and technological processes of the most important feedstuffs such as oilseeds and cereals that are used in animal nutrition.

Extrusion proces

Extrusion is the process in which the feedstuff or mixture is pushed through the barrel by means of screws of different configurations and pressed through the die at the end of barrel. Extrusion is the technological treatment in which the material is exposed to high temperatures, up to 200˚C for 1-2 minutes or more precisely the material temperature increases progressively within last 15 to 20 seconds up to the optimum one to achieve the desired effects (Riaz, 2007). For that reasons, extrusion is a process classified as heat treatment with high temperatures and short period of its action. The feedstuffs for extrusion are also exposed to high pressure, which can range up to 25MPa (Bekrić et al., 1997; Jovanović et al., 2006; Kirchner, 2009). Extrusion is a complex and complicated technological process, but it is very flexible and provides the possibility for processing of a range of different raw materials such as oilseeds, cereals, legumes, raw materials with high moisture content, combinations of raw materials, by-products and wastes from food industry and complete animal feed mixtures (Smoje et al., 1996). Extrusion modifies the internal structure of feedstuffs. After treatment, the product is different, from nutritional point of view, compared to the raw material. Properly extruded material is much better, according to its nutritional and physical properties that the pelleted material. During extrusion process, feedstuffs passing through a whole range of changes, primarily in starch and protein components (Bekrić et al., 1997). However, beside positive effects of extrusion, irregular extrusion can result in negative effects (Lević et al., 1999).

Nutritive value of extruded feedstuffs

Soybean processing into high protein and high energy feed involves application of heat treatment process such as extrusion. Advantage of this process, the final result of which is full fat extruded soybean grits, soybean processed by dry or moist extrusion and heat treated soybean seeds, is that it offers possibility for the production of quality product with improved hygienic and physicochemical properties. Soybean seed has to be subjected to thermal treatment to inactivate or reduce inhibitory substances contained in soybean seed, such as trypsin and chimotrypsin inhibitor, chemaglutinin, phytate, saponin, antivitamin A, E, B12, so it could be used in animal and human nutrition (Bohm and Taufel, 1993; Verheul, 1997; Van der Poel, 1997). Quality of the feed made in dry extrusion process can be determined based on result obtained by Filipović et al., 2011, for chemical composition, amino acid composition and antinutritional factors of soybean seeds before and extruded full fat soy grits after treatment (Table 1).

Table 1. Quality indicators of soybean seeds and extruded full fat soy grits

Quality indicators	**Soybean seed**		**Extruded full fat soy grits**	
Chemical composition	% in sample	% in dry	% in sample	% in dry
Moisture	10.06	-	4.67	-
Crude protein	37.48	41.67	39.40	41.33
Crude fat	19.27	21.26	20.26	21.25
Crude fibre	4.39	4.88	4.08	4.28
Mineral matter	4.63	5.15	4.81	5.05
Amino acid composition (% in protein)				
Asparaganinic acid	12.00		10.35	
Treonine	4.59		3.63	
Serine	5.02		5.00	
Cystine	7.90		7.89	
Alanine	6.10		5.03

Trypsin inhibitor (mg/g)	61.66		3.27	
Urease activity	10.95		0.26	
NSI (%)	65.82		25.64	

Filipović et al., 2001.

Rapeseed is an oilseed crop having a huge potential from an energy and protein standpoint, and containing components of high nutritive value. Beside proteins and oil, also contain antinutritional factors such as erucic acid and glucosinolates (Sakač et al., 2005; Sakač et al., 2007; Stanaćev et al., 2006; Stanaćev et al., 2008). Although rapeseed is a good source of quality protein, its use in rations is limited by its fibre, phytic acid, glucosinolates, polyphenols content. The use of rapeseed in compound feed is rather limited by its poor sensory properties because of high glucosinolate content, which is responsible for the pungent odour and biting taste particularly in non-ruminants nutrition (Stanaćev et al., 2011). When rapeseed is extruded alone its high oil content prevents adequate heating and produces an oily pulp which is susceptible to lipid oxidation. For this reason, rapeseed needs to be extruded in combination with other feedstuffs how the resultant product would have longer shelf life and be sustainable for storage (Stanaćev et al., 2006; Puvača, 2011). Reduction of total glucosinolates content, after dray extrusion process on 135˚C is shown in table 2.

Table 2. Glucosinolate content in rapeseed alone and in combinations with other feedstuffs before and after extrusion process

Sample	**Glucosinolate µmol/g DM (before extrusion)**	**Glucosinolate µmol/g DM (extruded)**	**Glucosinolate reduction (%)**
Rapeseed	65.91	46.43	29.56
Rapeseed + Corn 30:70	21.35	15.67	26.60
Rapeseed + Corn 50:50	32.83	24.62	25.01
Rapeseed + Barley 30:70	19.76	14.05	28.90
Rapeseed + Barley 50:50	33.57	25.35	24.49
Rapeseed + Triticale	23.34	16.56	29.05
Rapeseed + Triticale	36.73	27.86	24.15
Rapeseed + Wheat 30:70	19.80	15.25	22.98
Rapeseed + Wheat 50:50	41.70	32.26	22.64

Sakač et al., 2005

Corn is the most commonly used grain in the animal feed production in Serbia due to its high energy content (16.2 MJ/kg), relatively high oil content (3.9%) and low fibre content (2.2%) (Kovčin, 1993). In addition to its excellent digestibility, corn is considered to have better flavour than other grains. However, thermal treatments is used to enhance nutritional, hygienic, physico-chemical and other properties of grains, to improve nutritive value of some ingredients, upgrade sensory characteristics, ensure the microbiological wholesomeness of final product and inactivate thermo-labile anti-nutrients (Bekrić, 1999; Jansen 1991). Chemical characteristics of corn and corn extruded at 90 and 95˚C are given in table 3.

Table 3. Chemical composition of ground and extruded corn

Quality indicators	Corn	Corn extruded at	Corn extruded at
Crude protein	9.25	9.07	8.97
Crude fibre	3.45	2.47	2.80
Crude fat	4.80	2.08	2.66
NSI	13.11	6.06	5.88
Starch	70.90	67.06	64.98
Total sugar	1.00	3.99	4.12

Filipović et al., 2009.

Structure changes in protein, during the process of extrusion, leading to decrease in protein solubility (Filipović et al., 2003). Also starch is gelatinized and degraded and accessibility of enzymes to starch granules in the digestive tract is improved. Starch content in extruded corn is lower than in non-extruded corn, and as the result, total and reducing sugars content is increased, thus contributing to the change of sensory parameters.

CONCLUSION

At the end of the paper, it can be concluded that the extrusion of soy grain is one of the heat treatments, used to improve nutritional, hygienic and physico-chemical properties, and also to inactivate thermo labile antinutritients and upgrade sensory properties. When is extrusion of rapeseed in question it can be seen that thermal process led to reduction of glucosinolate content in extruded material in relation to untreated material. Extrusion of corn resulted in improved nutritional value, with increased sugar content due to changes in starch structure.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project III046012 “Study of modern biotechnological methods in the production of animal feed in order to increase competitiveness, quality and safety of the feed”, financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT: Analysis of the fiber or cell wall present in forages is of major concern in ruminant nutrition because diets often contain large amounts of forage, and the fiber fraction affects both feed intake and animal performance. Research has revealed that plant genetics can affect the quality and digestibility of whole plant maize silage. All carbohydrates in plant feeds are grouped into: 1. Structural carbohydrates (carbohydrates of cell walls) including NDF (neutral detergent fibers-hemicellulose+cellulose+lignin), ADF (acid detergent fibers-cellulose+lignin), ADL (lignin), and 2. Non-structural carbohydrates-NFC (carbohydrates located inside the plant cell) made of starch, sugars and pectin. The aim of this present study was to observe quality parameters of ZP hybrids biomass with different genetic background for silage and to determine the relationship of these parameters, as well as, their effects on the digestibility of maize biomass dry matter. The contents of lignocelluloses fraction were determined by the modified Van Soest detergent method while *in vitro* digestibility of the whole plant was done by the Aufréré method. Obtained results showed that the NDF, ADF and ADL contents in the whole maize plant of the observed different ZP hybrids varied from 42.6% to 50.9%, 19.3% to 25.7%, and 1.6% to 2.5%, respectively. The difference in the digestibility of the dry matter of the whole plant between hybrids amounted to 10.4%. The differences in the contents of lignocelluloses fraction affected the differences in digestibility of dry matter.
Key words: *NFC, NDF, ADF, ADL, digestibility, maize hybrids*

INTRODUCTION

Maize is one of the most important naturally renewable carbohydrate raw materials. As a high-yielding carbohydrate plant, maize is very competitive in relation to other cereals (Radosavljevic et al., 2010). All carbohydrates in plant nutrients are grouped into: I structural carbohydrates (carbohydrates of cell walls), which include NDF (neutral detergent fibers - hemicellulose+cellulose+lignin), ADF (acid detergent fibers - cellulose+lignin), ADL (lignin) and II nonstructural carbohydrates - NFC (carbohydrates present in the plant cell content) that are made of starch, sugars and pectin (Jovanović et al., 1993). However, according Polakova et al. (2010) the NFC of substances comprises a diverse group of substances in terms of their composition and nutrient contents, excluding carbohydrates inherent to NDF. The NFC group of substances includes organic acids, monosaccharides, oligosaccharides, fructans, starch, pectin substances and □-glucans. There are numerous confirmations that the feeding ration with a high NFC content ferment and produce a great quantity of propionic acid in the rumen, which results in a higher insulin concentration in blood, i.e. in animal weight gain. Feeding rations rich in digestible fibers (hemicellulose and cellulose) produce acetic acid in the rumen and increase the growth hormone level in blood, which results in the increased milk production (Jovanović et al., 1993). Analysis of the fiber or cell wall present in forages is of major concern in ruminant nutrition because diets often contain large amounts of forage, and the fiber fraction affects both feed intake and animal performance. Research has revealed that plant genetics can affect the quality and digestibility of whole plant maize silage (Jung, 1997). Considering all stated, as well as, the fact that the digestibility does not depend on

the energy concentration, the objective of this present study was to observe quality parameters of the whole plant of ZP hybrids with different genetic background for silage and to determine the relationship of these parameters, as well as, their effects on the digestibility of maize biomass dry matter.

MATERIALS AND METHODS

The hybrids of the FAO maturity group 100-700 (ZP 161, ZP 388, ZP 434, ZP 555, ZP 677, ZP 704) were used in this study. The two-replicate trail was set up according to the randomized complete-block design in the experimental plot of the Maize Research Institute, Zemun Polje. The experimental plot size amounted to 21m^2, while sowing density was 60,000 plants per hectare. Plants of each replicate were harvested in the full waxy maturity stage from the area of 7m^2 (two inner rows), and yields of fresh biomass of the whole plants, plants without ears and ears were estimated. Five average plants per replicate were selected for further tests. Samples of the whole plants were cut and dried at 60^{o}C for 48h. In order to determine the content of dry matter the whole plant samples were ground in the 1-mm mesh mill. Then, the analysis of the absolute dry matter was done on the oven dry basis (105^{o}C for 12 h) in order to estimate the total dry matter. Moreover, the analysis of the content of forage fibers (NDF, ADF, ADL, cellulose, hemicellulose) was performed by the modified Van Soest detergent method (Van Soest, 1963). The method was modified by Mertens (1992). *In vitro* digestibility of the whole maize plant was done by the Aufréré method (Aufréré, 2006). This method is based on the hydrolysis of proteins of the whole plant in the pepsin acid solution (Merck 2000 FIP u/g Art 7190) at 40^{o}C for 24 h, and then on the hydrolysis of carbohydrates in the cellulase solution (cellulose Onozuka R10) in duration of 24 h. Methods applied in order to determine basic chemical content of the maize plant samples (contents of ash, protein and fat) were described in previously published paper (Radosacljević et al., 2000). The NFC content in the whole plant samples is calculated according to the formula: (%) NFC = 100%DM – ((%) crude protein + (%) NDF + (%) fat + (%) ash) (Polakova et al., 2010).

Statistical analysis of data

Data reported for quality parameters of ZP hybrids biomass was assessed by analyses of variance (ANOVA) and LSD multiple test was used for any significant differences at the $P<0.05$ level between the means. All the analyses were conducted using statistical software package STATISTICA 8.1. (StatSoft Inc. USA).

RESULTS AND DISCUSSION

Table 1 presents the NFC content of the whole plant and evaluation of significance of difference between the observed ZP maize hybrids. The results showed that the NFC content in the whole maize plant of the observed different ZP hybrids varied from 33.20% to 41.22%. The difference in the NFC content of the tested ZP hybrids was 8.02%. Differences in the contents of NFC were statistically significant between hybrids ZP 388, ZP 555, ZP 704, and between these and the ZP 161, ZP 434 and ZP 677. Differences in the contents of NFC were not statistically significant between the ZP 161, ZP 434 and ZP 677.

Table 1. Content of NFC of the whole plant of the ZP maize hybrids

Hybrids	NFC (%)
ZP 161	39.93^{d}
ZP 388	41.22^{a}
ZP 434	33.20^{d}
ZP 555	39.63^{b}
ZP 677	34.33^{d}
ZP 704	38.14^{c}
$LSD_{0.05}$	1.29

Means in the same column with different superscripts differ (p<0.05)

Data on the content of NDF, ADF, ADL, hemicellulose and cellulose are presented in Table 2. The results showed that the NDF, ADF, ADL, hemicellulose and cellulose contents in the whole maize plant of the observed different ZP hybrids varied from 42.57% to 50.84%, 19.32% to 25.74%, 1.63% to 2.51%, 23.26 to 26.07% and 17.69 to 23.62%, respectively. The differences in the content of NDF, ADF, ADL, hemicellulose and cellulose among observed ZP hybrids were 8.27%, 6.42%, 0.88%, 2.82% and 5.83%, respectively. Statistically significant differences in the NDF content of tested ZP hybrids were found, except between the ZP 434 and ZP 677, ZP 555 and ZP 704. Differences in ADF content were statistically significant except between hybrids ZP 161 and ZP 704. Statistically significant differences in the ADL case were found only between hybrids ZP 161 and ZP 555. The difference in ADL content was statistically significant only between hybrids ZP 161 and ZP 388. In other ZP hybrids these differences were not significant. Differences in hemicellulose content were not statistically significant between the ZP 161 and ZP 434 and ZP 677, and between ZP 388, ZP 555 and ZP 704. Statistically significant differences in cellulose content in the examined maize hybrids were found. The differences in cellulose content were not statistically significant between the ZP 161 and ZP 704.

Table 2. Content of forage fibres of the whole plant of the ZP maize hybrids

Hybrids	NDF (%)	ADF (%)	ADL (%)	Hemicellulose (%)	Cellulose (%)
ZP 161	49.08^{b}	23.73^{c}	2.51^{a}	25.35^{ab}	21.22^{c}
ZP 388	42.57^{d}	19.32^{e}	1.63^{b}	23.25^{c}	17.69^{e}
ZP 434	50.84^{a}	24.77^{b}	2.19^{ab}	26.07^{a}	22.58^{b}
ZP 555	45.35^{c}	22.05^{d}	1.63^{b}	23.26^{c}	20.42^{d}
ZP 677	50.83^{a}	25.74^{a}	2.12^{ab}	25.09^{b}	23.62^{a}

$LSD_{0.05}$	1.22	0.84	0.64	0.77	0.59

Means in the same column with different superscripts differ (p<0.05)

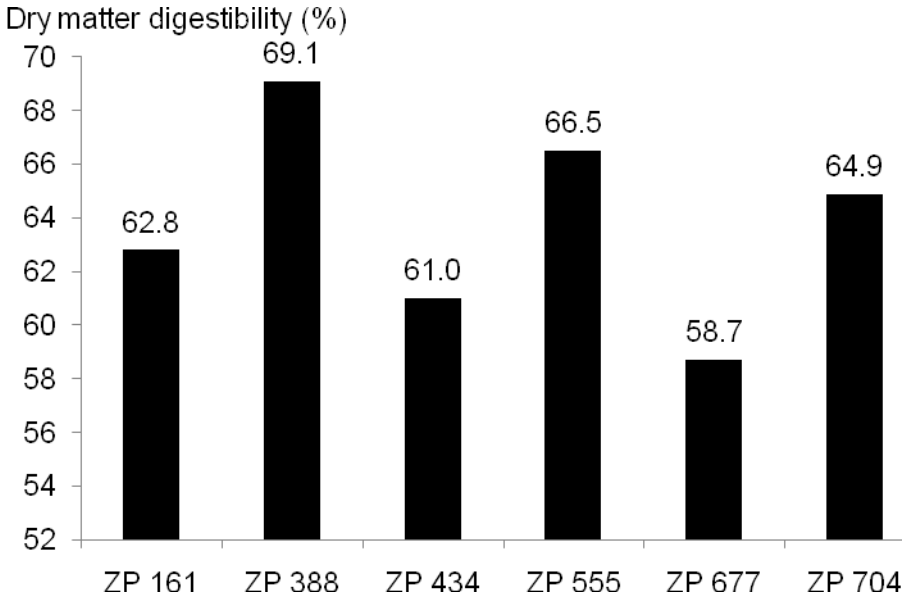
Considering the crucial effect of the NFC and forage fibers on the digestibility of the whole maize plant dry matter, the correlation dependence between the content of these components and the dry matter digestibility was observed (Table 3). A highly significant correlation between NFC content and dry matter digestibility of whole plant maize hybrids (r = 0.90), and a significant negative correlation between the content of NFC and the content of NDF, ADF, ADL, hemicellulose and cellulose were established (r = - 0.97, r = -0.90, r = -0.83, r = -0.96, r = -0.84). A very significant negative correlation was determined between the digestibility and NDF, ADF, hemicellulose and cellulose content (r=-0.96, r=-0.98, r=-0.79, r=-0.97), and significant negative correlation between the ADL content and the dry matter digestibility. Wermke (1986) ascertained a significant negative correlation (r=-0.67) between the digestibility and the ADF content, as well as, between the digestibility and lignin (r=-0.95). Burritt et al. (1985) studied three grass species and found high correlation dependence between the dry matter digestibility and the content of forage fibers. The coefficient of correlation between the digestibility and NDF, ADF, ADL and cellulose amounted to r=-0.84, r=-

0.93, r=-0.91 and r=-0.86, respectively (Burritt et al., 1985). Very significant positive correlation was determined between the NDF content and content of ADF, ADL, hemicelluloses and cellulose amounted to (r=0.97, r=0.74, r=0.90, r=0.94). Significant positive correlation was determined between content of ADF and content of ADL and hemicellulose amounted to (r=0.66, r=0.77) and very significant positive correlation with cellulose content (r=0.99). Positive significant correlation was determined also between content of ADL and hemicellulose (r=0.76) and also between hemicellulose and cellulose content (r=0.72). Wermke (1986) established that there were maize hybrids with a low digestibility and a high content of stover cell wall constituents, as well as, there were hybrids with a high digestibility and a low content of cell wall constituents. These hybrids were defined as a dislocation type of hybrids. Hybrids with a high digestibility and a low NDF content of stover and a high NDF content of stover and a low ear digestibility are classified into types of hybrids with prolonged stover assimilation.

Table 3. Correlation dependence between digestibility, NFC and forage fibres of the whole plant of the ZP maize hybrids

	NFC	NDF	ADF	ADL	Hemicellulose	Cellulose
Digestibility	0.90**	-0.96**	-0.98**	-0.64*	-0.79**	-0.97**
NFC		-0.97**	-0.90**	-0.83**	-0.96**	-0.84**
NDF			0.97**	0.74**	0.90**	0.94**
ADF				0.66*	0.77*	0.99**
ADL					0.76**	0.55
Hemicellulose						0.72**
Cellulose						

The Figure 1 presents results of the digestibility of the whole ZP maize hybrid plant dry matter. The digestibility of the whole ZP maize hybrid plant dry matter ranged from 58.7% to 69.1%. The difference in the digestibility of the whole maize plant dry matter amounted to 10.4%. According to results obtained by Deinum et al. (1981) and Andreu et al. (1974) this difference varied from 2% to 3%, while Terzić (2006) and Terzić (2010) established the highest difference among observed hybrids of 11.52% and 8.56%, respectively. Differences in the digestibility of whole plant corn were statistically significant between the ZP hybrids.



$LSD_{0.05} = 1.07$; $LSD_{0.01} = 1.68$

Figure 1. Dry matter digestibility of the whole plant of the ZP maize hybrids

CONCLUSION

Obtained results showed that the NFC content in the whole maize plant of the observed different ZP hybrids varied from 33.20% to 41.22%. The difference in the NFC content of the tested ZP hybrids was 8.02%. The results also showed that the NDF, ADF, ADL, hemicellulose and cellulose contents in the whole maize plant of the observed different ZP hybrids varied from 42.57% to 50.84%, 19.32% to 25.74%, 1.63% to 2.51%, 23.26 to 26.07% and 17.69 to 23.62%, respectively. The digestibility of the whole ZP maize hybrid plant dry matter ranged from 58.7% to 69.1%. The difference in the digestibility of the dry matter of the whole plant between hybrids amounted to 10.4%. The differences in the contents of NFC and forage fibers affected the differences in digestibility of dry matter.

INTRODUCTION

Red beet juice is very useful food product, because it contains significant amount of sugars, mineral substances and vitamins. It is also valuable because it's used for producing food grade dye.

Nowadays in order to give to food products a color, close to natural coloring of fruits and vegetables, expensive synthetic dyes are used, which might have cancer-inducing effect when being accumulated by human organism. Therefore improving the technology for producing food grade dye from red beet juice is remarkably important task.

Currently for the purpose of obtaining dye from red beet juice, a part of pectin substances, which make the process of juice concentration more difficult, is removed with the help of expensive enzymatic agents (Tymofeeva V.N. et al., 2002).

The authors have suggested using natural carbon-bearing adsorbent shungite to purify red beet juice from pectin substances (Sheiko and Melnyk, 2009; Sheiko and Melnyk, 2010).

Shungite is a mineral consisting of amorphous carbon and fractured graphite. Its chemical composition is not constant: shungite contains 60-70% of carbon and 30-40% of other elements.

Shungite is the only known mineral to have fullerenes (recently discovered new globular form of carbon existence). Fullerenes' structure is peculiar because carbon atoms in molecules are situated at the tops of regular pentagons and hexagons, which cover sphere's surface and present themselves as closed polygons composed of paired quantity of coordinated carbon atoms.

Fullerenes differ from particles with metallic properties due to the location of electron cloud and ability to change the form of carbon structure.

Sizing of electro-magnetic waves is determined by vibration of electrons which are divided into $\pi - \sigma$ and π- states. During adsorption on electrically neutral surface the localization of fullerenes' π-states takes place, and a particle loses its metallic

properties, and because of that connected electron pair appears in the activated form. Thus mineral shows bipolar properties.
Shungite's important characteristic is the presence of fullerene carbon nanotubes with the diameter of their cylindrical pores constituting 1-6 nanometers and the width - up to several micrometers. The cylindrical surface of tubes is formed by active carbon circles and also has empty pores.
The basis of shungite's structure is a globule composed of graphitic networks, formed into packages. Each package has 6 graphitic flat networks with the quantity of carbon atoms attaining to 300-600 and one curved network, having 400 carbon atoms.

MATERIAL AND METHODS

Shungite to be used for research was prior washed out with cold water and then termoactivated at 100℃ during 90 minutes. Cooled a dsorbent in concentrations of % mass.: 2.44; 3.23; 4.76; 9.09 was put into fresh red beet juice at temperature of 20, 40, 50, 60ºC, mixed during 10, 20, 30, 60 min., filtrated. The content of pectin substances in filtrate was measured in accordance with **calcium** pectate **method under formula:**

$$. \quad ПР = \frac{(g - g_0) \cdot 100 \cdot 0.9235}{V \cdot d}$$

whereas ПР – content of pectin substances in juice, mg/g;
g – weight of weighting cup with precipitate before exsiccation, g;
g0 – weight of empty weighting cup, g;
V – juice volume, cm3;
d – juice density, g/cm3;
0,9235 – coefficient for conversion of calcium pectate into pectic acid.

The obtained results were compared by effect of purification:

$$E = \frac{100 \cdot (K_1 - K_2)}{K_1}$$

whereas К1 and К2 – quantity of target component in juice which was not processed by adsorbent and juice which was processed by adsorbent.
The obtained results are shown in table below.

Table 1. Effect of purification (E,%) from pectin substances in red beet juice by shungite at different adsorbent concentrations, temperature of mixtures, duration of interactions between adsorbent and juice, initial content of pectin substances is 1.9 mg/g

RESULTS AND DISCUSSIONS

The obtained data shows that adsorption of pectin substances from red beet juice by shungite takes place already at temperature of 20ºC. If temperature rises the process is somewhat accelerated. The rise of temperature of processing juice over 60ºC is unreasonable because coloring components are destroyed and that causes the changes in juice color.

Comparing the obtained results and their practical efficiency the authors determined optimal parameters, concluding that the optimal parameters for processing juice by shungite is adsorbent concentration of 4.76% mass, temperature of processing 50, 60º C, duration - 30 min. Under such conditions 36.8%-42.1% of pectin substances are removed.

The mechanism of adsorbing pectin substances from red beet juice by shungite is explained not only due to the fact that impurities infiltrate the mineral's pores, but also due to ion-exchange adsorption in places where reactive centers of fullerenes are formed and hydrogen bonds with pectin molecule are created.

Shungite's selectivity is explained not only because of the existence of micro-, mezzo- and macropores, but also because nanotubes participate in adsorption processes and there are pores in between them, created when packages are formed, and also because of free non-compensated charges which appear on adsorbent's surface.

The next phase of research was determining the content of coloring substances of red beet juice, processed by shungite at temperature of 50ºC. Preparation of shungite was performed in the same way as for adsorption of pectin substances. The content of coloring substances was determined according to standard methodology – reaction of Neubauer-Levental. Estimation of mass content of coloring substances was performed under formula:

$$X = \frac{(M_1 - M_2) \times K \times 0{,}004157 \times O_1 \times 100}{H \times O_2}$$

whereas X – mass content of coloring substances,%;

M1 – quantity of 0.1 normality of solution of potassium permanganate, used for the first titration, cm3;

M2 - quantity of 0.1 normality of solution of potassium permanganate, used for the second titration, cm3;

O1 – volume of the primary extraction, cm3;

H – quantity of juice used for experiment, cm3;

O2 – volume of the secondary extraction, used for titration, cm3;

0.004157 – coefficient which takes into account correlation between potassium permanganate and juice coloring substances.

The research was performed and its results are showed in figure 1.

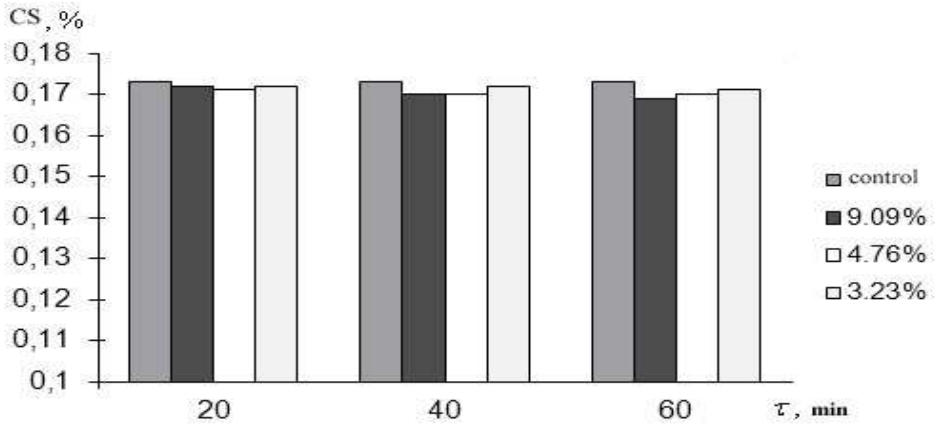

Figure 1. Quantity of coloring substances (CS) in juice processed with shungite depending on the duration of its processing at temperature of 50ºC.

Analysis of data presented in fig.1 gives grounds to state that content of coloring substances in red beet juice, after it was processed by shungite, practically does not change. This can be explained by the fact that the basis of coloring substances in red beet juice is anthocyanins (Saburov and Antonov, 1951; Tanchev S.S., 1980). By their structure they are chains of glicosides, composed of heterocyclic compounds. By their chemical nature they are surface active substances. On interphase border anthocyanins' molecules are situated in such a way that hydrophilic group remains in liquid state. Hydrophobic effect takes place and thus coloring substances are not adsorbed by shungite.

The authors improved apparatuses and technological scheme for producing food grade dye from red beet juice by installing two adsorbing devices with shungite which work in regime of sorption-desorption.

After part of pectin substances are removed in adsorbing device, red beet juice is placed in vacuum evaporator where it is concentrated around 6 hours. Concentration of juice by its evaporation takes place with discharge of 0.055 – 0.060 MPa and temperature of 55-60ºC, concentrated red beet juice, already as food grade dye, is packed in the sealed container, made of dark glass. The level of pH in the obtained food grade dye does not exceed 4.5.

The used adsorbent is sent for regeneration, utilization.

CONCLUSIONS

It was established that shungite effectively adsorbs pectin substances from red beet juice and does not adsorb coloring substances. The technology of producing food grade dye was improved by additional purification of red beet juice from pectin substances by shungite. The obtained optimal technological parameters for purifying juice with shungite are as follows: adsorbent's concentration constituting 4.76% mass., temperature is 50-60ºC, duration of processing is 30 min. Apparatuses and technological scheme of producing food grade dye is supplemented with two adsorbing devices with shungite, which work in regime of sorption-desorption. The used adsorbent is recommended to be regenerated, utilized.

ABSTRACT: Storage of tomato after harvest at low temperature in order to prevent decay and prolong its postharvest shelf life induces chilling injuries and makes fruit susceptible to the colonization of microorganisms that can cause fruit deterioration. One of postharvest treatments used for reducing of chilling injuries is the heat treatment in water or in the air flow. In order to investigate influence of heat treatment in water on properties of tomato stored at low temperature (4℃) during three weeks, commercial tomato was harvested at mature green and red-ripe stages. Tomato harvested in mature green stage was treated in water at 42℃ for 1 h. Samples of treated and non treated to mato harvested in mature green stage, as well as sample of non treated tomato harvested in red-ripe stage were stored at 4℃. Tomato ripening was monitored once a week by instrumental measurement of fruit color using Minolta Chroma Meter CR-400. After three weeks of cold storage, all tomato samples were evaluated by sensory panel consisting of 10 trained assessors. Differences between treated and non treated tomato samples were observed and compared with properties of red-ripe harvested tomato.
It was concluded that heat treatment in water of 42℃ for 1 h results in less chilling injuries, delayed but more uniform development of red color, less presence of vessels, and lower intensity of non-characteristic odor and taste.
Key words: *tomato, heat treatment, storage, ripening, color, sensory evaluation*

INTRODUCTION

Postharvest heat treatments are used for disinfestation and disinfection, modification of fruit response to temperature extremes and controlling of ripening process (Lurie, 1998, Paull and Chen, 2000). In the last decades, there has been increased interest for heat treatments partly because they can replace chemicals used against pathogens and insects (Lurie, 1998). Subtropical fruit, such as tomato (*Solanum lycopersicum* L.), develop chilling injury when stored at temperatures below 10-12℃ (Lurie and Klein, 1991, Sabehat et al., 1996). Chilling injury is physiological disorder whose symptoms are tissue browning, appearance of pits and discolorated areas on skin, non-uniform ripening and increased susceptibility to diseases (Luengwilai et al., 2012).
Heating induces many physiological changes in fruit. High temperature treatment (38℃ for 3 days) inhibited reversibly ethylene pro duction, color development and softening in tomatoes by decreasing expression of mRNAs related to ripening (Lurie et al., 1996). However, fruits held at low temperature (2℃ for 14 days) after heating ripened normally when placed at 20℃. Lurie et al. (1996) explained this by accumulation of heat-shock proteins (HSPs) caused by high temperature stress. It is supposed that HPSs stabilize structure and function of membrane proteins during and after heat treatment. This allows tomatoes to be stored at lower temperatures without developing of chilling injuries (Sabehat et al., 1996).
There are three methods for heating fruits: hot water, vapor heat and hot air. Vapor heat and hot air can be static or with high flow rate; in addition, hot air can have

humidity regulation. All these methods require different time of application in order to achieve desired effect on fruit (Lurie, 1998). Uniformity of heating is also an important factor for tomato ripening and chilling injury development. In research conducted by Lu et al. (2010), one half of tomato was exposed to heated air flow at temperature of 39℃ and velocity of 0,24 m/s, while the other half was held at room temperature (39℃) and same air flow velocity. Heated tomato halves were significantly different from unheated halves in terms of chilling injuries and color because process of postharvest ripening was delayed.

Different temperatures of hot water and treatment durations have been used for postharvest treatment of tomato. McDonald et al. (1999) found that treatment of tomatoes in water for 1 h at 42℃ reduced decay by 60%, when tomatoes were stored at 2℃ for 14 days before ripening at 20℃. Tomato fruits immersed in 40℃ water for 7 min showed reduced chilling injury symptoms (Luengwilai, 2012).

Postharvest heating of tomatoes in air at 34℃ for 24 h before storage at 4℃ or 10℃ for up to 4 weeks resulted in little heat injury and the least losses in antioxidant content, and fruit color developed normally (Yahia et al., 2007, Soto-Zamora et al., 2005).

The aim of this research was to compare sensory properties of heat treated tomatoes harvested at mature green stage with non treated mature green and red-ripe harvested tomatoes, after storage at 4℃ for 4 weeks. Changes in color values during cold storage were also determined.

MATERIAL AND METHODS

Heat treatment

Commercial tomato, grown in greenhouse, was harvested at mature green and red-ripe stage. Tomato harvested in mature green stage was treated in water at 42℃ for 1 h (McDonald et al., 1999). Samples of treated and non treated tomato harvested in mature green stage, as well as sample of non treated tomato harvested in red-ripe stage were stored at 4℃ for 4 weeks.

Color measurement

Tomato ripening was monitored on 0, 5, 14, 21 and 28 days of storage by instrumental measurement of fruit color using Chroma Meter CR-400 (Konica Minolta, Japan). The CIE L* (lightness), CIE a* (red-green) and CIE b* (yellow-blue), C* (chroma), h (hue angle), and DWL (dominant wavelenght) were read using a D_{65} light source and the observer angle at 2℃. Each sample was measured at six locations: two locations between the equator and the stem; two on the equatorial region, and two between the equator and the blossom end.

Sensory evaluation

Sensory profiling was performed by ten trained panellists between (35-50) years old. The assessors were selected from previously trained academic staff of the Institute of Food Technology, Novi Sad. Sensory evaluation was performed using a generic descriptive analysis technique, included 19 selected representative properties. The properties were evaluated using a 150 mm unstructured line scale (anchored at 15 mm and 135 mm with slight to very, respectively) (ISO, 2003). The anchored reference terminology definitions and evaluation techniques were agreed upon by the assessors during training (Pestorić, 2011). A total of two sessions was held during storage of samples. Samples of treated and non treated tomato harvested in breaker stage, as well as sample of non treated tomato harvested in red-ripe stage were presented to each assessor in each session providing a total of two replicate evaluations. All samples were presented to each assessor at the same time. The

order of sample presentation was completely randomized among assessors, indentified with three random numbers.

Data analysis

Results were expressed as the mean of replications for all measurements. Analysis of variance (ANOVA) and Duncan's multiple range test were used to compare means at 5% significance level by using the statistical data analysis software system STATISTICA (StatSoft, Inc. (2011), version 10.0 (www.statsoft.com)).

RESULTS AND DISCUSSION

Comparison of L*, a*, b*, C*, h, and DWL values of non treated, treated and red-ripe tomatoes is presented in Table 1. After 28 days of cold storage, L* values for neither non treated nor treated tomatoes reached value obtained by red-ripe tomato. On 21 and 28 day of storage, a* values for both non treated and treated tomatoes didn't differ significantly from that of red-ripe tomatoes. This can be explained by accumulation of lycopene in non treated and treated fruits in quantities similar to that in red ripe tomatoes, because increase of a* value is directly related to lycopene synthesis (Arias et al., 2000). The greatest increase of a* values can be seen between 5 and 14 days for treated tomatoes. Second to that is increase between 0 and 5 day of storage for non treated tomatoes. From these results, it can be concluded that ripening process is delayed in treated tomatoes in comparison to non treated tomatoes. Change of b* values cannot be connected with ripening in both samples. C* values for both non treated and treated tomatoes increased sharply between 5 and 14 day of storage and then remained constant. In contrast, hue angle values for both non treated and treated tomatoes decreased during storage period, and on 28 day there was no significant difference between them and red-ripe tomatoes. On 5 and 14 day of storage, significant difference between treated and control fruits can be observed. Similar results are obtained for dominant wavelenght in terms of change during storage. However, its values for both samples were significantly different from value for red-ripe tomato even on 28 day of storage.

Table 1. Comparison of color values of non treated, treated and red-ripe tomatoes

Treatment	Storage period [days]	L*	a*	b*	C*	h	DWL [nm]
Red-ripe	0	40,106^{a}	31,666^{a}	27,503^{cd}	42,004^{b}	41,013^{a}	598,264^{a}
Non treated	0	60,871^{g}	-8,314^{f}	25,947^{d}	27,311^{d}	107,572^{i}	570, 205^{h}
Treated	0	60,764^{g}	-6,462^{f}	26,021^{d}	26,918^{d}	103,839^{h}	571,549^{h}
Non treated	5	56,035^{e}	10,486^{d}	24,092^{e}	27,072^{d}	66,599^{f}	583,974^{f}
Treated	5	58,540^{f}	2,069^{e}	26,029^{d}	26,503^{d}	85,256^{g}	577,648^{g}
Non treated	14	47,705^{d}	26,366^{b}	32,010^{ab}	41,836^{b}	51,268^{de}	592, 087^{d}
Treated	14	48,985^{d}	22,946^{c}	30,809^{b}	38,680^{c}	53,711^{e}	590, 268^{e}
Non treated	21	44,867^{c}	30,080^{a}	33,535^{a}	45,256^{a}	48,294^{cd}	594,203^{c}
Treated	21	44,985^{c}	30,128^{a}	32,123^{ab}	44,236^{a}	46,912^{bc}	594,709^{bc}
Non treated	28	42,784^{b}	30,003^{a}	27,503^{c}	41,736^{b}	43,836^{ab}	596,197^{b}
Treated	28	44,223^{bc}	31,278^{a}	31,030^{b}	44,256^{a}	44,783^{abc}	595,967^{b}

Values are means of thirty measurements.
Values with the different superscript within a column are statistically different (P < 0.05).

Concerning the sensory properties (Table 2), non treated and treated tomatoes stored for 21 day at 4℃ were significantly differe nt from red-ripe tomatoes in terms

of: fruit red color intensity, fruit color uniformity, firmness, juice leakage, fruit compactness and juiciness. In research conducted by Auerswald et al. (1999), properties that changed most during postharvest period were, among others, red color of tomato surface, color intensity of fruit flesh, firmness (finger touch) and juiciness. In our research, all samples differ significantly from each other in terms of cross-section red color intensity, with highest scores for red-ripe and lowest for non treated tomatoes. Cross-section red color uniformity was significantly lower for non treated tomatoes. Non treated tomatoes had significantly higher scores for vessels, off-odor intensity and off-taste intensity. There were no significant differences in terms of cross-section cavities, skin and pulp chewiness, sweetness, sourness and taste intensity between evaluated tomato samples.

Table 2. Sensory evaluation of tomatoes at 21 day of storage

Sensory property	Red ripe	Non treated	Treated
Fruit red color intensity	64,86^{a}	36,14^{b}	39,14^{b}
Fruit color uniformity	112,14^{a}	50,71^{b}	40,71^{b}
Firmness	74,29^{a}	127,14^{b}	120,29^{b}
Juice leakage	58,57^{a}	9,14^{b}	5,14^{b}
Cross-section red color intensity	55,57^{a}	22,57^{c}	40,86^{b}
Cross-section color uniformity	84,57^{a}	21,43^{b}	100,43^{a}
Vessels	5,29^{a}	54,86^{b}	5,86^{a}
Fruit compactness	107,14^{a}	130,29^{b}	133,42^{b}
Odor intensity	98,29^{a}	48,86^{b}	75,71^{ab}
Off-odor intensity	1,57^{a}	17,86^{b}	1,43^{a}
Cross-section cavities	1,86^{a}	2,43^{a}	1,86^{a}
Skin chewiness	122,42^{a}	124,43^{a}	98,14^{a}
Pulp chewiness	51,57^{a}	75,14^{a}	61,14^{a}
Juiciness	95,86^{a}	38,29^{b}	39,57^{b}
Granularity	57,43^{a}	86,86^{ab}	100,57^{b}
Sweetness	30,14^{a}	32,00^{a}	26,00^{a}
Sourness	78,00^{a}	87,57^{a}	101,43^{a}
Taste intensity	71,29^{a}	50,86^{a}	57,29^{a}
Off-taste intensity	0,71^{a}	16,14^{b}	2,57^{a}

Values are means of two measurements.
Values with the different superscript within a row are statistically different (P < 0.05).

CONCLUSIONS

Heat treatment in water increased cross-section red color intensity and color uniformity, and also caused less presence of vessels, as well as lower intensity of off-odor and off-taste. It also induced delay of ripening in treated tomatoes in comparison with non treated samples.

ABSTRACT: Due to the greater awareness among the scientists and technologists regarding unbalanced diet of celiac patients, buckwheat flour has been recently in a focus as a novel material in gluten-free formulations because of its unique nutritional profile. However, the use of buckwheat flour in baked product formulations has been limited due to the lack of gluten-forming protein which imparts the dough viscoelastic properties and gas retention. In order to improve the processing properties of gluten-free cereals and pseudocereals hydrocolloids are commonly used as gluten substitutes.
Therefore, the aim of the present study was to investigate the influence of different hydrocolloids (xanthan and hydroxypropyl methylcellulose) on thermomechanical and viscoelastic properties of buckwheat dough. Concerning the thermomechanical behaviour determined by Mixolab, xanthan and hydroxypropyl methylcellulose incorporation in buckwheat dough resulted in significantly decreased water absorption and increased dough development time. Moreover, due to the specific behaviour of examined systems, standard Mixolab protocol was modified by increasing the dough weight from 75 to 90 g and duration of dough mixing during the cold stage from 8 to 15 min. During the heating stage, the addition of xanthan significantly affected the weakening of the buckwheat dough induced by mixing and temperature enhancement, as well as the peak viscosity, while hydroxypropyl methylcellulose significantly affected breakdown torque. The study of rheological properties of dough by oscillatory and creep measurements showed that xanthan significantly strengthened the buckwheat dough.
Key words: *hydrocolloids, buckwheat dough, Mixolab, rheology*

INTRODUCTION

Coeliac disease may be defined as a long-life intolerance to wheat gliadin fraction and rye prolamins (secalins), barley (hordeins) and possibly oats (avidins) (Murray, 1999). Since gluten is the main structure-forming protein in flour which is responsible for the elastic properties of dough, its removal in gluten-free products represents major challenge to the cereal technologist (Gallagher et al., 2004). Lack of viscoelasticity of different gluten-free dough might be overcome by the addition of different gums and hydrocolloids which represents essential ingredient in gluten-free formulations for texture and appearance improvement of the final product. The incorporation of gums and hydrocolloids assures higher dough consistency, improved gas retaining properties and longer shelf life due to their structure forming ability (Mariotti et al., 2009). According to Thompson (1999) gluten-free food formulation are frequently produced from refined gluten-free flour or starch and they are generally not enriched or fortified (Thompson, 1999). Therefore, there is a rising trend in the addition of different ingredients with improved nutrient profile in gluten-free formulation. Due to its high content of polyphenol/flavonoids compounds, minerals,

essential amino acids (Mariotti et al, 2008; Morita et al., 2006) etc., buckwheat flour is gaining more popularity in gluten-free formulations.
Since influence of different hydrocolloids on rheological properties of wheat flour, rice flour and gluten-free mixtures was already investigated, the aim of the present study was to investigate the effect of xanthan and hydroxypropyl methylcellulose on thermomechanical and viscoelastic properties of buckwheat dough.

MATERIAL AND METHODS

Wholegrain buckwheat flour, BF (11.1% moisture) was purchased from a local market. The hydrocolloids used in this study were hydroxypropyl methylcellulose, HPMC (Alfa Aesar, Germany) and xanthan (Roth, Germany) which were added to buckwheat dough at 1.5%.
The effect of hydrocolloids on dough thermomechanical properties was investigated using Chopin Mixolab (Tripette et Renaud, Paris, France) with the modified Chopin+ protocol. The parameters of the protocol are listed in Table 1.

Table 1. Modified Chopin+ Mixolab parameters

Setting	Values
Mixing speed	80 rpm
Target torque (for C1)	1.1 Nm
Dough weight	90 g
Tank temperature	30 ℃
Temperature first step	30 ℃
Duration first step	15 min
Heating rate	4 ℃/min (15 min)
Temperature second step	90 ℃
Duration second step	7 min
Cooling rate	4 ℃/min (10 min)
Temperature third step	50 ℃
Duration third step	5 min
Total analysis time	52 min

Dough samples for the rheological tests were prepared using Mixolab bowl, at 30 ℃. The amount of added water corresponded to Mixolab water absorption, on 14% moisture basis. Total mixing time was 15 min. For the rheological measurements of buckwheat dough, Haake Mars rheometer (Thermo Scientific, Germany), operated at 30 ℃ and equipped with two 35 mm serrated plates was used. The buckwheat dough was placed between plates within 10 min after mixing. The excess edges of the sample were trimmed; the rim of the sample was coated with paraffin oil and the test was started after the dough was rested for 10 min. The tests performed on the dough samples were: a) frequency sweep test from 0.1 to 10 Hz under a 5 Pa stress, which was within the linear viscoelastic region and b) creep test at constant shear stress of 200 Pa for 300 s, followed by strain recovery in 600 s after removal of load.

RESULTS AND DISCUSSION

The effect of xanthan and hydroxypropyl methylcellulose on the thermomechanical properties of buckwheat flour is shown in Figure 1. While the first stage (from the beginning to C2 value) mainly described the properties of BF proteins, the second stage (from C2 to the end of the profile) reflected the behaviour of starch component.

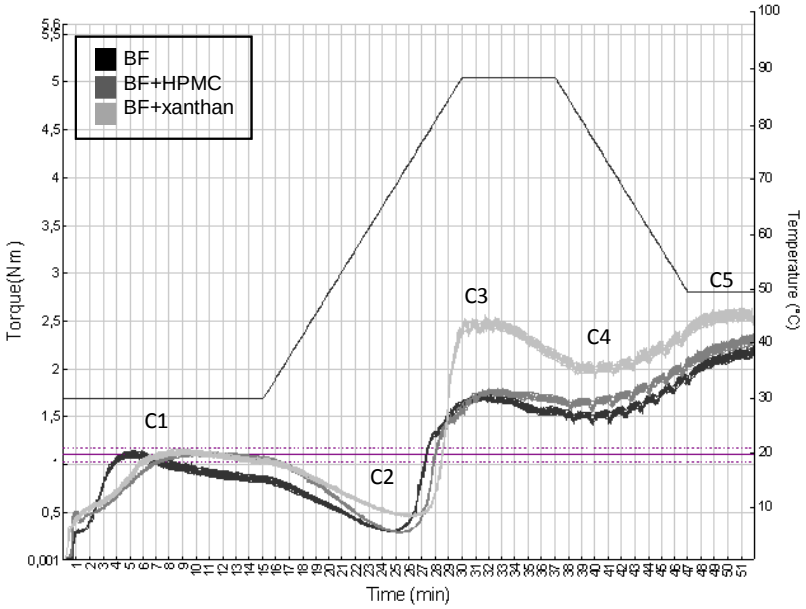

Figure 1. Effect of hydrocolloids addition on mixolab profile of buckwheat dough

In contrast to wheat flour (Rosell et al., 2007) and gluten-free flour blends (Lazaridou et al., 2007), water absorption of buckwheat flour decreased with the hydrocolloids addition. Wholegrain buckwheat flour exhibited higher water absorption (WA = 67.3%) than wheat flour (Rosell et al., 2007) and the presence of HPMC and xanthan lowered the WA values to 65.3 and 62%, respectively. Due to the ability of hydrocolloids to slowly hydrate, the dough development time of buckwheat flour was greatly increased in the presence of hydrocolloids, resulting in an increase of 93% for HPMC and 76% for xanthan. Due to the specific behaviour of examined systems, standard Mixolab Chopin+ protocol was modified by increasing the dough weight from 75 to 90 g and duration of dough mixing during the cold stage from 8 to 15 min (Table 1). According to results obtained by Rosell et al. (2007) who examined the influence of HPMC, pectin, guar and xanthan addition on thermomechanical properties of wheat flour, HPMC was the polymer with the strongest effect on dough development time and dough stability. Similar results had also been reported by Sivaramakrishnan et al. (2004) in the case of rice flour fortified with 4.5% HPMC. As can be observed in Figure 1, the addition of xanthan strengthened the buckwheat dough, as revealed by increase in C2 value, which reflects the dough resistance to mechanical and thermal stress. On contrary, HPMC did not affect the C2 parameter value. Except buckwheat protein weakening and denaturation, further increase in temperature (from 59 – 60.8 ℃ to 90 ℃) led to sta rch granule swelling, disintegration and leaching of amylose and amylopectin. C3 is the parameter which indicates starch gelatinization (Ozturk et al., 2008). The value of peak torque, C3, was greatly increased by xanthan incorporation, while hydroxypropyl methylcellulose decreased breakdown torque (difference between C3 and C4 value). On contrary, setback torque (difference between C5 and C4 value) which refers to starch retrogradation was not affected by hydrocolloids addition.

The effect of hydrocolloids on viscoelastic properties of buckwheat dough was also investigated. Mechanical spectra (Figure 2) of all samples showed that the value of storage modulus (G') increased with an increase in frequency, while loss modulus (G") was nearly independent of frequency. This characteristic of buckwheat dough was also reported by Han et al. (2011).

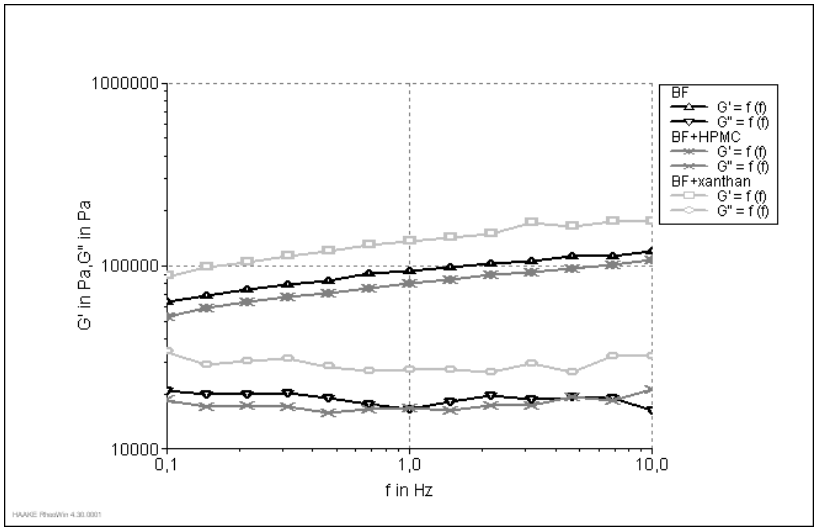

Figure 2. Effect of hydrocolloids addition on mechanical spectra of buckwheat dough

In general, the value of G' was higher than G" (tan δ < 1) in the whole range of frequencies which indicated a prevalence of elastic properties over viscous. The highest dough strength, as revealed by G' value, was observed in xanthan, following by control sample (pure buckwheat dough) and the lowest in HPMC containing sample.

Creep and recovery curves of the control dough and samples with the addition of hydrocolloids are shown in Figure 3. The lowest value of maximum strain, i.e. the highest resistance to deformation was obtained for sample which contained xanthan, while the lowest resistance to deformation was observed in samples with HPMC. Therefore, it can be concluded that parameters which are related to dough strength (C2 value in Mixolab, G' value in frequency sweep test and maximum strain value in creep and recovery test) were in accordance.

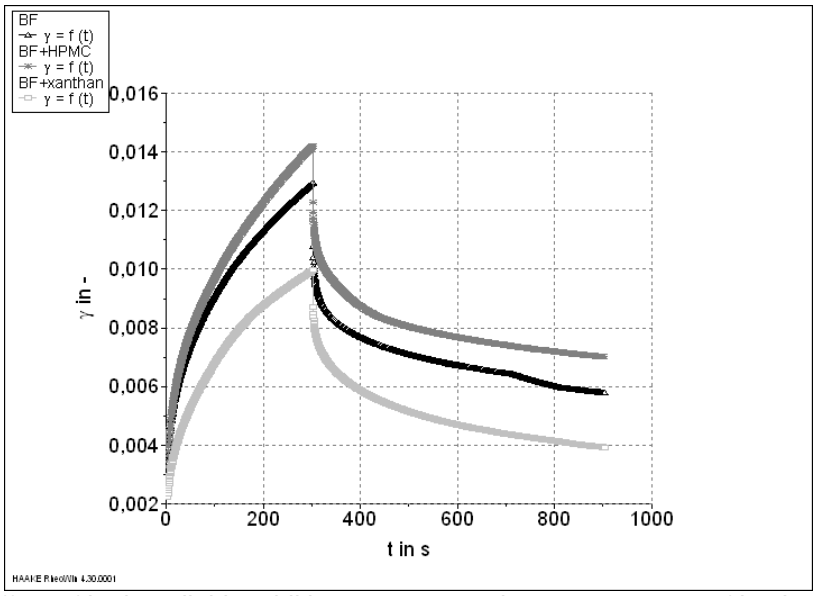

Figure 3. Effect of hydrocolloids addition on creep and recovery curves of buckwheat dough

In the recovery phase, approximately 60% elastic recovery could be seen for xanthan containing dough, while the recovered deformation for HPMC and control dough was 51 and 55%, respectively.

The ability of xanthan to enhance dough strength and elasticity was reported earlier for gluten-free flour blend (Lazaridou et al., 2007) and ascribed to its rigid, ordered chain conformation and high viscosity of its solution.
On contrary, HPMC addition slightly lowered buckwheat dough rigidity and elasticity. According to literature findings, opposite conclusions concerning the influence of HPMC have been reported. Sivaramakrishnan et al. (2004) have revealed that high viscous character has been imparted by HPMC addition to rice flour. On contrary, Lazaridou et al. (2007) have reported that the addition of HPMC into gluten-free flour blend resulted in creep and recovery curves which shifted to higher values.

CONCLUSIONS

It can be concluded that influence of the HPMC and xanthan on thermomechanical and viscoelastic properties of buckwheat dough greatly depend on the nature of added hydrocolloid. While the incorporation of HPMC mainly affected dough development time and only slightly decreased dough strength, xanthan caused greater effects on buckwheat dough, which was expressed as increase in dough strength and elasticity as well as rise in maximum viscosity during heating. Moreover, in buckwheat flour, which already contains natural hydrocolloids in contrast to wheat and rice flour, the changes induced with further hydrocolloid addition are somewhat different than the one observed in other flours.

ABSTRACT: The aim of this research was to study influence of turbulence promoters on permeate flux improvement and energy savings during microfiltration of milk. Low pressure loss turbulence promoters, twisted tape and blade shaped static mixer, named Koflo, were used. The chosen turbulence promoters are of the same aspect ratio (ratio of pitch length to diameter of promoter) 2.5 and inserted into the tubular ceramic membrane (0.1 μm pore size). By applying turbulence promoters, fouling was reduced and the permeate fluxes were increased by a factor of three for twisted tape and by a factor of four for blade shaped static mixer. Intensity of turbulence in a module fitted with promoter depends on the applied cross flow rate. An increase of cross flow rate induces a rise of flux in the both modes of operation, with and without turbulence promoters. When compared at the same cross flow rate, the flux obtained by application of turbulence promoters is always higher than the flux obtained without promoters. The cross flow rates, under which the maximal flux improvement was achieved (300% for twisted tape and 320% for Koflo), are several folds lower than that applied in operation without promoter. In the presence of turbulence promoters permeate flux was increased as well as the pressure drop along membrane. Despite the higher pressure drop, operation with turbulence promoters provides significantly reduced energy consumption compared to operation without turbulence promoters.
Keywords: *turbulence promoters, twisted tape, blade shape static mixer, microfiltration*

INTRODUCTION

Pressure driven membrane processes are widely used in the food industry to substitute conventional concentration, separation and clarification techniques. Applications of membrane filtration in the dairy industry include bacterial removal, selective separation of micellar casein and milk fat, fat removal from whey by microfiltration (MF), milk concentration by ultrafiltration, cheese or milk permeate concentration by nanofiltration [Saboya, Maubois, 2000]. The efficiency of a pressure driven membrane process essentially depends on maintenance the stable permeate flux. Permeate flux value is limited by membrane fouling [Palacio at al., 2003]. During microfiltration, membrane fouling can lead to more than an order of magnitude reduction in the filtrate flux and this fouling is typically caused by the deposition of large protein aggregates on the membrane surface [Bowen, Gan, 1991; Belfort at al., 1994]. Both protein adsorption and protein–protein interactions can narrow or plug pores hence increasing the rejection of permeate particles. Rejected particles can be accumulated at the surface of the membrane due to their slow diffusion back into the retentate, which can be reduced, but not eliminated by cross-flow filtration. Accumulation of particles causes concentration gradient at the membrane surface resulting in the fouling mechanism known as concentration polarization [James et al., 2003].
Physicochemical properties of the solute and the hydrodynamics of the membrane system also have significant effects on membrane fouling. The rate and extent of irreversible membrane fouling depend on the membrane material and operating parameters (transmembrane pressure, crossflow velocity, temperature) [Jones, O`Melia, 2001]. Chemical, mechanical and hydrodynamic methods and/or pre-treatment are used to reduce fouling [Brans et al., 2004]. Also, in order to reduce

fouling, different techniques such are vibrations, backflushing, backpulsing, rotations, have been developed [Fuente et al., 2010; Sondhi, Bhave, 2001; Williams, Wakeman, 2002]. One of the hydrodynamic techniques for fouling reduction is an increase of turbulence intensity by the introduction of motionless turbulence promoters in the flow channel. The insertion of turbulence promoters in the membrane module is proved to be efficient technique from the point of view of energy consumption, capital costs and maintenance, while the achieved flux improvement can be above 300% depending on the filtered system and applied operating conditions [Krstić et al., 2003, 2007]. Hydrodynamics in module can be changed using different types of turbulence promoters such as KM Kenics^{TM} static mixers, helical screw-thread, cone shape inserts, metal grills, spiral wire, disc and doughnut shape inserts, twisted tapes and smooth rods.
The objective of this study was to investigate influence of turbulence promoters geometry on the permeate flux improvement in the MF process. In this work, twisted tape and blade shaped static mixer, named Koflo^{TM}, were chosen because they cause low pressure drop along the membrane. The effects of these two turbulence promoters, with different geometry and same aspect ratio of 2.5, on permeate flux improvement are analysed. Also, energy consumption using the turbulence promoters was investigated in this work.

MATERIALS AND METHODS

Pasteurized and homogenized (one stage, 150bars), partially skimmed milk was used as feed throughout the cross-flow microfiltration experiments. The composition of fresh milk (%, w/w) was as follows: 3.1 proteins, 2.8 fat, 3.5 lactose and 0.7 ashes (Dukat Dairy Industry, Serbia). The pH of milk was 6.8 ± 0.15 at 50 ◦C. The particle size distribution in milk was measured using a Malvern Nano ZS analyser at 20 ◦C (Malvern Instruments Ltd., Worcestershire, United Kingdom). For the particles in milk, an average hydrodynamic diameter of 185 ± 8.0 nm was determined.
All experiments were performed using the laboratory scale microfiltration/ ultrafiltration experimental unit made of stainless steel. Experiments were performed using a single channel ceramic membrane, 250 mm long, with 7 mm ID and 10 mm OD (GEA, Germany). The 0.1 µm membrane made of a zirconium filtering layer on an α-alumina support. Active filtering area of membrane was 46.2 cm^2. Permeate was collected in the container placed on the digital balance (EW 1500-2 M, KERN Germany) and continuously weighted while the data were transferred to personal computer.
Each experiment included the following steps: pure water flux measurement, microfiltration, rinsing, chemical cleaning, rinsing, and pure water flux measurement. The feed flow rate was varied from 1.0 to 6.0 L min^{-1} while the transmembrane pressure was 50 kPa in all of the tests. All experiments were carried out at 50 ± 0.5 ^{o}C.
Experiments were carried out with and without turbulence promoters in order to examine effects of turbulence promoters on microfiltration process. As turbulence promoters the twisted tape and Koflo static mixer were used (Fig.1). For turbulence promoters the main geometrical characteristic is an aspect ratio (O_{TP}) defined as ratio of the pitch length to the diameter. Turbulence promoters were manufactured in the workshop Inox Bravarija (Bački Petrovac, Serbia) and their overall characteristics are given in Table 1.

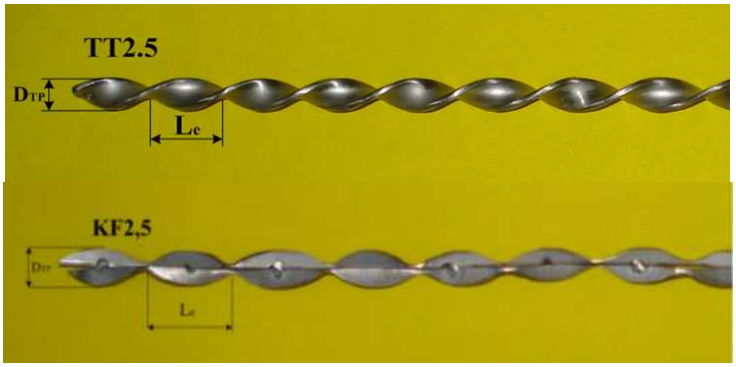

Fig. 1. Turbulence promoters

Table 1. Characteristic of twisted tape and Koflo static mixer with aspect ratio of 2.5

	TT2,5	KF2,5
Material	Stainless still	
D_{TP} (mm)	6,3	6,2
L_{TP} (mm)	243	250
Le (mm)	15.5	15.6
N_{TP}	16	16
O_{TP}	2,5	2,5

To evaluate the efficiency of turbulence promoters two references are chosen: flux improvement (FI) and specific energy consumption (E). The FI represents a relative comparison of fluxes obtained with and without a turbulence promoters application, as follows:

$$FI = \frac{J_{TP} - J_{NTP}}{J_{NTP}} \times 100\% \quad (1)$$

The specific energy consumption (E) represents the hydraulic power dissipated (HDP) per unit volume of permeate. The HDP depends on the pressure loss (ΔP) along the membrane module and the applied cross flow rate (Q), so the specific energy consumption is calculated from:

$$E = \frac{Q\Delta P}{J_p A_{ac}} \quad (2)$$

where A_{ac} is active surface of a membrane (m^2) and J_p is permeate flux ($Lm^{-2}hr^{-1}$).

RESULTS AND DISCUSSION

Comparison under constant cross flow rate

Permeate fluxes recorded during microfiltration of milk under the cross flow rate of 3 L min^{-1} and transmembrane pressure of 50 kPa is shown at Figure 2. The use of turbulence promoters, twisted tape (TT2.5) and Koflo (KF2.5) provided a significant flux enhancement compared to the operation without turbulence promoters (NTP). Namely, application of the twisted tape enables increase of the permeate flux from 17 to 55.5$Lm^{-2}hr^{-1}$ while Koflo static mixer enables increase from 17 to 75$Lm^{-2}hr^{-1}$.

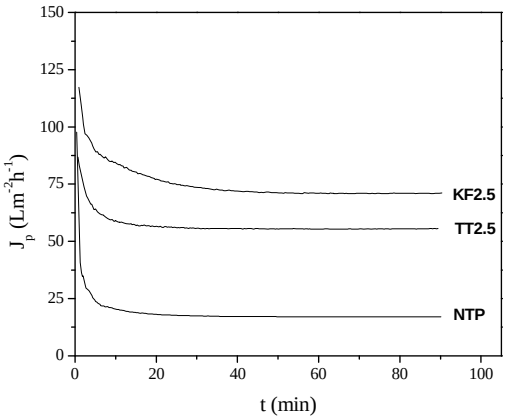

Fig.2 Time dependency of flux during milk microfiltration

The curves of permeate flux have the shape which indicates type of fouling typical for the microfiltration of milk (Popović, Tekić, 2011). The sharp flux decline is usually attributed to the concentration polarization and gel layer formation at the membrane surface. Application of turbulence promoters contributes to fouling reduction. In the presence of turbulence promoters, fluid acceleration occurs due to reduction in cross-sectional area of membrane. The local acceleration of fluid nearby the membrane surface reduces the formation of the boundary layer. This contributes to reduction of concentration polarization and consequently results in a high permeate flux.

Influence of cross flow rate

The permeate flux variation with cross flow rate for both NTP and turbulence promoters operation is shown in Fig. 3. As obvious, the much higher fluxes were obtained at lower flow rates by using turbulence promoters.

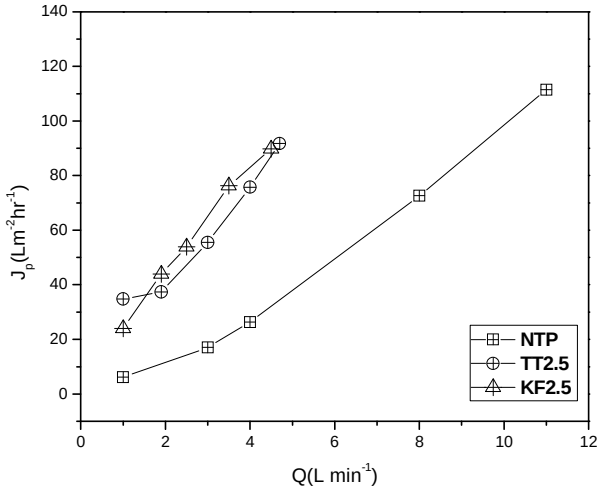

Fig.3. Permeate flux as a function of the cross flow rate

At the same cross flow rate, higher flux has been achieved using TT2.5 and KF2.5 compared to membrane without turbulence promoters (NTP). Further, when comparing values of permeate fluxes achieved with TT2.5 and KF2.5, it can be seen that KF2.5 gives higher permeate flux.

Change of hydrodynamic regime is not the only factor that is responsible for flux improvement. The most important factor in flux improvement is change in streamline path. In the presence of turbulence promoters, hydrodynamic regime in the

membrane is changed using only the energy of a moving fluid. The helical geometry of the twisted tape elements results in a change of axial flow to the helical flow. Helical path of the streamlines and the appearance of local vortices reduce the effects of concentration polarization and deposition of particles and results in a higher permeate flux. In the presence of Koflo static mixer, center of the membrane is blocked periodically in places where the blades intersect. Koflo divides fluid into two parts after each blade. A part of the fluid is forced to move helically along the wall membrane and reducing deposition of large proteins at the membrane surface.
The increase of the cross flow rate in NTP operation never resulted in such increase of the flux as it can be obtained by application of a turbulence promoters.

Efficiency of turbulence promoters
In order to completely prove the efficiency of turbulence promoters the values of flux improvement and energy consumption were analyzed. Fig. 4 shows the flux improvement obtained by application of turbulence promoters under the investigated range of cross-flow rates. The flux improvement of 180–300% is achieved by applying the TT2.5 while the flux improvement of 200–320% is achieved using KF2.5 static mixer. The cross-flow rate under which the maximal flux improvement can be achieved is about 2 L min^{-1} for twisted tape and about 1,5 L min^{-1} for Koflo static mixer.

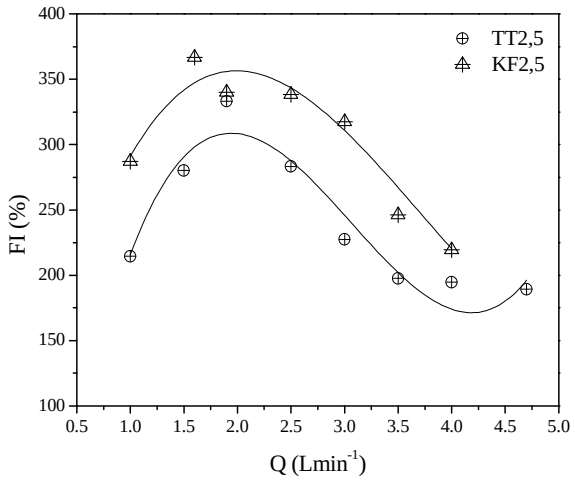

Fig. 4. Flux improvement as a function of the cross-flow rate.

In the presence of turbulence promoters permeate flux and pressure drop along membrane are increased. Pressure drop influences on the choice of transmembrane pressure and economic viability of microfiltration. With regard to empty membrane, turbulence promoters cause higher pressure drop and increase of power dissipation. To demonstrate that they are still efficient, the flux improvement for the same hydraulic dissipated power is presented in the Table 2.

Table 2. Flux improvement as function of the hydraulic dissipated power.

HDP (W)	J_p ($Lm^{-2}h^{-1}$)			FI (%)	
	NTP	KF2,5	TT2,5	KF2,5	TT2,5
0,08	12	24	20	100	67
0,25	29	44	43	52	48
0,4	35	51	56	54	70
1,0	52	74	78	42	50
2,0	73	86	92	19	26

The flux improvement of 19-100% was achieved by applying KF2.5 and improvement of 26-67% by applying TT2.5. This improvement decreases with an increase of the hydraulic dissipated power for turbulence promoters.
Despite the higher pressure drop, application of turbulence promoters enables significant reduction of energy consumption in the range of 45-67% for the twisted tape and 23-67% for the Koflo static mixer.

CONCLUSION

The results of experiments clearly show that application of turbulence promoters contributes to fouling reduction and improvement of permeate flux compared to results achieved in conventional microfiltration of milk. Permeate flux improvements of 300% for twisted tape and of 320% for Koflo static mixer were obtained at the same cross flow rate. The flux improvement using turbulence promoters was obvious also under the same hydraulic dissipated power indicating that an energy saving is possible using the turbulence promoters compared to operation without the promoters.

ABSTRACT: This paper presents a study on the mathematical modelling of solar drying of unprocessed apricot and sulphurated apricot. In this purpose, natural convection solar food dryer which has solar air collector was designed and manufactured for drying food products. Solar drying experiments of apricots were conducted in Izmir, Turkey and experiments were realized in two steps. In the first experiment, natural drying was done without applying any pretreatment. In the second experiment, apricots were dried after sulfuring pretreatment. During the drying period, relative humidity, air flow rates, drying air temperature, solar radiation and lose of food product's mass were measured continuously in the different parts of the dryer. Drying time is examined with mass ratio for each apricot type as polynomial and exponential correlations, separately. Fourteen different mathematical drying models available in literature were compared based on their coefficient of determination, mean bias error, root mean square error, modelling efficiency and reduced chi-square to estimate the solar drying curves. According to statistical analysis results, the Midilli and Kucuk drying model has shown a better fit to the experimental drying data of untreated apricot and sulphurated apricot with a coefficient of determination R^2 of 0, 9982 and 0, 9948, respectively.
Keywords: *mathematical modelling, apricot, sulphated apricot, solar food drying, mass ratio.*

INTRODUCTION

Turkey has a high potential solar enegy and means annual bright sunshine hours. According to experimental data, annual mean sunshine hours is 2640 hours/year (7.2 hours/day), annual mean solar energy is 1311 kWh/m^{2}year (3.6 kWh/m^{2}day) for Turkey (EIE, 2006). Many different types of vegetables and fruits have been produced in Turkey because of its suitable climate. Drying has always been of great importance for conserving agricultural products in agricultural countries like Turkey. Drying process is the most common form of food preservation and extends the food self-life. It is a simultaneous heat and mass transfer operation in which moisture is removed from food material and carried away by hot air. Open sun drying is a well-known food preservation technique that is still the most common method used to preserve agricultural product in most tropical and subtropical countries.
In Turkey, drying is achieved method by spreading out the material on the ground. In this way, there are many disadvantages like low quality and hygienic problems. The resulting loss of food quality in the dried products may have effect negatively trade potential and economical worth. For preventing the deterioration of the materials different types of drying methods have been developed. On the other hand, the conventional dryers are not economic due to high energy cost. For that reason, direct or indirect sun dryers have good opportunity for about quality and efficiency improvement. In this purpose, this study was undertaken to investigate drying characteristics of unprocessed apricot and sulphurated apricot in a solar dryer in Izmir, and to fit the experimental data to mathematical models available in literature.

MATERIAL AND METHODS

In this experimental study, solar dryer who has the dimensions of the drying unit are 1 m x 1 m x 1.1 m is used for drying of apricot. This solar dryer consists of a flat plate solar air collector and drying unit as shown in Figure 1. The dryer and solar air collector was oriented in an east-west direction to make the incident solar radiation more efficient on the solar dryer. Drying unit was covered with polyethylene plastic film material. Three drying trays, having dimensions of 1 m x 1 m, were placed in the solar dryer. These trays were used to accommodate apricots to be dried. The solar air collector dimensions were 1 m wide by 2 m long and 0.17 m high. A corrugated galvanized iron sheet painted black was used as an absorber plate for absorbing the solar radiation. A polyethylene plastic film material was used as a transparent cover for the air collector to prevent the heat losses. Styrofoam is used as insulation material to prevent heat losses from the sides and bottom of solar collector. Heat is transferred from the absorber surface to the air in the collector and heated air while passing over the product absorbs moisture.

Figure 1. View of solar dryer

Drying experiments were conducted in Izmir and experiments were realized in two steps. In the first experiment, natural drying was done without applying any pretreatment. In the second experiment, apricots were dried after sulfuring pretreatment. The important parameters as drying air temperature, relative humudity, air flow rates, solar radiation, and lose of mass affecting the performance of the dryer were measured. A pyranometer was used to measured the solar radiation on the horizontal surface. The temperature and relative humidity inside and outside of the dryer were measured with a temperature and relative humidity probes. The velocity of drying air was measured with an anemometer at the inlet of the dryer.

Mathematical Modeling of Solar Drying Curves

The drying curves obtained were fitted with fourteen different moisture ratio equations by several authors in Table 1 (Diamente et al., 1993; Sharaf-Elden et al., 1980; Togrul and Pehlivan, 2002; Liu and Bakker-Arkema, 1997; Karathanos and Belessiotis, 1999; Koua et al., 2009; Goyal et al, 2006; Gungor and Ozbalta, 2003; Tunde-Akintunde, 2011; Vega-Galvez, 2010; Midilli et al., 2002; Gurlek et al., 2009). The moisture ratio (MR) was simplified to M_t/M_o as written in the following table and M_o is sample mass at the beginning and M_t is sample mass in time t.

Table 1. Mathematical models given by various authors for the solar drying curves

Model	Model equation	Model name

10	$(M_t / M_o) = 1 + at + bt^2$	Wang and Singh
11	$(M_t / M_o) = a \exp(-kt) + (1-a) \exp(-gt)$	Verma et al.
12	$(M_t / M_o) = a \exp(-kt) + (1-a) \exp(-kbt)$	Diffusion approximation
13	$(M_t / M_o) = a\exp(-kt^n)+bt$	Midilli and Kucuk
14	$(M_t / M_o) = at^3+bt^2+ct+1$	Authors approximation

The experimental drying data for unprocessed apricot and sulphurated apricot were fitted to drying models in Table 1 by using regression analysis. The coefficient of determination (R^2) was one of the important criteria to select the best equation in the solar drying curves of the dried samples as apricot. In addition to R^2, the various statistical parameters such as; reduced Chi-square ($\chi 2$), mean bias error (MBE), the root mean square error (RMSE) and the modelling efficiency (EF) were used to determine the quality of the fit. The lower the values of the $\chi 2$, the better the goodness of the fit. The RMSE gives the deviation between the predicted and experimental values and it is required to reach zero. The EF also gives the ability of the model and its highest value is 1 (Gurlek et al., 2009). These parameters can be calculated as;

$$\chi^2 = \frac{\sum_{i-1}^{N} \left(MR_{\exp,i} - MR_{pre,i}\right)^2}{N-n}$$

$$MBE = \frac{1}{N}\sum_{i-1}^{N}\left(MR_{pre,i} - MR_{\exp,i}\right)$$

$$RMSE = \sqrt{\frac{\sum_{i-1}^{N}\left(MR_{pre,i} - MR_{\exp,i}\right)^2}{N}}$$

$$EF = \frac{\sum_{i=1}^{N}\left(MR_{\exp,i} - MR_{i,\exp mean}\right)^2 - \sum_{i=1}^{N}\left(MR_{pre,i} - MR_{\exp,i}\right)^2}{\sum_{i=1}^{N}\left(MR_{\exp,i} - MR_{i,\exp mean}\right)^2}$$

where $MR_{exp,i}$ is the experimental moisture ratio found in any measurement and $MR_{pre,i}$ is predicted moisture ratio for this measurement. N the number of observations, n the number of constants and $MR_{expmean}$ is the mean value of the experimental MR. The best model describing the drying behaviour of apricot was chosen as the one with the highest coefficient of determination and the modelling efficiency and the least reduced Chi-square, mean bias error and root mean square error (Gurlek et al., 2009).

RESULTS AND DISCUSSION

In this study, the constant and coefficients of the best fitting mathematical model involving the drying variables such as temperature, humidity of the drying air were determined. The changes in the moisture ratio of natural drying of apricot with drying time are shown in Figure 2. The experimental data obtained for air at temperature

ranging from 48 ^{0}C to 57.1 ^{0}C. The interruptions of the lines in this figure represent the night periods of the drying operation. The drying continues after the sunset due to the thermal inertia of the system. There is not any constant-rate drying period in this curve and all the drying operations are seen to occur in the falling rate period.

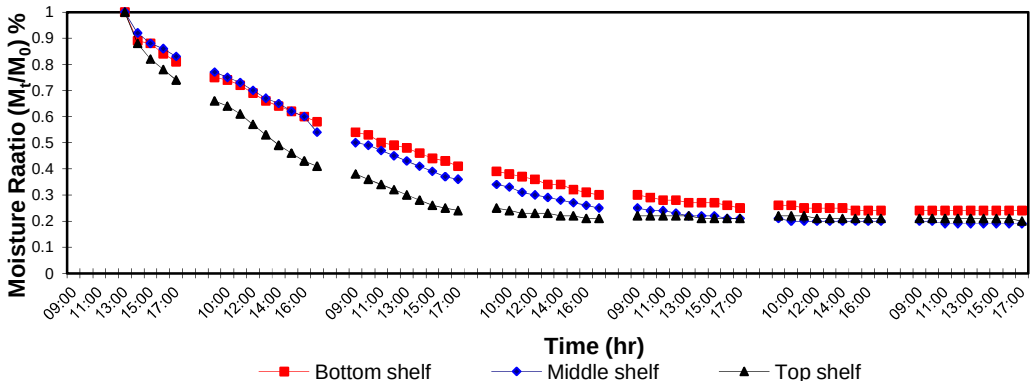

Figure 2: The changes in moisture ratio of unprocessed apricot with time.

The changes in the moisture ratio of sulphated apricot with drying time are shown in Figure 3. The experimental data obtained for air at temperature ranging from 44,8 ^{0}C to 59,7 ^{0}C. There is not any constant-rate drying period in this curve and all the drying operations are seen to occur in the falling rate period. During the falling rate drying period, the drying rate decreases continuously with decreasing moisture content and increasing drying time.

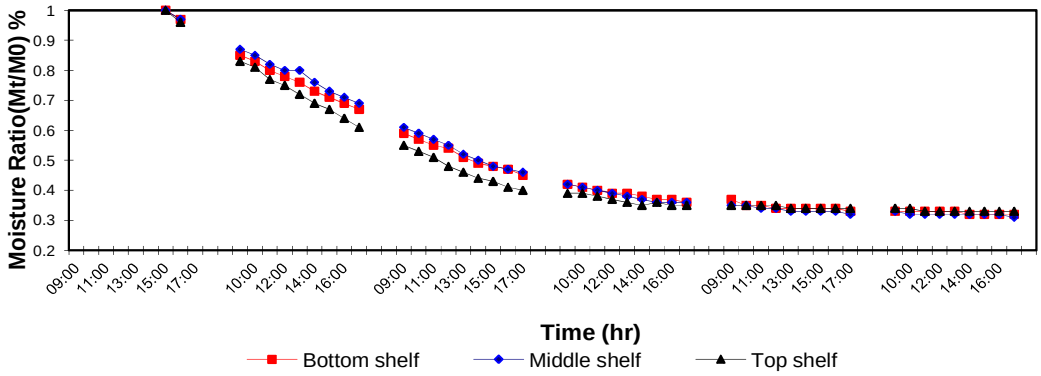

Figure 3: The changes in moisture ratio of sulphated apricot with time.

The effect of these variables on the constant and coefficient of drying expression were also investigated by regression analyses. The drying data as the moisture ratio (MR) versus drying time were fitted to the fourteen drying models. Table 2 for unprocessed apricot drying and Table 3 for sulphated apricot drying show drying model coefficients and the comparison criteria used to evaluate goodness of fit, namely the coefficient of determination (R^2), the reduced Chi-square ($\chi 2$), mean bias error (MBE), the root mean square error (RMSE) and the modelling efficiency (EF) for solar drying. For unprocessed apricot drying the values of R^2, $\chi 2$, MBE, RMSE, and EF for models range from 0,9375 to 0,9982; 0,00010 to 0,00432; -0,01211 to 0,060406; 0,01016 to 0,05989 and 0,8574 to 0,99807 ,respectively. According to Table 2, Midilli and Kucuk model showed good agreement with the experimental data and gave the best result for unprocessed apricot samples.

For sulphated apricot drying the values of R^2, χ2, MBE, RMSE, and EF for models range from 0,9315 to 0,9948; 0,00021 to 0,00280; -0,00491 to 0,000240; 0,01518 to 0,05326 and 0,93083 to 0,99472, respectively. According to Table 3, Midilli and Kucuk model showed good agreement with the experimental data and gave the best result for sulphated apricot samples. The constants and coefficients of the accepted model for the solar drying of sulphated apricot drying were as below:

$$(M_t / M_o) = a\exp(-kt^n)+bt, \text{ where } a=1,001;\ b=0,00598;\ k=0,02951;\ n=1,208.$$

CONCLUSIONS

In this study, the solar dryer can be used for drying of various agricultural products as well as apricot under the climatic conditions of Izmir. The moisture content was reduced in seven days for unprocessed apricot drying and in six days for sulphated apricot drying. All drying processes occured in the falling rate period. In adddition, the apricot samples of solar dryer were completely protected from birds, insects, rain and dusts.

In order to explain the drying behaviour of unprocessed and sulphated apricots, fourteen different mathematical models were compared according to their coefficient of determination values. According to the results, Midilli and Kucuk model could adequately describe the solar drying behaviour of unprocessed and sulphated apricots in a solar dryer.

It is expected that this system will help growers reduce the cost of drying and obtain more quality dried products. The results of the predicted models showed that used for solar dryers design for different capacity.

ABSTRACT: The mathematical model can be defined as a set of mathematical relations that describe or define the relationship between certain physical quantities in the reporting process. The aim of this paper was to developed a one-dimensional (FD) model for temperatures prediction during heat treatment of pork meat for non-stationary heat transfer conditions.The pork meat sample was processed in the oven by dry method of heat treatment (one-sided rasting) at three different ambient tremperatures of about 114℃, 152℃ and 204℃ to reach 71˚C in the center of the sample at a given distance x from the bottom surface.The temperature is controlled using a thermocouple.After the heat treatment system, we developed parameters which served to verify the validity of the model. In the end we made an experimental comparison of results with those obtained in the FD model.The developed model showed a high degree of determination and correlation with experimental results, ranging in the interval R = 0,9622 – 0,9948 and determination R^2 = 0,9259 – 0,9897.
Keywords: *FD model, pork meat, heat processing of meat, temperature in the oven*

INTRODUCTION

A model proposed to predict the temperature profiles during one-sided pan-frying of pork meat patties (Zorrillaand Singh, 2003). Enthalpy formulation was used to solve the heat transfer equation due to the phase change in the process.Food and Drug Administration (FDA) recommended that the cooking process of patties to a center temperature should be at least 71℃ or 68,3℃ and h old for 15 seconds (FDA, 1999). Rate of heating to ground pork patties related to some properties such as retention of patty color, texture total crude lipid content, fatty acid, and cholesterol composition (Pan and Singh, 2001). The heat transfer coefficient is an essential parameter in thermal processing of food materials. Beside of the center temperature, soluble protein can be used as an indicator to determine the degree of cooking (Murphyet al., 2002).

Pan and Singh studied ground beef and determined the rate of change in physical and thermal properties of it (Pan et al., 2001). Temperature and holding time affected fat and water holding capacities. In one-sided cooking of pork meat patties, there is a contact between patty and heatingsurface. The rate of heat transfer between them is described by the contact heat transfer coefficient. The contact heat transfer coefficient is a function of heating temperature and time. Physical and thermal properties of heating surfaces, heating temperature and characteristics of medium at the interface may affect the heat transfer rate. Heat transfer process that is predicted using this model is sensitive to fat content. A mathematical model of onesided cooking was developed to predict temperature profiles in meat patties. In this mathematical model the approach of enthalpy formulation was used for heat transfer equation (Ou and Mittal, 2005a).

Transfer processes in meat patties were studied in a one-sided pan fryer. Water and fat losses affect the heat transfer. It was shown that the frying time is a function of fat content and grill temperature. Water loss is increased with the increase in average

temperature (Oroszvári et al., 2005b). Ou and Mittal developed a model of heat and mass transfer for the frying of frozen hamburger patties. Moisture transfer was due to diffusion and capillary flow, but the contribution of diffusion was lower (Ou and Mittal, 2005a). Amézquita et al. studied the effect of various IR-grilling/hot air cooking condition on moisture and fat content and on some physical properties of meat patties. The IR-grilling resulted in crust formation and reduced the fat and moisture content during subsequent convection cooking (Amézquita et al., 2005a).
The aim of the study presented in this paper was to develop 1-D modeling program for temperatures prediction in centre of sample during heat treatment of pork meat for non-stationary heat transfer conditions as function of time and temperature in the oven.Thus, hamburgers were cooked in a one-sided scheme, at a static electrical oven with constant moisture and temperature. A mathematical model of heat transfer was developed to study the change of temperature in the hamburgers. The 1-D modeling program was written in a simulation program (MATLAB 7) along the thickness. The predicted data were compared to experimental ones to validate this modeling process.

MATERIAL AND METHODS

The process of heat treatment

We conducted a dry heat treatment of pork slices samples until the reaching center sample temperature of 71℃ at a given distance "x" from the bottom surface. In doing so, we used three ambient temperatures in the oven "Elit" 3kW, about 114℃, 152℃ and 204℃. Slices were placed between two copper pl ates, a square measuring 10x10 cm. Before the start of heat treatment, copper plates are placed into the oven to reach the temperature of the oven. Slice was placed between the copper plate and heat treated in **the** oven. The process of heat treatment is completed when in the slice center reached a desired temperature. Two K-type thermocouples "Testo" and "HANNA" HI 98 810, (-50˚C and +250˚C) were used to measure surface temperature and the temperature in the center of the sample. The surface temperature of the top copper plate and the temperature inside the oven was measured by analog thermometers. The temperature inside the oven was measured at specific time intervals and expressed as the arithmetic mean value for a given number of measurements. Initial temperature of the samples was around -6℃, to prevent moisture loss. The diameter of the slice was about 90 mm, a thickness of about 14 mm. The initial moisture content was about 60%.
A simple one-dimensional *finite difference* (FD) model was developed, which allows shortening the time required for the calculation of temperature in the center of the sample T_c.This model is based on a numerical method which can predict the temperature in the center of the sample, Tc. Then, carried out to compare results obtained in the FD model with experimental results in order to verify the validity of the model.

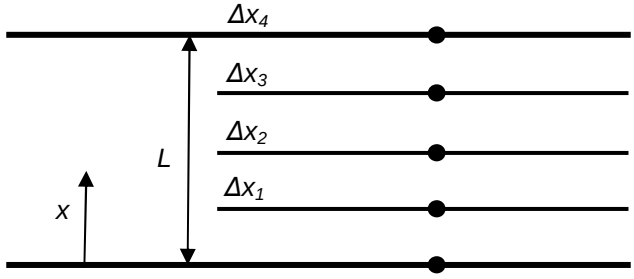

Figure 2. Schematic of nodes considered in the axial direction for finite difference model

Finite difference (FD) model

FD model of heat transfer, presented in this paper, a similar model developed by Ou and Mittal (2006). The process of heat transfer is divided into three phases, the process of heat transfer before the thaw, **in** during thawing and after thawing of the

sample. The assumption is that if the diameter of the slices five times greater than its thickness, in this case, heat transfer can be regarded as one-dimensional in the axial direction. Other important prerequisites for establishing the model of heat transfer involved the assumption of constant physical and thermal properties during heat treatment, constant chemical changes in the sample and the slices were observed as a uniform medium.The assumption is that the top and bottom slice surfaces in contact with the convective transfer coefficientmedium "h_b" (bottom surface) and "h_t" (top surface).

RESULTS AND DISCUSSION

The equations that describe the process of heat transfer in frozen and thawed state for each node can be written as:

Period I (T_0 do 0℃):

Top surface: $K\frac{\left(T_2^j - T_t^j\right)}{\Delta x_4^j} = h_t\left(T_t^j - T_{tp}\right) + \rho C_p \frac{\left(T_t^{j+1} - T_t^j\right)}{\Delta t}$

Node 2: $K\frac{\left(T_c^j - T_2^j\right)}{\Delta x_3^j} = K\frac{\left(T_2^j - T_t^j\right)}{\Delta x_4^j} + \rho C_p \frac{\left(T_2^{j+1} - T_2^j\right)}{\Delta t}$

Node T_c: $K\frac{\left(T_1^j - T_c^j\right)}{\Delta x_2^j} = K\frac{\left(T_c^j - T_2^j\right)}{\Delta x_3^j} + \rho C_p \frac{\left(T_c^{j+1} - T_c^j\right)}{\Delta t}$

Node T_1: $K\frac{\left(T_b^j - T_1^j\right)}{\Delta x_1^j} = K\frac{\left(T_1^j - T_c^j\right)}{\Delta x_2^j} + \rho C_p \frac{\left(T_1^{j+1} - T_1^j\right)}{\Delta t}$

Bottom surface: $h_b\left(T_{bp} - T_b^j\right) = K\frac{\left(T_b^j - T_1^j\right)}{\Delta x_1^j} + \rho C_p \frac{\left(T_b^{j+1} - T_b^j\right)}{\Delta t}$

The initial condition for solving the above equation is: $T(x,0) = T_0$.

Period II (of ice melting):

Top surface: $h_t\left(T_t^j - T_{tp}\right) = L_f \frac{\left(\Delta x_4^{j+1} - \Delta x_4^j\right)}{\Delta t}$

Node T_2: $K\frac{\left(T_2^j - T_t^j\right)}{\Delta x_4^j} = L_f \frac{\left(\Delta x_3^{j+1} - \Delta x_3^j\right)}{\Delta t}$

NodeT_c: $K\frac{\left(T_c^j - T_2^j\right)}{\Delta x_3^j} = L_f \frac{\left(\Delta x_2^{j+1} - \Delta x_2^j\right)}{\Delta t}$

Node T_1: $K\frac{\left(T_1^j - T_c^j\right)}{\Delta x_2^j} = L_f \frac{\left(\Delta x_1^{j+1} - \Delta x_1^j\right)}{\Delta t}$

Period III (0℃ to end of the process):

Equations of this period are similar to the equations of period I.

The amounts of Δt and Δx were selected as followed: $F_0 \le 0{,}5 \Rightarrow \frac{\alpha \Delta t}{(\Delta x)^2} \le 0{,}5$

Thermal diffusivity: $\alpha = \frac{K}{\rho C_p}, \left[\frac{m^2}{s}\right]$

Where the value of Δt and Δx used in this model are 60s and 3,50 mm. Superscript *j*- time numerator.

Combining and solving the previous equation for the nine observed experiments, can be performed equationsof curves, depending on the center temperature "Tc" of the sample with the time "t" required to achieve temperature Tc=f(t). In this way, given the computational data on the value in the center of the sample temperature "Tc", which is then used to compare with as experimental data measured using a thermometer with a thermocouple. In this way, comparing computational and experimental data can be assessed validity of one-dimensional (FD) axial heat transfer model.

Based on the program developed in MATLAB, was performed the correlation of experimental data by the model proposed of Sargolzaei (2009) that created polynomial dependencies, where, as can be seen from the table 4,obtained a high degree of correlation, which ranges in the interval R = 0,9622 - 0,9948, and determination R^2 = 0,9259 - 0,9897.

Standard deviation of regression, or an average deviation of actual (experimental) values of dependent variable (temperature) from regression values, ranging from 2,82 (experiment 4),where the coefficient of variation of 8,14% to 7,44 (experiment 5) with a coefficient of variation of 22,11%.

The following diagram shows the variation of temperature in the oven and the center of the sample compared to the computational results obtained in the FD model and experimental results.

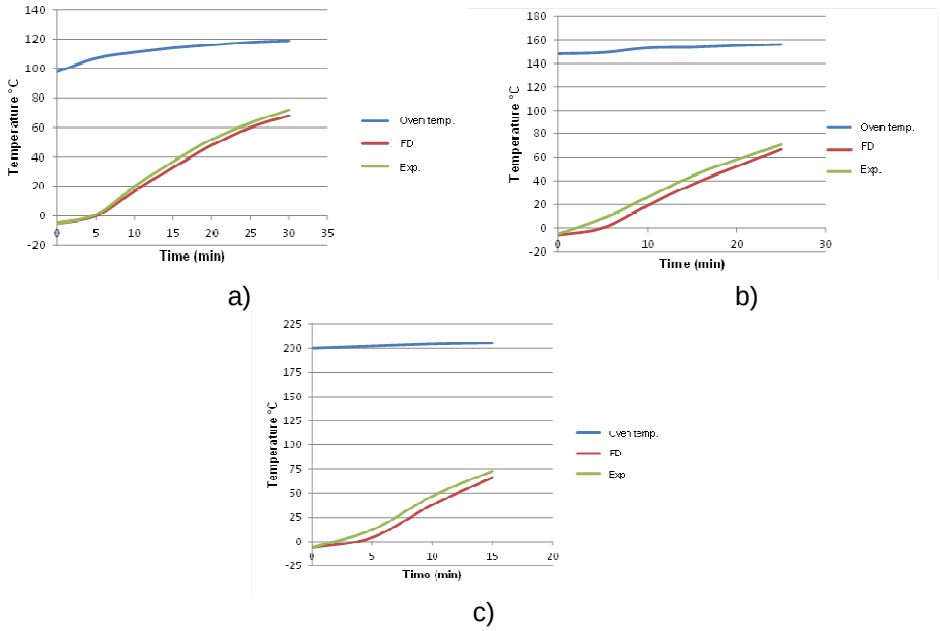

Diagram 1. Comparison of experimental results and the results obtained in the FD model for the three experiments: a)Exp. 2; b)Exp. 5; c)Exp. 8

As shown in the diagram 1 a curve of temperature change in the center of the sample has a very small angle, seen from the beginning to achieve the 0˚C, because the main mechanism of heat transfer during this period is conduction through the solid phase (meat, ice, grease).The amount of heat transferred in this period is not great because of the low coefficient of thermal conductivity of ice. As soon as a thaw of ice, slope will increase as seen from the chart, because the main mechanism of heat transfer **is** fluid (water and fat). This change occurs because water has a much higher coefficient of thermal conductivity than ice.

CONCLUSIONS

A one-dimensional finite difference (FD) mathematical model prediction of temperature in the center of the meat samples at different distances as a function of time and ambient temperature were developed**.** The model showed a high degree of determination and correlation with experimental results, which range in the interval R = 0, 9622 - 0, 9948, and determination R^2 = 0, 9259 - 0, 9897. Standard deviation of regression, or an average deviation of actual (experimental) values of dependent variable (temperature) from regression values, ranging from 2,82 (experiment 4), where the coefficient of variation of 8,14% to 7,44 (experiment 5) with a coefficient of variation of 22,11%.Such a set model developed in Matlab is an important tool in industrial conditions to predict the temperature at the desired distance in the center of the sample with respect to environmental conditions during the heat treatment of the pork meat sample.

ACKNOWLEDGEMENTS

This paper is based on the scientific research project entitled "Effect of heat treatment temperature on protein structure and properties of pork meat." The project is funded by the Ministry of Science and Technology of the Republic of Srpska.

ABSTRACT: The aim of this paper was to optimize the technological process of broccoli drying. The drying experiment were carried out in the laboratory dehydrator, at two temperature regimes of drying, batch process (constant air temperature of 70 ^{o}C for a period of 8h) and simulated continual process (the air temperature of 70 ^{o}C for a period of 3h and then the air temperature of 50 ^{o}C for a period of 5h). The amount of evaporated water was expressed in relative and absolute units of measure. The experiment was conducted to follow the moisture rate of drying of broccoli and was expressed as speed changes in the ratio of moisture content in the moist material depending on the current moisture content. The results showed that in simulated continual process of drying the lower maximum moisture rate of drying was achieved, drying was more evenly and in this way the technological process was finished with a smaller temperature stress for plant tissue, resulting in a better quality of the final product. The second temperature regime of draying, which simulated continual process, was more acceptable in terms of the final product.

Key words: *broccoli, drying, kinetics, quality*

INTRODUCTION

Broccoli (*Brassica oleracea* L.) is a vegetable with exceptional medicinal and nutritional properties. In Serbian traditional diet broccoli has been poorly presented or not presented at all. Dried broccoli in Serbia has not been produced, but on the international market it has been used in the production of dehydrated soups, sauces even for the tea production. Broccoli is a vegetable with numerous bioactive substances with health-promoting properties. Broccoli is a rich source of glucosinolates and has a high content of flavonoids, vitamins and mineral nutrients. (Moreno et al., 2006). The results of many studies of prevention of certain types of cancer suggest a positive effect on the consumption of vegetables from the cabbage family, especially broccoli (Hecht, 2000; Murillo and Mehta, 2001, Finley et al., 2001; Kristal and Lampe, 2002). Anticancer compound from the group of isothiocyanates, sulforaphane (Jeffery et al., 2003), were determined by the HPLC and ELSD methods, and it was found that the germ contained 10 times larger volume compared to the mature broccoli, and that the concentration of this compound decreased during processing (Nakagawa et al., 2006). In addition, the compound indole-3-carbinol in broccoli has shown anticancer, antioxidant and antiatherogenic properties (Dashwood et al., 1989, Hsu et al., 2006, Higdon et al., 2007).

Preserving by drying is one of the oldest methods of preserving foods in the technological, microbiological and nutritional terms. Drying is a complex process involving heat and mass transfer phenomena. The convective drying method is drying by flow of heated air under controlled and adjusted conditions (Niketić – Aleksić, 1994). Drying of broccoli florets at different temperatures of air and the quality of dried product were studied in the papers of Icier et al. (2010) and Jin et al. (2011).

The aim of this paper was to investigate the two different temperature regimes of broccoli drying in order to show which one has represented the better options for drying. This was achived by determining the rate of the water loss from broccoli florets, not just in a function of time (such analysis can only be indicated to the dryer), but in changing the speed of evaporation of water in relative and absolute units of measure (in % and g) depending on the broccoli current moisture content as has been invasigated in previous papers of apple drying (Paunović et al. 2010; Paunović et al. 2011). The other purpose was to determine which regimes of drying provided the final product with more acceptable characteristics from the technological and organoleptical point of view.

MATERIAL AND METHODS

Broccoli used for experiment was purchased at a local supermarket; the leaves were removed and the florets were separated from stems so that, the diameter of each florets was approximately 1 cm. The broccoli florets were laid out on the three mesh trays of the laboratory dehydrator Stöckli, Switzerland. On the each mesh tray 500 g of the sample was placed. Dehydrator has its own thermostat which controls the heater of 600 watts and maintains a set air temperature. One of the initial assumptions was that in the dryer the same amount of broccoli has always been presented. It was taken care of this, also as the quantity of sample on the mesh trays, for uniform air flow and relation of broccoli air amount. The important initial assumption was that the characteristics of air (T, φ, V) were not changed during the experiment.
The experiment was conducted to follow the drying rate of broccoli florets which was expressed as drying rate changes in the ratio of moisture content of material in the wet material ($\frac{dw}{d\tau}$; %/h) depending on the current moisture content of material (w; %). The kinetics of drying was monitored by two different air temperature regimes as followed:

- sample A – drying at constant air temperature of 70 ^{o}C for a period of 8 h
- sample B – drying at air temperature of 70 ^{o}C for a period of 3 h and then in the next 5 h the air temperature was lowered at 50 ^{o}C

For every 60 minutes the broccoli sample was taken for measurement of moisture content. Each sample was selected by random sampling, in order to reduce experimental error, (from each mesh tray, a certain amount of sample has been taken). The moisture content in each sample was determined by standard gravimetric method.
Moisture content of sample was expressed as the rate of moisture in moist broccoli florets (w; %) and as moisture content in grams which binds 1 g of dry matter of the broccoli (u; g/g). The actual loss of moisture from 100 g of the broccoli florets was calculated Eq. (1):

$$W = G(1 - \frac{C_1}{C_2}) \quad (1)$$

where are: W - mass of evaporated moisture (g),
G - initial mass of fresh broccoli (g)
C_1 - dry matter content in fresh broccoli (%)
C_2 - dry matter content in dried broccoli (%)

RESULTS AND DISCUSSION

The results of determination of the moisture content (w) in the broccoli during drying and the moisture rate of drying expressed as a moisture content over time ($\Delta w/\Delta \tau$) are shown in Table 1.

Table 1. Moisture content in broccoli and moisture rate of drying.

Time (h)	Sample A		Sample B	
	w (%)	$\Delta w/\Delta \tau$ (%/h)	w (%)	$\Delta w/\Delta \tau$ (%/h)
0	84.9	0	85.1	0
1	82.8	2.1	83.1	2.0
2	67.9	14.9	69.2	14.0
3	45.1	22.8	51.9	17.3
4	40.5	4.6	44.1	7.7
5	30.6	9.9	33.5	10.6
6	18.9	11.7	24.0	9.6
7	13.6	5.3	20.7	3.3
8	12.1	1.5	15.1	5.6

w (%) - moisture content; $\Delta w/\Delta \tau$ (%/h) - moisture rate of drying

Based on these results, the graphs on moisture rate of drying depending on the current moisture content of the broccoli florets were constructed and presented in Figures 1 and 2.

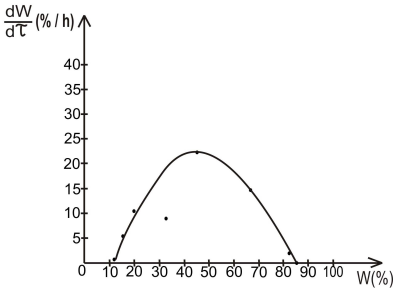

Figure 1. Moisture rate of drying depending of moisture content of broccoli (sample A).

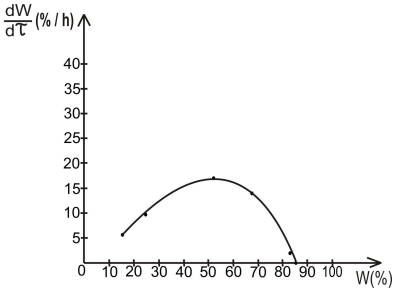

Figure 2. Moisture rate of drying depending of moisture content of broccoli (sample B).

From these figures it can been seen that the moisture rate of drying was gradually increased in both samples and the maximum was achieved at the current moisture content of 45.1 % and 51.9 % for the samples A and B, respectively. After that the moisture rate of drying was gradually decreased. In the sample B the maximum moisture rate of drying was achieved at the lower value compared to the sample A. After that the decreasing of draying rate after reaching the maximum moisture rate of drying was moderate (consistent drying) resulting in a much better quality of the final product. On the other hand, the sample A achieved the maximum moisture rate of

drying at higher value and after reaching it the moisture rate of drying was rapidly decreased, which might cause the stress for the plant tissue, inevitably resulting in worse quality of the final product. These results are in accordance with the previous results of drying kinetics of apple described in the papers of Paunović et al. 2010 and Paunović et al. 2011. It can be concluded that the second regime of draying, which simulated continual process, was more acceptable in terms of the quality of the final product. This indicates that the lower temperatures of air are more favorable for drying the foodstuffs prone to enzymatic browning.

Also, it was significant to determine the actual loss of moisture content from 100 g of the broccoli florets. The total dry matter in fresh broccoli was 15.1 % and 14.9 % for the samples A and B, respectively, while in the dried form it was 87.9 % and 84.9 %. According to the relation Eq. (1), it was calculated that in the sample A from 100 g of broccoli 82.82 g of moisture was evaporated during drying while in the sample B it was 82.45 g.

$$W = 100 \times \left(1 - \frac{15.1}{87.9}\right) = 82.82 \text{ g (sample A)} \qquad \text{(Eq 1)}$$

$$W = 100 \times \left(1 - \frac{14.9}{84.9}\right) = 82.45 \text{ g (sample B)}$$

Since the drying of broccoli lasted 8 hours, this means that the average moisture content loss per hour of drying was approximately 10.35 g of water and 10.30 g of water for samples A and B, respectively. It was also necessary to define the distribution of water according to its activity, ie. the binding energy to the dry matter (Paunović et al., 2010; Paunović et al., 2011).

In order to acchive the percentage distribution of the evaporated amount of moisture content over time, its content was expressed in relation to dry matter. Table 2. shows the data for the calculated values of amount of moisture content in relation to dry matter (u) and evaporated moisture content (in g) during each hour of drying (the starting point was that in the dryer it was 100 g of broccoli).

Table 2. Mass of evaporated moisture content from 100 g of broccoli during drying

Time (h)	Sample A		Sample B	
	Moisture content u (g/g)	Evaporated moisture content W (g)	Moisture content u (g/g)	Evaporated moisture content W (g)
0	5.6225	0	5.7114	0
1	5.4834	12.21	5.5772	11.83
2	4.4967	40.75	4.6443	39.79
3	2.9867	19.53	3.4832	17.40
4	2.6821	2.13	2.9597	4.33
5	2.0265	3.62	2.2483	4.25
6	1.2517	3.14	1.6107	2.79
7	0.9007	1.14	1.3893	0.82
8	0.8013	0.30	1.0134	1.24
Σ	-	82.82	-	82.45

From the Table 2. it can be seen that in the conditions of convective drying the largest amount of moisture content was lost in the first three hours of drying, while during the continuation of the technological process, that amount was significantly reduced. After the first hour of drying 14.74 % and 14.35 % of moisture content was evaporated from the samples A and B, (Fig.3), while after eighth hour of drying 0.43 % and 1.50 % of moisture content from the samples A and B was evaporated, respectively. The amount of evaporated moisture content during 8 h of drying on both air temperature regime is shown in Figure 3.

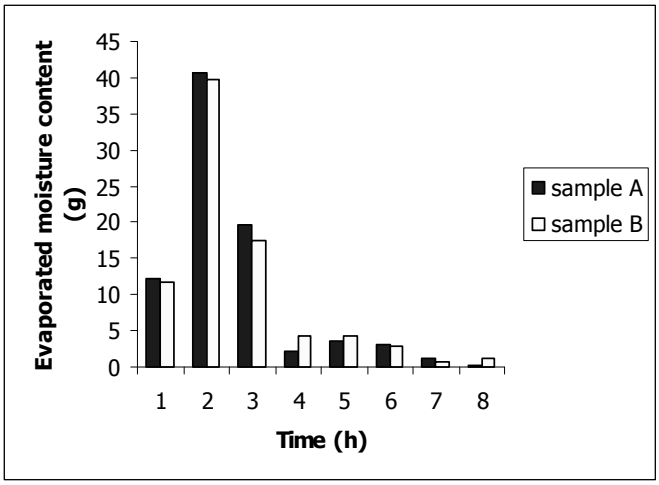

Figure 3. Evaporated moisture content during 8 h drying on both air temperature regime

After the first hour of drying, the broccoli in the both samples started to brown as a result of poliphenol oxidase activity, an enzime that catalyses flavonoid oxidation (Yamaguchi at al., 2003). Browning was intensified during the next two hours of drying. In the fourth and fifth hour in the sample A it was noticed significantly increase of browning, while in the sample B it was slightly reduced than it was observed after the third hour of drying.

The assumption was that the blanching before drying largely prevent oxidation and thus browning of broccoli. However, in the study of Mrkić et al. 2006, it was performed that the blanching and drying processes reduced the ascorbic acid content of broccoli. Also, Yuan et al. (2009) investigated the effect of different ways of processing and the lost of bioactive components in broccoli. They concluded that the content of chlorophyll, vitamin C and glucosinolates decreased after cooking, frying and treatment in a microwave oven, while the smallest lost of these bioactive components was after steam treatment.

CONCLUSIONS

It can be concluded that the second regime of draying, which simulated continual process, was more acceptable in terms of the quality of the final product. The largest amount of moisture content was lost in the first three hours of drying in both air temperature regimes. Following the drying rate of broccoli it can be concluded that the moisture rate of drying increased and reached a maximum at 45.1 % and 51.9 % for samples A and B, respectively. The results showed that in simulated continual process of drying (sample B) the lower maximum moisture rate of drying was achieved, the drying was more evenly and the lower temperature of air was less affected the plant tissue, resulting in a much better quality of the final product. The assumption was that the blanching before drying largely prevent oxidation and thus browning of broccoli. These indications will definitely be re-tested and more precise modeled to accurately optimize the conditions of convective drying of broccoli in order to preserve its bioactive components.

ABSTRACT: Osmotic dehydration is an environmentally acceptable, material gentle drying process, which received considerable attention because of the low processing temperature, base waste material and low energy requirement. Response surface methodology (RSM) was used to determine the optimum processing conditions that yield maximum water loss and dry matter content and minimum solid gain and water activity during osmotic dehydration of apple in sugar beet molasses, and that reduce energy requirements for the process, on the other hand. Temperature (45–65℃), processing time (1–5 h), mol asses concentration (40–80%) were the factors investigated with respect to water loss, solid gain, dry matter content and water activity. Experiments were designed according to 3^3 full factorial experimental designs with these three factors each at three different levels. For each response, second order polynomial models were developed using multiple non-linear regression analysis. Analysis of variance (ANOVA) was performed to check the adequacy and accuracy of the fitted models. The response surfaces analysis showing the interaction of process variables were constructed. Using *Maple 13 Software* optimum operating conditions were found to be at temperature of 45℃, molasses concentration of 80%, and treatment time of 222 min. At this optimum point, water loss, solid gain, dry matter content and water activity were found to be 0.6628 (g/ g initial sample weight), 0.1156 (g/ g initial sample weight), 49.34% and 0.879, respectively.
Key words: *osmotic dehydration, sugar beet molasses, Response surface methodology*

INTRODUCTION

Osmotic dehydration is an effective way to reduce the water content in plant and animal tissue with minimal negative effect on nutritive and sensorial properties of the final product. Osmotic dehydration, used mainly on fruits and vegetables, is performed by immersing them in various hypertonic solutions. Sugar beet molasses can be excellent medium for osmotic dehydration, primarily due to the high dry matter (80%) and specific nutrient content.

The complex cellular structure of plant tissue acts as a, not completely selective, semi-permeable membrane, which allows two main countercurrent flows: water from the plant tissue flows into the osmotic solution whereas osmotic solute diffuses from the solution to the tissue (Kowalska and Lenart, 1998; Rastogi and Raghavarao, 1997; Salvatori et al., 1997). During osmotic dehydration, the tendency is to increase the diffusion of water from the sample into the surrounding solution and decrease penetration of solids from the solution into the plant tissue, on the other hand (Matuska, 2006). However, in the case when sugar beet molasses is used as hypertonic solution, the penetration of mineral substances, vitamins, etc. to the tissue can be considered as favorable because the nutritional value of thus treated fruits and vegetables is higher (Filipčev et al., 2010; Koprivica et al., 2008).

Response surface methodology (RSM) is a statistical approach useful for the modeling and analysis of problems in which a response of interest is influenced by several variables and the objective is to optimize this response (Montgomery, 2005).

The first goal for RSM is to find the optimum response. When there is more than one response then it is important to find the compromise optimum that does not optimize only one response (Oehlert, 2000).
The objectives of here presented article were to: 1) investigate the effects of temperature, processing time and concentration on dry matter content (DM), water loss (WL), solid gain (SG) and water activity (a_w); *2)* find the optimum conditions for osmotic dehydration of apple in sugar beet molasses in order to reduce energy requirements and environmental risks, and to reach satisfactory quality of final product, on the other hand.

MATERIAL AND METHODS

Material

Apples (*Idared* type) were purchased from a local market in Novi Sad, Serbia and stored at 4℃ until use. Just before use, apples we re carefully washed, peeled and cut into cubes, dimensions 1x1x1 cm. Initial dry matter content in apple was 14.05±1.49%. The amount of 100g of apple cubes was prepared for each treatment.
Sugar beet molasses was obtained from the sugar factory in Crvenka, Serbia. Initial dry matter content in sugar beet molasses was 80.96%. For the dilution of sugar beet molasses distilled water was used.

Experimental procedure

The process of osmotic dehydration was performed by immersing 100 g of apple sample in a glass jar with the appropriate concentration of osmotic solution in it, which was previously heated to test temperature. All experiments were carried out at atmospheric pressure. To prevent the impact of changes in solution concentration, due to diffusion of water from the sample into solution, 1:10 material/osmotic solution ratio was used. Different concentrations of sugar beet molasses (40.0%, 60.0% and 80.0% dry matter) were used as osmotic solution. The effect of temperature was also investigated and the experiments were conducted at temperatures of 45, 55 and 65ºC. The osmotic dehydration process was performed in a period of 0-5 h under constant conditions. Samples were separated from the osmotic solution at determined intervals of time (1, 3 and 5 h), washed and gently blotted with filter paper in order to remove the excessive water.
Dry matter content of the samples was determined by drying the material at 105 ºC for 24h in a heat chamber (Instrumentaria Sutjeska, Serbia) and measuring the weight loss of the product, gravimetrically on a scale PLJ 360 M**,** KERN with accuracy of ±0.001 g. The solid content of the osmotic solutions was determined refractometrically by Abbe refractometer, Carl Zeis Jenna. Water activity was measured by TESTO 650 (Germany) measurement device with an accuracy of ±0.001 at 25 ºC. All measurements were carried out according to AOAC methods (2000).

Calculations

Evaluation of mass exchange between the solution and the sample during osmotic dehydration were made by using the parameters such as dry matter content *(*DM*)*, water loss (WL*)* and solid gain (SG*)*. In order to account for initial weight differences between the samples, WL and SG were calculated according to the following equations:

$$WL = \frac{m_{s,i} - m_{s,f}}{m_i} \quad \left[\frac{g}{g_{i.s.w}}\right] \tag{1}$$

$$SG=\frac{m_f s_f - m_i s_i}{m_i}\left[\frac{g}{g_{i.s.w.}}\right] \quad (2)$$

where m_i and m_f are the initial and final weight (g) of the samples, respectively; z_i and z_f are the initial and final mass fraction of water (g water/ g sample), respectively; s_i and s_f are the initial and final mass fraction of total solids (g total solids/ g sample), respectively; *i.s.w.* means initial sample weight.

Experimental design and data analysis

In this paper full factorial experimental design was used, with three process variables at three levels (Table 1). The responses measured were WL (Y_1), SG (Y_2), DM (Y_3) and a_w (Y_4).

Table 1. The levels of process variables in coded form

		Coded values		
		-1	0	+1
X_1	Temperature, ^oC	45	55	65
X_2	Time, h	1	3	5
X_3	Concentration	0.4	0.6	0.8

The experimental design, along with values of different responses is given in Table 2.

A model was fitted to the response surface generated by the experiment. The model used function of the variables:

$$Y_k=f_k(\text{temp., time, conc.}) \quad (3)$$

The following second order polynomial (SOP) model was fitted to the experimental data. Four response equations were obtained depending on three examined variables:

$$Y_k=\beta_{k0}+\sum_{i=1}^{4}\beta_{kI}X_i+\sum_{i=1}^{4}\beta_{kII}X_i^2+\sum_{i=1}^{3}\sum_{j=1+1}^{4}\beta_{kIJ}X_iX_j \quad (4)$$

where β_{kij} are constant regression coefficients; *Y,* either *WL* (Y_1), *SG* (Y_2), *DM* (Y_3) and a_w (Y_4); X_1, osmotic temperature; X_2 treatment time and X_3, solution concentration.
Analysis of variance (ANOVA) and response surface regression method (RSM) were performed using *StatSoft Statistica* 10. The model was obtained for each dependent variable (or response) where factors were rejected when their significance level was less than 90%. Optimal combination of the tested variables was found using *Maple 13 Softwar*e.

RESULTS AND DISCUSSION

Four models were obtained as a result of fitting Eq. 4 to experimental data shown in Table 2. These models were tested for adequacy and fitness by analysis of variance (Table 3). Results showed that developed models for all four responses were significant (high value of r^2) with no significant lack of fit indicating that they adequately described relationship between responses and independent variables.

*Significant at 95% confidence level, **Significant at 90% confidence level, ^{ns} Not significant, df – degrees of freedom

ANOVA test showed that all linear terms significantly contribute to the formation of statistically significant SOP models. All linear members are significant at 95% confidence level for all four responses. Results indicated that immersion time was the most important factor for WL, DM and a_w, then solution concentration and temperature at the end. Greatest influence on the SG has the solution concentration, then the immersion time and temperature, respectively.
Regression coefficients of the model (β's) are given in Table 4, as well as theirs statistical significance. Knowing those parameters allowed prediction of response values, if the independent variables are known.
Response surface plots (not given in the paper) show that WL and SG rapidly increase at beginning of the process, primarily due to big difference in osmotic pressure between sugar beet molasses and apple samples. After 2.5 - 3 hours WL approaches equilibrium value and intensity of water diffusion decrease, while SG values still rising and solids penetrate in the sample. Increasing temperature, concentration and immersion time caused higher WL, SG and DM, but lower a_w. The temperature dependence of DM and a_w is stronger at the later stages compared to the beginning of the process, but this increasing was the result of penetration of solute into the apple, not the result of water loss (drying). Relationship between SG and a_w was explained in the study of *Eren* and *Kaymak-Ertekin (2007).*

A graphical multi-response optimization technique was used to determine optimum conditions for osmotic dehydration of apple in sugar beet molasses. Optimum conditions for osmotic dehydration of apple cubes were determined in order to reduce energy requirements (lower immersion time and processing temperature) and, at the same time, to get product with satisfactory quality characteristics (high DM and WL, and low a_w and SG). Sugar beet molasses is by product of sugar producing and it has high dry matter content, therefore, in optimization, 80% sugar beet molasses is selected as solution concentration. Range of temperatures and immersion times were determined to reach following values of responses: WL 0.6 - 0.7 g/$g_{i.s.w.}$, SG 0.1 - 0.12 g/$g_{i.s.w.}$, a_w 0.87 - 0.88 and DM 45 - 55%. Requested values for SG are higher than stated in study of *Eren* and *Kaymak-Ertekin (2007),* because for lower SG values, satisfactory low a_w value cannot be achieved.

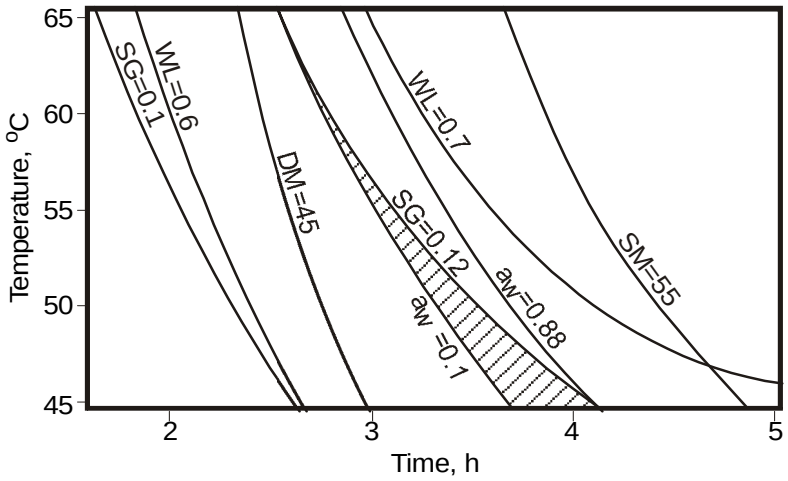

Figure 1. The range of temperature and time (marked) for osmotic dehydration of apples in 80% sugar beet molasses where WL ranges from 0.6 to 0.7 g / $g_{i.s.w.}$, SG from 0.1 to 0.12 g /$g_{i.s.w.}$, a_w from 0.87 to 0.88 and SM from 45 to 55%

Marked area in Figure 1 shows the range of time and temperature in which above values of responses can be achieved. The values of temperature and time range from 45 - 60 ºC and 2.8 – 4.05h, respectively. With increasing temperature setpointed response values were achieved in a shorter time of dehydration and vice versa.

Dehydration at higher temperatures has a negative effect on the nutritional characteristics of the product and increases the cost of the process. In the Table 5 two combinations of parameters that achieve the requested outputs are given. Recommended conditions are to perform dehydration at lower temperatures and shorter time. Response values in the table were obtained from a SOP which are defined for four responses of the system.

Table 5. Optimal conditions for osmotic dehydration of apples in 80% sugar beet molasses

Temperature, ºC	Time, h	Responses
60	2.8	WL=0.6687; SG=0.1202 a_w=0.879; SM=47.57
45	3.7	WL=0.6628; SG=0.1156 a_w=0.879; SM=49.34

CONCLUSIONS

According to applied RSM analysis, all responses (WL, SG, DM and a_w) were significantly influenced by investigated process parameters (immersion time, process temperature and solution concentration), during the osmotic dehydration of apple cubes in sugar beet molasses. Developed SOP models showed good correspondence to experimental data, at statistically significant level $p<0.05$, with the coefficient of determination $r^2>0.96$, for all cases. Determination of optimal conditions was accomplished by applying SOP regression coefficients to nonlinear analysis within Maple 15 code. The maximum WL and DM and minimum SG and a_w values correspond to temperature 45℃, molasses concentration of 80% and immersion time of 3.7h.

ABSTRACT: In order to improve the specific volume and textural properties of specialty bread made with molasses, the following natural ingredients were added: vital wheat gluten and flax seed. Individual and interactive effects of the added ingredients on specific volume, hardness, springiness and cohesiveness were evaluated using the method of response surface methodology (RSM). Effects were mainly related to the doses of the tested ingredients. In general, the increased doses of vital gluten increased bread volume and flax seed improved bread crumb resilience. Since there was a strong dose dependent relation among the tested attributes, the optimal doses of the ingredients were determined through the desirability function. The aim of the optimization was to maximize the specific volume and minimize hardness. It was found that the optimized doses for ingredients were the following: 5% of sugar beet molasses, 8% of flax seed and 3.96% of vital gluten. The estimated values for specific volume were 4.55 ml/g and hardness 953.25 gf.
***Key words**: sugar beet molasses, vital wheat gluten, flax seed, textural properties of bread, optimization*

INTRODUCTION

Sugar-beet molasses is a thick concentrated liquid syrup, by-product of the processing of sugar beet into sugar. In general, beet molasses contains approximately 50% of sucrose, 1% of farinose, and 0.25% of glucose and fructose by dry weight. The non-sugar compounds present in molasses include many important micronutrients such as minerals (potassium, calcium, sodium, magnesium and iron) and vitamins (B vitamins) (Šušić and Sinobad, 1989; Hickenbottom, 1996). Since sugar beet molasses alone has not been convenient for consumption for most people because of its palatability, the general idea of this research work was to include beet molasses in staple food such as white wheat bread to improve its nutritive value and functionality (Ranhorta, 1998; Lević et. al. 2005; Pribiš et al. 2008).
Previous research work showed that molasses decreases bread volume and increases crumb hardness, especially at higher doses (15% of flour basis) (Lević et al. 2005; 2006). In order to ameliorate these undesirable effects of molasses, natural dough and bread improvers were applied: vital wheat gluten and flax seed.
Vital wheat gluten, a by-product of wheat starch extraction process, is characterized by high protein content (75-85% of dry basis) and good viscoelastic properties (Stenvert et al., 1981). The addition of vital gluten increases dough stability, improves gas retention (Hoseney, 1984), loaf volume, crumb grain, texture, softness and shelf life (Stenvert et al. 1981; Wiepert and Zwingelberg, 1992).
Nowdays, flax seed is increasingly applied in human nutrition and production of functional food and bakery goods due to its nutritive and health value (Payne, 2000). Besides, flax seed is important from technological point of view due to a large quantity of pentosans (7-9%) and dietary fibers (24.5%), both soluble and insoluble

ones (Lagrange, 1995). It is known that pentosans have great capacity of water absorption. Due to that reason they influence the improvement of rheological dough capacities, the increase of volume and preserving of bakery goods freshness (4.7). By the addition of flax seed (8-16% of basis into flour) it can be achieved an increase in bread volume, improvement of crumb quality, aroma, taste and crumb and crust mastication of bakery goods (Bojat et al. 2000).
The main objectives of this study, therefore, were firstly to establish the factors (sugar-beet molasses, vital gluten and flex seed) affecting bread quality and secondly to determine optimum levels of these ingredients for maximum bread quality, especially to improve the specific volume and reduce crumb hardness.

MATERIALS AND METHODS

Commercially refined wheat flour with the following characteristics was used: 13.1 g/100 g water content, 0.52 g/100 g d.b. (dry basis) ash content and 11.3 g/100 g d.b. protein content. Moisture, crude protein, crude ash of flour were determined according to the standard ICC procedures (ICC, 2001).
The characteristics of the applied sugar beet molasses were the following: sucrose content 52.32%, water content 14.96%, ash content 17.91% d.b., NaCl 0.01% and mineral content K, Na, Mg, Fe, Ca is: 21102 mg/kg, 1178.40 mg/kg, 260.92 mg/kg, 102.12 mg/kg, 2110.17 mg/kg, respectively (ICC, 2001).
Chemical analyses of sugar beet molasses were performed according to AOAC methods (AACC, 2003). Mineral content of molasses was determined by atomic absorption spectrometry with an atomic spectrometer “Varian”, model “Spectra 10”.
Vital gluten was applied with the following characteristics: moisture content 8.06%, crude protein content (Nx6.25) 82.17%, crude fat content 2.21% and ash content 0.87%.
Reddish-brown flax seed of domestic origin was used with the following chemical composition: protein content 26.7% d.m., oil content 42.5%d.m., pentosans content 8.0% d.m. Flax kernels before the dough mixing were prepared by soaking with the addition of two times more water quantity at the temperature of 40°C during minimally an hour.
Baking tests were performed under laboratory conditions using rapid mixing procedure. The ingredients used (calculated on flour basis) for the basic wheat dough were the following: flour (100%), fresh yeast (5%), sugar (1%), salt (2%), fat (1%) and water according to farinograph water absorption (FWA) (ICC standard No. 115) (ICC, 2001). Sugar beet molasses (SBM), vital wheat gluten (VWG) and flax seed (FS) were added according to the experimental plan shown in Table 2. Dough preparation and baking were done according to the method described in detail in the work of Filipčev et al. (2010).

Evaluation of bread quality

Quality analysis of fresh bread samples was carried out by measuring weight, volume (determined by seed displacement in a loaf volume meter) and specific volume. Specific volume was calculated as the ratio between volume and mass. Bread texture attributes were evaluated 24h after baking application ‘‘Texture Profile Analysis’’ (TPA). Slices of 2 cm thickness were compressed to 60% of their original height in a double compression test (TPA), at 0.5 mm/s speed test, with a 75 s delay between the first and second compression. Parameters (hardness (gram-force, gf), springiness and cohesiveness) were collected from the TPA graphic.

Experimental design and statistical methods

An incomplete 3^3 factorial design and three replicates at the central point were used to investigate the effect of the three independent variables of physical and sensory properties of the speciality bread (Table 1) (Box & Benhken, 1960).

Table 1. Real and coded values of independent variables used for experimental design

	Independent variables	Coded values		
		-1	0	+1
Real values	Sugar beet molasses, %	5	10	15
	Flax seed, %	4	6	8
	Vital wheat gluten, %	0	2	4

The independent variables SBM, FS and VWG) were assessed at three equidistant levels of variation. For each response (specific volume (SV), hardness (HD), springiness (SP) and cohesiveness (COH)) a quadratic model was used:

$Y= b_0+ b_1X_1 +b_2X_2 +b_3X_3 +b_{11}X_1^2 +b_{22}X_2^2 + b_{33}X_3^2 + b_{12}X_1X_2 + b_{13}X_1X_3 +b_{23}X_2X_3,$

Where Y is the response function of the experimental data, X_1, X_2 and X_3 are the independent variables, and b parameters are the estimated coefficients. The adequacy of the model was evaluated by the coefficient of determination, R^2, F-value and model p-value at the 0.1 significance.

The significance of regression coefficients was assessed by p-values at 0.1 significance level. For the optimization of the responses we applied the Design-Expert 8.1 (Stat-Ease Corporation, Minneapolis, MN, USA)_using the desirability function. The desirability function approach (DFA) was used to simultaneously optimize both specific volume and hardness of the specialty bread. Table 4 shows the conditions of the optimization process.

RESULTS AND DISCUSSION

Fifteen experiments were performed according to the experimental design and the results are shown for SV, HRD, SP and COH in Table 2.

Table 2- Experimental design and obtained results

Run	SBM (%)	FS (%)	VWG (%)	SV (ml/g)	HRD (gf)	SP	COH
1	-1	0	-1	4.2	1361.16	0.91	0.54

[c]SBM-the concentration of sugar beet molasses; VWG- the concentration of vital weat gluten
[d]F-test>F_{listed} (4.735)

On the basis of the results in Table 3, all the models had a coefficient of determination (R^2) higher than
0.94, showing that more than 94% of the total variations around the mean values were provoked by the experimental conditions. Molasses significantly affects ($p<0.1\%$) bread specific volume, and by quadratic increase of its dose specific volume significantly decreases. However, increasing gluten concentration significantly increases bread volume which led to positive interaction effect between molasses and wheat gluten (+0,005SBM*VWG). The addition of flax seed did not considerably affect bread volume.
All the three ingredients at their initial doses significantly affect crumb hardness. At the tested dose interval, vital wheat gluten significantly increases crumb hardness but the quadratic effect of vital gluten dose reduces crumb hardness (although not significantly). Molasses is an important ingredient that affects bread crumb structure: at low doses, molasses softens bread crumb, whereas with quadratic dose increase, it hardens the crumb. This is probably due to its composition, i.e. high sucrose content of 52.32%. It is known that sucrose at 5% dose positively affects the textural properties of bread crumb, whereas higher doses generally produce negative effect on bread quality (Colliery, 1967; Payer, 1973). Flax seed significantly decreases crumb hardness at the tested doses (4-8%), whereas quadratic effect does not have any further significant effect.
Bread crumb springiness is significantly affected by doses of molasses and flax seed. At lower doses, molasses improves crumb springiness, whereas with quadratic dose increase molasses decreases crumb springiness. Flax seed produces effects on bread crumb opposite to those of molasses. Positive effect of flax seed on crumb springiness is due to its high content of soluble and insoluble dietary fibers and pentosans (Lagrange, 1995; Payne, 2000).
Bread crumb cohesiveness was affected only by molasses and its action depends on the dose. At lower applied doses (5%-10%), the intensity of internal bonds increases in bread crumb, whereas crumb stability decreases with quadratic increase in molasses dose. The addition of molasses imputs into bread which lowers crumb cohesiveness. This is in accordance with the findings of Collyer (1967), who concluded that higher sucrose doses affect the consistency of baked products by reducing crumb cohesiveness.

Process optimisation through the desirability function

In Table 4, the conditions of the optimization process to maximize specific volume and minimize hardness in the specialty bread are displayed. The selection of bread

quality attributes (responses) in the optimization process and their relative importance was based on literature data and consumer preference (Pestorić et al. 2011). The simultaneous evaluation of the experimental design responses which resulted in the overall desirability profile are shown in Fig.2. By applying the desirability function, the optimum concentrations were sugar beet 5% of molasses, 8% of flax seed and 3.96% of vital wheat gluten into flour, with a desirability value of 0.984. In these concentrations, maximum specific volume and minimum hardness were obtained, showing predicted values of 4.55 ml/g and 953.255 gf, respectively.

Table 4. Conditions and obtained results of the optimization process to maximize specific volume and and minimize hardness of the specialty bread with sugar beet molasses, flax seed and vital wheat glute

Factors and responses	Goal	Lower limit	Upper limit	Importance	Optimum
Vital wheat gluten (%)	in range	0	4	3	3.96
Sugar beet molasses (%)	in range	5	15	3	5.00
Flax seed (%)	in range	4	8	3	8.00
Spec Volume (ml/g)	MAX	2.7	4.6	5	4.55

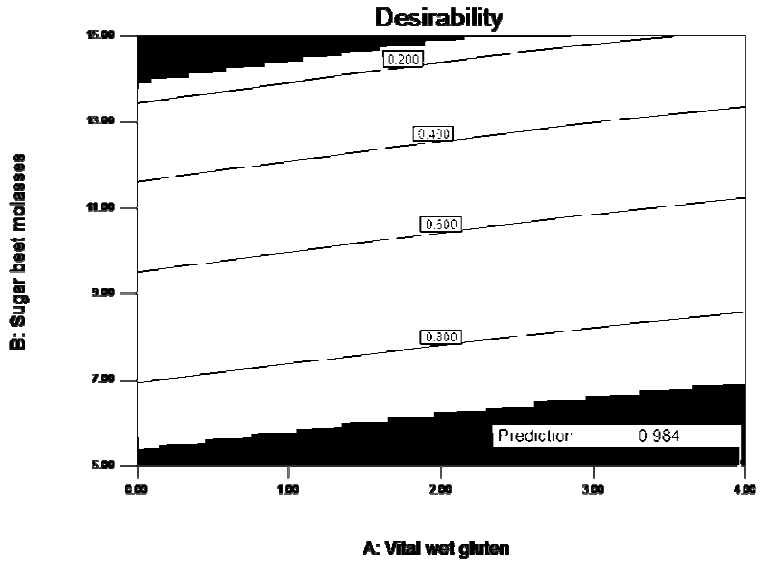

Figure 2. Dependence of overall desirability function on the dose of sugar beet molasses and vital wheat gluten in the specialty bread formulation containing sugar beet molasses, flax seed and vital wheat gluten factors (flax seed) was set to its constant (medium) value

CONCLUSIONS

Upon the analysis of the presented results, the application of natural ingredients like flax seed and vital wheat gluten to improve the quality of the specialty bread enriched with molasses seems to be justified. Vital wheat gluten produced significant positive effect upon bread specific volume and flax seed improved crumb elasticity and lowered bread crumb hardness. The intensity of these effects was dose dependent. In this paper, we successfully applied the statistical method for the optimization of concentration of natural raw materials like gluten and flax seed aiming at achieving maximal bread quality. The final result of the optimization suggested that the optimal ingredients doses to achieve bread with maximal volume and minimal crumb hardness amounted to 3.96% for vital gluten, 8% for flax seed and 5% for molasses. The estimated values of specific volume and crumb hardness in optimally formulated bread were 4.55 ml/g for specific volume and 953.25 gf for hardness. Beside the

achieved improvement of bread quality, the added flax seed also contributes to the improvement of bread nutritive value, which is the topic of some researches to come.

ABSTRACT: The presented paper describes an investigation of osmotic dehydration of pork (*M. triceps brachii*) in three different osmotic solutions (sugar beet molasses, ternary solution and combination of these solutions in a 1:1 ratio) under atmospheric pressure and room temperature (20^{o}C). The main objective was to examine the influence of different osmotic agents and immersion time on the mass transfer kinetics during osmotic treatment. The most important kinetic parameters of the process: water loss (WL), solid gain (SG), water loss/solid gain ratio (WL/SG), weight reduction (WR), normalized solid content (NSC) and normalized moisture content (NMC) were determined after 1, 3 and 5 hours of dehydration. Mass transfer coefficients were calculated using Hawkes and Flink's model. The results indicate that all three solutions are satisfying osmotic agents and that extensive dehydration occurred during the first 3 hours of the process.
Key words: *Osmotic dehydration, pork meat, mass transfer kinetic, sugar beet molasses, ternary osmotic solution*

INTRODUCTION

In recent years, the process of osmotic dehydration (OD) is considered an important tool for preserving fruits and other raw materials. Osmotic dehydration is used as a pretreatment for many processes, to improve nutritional, sensorial and functional properties of food without changing its integrity. This technique also is interesting because it provides partial water removal from a food product, with low energy consumption and mild heat treatment (*Vieira* at al., 2012; Manivann at al., 2011). At the Faculty of Technology in Novi Sad, a method has been developed for osmotic drying in sugar beet molasses as hypertonic solution. Sugar beet molasses appears to be an excellent medium for osmotic dehydration, primarily due to the high content of dry matter (80%), which provides high osmotic pressure in the solution as well as the specific chemical composition, characterized by high contents of vitamins, minerals, antioxidants and betain (Šušić at al., 1989; Kowalska at al., 1998; Mišljenović at al., 2009).

Physicochemical, sensory and technological properties of fresh meat are related with water content. Water is held in myofibrils, functional proteins of meat, but also it may exist in the intracellular space between myofibrils and sarcoplasm. The water content in meat depends on many factors, including the tissue itself and how the product is handled (time, temperature, treatments) (Barat at al., 2009) .The knowledge of the kinetics of water and salt transfers during the processing is of great technological importance because it allows estimating the immersion time of meat cuts in an osmotic solution to obtain products with determined salt and moisture contents (Schmidt at al., 2009).

The difference in the chemical potential of water between the food and the osmotic medium is the driving force for dehydration. In this process, two counter-current mass transfer flows take place in cell wall of the food: water loss from the food to the solution and solute gain from the solution to the food. The existence of these

simultaneous and opposite fluxes is one of the major difficulties in modeling osmotic dehydration kinetics (Koprivca at al., 2010; Mercali at al., 2010). Temperature, osmotic solution concentration and total processing time are the most important variables in osmotic process. Increasing the osmotic solution concentration induces an increase in the mass transfer (Ferrari at al., 2011; Corrêa at al., 2010; Silva at al., 2012). Great influence on the kinetics of water removal and solid gain has the type of osmotic agent. Ternary aqueous solutions containing salt and sugar are usually used as osmotic agents for meat dehydration (Damez at al., 2008; El-Aouar at al., 2006).
This study was aimed at investigating the influence of different osmotic solutions and immersion time at room temperature on the efficiency of osmotic dehydration process of pork. Kinetics parameters, mass transfer coefficients for water, and rate of mass transfer were defined.

MATERIAL AND METHODS

Pork (*M. triceps brachii*) was purchased at the local butcher shop in Novi Sad, shortly before use. Initial moisture content of the fresh meat was 72.83%. Prior to the osmotic treatment, fresh meat was cut into cubes, dimension of nearly 1x1x1cm. As hypertonic medium three different solutions were used.The first one, ternary osmotic solution, was made from sucrose in the quantity of 1.200 g/kg water, NaCl in the quantity of 350 g/kg water and distilled water (in further text indicated as solution 1). The second osmotic solution was combination of the first and third in ratio 1:1 (in further text indicated as solution 2). The third, sugar beet molasses, with inital dry matter content of 85.04%, was obtained from the sugar factory Pećinci, Serbia (in further text indicated as solution 3). The material to solution ratio was 1:5 (w/w). Dehydration was performed at room temperature (20^{o}C), with stirring on every 15 minutes under atmospheric pressure. Samples from all three solutions after 1, 3 and 5 were taken out to be lightly washed and gently blotted, to remove excess water. Dry matter content of the fresh and treated samples was determined by drynig at 105^{o}C for 24h in a heat chamber (Instrumentaria Sutjeska, Serbia) until constant weight. All analytical measurements were carried out in accordance to AOAC (2000).
In order to follow mass transfer kinetics of the OD, three key process variables were measured: moisture content, change in weight and change in the soluble solids. Using these, water loss (WL), weight reduction (WR), solid gain (SG), normalized moisture content (NMC), normalized solid content (NSC) were calculated, also mass transfer coefficients were obtained using Hawakes and Flink's model as described by Mišljenović at al., 2009.

RESULTS AND DISCUSSION

Table 1 shows changes in dry matter content in the samples of pork meat during OD as a function of different type of osmotic solution and dehydration time. The increase of immersion time during the process resulted in higher dry matter content in pork samples and the highest value was achieved in solution 3 after five hours of immersion (60.07%).
Along with changes in dry matter content, changes in kinetic parameters occurred and they are as well shown in table 1.

Table 1. Changes of dry matter content and the kinetic parameters during osmotic dehydration of pork meat

Type of osmotic solution	Time (h)	Dry matter, (%)	WR, g/g initial sample weight	SG, g/g initial sample weight	WL, g/g initial sample weight	WL/SG
Solution 1	1	42.96	0.17032	0.093922	0.243504	2.592619
	3	51.75	0.250872	0.128663	0.355132	2.760172
	5	54.90	0.291313	0.122204	0.404643	3.311209
Solution 2	1	41.17	0.179362	0.073694	0.234615	3.183638
	3	49.83	0.303366	0.089973	0.364276	4.048726
	5	58.13	0.354506	0.123076	0.439144	3.568072
Solution 3	1	41.22	0.142639	0.081734	0.224373	2.745161
	3	51.07	0.304302	0.083602	0.387904	4.639889
	5	60.07	0.287079	0.120576	0.407655	3.380897

As a consequence of the process mass of the samples was reduced. The highest value of WR parameter (0.354506 g/g i. s. w.) was obtained after 5h in solution 2.

SG value shows the degree of penetration of solids from hypertonic solution into the meat samples. SG, during osmotic dehydration of pork meat, showed a tendency to increase with increasing the immersion time. The lowest value of SG parameter after five hours of process was obtained in samples dehydrated in solution 3.

High value of WL/SG ratio is the most important indicator of the effectiveness of OD treatment (Lević at al., 2007). The highest value of the WL/SG (4.639889 g/g i.s.w) was achieved in by using sugar beet molasses as osmotic solution after 3h of the treatment.

Increasing the dehydration time causes a greater water loss from meat samples. The highest WL value (0.439144 g/g i.s.w.) was noticed in samples dehydrated 5h in solution 2.

Changes of NMC and NSC parameters for the meat samples immersed in three different osmotic solutions at 20^{o}C for 5h are shown in fig 1.

During first 3 hours of OD intensive decrease of NMC and at the same time increase of NSC parameter occurred for all three solutions. During this time water removal was about 50% of initial moisture content. After third hour of OD, the water and solid diffusion slowed down. According to these results the time of dehydration can be limited to 3 hours.

The lowest value of NMC parameter was obtained in samples dehydrated in solution 2, after five hours of dehydration (0,384). Comparing results for NSC parameter for three solutions, samples dehydrated in solution 3 at the end of process had the lowest value (1.446). This makes molasses desirable as osmotic agent, considering that the aim of dehydration, besides obtaining the highest water loss, is to avoid great penetration of solids into the sample (Mišljenović at al., 2011).

The overall mass transfer coefficients for water and solute are shown in fig. 2 and 3. These coefficients were studied as a function of immersion time and different type of osmotic medium.

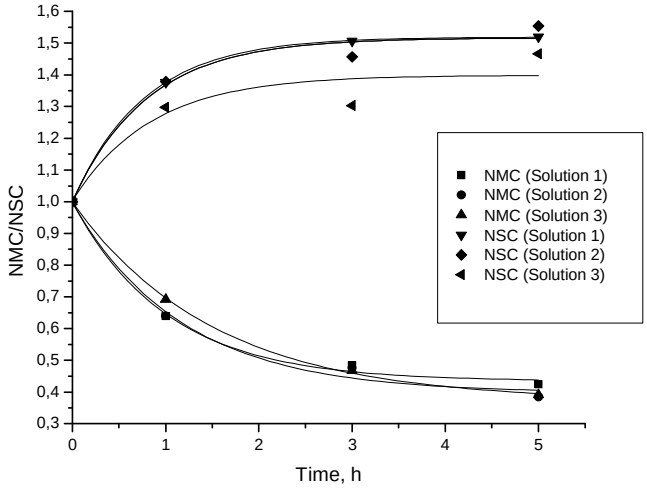

Fig 1. Influence of different osmotic media and dehydration time on the NMC and NSC parameters

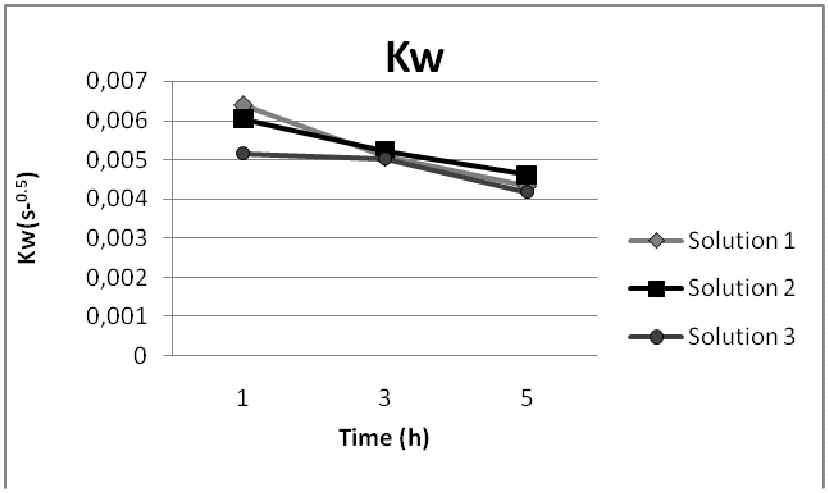

Fig.2**.** Mass transfer coefficient for water during osmotic dehidration of pork meat in three different osmotic solutions at 20^{o}C

Mass transfer coefficients decreased with duration of the treatment. Higher values of mass transfer coefficients for water at the first 3 hour of process can be explained by a greater driving force at the beginning of the process.

Comparing values of mass transfer coefficients obtained for three osmotic solutions it can be noticed, that all three solutions are efficient osmotic mediums, considering that Kw values were similar after 3h of OD.

As mentioned, great solid uptake should be avoided during OD. Ks values were similar for first two solutions, but solution 3 gave lower values. This also goes in favor to sugar beet molasses being convenient agent for OD.

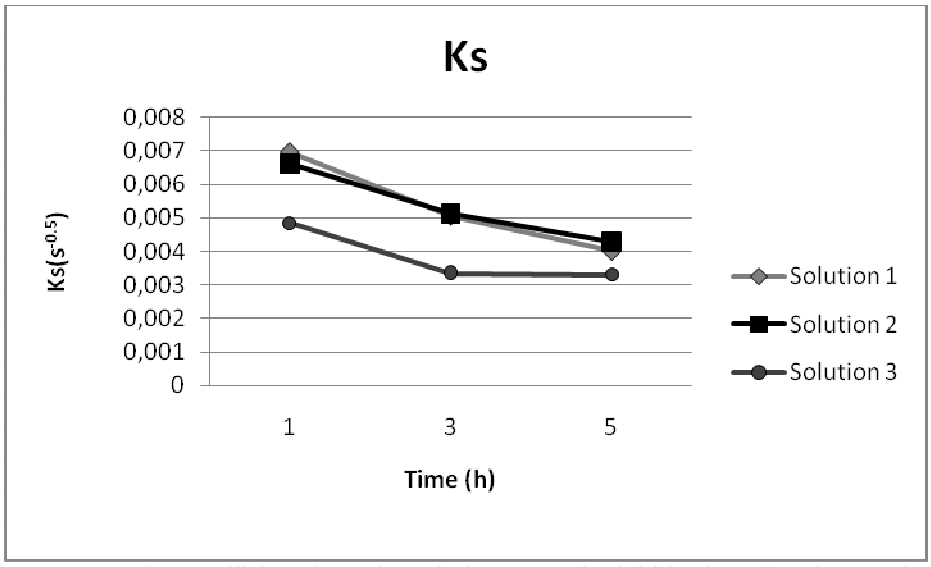

Fig.3. Mass transfer coefficient for solute during osmotic dehidration of pork meat in three different osmotic solutions at 20^{o}C

CONCLUSIONS

Considering obtained results it can be concluded that all three solutions are satisfying osmotic agents. The best results regarding dry matter content, weight reduction, solid gain and *WL*/*SG* ratio were achieved using sugar beet molasses as osmotic agent, which is economy reasonable considering that molasses is side product of sugar industry. During osmotic dehydration of pork in all three osmotic solutions, water removing process was most intensive at the beginning and after 3 hours had tendency of stabilization, therefore processing time can be limited to 3 hours.

ABSTRACT: Chewing gum is one of the most popular confectionery products, due to its sensory properties and possible health effects, such as positive influence on dental health, reduction of the post-operative ileus following gastrointestinal surgery, reduction of muscular tension and relief of gastroesophageal reflux disease symptoms. Different chewing gum recipes were designed in order to study influence of carbohydrate ingredients and commercial aroma preparations on sensory and textural properties of final product. Chewing gum samples were produced in the lab scale sigmoid kneader (Heligear HDMO) coupled with Thermomix 1480 thermostat. Sensory analysis was performed by evaluation of basic chewing gum properties (smell, taste, appearance, texture), together with hardness at the beginning of chewing, bubble size and gum extensibility. Instrumental texture analysis was measured with Stable Micro Systems Texture Analyser TA.HD.plus with 4 mm cylinder stainless steel probe. Texture analysis revealed lemon chewing gum with glucose syrup (DE=38) as the hardest of produced samples. Orange flavoured chewing gum produced with the same syrup was the softest. Sensory analysis results showed fructose syrup chewing gum being the most acceptable. Both sensory and instrumental texture analysis methods are only partly comparable.
Keywords: *chewing gum, sensory analysis, texture measurement*

INTRODUCTION

Chewing gum has been one of the most popular confectionery products for over one and half century but it is not very well known that chewing gum history is more than 10000 years old. The oldest evidence of people chewing gum was found in Huseby Klev in Sweden. The found chewing gum was from around the year 8000. BC (Kjellström et al., 2010). The popular history of chewing gum began in 1848. when John B. Curtis produced State of Main Pure Spruce Gum, which was made from spruce resin (Lee, 2001). But probably the most famous chewing gum producer was William Wrigley Jr, who started selling Juicy Fruit and Wrigley's Spearmint chewing gum in the year 1893 (Matthews and Schultz, 2009).
Chewing gum mainly consists of the following main ingredients: gum base, carbohydrate or some other sweetener syrup, different bulk sugars and sweeteners, moisturisers, softeners, different flavours and colours and organic acids. Different ingredients have different influence on sensory and textural properties. Since gum base is one of the most important chewing gum ingredients, it is very important to choose suitable gum base. It has also been shown that dextrose equivalent of glucose syrup is very important. The most recommendable is glucose syrup with DE 38-44, while higher DE are responsible for stickier chewing gums which can be too soft (Howling and Jackson, 2005). The most frequently used bulk sweetener in chewing gums is sucrose. Although it has pleasant taste, it can be problematic because of hygroscopicity under unsuitable process conditions, which leads to crystallisation and formation of lumps. This problem may also occur with syrups, and the higher DE, the higher will be the rate of moisture pickup (Hull, 2010). Flavour is

the chewing gum ingredient which can be found in very small content but it has very important influence on sensory properties of chewing gum, as well as on its textural properties because of gum base and flavour interactions. Different flavours have different influence on the softness of gum base and chewing gum in general. Therefore, if flavour doesn't soften gum base enough, softer gum base must be used (Wright, 2010).

Many positive health effects of chewing gum have been discovered and many scientific research deal with that topic. It has been showed that chewing gum may limit the increase in daytime sleepiness (Johnson et al., 2012), may reduce postoperative ileus (Noble et al., 2012), may alleviate negative mood and reduce cortisol (Scholey et al., 2009), may suppress hunger, appetite and cravings for snacks and promote fullness (Hetherington and Reagan, 2011). However, scientific activity performed on physical properties of chewing gum, as well as their production procedures, has been very scarce. Therefore the aim of this study was to investigate the influence of different ingredients on the sensory and textural properties of chewing gums.

MATERIAL AND METHODS

Materials

Different chewing gum recipes were designed in order to study influence of carbohydrate ingredients and commercial aroma preparations on sensory and textural properties of final product. The following materials were used for the production of seven different chewing gums: gum base, glucose syrup DE=60 (Cargill, Germany), powdered glucose syrup DE=60 (Cargill, Germany), fructose syrup (Cargill, Germany), sorbitol syrup (Cargill, Germany), sucrose, fructose (dm-drogerie markt, Germany), powdered citric acid, glycerol (Prima Pharme, Croatia), powdered flavours of lemon, strawberry and sour cherry (Ireks Aroma d.o.o., Croatia), liquid flavours of blueberry, pear, orange, strawberry and acerola (Symrise GmbH&Co.KG, Germany), powdered colours (beetroot, strawberry, apocarotenal) and liquid colours (yellow E 102 and red E 122; AROMAR d.o.o., Croatia). All the mentioned materials were added in their primary state, except powdered glucose syrup DE=38 and powdered colours. Powder glucose syrup was diluted in water to form 80% solution. Powdered colours were diluted in few drops of water. Developed chewing gum recipes can be seen in table 1.

Table 1: Chewing gum recipes

Flavour type	Blueberry	Pear	Orange	Lemon	Strawberry	Acerola	Sour Cherry
Gum base (%)	19,76	19,87	20,02	19,96	19,11	19,79	16,99

Chewing gum production
Chewing gums were produced in the lab scale sigmoid kneader (Heligear HDMO) coupled with Thermomix 1480 thermostat. Gum base was melted in kneader at temperature between 65 and 70 ℃. Different ingredi ents were added to the gum base after melting in the following order: syrup, first half of sugar (or other bulk sweetener) and citric acid, second half of sugar (or bulk sweetener), softener, colour and flavour. Materials were added in intervals of around 5 minutes and the whole production process lasted 30-40 minutes. Chewing gum was then removed from the kneader and, after 10-15 minutes of cooling, cut into pieces.

Sensory evaluation
Sensory analysis was performed by evaluation of basic chewing gum properties (smell, taste, appearance, texture), together with bubble size and gum extensibility. Sensory analysis was performed by trained panel. Ten panellists were grading chewing gum smell, taste, appearance, texture, bubble size and extensibility. Smell, taste, appearance and texture were graded with scores from 0 to 10, with 10 being the highest score and 0 being the lowest. Bubble size was graded from 0-3 (0 - it is not possible to make a bubble, 1 - small bubble, 2 - medium bubble, 3 - big bubble). Extensibility was measured by stretching chewing gum with one's hand from teeth until the maximum extensibility of 100 cm. Bubble size and extensibility were measured in the first, sixth and eleventh minute of chewing. Chewing gum hardness at the beginning of chewing was also graded in order to compare it with instrumental analysis hardness results. The scores were also from 0 to 10, with 0 being very hard and 10 being very soft (Delarue and Loescher, 2004; McGowan and Lee 2006).

Texture analysis
Instrumental texture of chewing gum was measured with TA.HDPlus texture analyser (Stable Micro Systems, Great Britain) by samples penetration with 4 mm cylinder stainless steel probe. Chewing gum samples had the following dimensions: 20 x 20 x 5 mm, test speed was 1 mm/s and distance was 2mm (Bourne, 2002).

RESULTS AND DISCUSSION

When comparing total sensory evaluation results of chewing gum in table 2, it can be seen that chewing gums flavoured by pear (25,4), orange (25,3) and strawberry (24,5) received the highest scores. Pear flavoured gum received the highest texture score (7,9) and very high scores for taste (6,6) and appearance (7,5). Although it received lowest grade for smell (3,4), that didn't have very big influence on reaching the first place when it comes to overall acceptance of chewing gum. This gum had very pleasant aroma and adequate sweetness, together with prolonged soft texture. Although orange flavoured gum received the highest scores when it comes to taste (7,0) and smell (9,2), it received very low score for texture (2,5). The problem was stickiness of orange chewing gum, caused by the addition of higher content of aroma. That caused the gum to stick to teeth which made it almost impossible to chew. Strawberry flavoured gum received good scores for appearance and smell but the gum was not very well accepted, which can be seen from low scores for taste and texture. The three mentioned chewing gums had the same content of sucrose (around 60%) and gum base (around 20%), but different content of syrups. Therefore, it can be noticed that fructose syrup in pear and glucose syrup (DE=30) in orange flavoured gums give products with acceptable sweetness and texture properties, while the same cannot be said for the strawberry recipe which contained sorbitol syrup. Strawberry gum was very crumbly at the beginning of chewing, probably because of the crystallisation of main chewing gum ingredients. Crumbling at the beginning of chewing led to swallowing of main part of bulk sweetener and

aroma, which caused hardness of chewing gum with aroma which didn't last very long.

Table 2: Average scores of sensory evaluation of appearance, taste, texture and smell

Sample	Appearance	Taste	Texture	Smell	TOTAL
Blueberry	4,6±1,6	4,5±1,2	2,3±2,1	7,5±1,3	18,9
Pear	7,5±2,0	6,6±0,9	7,9±0,8	3,4±2,7	25,4
Orange	6,6±1,4	7,0±1,3	2,5±2,3	9,2±1,2	25,3
Lemon	8,7±1,6	6,0±1,3	5,3±2,4	3,7±2,1	23,7
Strawberry	8,7±1,0	4,6±1,4	3,4±2,1	7,8±1,9	24,5
Acerola	4,2±1,6	5,2±1,4	4,2±2,1	6,8±1,8	20,4
Sour Cherry	6,9±2,1	0,5±0,5	0,2±0,4	6,1±2,1	13,7

Chewing gums flavoured by sour cherry, blueberry, acerola and lemon received the lowest total scores, with sour cherry flavoured gum as the worst one. The problem of this gum was crumbling at the beginning of chewing, which led to hard texture and poor aroma of the gum. Therefore, combination of sorbitol syrup (15%) and fructose as bulk sweetener (68%) with gum base (17%) showed to be non satisfactory. The problem of blueberry flavoured chewing gum was inadequate syrup (glucose syrup DE=60), which made the chewing gum too hard and crumbly at the beginning of chewing. Also, the colour from beetroot showed to be inadequate, while the chewing gum completely lost the colour after the production process. The problem can be betalain, beetroot colour component, which can have lower stability in the presence of oxygen, light and increased temperature (Azeredo, 2009). Acerola flavoured chewing gum was also very crumbly because of higher glucose syrup content (30%) and lower sucrose content (48%). Higher moisture content of the chewing gum led to crystallization of main ingredients and crumbly texture at the beginning of chewing gum, which caused the loss of aroma and very hard texture during chewing. Lemon flavoured chewing gum didn't show any crumbling at the beginning of chewing but it was very hard throughout the whole chewing period. The reason may be lower moisture content because of the use of powdered aroma.

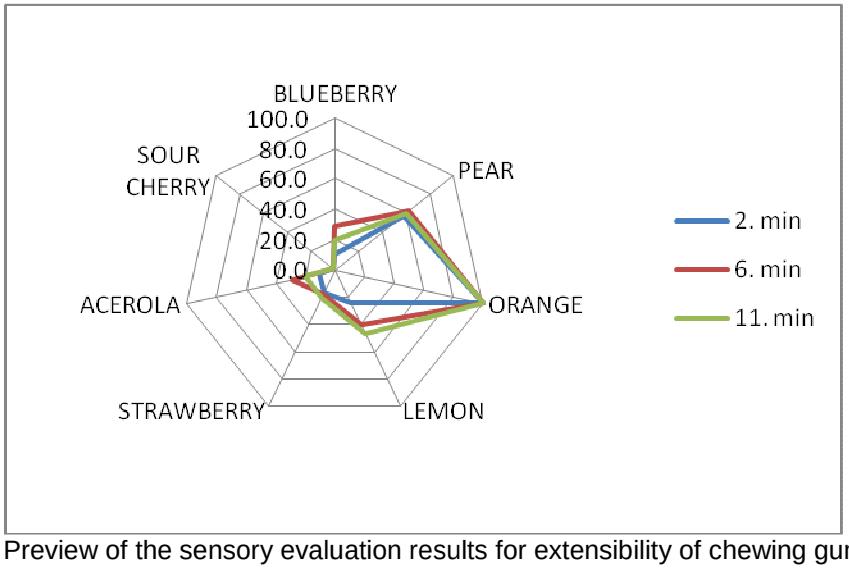

Figure 1: Preview of the sensory evaluation results for extensibility of chewing gum (in cm)

The most extensible chewing gum was orange with maximum extensibility during the whole period of chewing (100 cm), which can be seen in figure 1. It was also shown that pear and lemon flavoured chewing gums showed reasonable extensibility, while chewing gums flavoured by blueberry, acerola, strawberry and sour cherry didn't show reasonable extensibility. It can be seen that all chewing gums have the lowest extensibility at the second minute of chewing. The extensibility grows during chewing

period and reaches the highest point at the sixth minute, after which it starts to fall down until the eleventh minute of chewing.

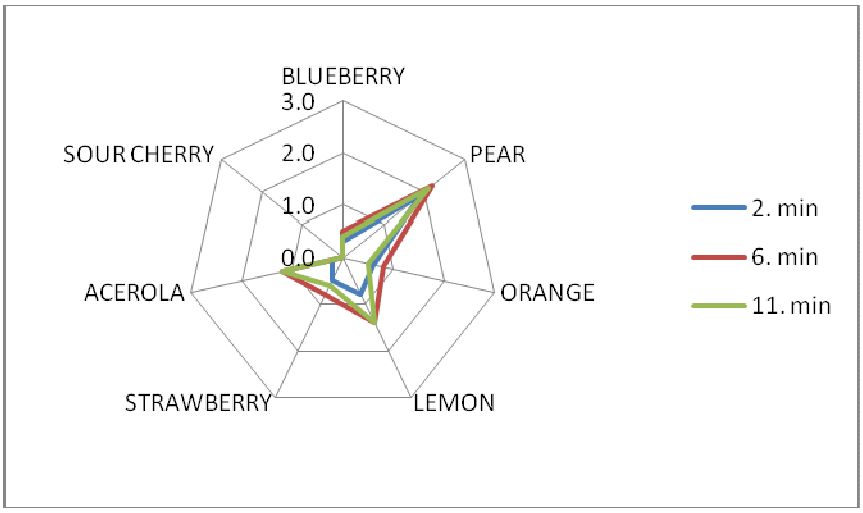

Figure 2: Preview of the sensory evaluation results for bubble gum size of chewing gum

The results in figure 2 showed that it is possible to make the biggest bubbles with pear flavoured chewing gum. While testing was performed during 11 minutes of chewing, it was shown that at the second minute of chewing it is possible to make small bubbles, but after 6 or 11 minutes it is possible to make medium bubbles. The results also showed that it was possible to make small bubbles with lemon and acerola flavoured chewing gums after 6 and 11 minutes of chewing. It was very hard, or almost impossible to make bubbles with chewing gums flavoured by blueberry, strawberry and sour cherry because of the crumbling and hard texture of chewing gums. It was also very hard to make bubbles with orange flavoured chewing gum because of the stickiness of the chewing gum.

Table 3: Sensory evaluation of hardness of chewing gums at the beginning of chewing

	Blueberry	Pear	Orange	Lemon	Strawberry	Acerola	Sour Cherry
Hardness	8,4	8,5	7,9	2,0	8,3	8,0	8,9

Table 4: Results of the instrumental texture measurement with 4 mm cylinder probe

SAMPLE	HARDNESS (N)	ELASTICITY (mm)	CHEWING WORK (kg/s)
Blueberry	14,214±1,508	1,9432±0,092	4,595±0,358
Pear	7,084±0,493	2,947±0,156	4,569±0,536
Orange	0,926±0,055	0,041±0,041	0,995±0,054
Lemon	35,675±1,397	2,275±0,188	16,833±1,284
Strawberry	12,260±0,343	1,655±0,356	4,837±0,686
Acerola	2,360±0,240	4,639±0,277	1,586±0,159
Sour Cherry	30,076±1,720	0,688±0,157	5,587±0,607

Instrumental texture analysis results from table 4 showed that lemon flavoured chewing gum (35, 675 N) was the hardest gum, followed by sour cherry (30,076 N), blueberry (14,214 N) and strawberry (12,260 N). The softest chewing gums were orange (0,926 N), acerola (2,360 N) and pear (7,084 N). Results of sensory evaluation of hardness (table 3) also showed that lemon flavoured gum was the hardest product, but all other chewing gums were graded as very soft and received scores between 7.9 and 8,9. This shows that instrumental and sensory analyses of hardness cannot be compared in this case. The reason may be that most of the chewing gums were crumbly at the beginning. While the texture analyzer recognized

carbohydrate crystals in chewing gums reasonably hard, panellists experienced those chewing gums as very soft in the mouth.
The results for chewing work can be compared to hardness results, while the highest chewing work is needed for the hardest chewing gums. Therefore the highest chewing work was measured for lemon flavoured chewing gum, followed by sour cherry, strawberry and blueberry. The lowest chewing work was measured for gums flavoured by orange, acerola and pear.
Instrumental texture analysis also showed acerola flavoured gum as the most elastic chewing gum, followed by pear, lemon, blueberry and strawberry gums. The least elastic chewing gums were sour cherry and orange. The results in this case are very confusing while orange chewing gum, when stretched with hands, was the only gum showing any elasticity at all. All other chewing gums, except pear and lemon flavoured gums, showed no elasticity and they would instantly break.

CONCLUSION

Based on the results of sensory evaluation it can be concluded that the most acceptable chewing gum recipe contains gum base (20%), fructose syrup (18%) and sucrose (60%) with addition of low content of flavour, colour and glycerol. Glucose syrup with DE=60 is not acceptable for chewing gum production because of the hardness of chewing gums. Glucose syrup with DE=38 is more acceptable because chewing gums are softer. However, recipes with glucose syrup DE=38 (18%), gum base (20%) and sucrose (60%) are not acceptable because of the chewing gum crumbling at the beginning of chewing, and consequentially, hardness and flavour loss. Orange flavour content of 0,6% is not acceptable in chewing gum recipes because of the chewing gum stickiness. Instrumental texture analysis of hardness and sensory analysis of hardness cannot be correlated precisely. The problem occurs with chewing gums which show signs of crystallization, while texture analyser recognizes them as hard, and panellists recognize them as soft.

ABSTRACT: Three batches of fermented sausages were made: control (C – 75/25 meat/backfat ratio) and two variants (20% of backfat was substituted by grapeseed oil): variant 1 (var1) with pre-emulsified oil and variant 2 (var2) with encapsulated oil as microspheres. pH (days 2, 7 and 15), basic chemical composition (days 0 and 15), colour, texture profile analysis (TPA) and sensory evaluation (day 15) were monitored. Single-factor analysis of variance was used ($P<0.05$). Changes of pH value were similar in all variants, reaching minimum 5.08–5.16 (day 2) and values 5.21–5.35 (day 15). As for the basic chemical composition, there was a significant difference in the moisture content between variants C and var1 with respect to var2 (day 15). Colour measurements showed a significant difference in terms of lightness (L* – var1 and var2), redness (a* – var2 and C), yellowness (b* – in all variants). As for TPA, the most pronounced differences were observed in terms of hardness and chewiness; the highest were in var1, 2–4 times greater when compared to C and var2. Sensory evaluation showed no differences in terms of appearance, cut appearance or colour. In terms of odour and taste, the best graded was var2. The texture of var1 was graded significantly lower than the other two variants. Backfat can be substituted with oil prepared as illustrated in the experiment, though with certain corrections primarily because of texture. More research is required in order to monitor the changes in observed parameters during storage.
Key words: *fermented sausage, grapeseed oil, encapsulated oil, CIE L*a*b*, Texture profile analysis*

INTRODUCTION

Over the past years the demand for functional food has increased because nowadays the purpose of food is not only to satisfy hunger but also to prevent nutrition-related diseases and improve the physical and mental well-being of consumers (Siró et al., 2008). Apart from the basic nutrients, functional food should contain a component with a selective effect on one or various functions of the organism whose positive effects can be justified as functional (physiological) or even healthy (Zhang et al., 2010). Japan is the first country that developed the idea of functional foods (in 1980s) and has established regulations for the use of functional foods (Siró et al., 2008; Zhang et al., 2010).

Meat and meat products are important sources of proteins, fat, essential amino acids, minerals and vitamins and other nutrients (Vuković et al., 2009; Zhang et al., 2010). On the other hand, it seems that there is a relationship between a high-fat intake, especially of saturated fat, and an increased risk of some cancers (especially colon, breast and prostate cancer) and coronary heart diseases (Chizzolini et al., 1999; Rubio et al., 2008).

Fermented sausages have been manufactured for centuries. They are even mentioned in historic records of ancient Greeks, Romans and the Chinese (Zeuthen, 2007). For years these products were perceived as a significant source of proteins of

high biological and caloric value. Nowadays, with changes in the diet, as well as development of new and perfection of conventional preservation methods, fermented sausages are more highly appreciated because of their sensory characteristics.
In the sense of functional products, requirements for meat and meat products are reflected in the reduced level of fat, cholesterol, decreased contents of sodium chloride and nitrite, improved composition of fatty acid profile and incorporated bioactive compounds (Zhang et al., 2010). In the case of cured products, new formulations have facilitated the production of healthier dry fermented sausages by minimizing two of their major drawbacks: high salt content and the presence of saturated fatty acids (SFA) and cholesterol (Valencia et al., 2006). Improvement of functional properties of fermented sausages in the sense of changing the composition of fatty acids is reflected in the change of PUFA/SFA and ω-6/ω-3 ratios, which are the parameters for assessing the nutritional quality of the lipid fraction of food. This can be achieved by substituting one part of backfat with oils rich in unsaturated fatty acids, such as olive oil, canola oil, fish oil, linseed oil, grapeseed oil, etc. Bearing in mind that fat contributes to the colour, texture and flavour of fermented sausages, the addition of these oils makes sense only if the sensory quality is either not altered or slightly changed, because otherwise the acceptability of a product would be reduced.
The objective of this research was to establish the extent of changes of colour, texture and sensory characteristics of dry fermented sausages with the addition of grapeseed oil.

MATERIAL AND METHODS

Sausages manufacture and oil preparation

Three batches of dry fermented sausages were made. Pork meat and backfat were used in the ratio of 75:25 to produce control variant (C). Other two variants were made by substituting 20% of backfat with grapeseed oil: variant 1 (var1) with pre-emulsified oil and variant 2 (var2) with encapsulated oil. Meat and fatty tissue were ground in a cutter to about 5 mm and equal amounts of ingredients were added to all sausage variants: 2.5% salt, 0.011% $NaNO_2$, 0.2% dextrose, 0.15% sucrose, 0.04% sodium erythorbate, 0.20% garlic, 0.3% powdered white pepper and commercial starter culture mixture (*Lactobacillus curvatus*, *Staphylococcus carnosus* and *Staphylococcus xylosus*). Collagen casings (32 mm diameter) were used for filling. The ripening took place in a drying chamber under controlled conditions and under the following regime: day 1 – relative humidity (RH) 92% at 22 ℃, day 2 RH 90% at 19 ℃ with 6 h of smoking, day 3 RH 88% at 17 ℃ wi th 6 h of smoking; during the following days RH was reduced daily by 1% at 16 ℃. The production lasted 15 days.
Pre-emulsified oil (var1) was prepared by mixing for 2 min 5 parts of tap water with one part of soy protein isolate (SPI) (Solae, LCC) and then with 5 parts of grapeseed oil for another 3 min. Encapsulated oil (var2) was prepared in the following manner: alginate powder was dispersed in distilled water to produce solutions of 0.02 g/ml. The oil/alginate emulsion (40% w/w oil and 60% w/w alginate solution) was prepared using Ultra-Turrax T25 (T25 digital ULTRA-TURRAX®, IKA, Germany) at the speed of 10000 rpm for 5 min. Alginate/oil emulsion was extruded through 0.7 mm blunt stainless still needle using a syringe pump (Pump 11, Harvard Apparatus, SAD) under constant flow rate of 70 ml/h. The spherical droplets were formed by combined action of electrostatic force and gravity. Electrostatic potential (6.5 kV) was formed by electrostatic encapsulation unit (Nisco Encapsulator, Switzerland). The collecting solution was calcium chloride (0.015 g/ml). The distance between the needle tip and the collecting solution was 2.5 cm. After extrusion, the beads were left in the collecting solution for 45 min. After that, the beads were rinsed and left in distilled water at 4 ℃.

Methods

Three sausages were randomly taken from each group for pH, chemical analysis, texture profile analysis (TPA) and colour measurements.

On days 0 and 15 six individual sausages were weighed on the scales (Chyo MK-2000B) with a 0.1 g precision ratio, in order to determine weight loss. The chemical composition was determined in the following manner: water content by drying samples at 105 ℃ (ISO 1442, 1997); protein content by the Kjeldahl method and multiplying by factor 6.25 (ISO 937, 1978); fat content by the Soxhlet method (ISO 1443, 1973). Chemical analysis was conducted at the beginning (day 0) and the end (day 15) of production. pH value was measured by pH-meter Hanna, HI 83141 (Hanna Instruments USA) on days 0, 2, 7 and 15.

Sausage colour was determined by Chromameter CR-400 (Minolta Co. Ltd, Tokyo, Japan), in line with the CIE L*a*b* system (L* – lightness, a* – redness, b* – yellowness), on day 15. The colour of the cross section was determined immediately after the samples were cut and measurements were performed at room temperature (20±2 ℃). Texture profile analysis (TPA) was perfo rmed using the universal texture analyzer TAXP (Stable Micro System, Godalming, England). Samples were taken from the centre of the sausage, 2 cm in height and 2.54 cm in radius, held for equilibration to room temperature and compressed twice to their original height, with a compression aluminium platen of 75 mm (P/75) and a 250 kg load cell. Pre-test speed was 3 mm/s, test speed was 1 mm/s and post-test speed was 1 mm/s. Hardness, adhesiveness, springiness, cohesiveness, and chewiness were evaluated using the available computer software.

The evaluation of sensory characteristics of sausages was conducted at the end of production (15 day) by eight assessors. A numeric-descriptive scale with a nine-point system was used to evaluate the appearance, cross section, colour, odour, texture and taste of sausages (1 – extremely unacceptable, 9 – extremely acceptable).

The results were processed by single-factor analysis of variance (ANOVA). The differences between individual averages were tested using Tukey's method. Significant differences were considered for $P<0.05$. Calculations were done with software Statistica 6.0 PL, for Windows (Statsoft Inc.).

RESULTS AND DISCUSSION

The basic chemical composition of all three variants was very similar (Table 1). The variants with added oil had higher initial moisture content, but the difference is not significant. Consequently, their protein contents were lower, but this difference is also not significant. At the end production the weight loss of variants var1 and var2 was significantly higher than that of the control variant (40.47%, 39.87% and 37.94%), but the water content was significantly higher only in var2, most likely due to the water added through emulsion (var1) or microspheres (var2). Bloukas et al. (1997) found that the partial replacement of pork backfat with olive oil in the form of pre-emulsified fat with SPI resulted in lower moisture content and higher weight loss than control, and that the higher the incorporated emulsion, the higher the weight loss.

Table 1. Basic chemical composition

		C	Var1	Var2
moisture	Day 0	55.86±0.72^{a}	57.10±0.92^{a}	57.41±2.18^{a}
	Day 15	28.19±0.10^{a}	28.06±0.85^{a}	30.33±0.13^{b}
fat	Day 0	24.51±1.59^{a}	24.10±1.85^{a}	24.04±0.43^{a}
	Day 15	40.52±1.29^{a}	40.79±1.55^{a}	40.19±2.14^{a}
proteins	Day 0	15.21±0.73^{a}	15.22±0.16^{a}	14.61±0.98^{a}
	Day 15	24.06±1.09^{a}	25.52±0.91^{a}	23.61±1.03^{a}

Results are given as mean ± standard deviation (n = 3). Different superscripts in the same row for the same day indicate significant difference (P<0.05)

Muguerza et al. (2001) found that treatments with 20 and 30% replacing level of pork backfat with pre-emulsified olive oil (with SPI) showed higher water content than control. Kayaardi and Gok (2004) had lower weight loss in variants with added oil in the form of pre-emulsified fat (with SPI) when compared to control, but with no significant differences in terms of moisture content.
The change in pH values during production was of a similar pattern (Figure 1), with the minimum achieved on day 2, followed by a slight growth until production end. Kayaardi and Gok (2004) and Bloukas et al. (1997) emphasised that the addition of olive oil as soy emulsion has no effect on pH.

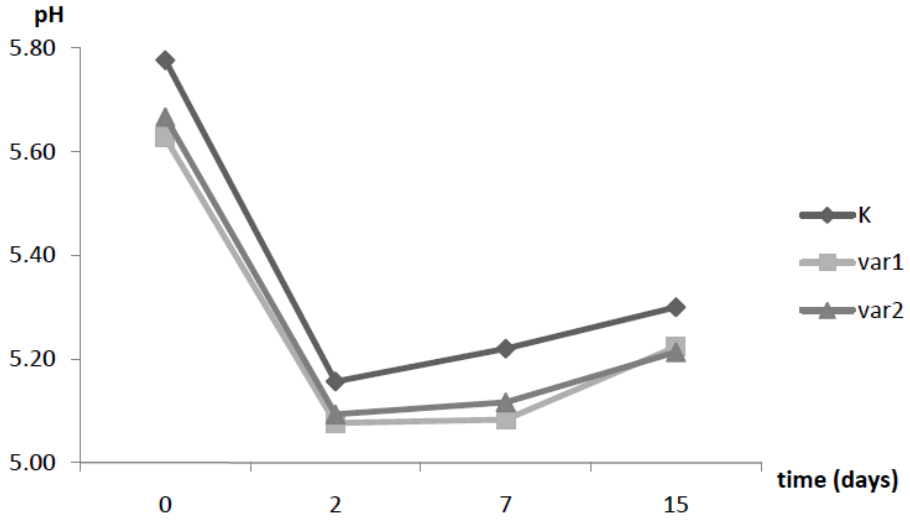

Figure 1. Changes of pH values during ripening

Colour is a very important quality characteristic of fermented sausages, since it influences consumer acceptability (Bozkurt and Bayram, 2006). Results of colour measurements are shown in table 2.

Table 2.Colour measurements

	C	Var1	Var2
L*	50.99±2.58^{ab}	52.23±0.91^{b}	49.05±1.30^{a}
a*	11.57±0.88^{a}	12.27±1.01^{ab}	12.99±0.82^{b}
b*	6.16±0.62^{a}	8.23±1.14^{b}	7.20±0.59^{c}

Results are given as mean ± standard deviation (n = 9). Different superscripts in the same row indicate significant difference (P<0.05)

Lightness measured in var1 was higher, and in var2 lower than in control, but the observed difference is not significant. Pelser et al. (2007) did not determine any higher values for L* in variants with added emulsified oil and encapsulated oil in comparison with the control variant. Muguerza et al. (2002) established that by replacing 20% of backfat with pre-emulsified olive oil in sausages with a higher initial backfat content, it is possible to create a lighter product. Bloukas et al. (1997) obtained greater differences in L* value in variants with added oil in respect to control. The addition of oils as microspheres resulted in darker product colour. Redness (a*) was the highest in var2 and significantly higher only in comparison with C. Pelser et al. (2007) did not determine any significant differences between variants with added emulsified and encapsulated oils. Similar conclusions were drawn by Muguerza et al. (2002) and Bloukas et al. (1997) for products with added emulsified oil. The control variant was less yellow (b*) than the modified variants and a significant difference was observed in all three variants. Other authors (Bloukas et al., 1997; Kayaardi and Gok, 2004; Muguerza et al., 2002; Pelser et al., 2007) reached similar conclusions.

Bloukas et al. (1997) found that fermented sausages with incorporated olive oil as pre-emulsified fat (with SPI) were harder than the control. Muguerza et al. (2001) on the contrary reported a reduction in hardness and chewiness in variants with pre-emulsified olive oil. In our case (Table 3), hardness and chewiness were by far higher in var1 when compared to control, as well as when compared to var2. Moreover, hardness and chewiness of var2 were significantly lower when compared to the control variant. There is a mutual dependency between moisture content on the one hand and hardness and chewiness on the other (Bozkurt and Bayram, 2006), and it was higher in var2; however, since hardness and chewiness in C were by almost 50% higher than in var2, it is possible that this was also a result of the addition of encapsulated oil. Bozkurt and Bayram (2006) remarked that adhesiveness during ripening is reduced by decreasing the moisture content, which makes sucuk easily sliceable. Since in our case the moisture content at the end of production was significantly lower in C and var1 when compared to var2, we can expect var2 to stick to the knife during slicing more than variant C. Data on the application of encapsulated oils is scarce and it mostly refers to the application of encapsulated fish and linseed oil in powder form (Pelser et al., 2007; Josquin et al., 2012), a product different from the one we used.

Table 3. Texture profile analysis

	C	var1	var2
Hardness (g)	6694.81±835.20b	15316.91±1047.97c	4446.70±318.74a
Adhesiveness (g*s)	-322.37±111.60b	-201.74±99.86ab	-152.34±66.23a
Springiness (mm)	0.46±0.03a	0.51±0.02b	0.48±0.02ab
Cohesiveness	0.51±0.02b	0.48±0.01a	0.46±0.02a
Chewiness (g*mm)	1583.38±246.19c	3700.22±359.09b	987.92±73.10a

Results are given as mean ± standard deviation (n = 6). Different superscripts in the same row indicate significant difference (P<0.05)

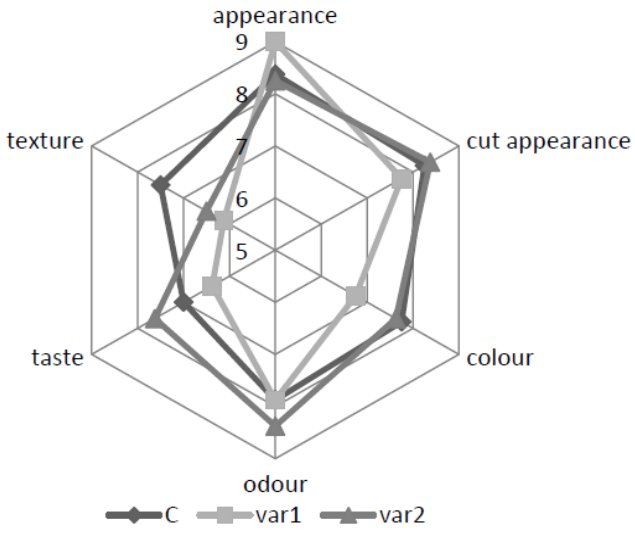

Figure 2. Sensory evaluation

Sensory evaluation (Figure 2) did not yield any significant differences between control and the variants with added oil. Assessors did not observe any significant differences in terms of appearance, cut appearance, colour and odour. In terms of taste there was only a difference between var1 and var2. Bloukas et al. (1997) reported similar results for fermented sausages with pre-emulsified olive oil added. The most pronounced differences were observed in terms of texture, where both var1 and var2 received grades lower than 7, but only var1 received a significantly lower grade in comparison with the control variant and var2. Since the measured values for hardness and chewiness in var1 were many times higher than in C and var2, it may

be possible that assessors perceived this as a flaw. Also, assessors gave a similar grade to texture in var2 in which significantly lower values of hardness and chewiness were measured, compared to C, as well as var1; however, this difference was not significant although texture received a grade lower than that of the control variant. It is possible that assessors perceive both too hard and too soft a texture as equally unfavourable. Kayaardi and Gok (2004) reported higher or equal marks for soudjouks prepared by replacing beef fat with olive oil in terms of colour, appearance, taste and texture than control.

CONCLUSIONS

The use of oil in ways described in the research is possible and it must be noted that the addition of oil did not render the product unusable. Variants with added oil had greater weight loss compared to the control variant, but the water content significantly differed only in var2. There were no significant differences in terms of protein and fat contents or pH values in all variants. Lightness significantly differed between var1 and var2, redness between C and var2, while yellowness differed between all three variants. As for texture profile analysis, the largest differences were observed in terms of hardness and chewiness, which were higher in var1 than in the other two variants. Assessors did not observe any significant differences in terms of appearance, cut appearance, colour and odour. Texture in var1 received the lowest grades, which may be related to the measured high values of hardness and chewiness. Grades of all sensory evaluation parameters were satisfactory (not lower than 6).
Further research should be focused on the changes of sensory characteristics during storage bearing in mind the shelf life of fermented sausages and tests to determine the fatty acid content and lipolytic changes.

ACKNOWLEDGEMENTS

Research was financed by the Ministry of Education and Science, Republic of Serbia, project III–46010. The authors thank Mr. Mladen Gavrilović (PALCO d.o.o., Šabac, Serbia) for alginate donation, Mr. Nenad Nikolić (Solae, LLC) for soy protein isolate donation, Mr. Mile Arnaut (Gram, Belgrade, Serbia) for calcium chloride (food grade) donation. We would also like to thank meat manufacturer PKB IMES Belgrade for their assistance with sausage production. We thank Marija Stajić for assistance with the translation.

ABSTRACT: Water-in-oil emulsions, consisting of demineralized water dispersed in sunflower oil and stabilized with polyglycerol polyricinoleate, have been prepared by using two emulsification methods: high-speed homogenizer and ceramic membranes (alpha-aluminum oxide), with mean pore size 20 nm. Influences of the water phase content on the mean droplet size and droplet size distribution were investigated. The mean droplet size and droplet size distribution of the prepared emulsions were measured using a laser light scattering instrument. As expected, the results showed that the mean droplet size and droplet size distribution depended on the dispersed phase content in the emulsion in a way that increasing the water phase content the mean droplet size was increased. The results showed that application of membrane emulsification process can significantly reduce mean size diameter of water droplets in emulsions of this type. However, when membrane emulsification is used, the small water droplets, which were initially of the diameters less than 100 nm, tend to reduce the total amount of interface by coalescence, and form the droplets of the mean peak diameter of about 400 nm. At the same emulsifier content in the continuous phase (3%, w/w), the mean droplet diameter was about 750 nm in emulsions produced using high-speed homogenizer.
Key words: water-in-oil emulsions, sunflower oil, PGPR, membrane emulsification

INTRODUCTION

Production of water-in-oil (W/O) and water-in-oil-in-water (W/O/W) emulsions shows increasing interest in the food industry, due to the fact that within these emulsion systems different active ingredients can be captured, allowing they use in masking bad tasting or bad smelling components, controlled releasing of active ingredients and stabilization food ingredients.

Preparation of W/O emulsions requires the presence of certain amounts of lipophilic surfactant (low hydrophilic-lipophilic balance (HLB)), which reduces interfacial tension between two phases, prevents the occurrence of aggregation and increases emulsion stability (Van der Graaf at al., 2005). Previous studies showed (Surh et al., 2007) that polyglycerol polyricinoleate PGPR (HLB ≈ 3) possesses the optimal characteristics for obtaining W/O emulsion, because of relatively good solubility in oil and the possibility of the formation emulsion with droplets of small diameter and narrow droplet size distribution (Mun at al., 2010). The temperature of emulsification process did not show a meaningful effect on the droplet size and droplet size distribution (Surh et al., 2007).

Also, the concentration of surfactant affects the mean diameter of formed emulsion droplets, in the manner that droplet size decreases with increasing concentration of surfactant (Marquez at al., 2010). On the other hand, maximum *per capita* mean daily intake of PGPR is 2.64 mg/kg body weight/day (Wilson at al., 1998), by limiting the application of surfactant.

Size and droplet size distribution depends, besides the content of surfactant, on the dispersed phase content in the emulsion in a way that the water phase content increase increases the mean droplet size (Kobayashi at al., 2005).

Emulsions are usually prepared using high-speed homogenizers and rotor-stator systems, where the fine droplets are formed in the dispersing zone, under the influence of high shear stress. Development of new emulsification methods allows the production of emulsions with significantly improved characteristics (Joscelyne at al., 2000).

Membrane emulsification (ME) involves the permeation of pure dispersed phase through a microporous membrane into the continious phase flowing inside the membrane. Techniques to produce emulsions using membranes can be divided in two groups: either a coarse pre-mixed emulsion can be pressed through the membrane to reduce the droplet size of the disperse phase, or only the dispersed phase is pressed through the membrane forming droplets in the membrane surface that are detached by the cross-flowing continuous phase (Gejsbertsen-Abrahamse at al., 2004).

Previous studies have shown that cross-flow emulsification processes have significant advantages in the production of monodispersed emulsions, emulsions with shear sensitive components and nanometer-size emulsions and allow the preparation of stable emulsions with a very narrow droplet size distribution in comparison with conventional methods, such as homogenizers (Vladisavljević at al., 2002).

The aim of this study was to compare the emulsification processes and the properties of W/O emulsions prepared using membrane emulsification system (ME) and high-speed homogenizer. Also, content of dispersed phase in the emulsions and concentration of surfactant (PGPR) in the continuous phase on the size and droplet size distribution were investigated. This paper will emphasize influence of these two factors on the mean droplet diameter, the peak width and the span of droplet size distribution (PSD). The span of PSD is given by an equation:

$$span = \frac{d_{90} - d_{10}}{d_{50}}$$

where d_{x0} is the diameter corresponding to $x0$ vol.% on a relative cumulative PSD curve (Vladisavljević at al., 2003).

MATERIAL AND METHODS

For the preparation of the continuous phases sunflower oil (“Vital”, Vrbas, R. Serbia), and polyglycerol polyricinoleate (PGPR 90), kindly provided by “Jaffa” a.d. (Crvenka, R. Serbia), were used. Concentration of PGPR in the continuous phase (E) was 3 and 5 wt.% in both method of emulsification. Vegetable oil was used in its original form. Demineralized water was used as the dispersed phase.

Preparation of W/O emulsions using ME

The experimental set-up used for membrane emulsification is shown in Fig. 1. The ceramic $\alpha - Al_2O_3$ tubular membrane (250 mm length and 7 mm inner diameter), with the mean pore size of 20 nm, was placed in a membrane module (1) of the membrane emulsification apparatus. The continuous phase, prepared by dissolving a certain amount of PGPR (3 or 5%) in sunflower oil at 50℃, by mixing on a magnetic stirrer for 1/2 h, was forced to recirculate inside the system by using a peristaltic pump 620U (2) (Watson-Marlow, England). The continuous phase content in a tank (6) at the beginning of the process was 1500 ml, while the capacity of the dispersed phase graduated vessel (3) was 600 ml. The dispersed phase (water) was poured (7) into the pressure vessel (3) and introduced in the annular space of the module (1) by compressed nitrogen (N_2) from the gas cylinder (4). Water droplets formed in the membrane were detached from the membrane surface inside the tube by the cross-

flowing continuous phase. The continuous phase circuit worked in a closed loop. The produced emulsion was gradually enriched with the water phase with each run through the membrane tube. Samples of prepared emulsions were taken for the water phase contents of 10, 12.75, 15.50, 18.25 and 21% (w/w). Volumetric flow of the continuous phase was measured (5) and kept on 2.5 $L \cdot h^{-1}$. Transmembrane pressure was $0.9 \cdot 10^5$ Pa.

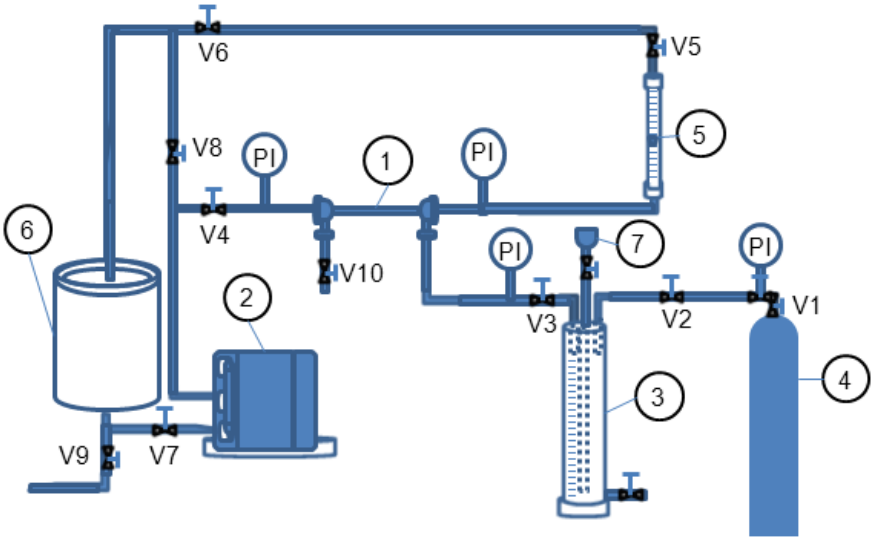

Figure 1. Membrane emulsification system: 1-membrane module, 2-peristaltic pump, 3-dispersed phase graduated vessel, 4-gas (N_2) cylinder, 5-flow meter, 6-continuous phase tank, 7-dispersed phase entrance, V1-10 – on-off valves.

Preparation of W/O emulsions using high-speed homogenizer

Continuous phase was prepared in the same way as in the previously described method, dissolving a certain amount of PGPR (3 or 5%) in sunflower oil at 50℃, by mixing on a magnetic stirrer for 1/2 h. The aqueous phase was dispersed drop by drop into the continuous oil phase with a continuous stirring by a high-speed homogenizer Ultra turrax T-25 (IKA, Germany) at 24 000 rpm for 5 min. Emulsification temperature was 25℃. The content of the disperse phase in the emulsions (W) was 21 wt. %.

Characterization of W/O emulsions

The mean droplet size and droplet size distribution of the water in W/O emulsions stabilized with PGPR was measured by laser light scattering instrument Zetasizer Nano ZS (Malvern Instruments, U.K.). The measurements were preformed immediately after the formation emulsions and repeated at least three times.

RESULTS AND DISCUSSION

The droplet size distribution properties of W/O emulsions prepared using ME system are shown in Figure 2. The effect of dispersed phase content on the size and droplet size distribution in the membrane emulsification process is shown in Figure 2a. The mean size diameter of water droplets (d) for the investigated water phase contents was in a range from 250 to 400 nm, with the peak width (pw) from 60 to 160 nm. As previous studies has shown the increase of the dispersed phase content leads to the increase of droplet diameter, nonetheless the investigated contents of the emulsifier. However, droplet size diameters were very similar to both concentration of PGPR, and when the content of dispersed phase was 21% (w/w) the diameters were almost the same of about 400 nm. The particle size distribution results depend also on the

storage time since the small water droplets, which were initially of the diameters less than 100 nm, tend to reduce the total amount of interface by coalescence, and form the droplets of the specified larger diameter within a short period of time after the emulsion production. The amount of surfactant needed for stabilisation of the interface depends on the amount of contact area between phases, which is significantly increased when such a small droplet diameters are produced by ME process. Therefore, the concentrations of emulsifier higher than 5% (w/w) are needed in order to prevent coalescence of small water droplets, and probably only these higher concentrations would show significant effect on droplet size diameter. But, PGPR content of 5% seems to reduce the peak width on the PSD curve when compared to the lower concentration of 3%. The same conclusion can be drown from the lower span values of PSD curve for 5% than for 3% of emulsifier, as it is shown in Figure 2b.

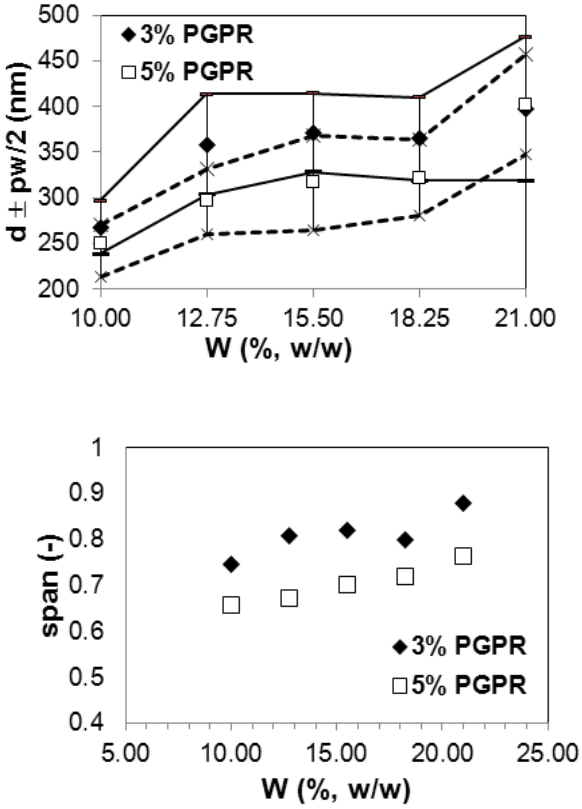

Figure 2. Results of the ME process as a function of dispersed phase content (W) for emulsifier contents of 3 wt.% (♦) and 5 wt.% (□); 2a) (on the left) The mean droplet diameter, d, (symbols) and the peak width values, pw, (lines) (symbols lie within d±pw/2 ranges placed between two solid lines (3 wt.% PGPR) or two dashed lines (5 wt.% PGPR). 2b) (on the right) The span of the particle size distribution curve.

W/O emulsions obtained by ME had a significantly smaller diameter of water droplets which was about 400 nm, for concentration of PGPR 3%, in comparison to the mean droplet diameter of emulsions obtained using homogenizer, which was about 750 nm, for the same dispersed phase content of 21 wt.% (Fig. 3a). As expected, increasing concentration of surfactant (5% PGPR) induced a decrease droplet diameter for emulsions obtained by homogenizer, but this behavior was not observed in the preparation of emulsions ME. This behavior can be explained by the fact that this is still very low concentration of surfactant for the ME process, taking into account that with decreasing droplet diameter increases the contact area between phases and therefore the greater amount of surfactant needed for interface

stabilization. However, the use of membranes, in a concentration of PGPR 5%, shows the reduction in the peak width on a relative cumulative PSD curve.
Membrane emulsification process demonstrated other one significant advantage in production W/O emulsions. Namely, the span of PSD curve of emulsions prepared in ME was considerably lower, especially for emulsions with 5% PGPR (Fig. 3b).

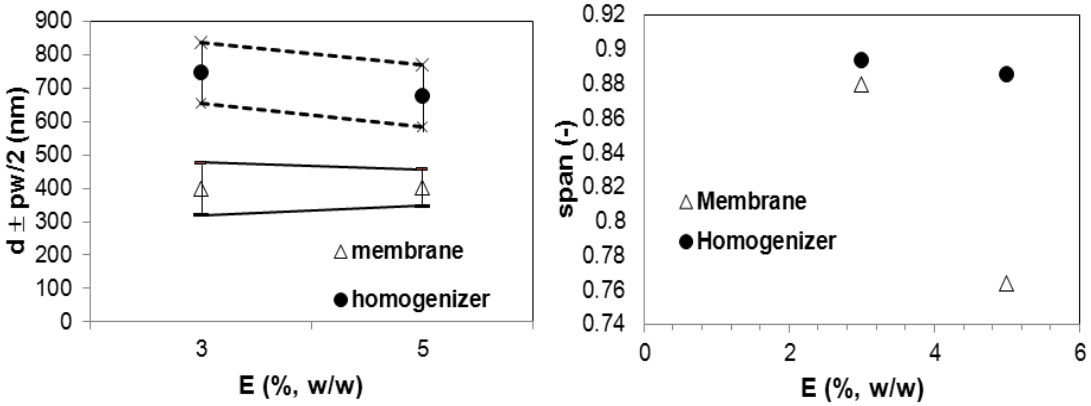

Figure 3. The particle size distribution properties of W/O emulsions with 21 wt.% of disperesed phase, prepared using membrane emulsification system (∆) and high-speed homogenizer (•) for the different contents of emulsifier. 3a) (on the left) The mean droplet diameter, d, (symbols) and the peak width values, pw, (lines) (symbols lie within d±pw/2 ranges placed between two solid lines (for ME) or two dashed lines (for homogenizer). 3b) (on the right) The span of the particle size distribution curve**.**

CONCLUSIONS

The mean size diameter of water droplets in W/O emulsions produced by membrane emulsification for the investigated water phase contents of 10, 12.75, 15.50, 18.25 and 21wt.% was in a range from 250 to 400 nm, with the peak width from 60 to 160 nm. By membrane emulsification process it is possible to produce W/O emulsions with a significantly smaller value of the mean water droplet diameter in comparison to the conventional emulsification process. For membrane and conventional processes, when the water phase content in the emulsion is 21 wt.%, and emulsifier content in the continuous phase is 3 wt.%, the mean droplet diameters are about 400 and 750 nm, respectively. For emulsifier content in the continuous phase of 5 wt.%, the span value of the particle size distribution curve of emulsions prepared in membrane emulsification process is considerably lower than corresponding values of emulsions obtained by homogenizer, 0.75 versa 0.90, respectively.

ABSTRACT: Solubility of phospholipids in propane were measured in pressure range from 20 bar to 70 bar and temperature range from 40℃ to 60℃. Extraction of oils from pumpkin seeds were performed in the pressure range from 50 bar to 150 bar and at temperatures from 20℃ to 60℃. Oils produced by laboratory extractio n at those conditions were evaluated for phospholipid content and were round 6,5 wt.% independent from extraction pressure.
Key words: *lecithin, extraction, pumpkin seeds*

INTRODUCTION

Design of new products with special characteristics or design of new processes, which are environmental friendly and have an impact to sustainable processes, are a great challenge for chemical engineers. Supercritical fluids are relatively new tool, which leads to sustainable manufacturing methods that are not only ecologically preferable but also gives products with special properties. One of the latest applications is extraction of oil from plant materials to obtain highly concentrated and very pure lecithin. Separation and formulation of products by supercritical fluids and production of substances and composites with unique properties and characteristics for the use in different applications are now days intensively studied. One of the most important advantages of use of supercritical fluids is design of solvent free products with special product properties [Lütge et al, 2007]. Lecithin is a natural emulsifier, which is found in high concentrations in soy beans [Knez et al, 2010, King et al, 1994] and is a by-product of the soy bean oil production. In high content it can be found in some other seeds, like pumpkin seeds. It is used as a neutraceutical, as emulsifying agent in the food industry and as a source for phosphatidylcholine (PC) in the pharmaceutical industry. Lecithin is not a single substances but a mixture of different phospholipids: phosphatidylcholine (PC), phosphatidylethanolamin (PE), phosphatidylinositol (PI), phosphatoic acid (PA) and others. Pumpkin seeds contain beside highly valuable oils and beside being a good source of polyunsaturated fatty acids, such as myristic acid, palmitic acid, steric acid, oleic acid, linoleic acid, linolenic acid, arachidic acid etc., contain a lot of protein, zinc, and other vitamins, tryptophan and they are even said to lower cholesterol. Pumpkin seeds are a good source of magnesium, manganese, phosphorus, and phytosterols (Bernardo-Gil et al, 2004, Murković et al, 1996, Murković et al, 2000). In our research isolation of phospholipids and isolation of oils using propane were studied.

Figure 1: Pumpkin seeds.

MATERIAL AND METHODS

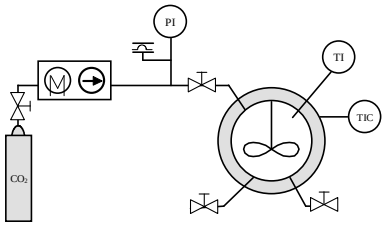
Materials

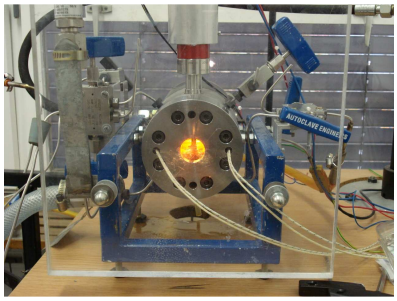
Propane with purity 3.5 was supplied by Messer (Ruše, Slovenia). Pumpkin seeds were supplied by Gea, d.d.(Slovenska Bistrica, Slovenia).Soybean lecithin (Sigma Aldrich) with 40% phosphatidylcholine was used for solubility studies.

Apparatus

High pressure view cell - Phase equilibria observation

For the process design solubility measurements and phase equilibrium observations were performed for the system lecithin (40% phospholipids)/propane in variable volume high pressure view cell was supplied by NWA (Lörrach – D) presented on Figure 2.





a b

Figure 2: High pressure view cell: flow sheet (a) and photo (b) of the apparatus (60 mL, max. operating pressure 700 bar and max. operating temperature 250℃).

Influence of pressure, temperature and stirring rate on:

- distribution of liquid and gaseous phases – possible phase inversions,
- qualitative evaluation of viscosity of mixtures,
- separation of phases after intensive stirring,

was observed.

High pressure extraction unit

Extraction experiments were performed on extraction unit presented in figure 3. The plant is operating up to pressure 400 bar and temperature 100℃.

4-HPLC pump	8- temperature regulator	V1…V6-valves

Figure 3: High pressure extraction apparatus

RESULTS AND DISCUSSION

Thermodynamic data

The main disadvantage using conventional solvents is that the extracts are contaminated with organic solvents which cannot be easily removed. The legal limitations of solvent residues and solvents (for products for use in human applications) and isolation/fractionation of special components from total extracts in combination with different formulation and sterilization processes will increase the use of dense gases for extraction applications [Stahl et al, 1987].

The solubility of extracted substance in the supercritical solvent is essential for the economy of extraction process. The highest possible loading of SC solvent should be achieved in extraction step of the processes, while in separation step of the process the solubility of solute in solvent should be the lowest [McHugh, Krukonis, 1996].

One of the major advantages of SC fluid extraction processes performed at high pressure - fractionation of extracts decreasing the solvent power of SCF is presented. Active compounds from pumpkin seeds with high contain of oil were very efficiently fractionated [Shi et al, 2007].

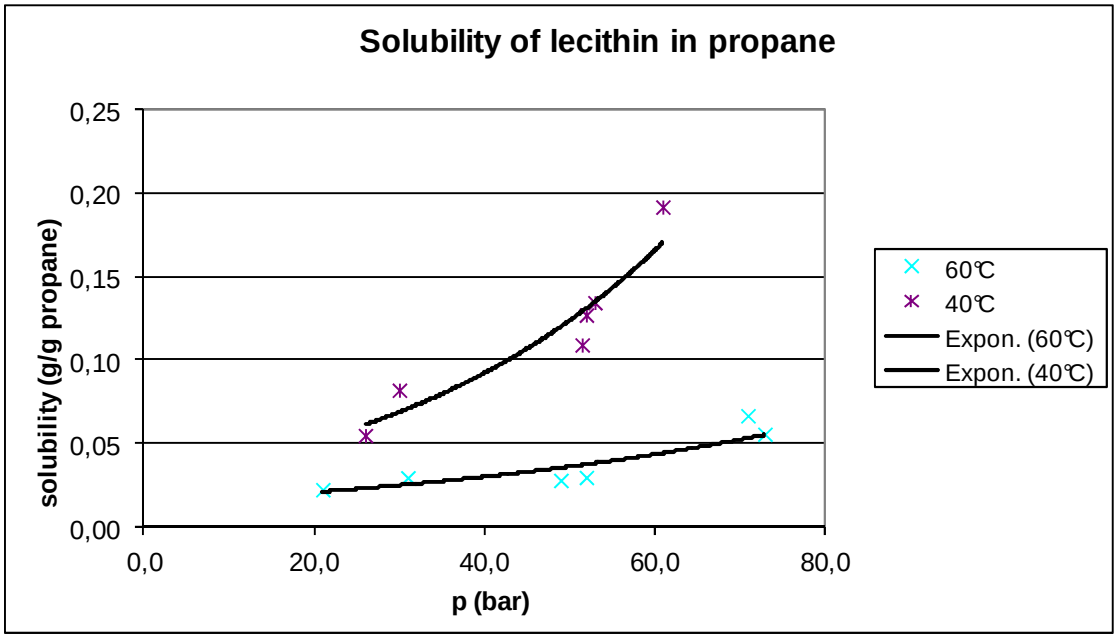

Figure 4: Solubility of lecithin (40%) in propane

Solubility measurements were performed in pressure range up to 70 bar and at temperatures 40℃ and 60℃ and results are presente d in Figure 4.
From the data in Figure 4 it is evident that at temperature 40℃ as well as at temperature 60℃ with increasing pressure from 20 b ar to 60 bar the solubility increases with increasing temperature. The solubility of lecithin in propane at constant pressure decreases with increasing temperature in temperature range from 40℃ to 60℃.

Phase observations for the system lecithin/propane
Phase observations were made at 40℃ and 60℃ in pr essure range from 30 bar to 170 bar. An example is presented in Figure 5. As seen in the figure, the bottom phase is always a lecithin rich phase.

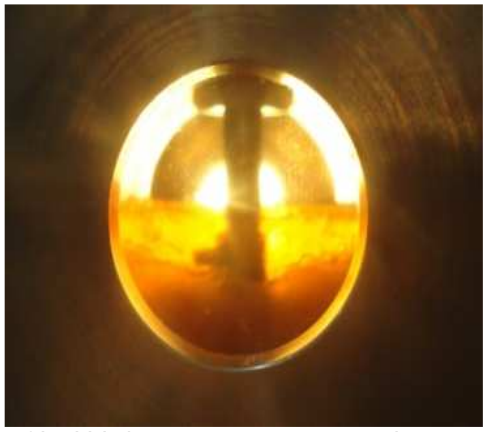

Figure 5**:** Phase behavior of lecithin/propane system at various pressures and temperatures

Extraction experiments

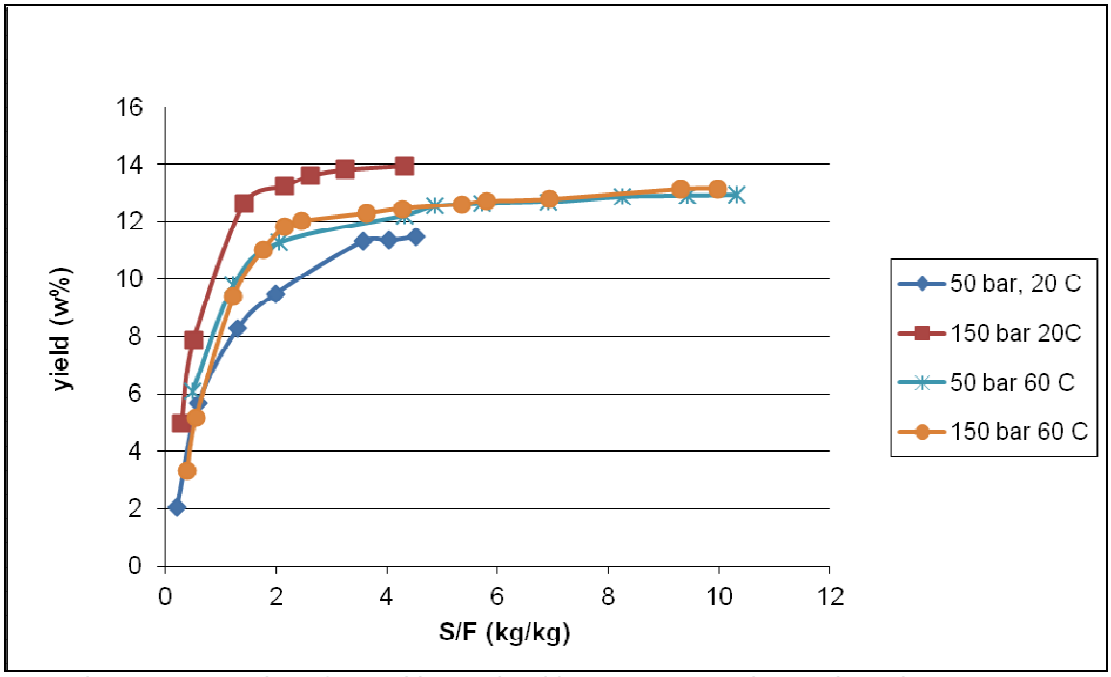

Figure 6: Extraction of pumpkin seeds with propane at 50 bar and 150 bar at 60℃.

At temperature of 20℃ (Figure 6) the yield of extr action is influenced by pressure, at higher pressure yield increases. At temperature of 60℃ the yield is practically independent from pressure.

CONCLUSIONS

Oils from pumpkin seeds, produced by laboratory extraction, were evaluated for phospholipid content. In general, oil had a high level of phospholipids, which was higher in case of SCF extraction at higher temperature and higher pressure.
Separation or formulation of products by supercritical fluids and production of substances and composites with unique properties and characteristics for the use in different applications are nowdays intensively studied. One of the most important advantages of the use of supercritical fluids is selective extraction of components or fractionation of total extracts.
The possible limitation of SCF technologies could be in high investment costs, but the legal restrictions on solvents and solvent residues, fractionation of highly valuable compounds from total extracts in combination with formulation processes will lead to an increase in the use of gasses under high pressure for extraction applications.

ABSTRACT; Production of meat products with lower salt/sodium content is the goal of today's meat industry because of bad influence of exceed sodium intake by food. In this paper are presented some physico-chemical parameters during processing of dried pork produced with lower salt content. Pork (*m. longissimus dorsi*) was cured with nitrite curing salt in amount of 3 kg/100 kg of meat. In meat were measured the weight loss during curing and drying; moisture content by standard method SRPS ISO 1442:1998, water activity using aw-meter (Wert-Messer, Durotherm) at temperature of 25℃; and pH value by pH-meter (MA-5730; PAT N° 35398, Iskra) according to SRPS ISO 29 17:2004. Average moisture content in dried meat at the end of production was 40.10%. Average weight loss was 2.39% after 7 days of production (after curing) and it is increased up to the end of production, average 34.57%. Acidity of meat during curing, smoking and drying was similar; pH value was around 6.00. Water activity was gradually decreased from average 0.985 after curing (7^{th} day) up to 0.899 at the end of production. During the storage of dried meat under vacuum conditions, pH value decreased from 5.43 in the final product up to 5.11 at the end of storage (120^{th} day). These values are characteristic for curing, drying and fermentation of meat. Dried meat was shelf stable for 120 day under vacuum conditions, without signs of rancidity and without changes in other sensory attributes.

INTRODUCTION

Sodium chloride (common salt) is essential ingredient in meat processing which contributes the saltiness (taste), water holding capacity of meat and consequently to textural characteristics (Ruusunen i Poullane, 2005). In modern meat processing, sodium chloride is added mostly through nitrite curing salt. Curing salts with sodium and potassium nitrate are mostly disappeared from industrial meat production, but sometimes they are used in the house-hold manufacturing of dried meat. Salt diffusion in meat and meat dehydration (drying) are common processes but sometimes it is difficult to control them (Arnau et al., 1995).

The first stage in the dry meat processing is dry curing at low temperature, mostly up to 5℃. Curing lasts different time, depending on s hape and size of meat. Curing lasts shortly if meat size is small and at higher temperature; it is also depended on relative humidity (Fantazzinia i dr., 2005). Salt diffusion is key process in dry meat production and solubility of salt on the meat surface is the first factor which regulates salt penetration in meat (Sörheim i Gumpen, 1986; Gil i dr., 1999).

Meat is cured traditionally with 6% of common salt or nitrite curing salt. Present trend in the nutrition is reducing the salt content in meat products, as reported by Ruusunen and Puolanne (2005). According to mentioned the goal of this paper was to investigate some physico-chemical characteristics of dried pork produced with lower salt content, during the curing, drying and storage under vacuum conditions.

MATERIAL AND METHODS

The material in this paper was pork (*m. longissimus dorsi pars thoracis*) originated from white pigs, six months old, with live average weight of 100 kg. After chilling the meat was treated with following mixture: 950 g of nitrite curing salt and 50 g of sucrose, in the amount of 300 g per 10 kg of meat. Curing lasted for 7 days and after that meat was smoked for next 7 days. Process of drying and ripening lasted for 14 days. Final products were packed in PA/PE bags under vacuum conditions and stored at room temperature for 120 days.
Samples for examination were taken on the first day of production (fresh meat), after curing and after 14^{th}, 21^{st} and 28^{th} day of production (final product). In these samples were determined weight loss calculated from differences in the mass of meat during curing, smoking and drying on the scale with sensitivity of 10^{-3}. Moisture content was determined by standard method SRPS ISO 1442:1998; water activity using a_w-meter (Wert-Messer, Durotherm) at temperature of 25℃; and pH value by pH-meter (MA-5730; PAT N°35398, Iskra) according to
SRPS ISO 2917:2004.

RESULTS AND DISCUSSION

The results of weight loss and moisture content of meat are presented in Figure 1. Average moisture content in meat was 77.85%. After curing, moisture content in the superficial layer was 71.59% and in inner part of meat 70.17%. After smoking (14^{th} day of production), moisture content is decreased up to 58.16% in the superficial layer and up to 49.71% in the inner part of meat. During drying of meat (21^{st} day of production), moisture content is also decreased up to 57.20% in the superficial layer of meat and up to 37.72% in the inner part of meat. At the end of production, moisture content was 40.10% in whole dried meat. Consequently to decreasing of moisture content in meat, it was increased weight loss, from 2.39% ± 0.58 in meat after curing up to 34.57% ± 1.48 at the end of production. There are common processes during the dried meat production and according to Incze (1992), the weight loss at meat drying could be very various, from 40 up to 50% and moisture content can be very low (18-22%).

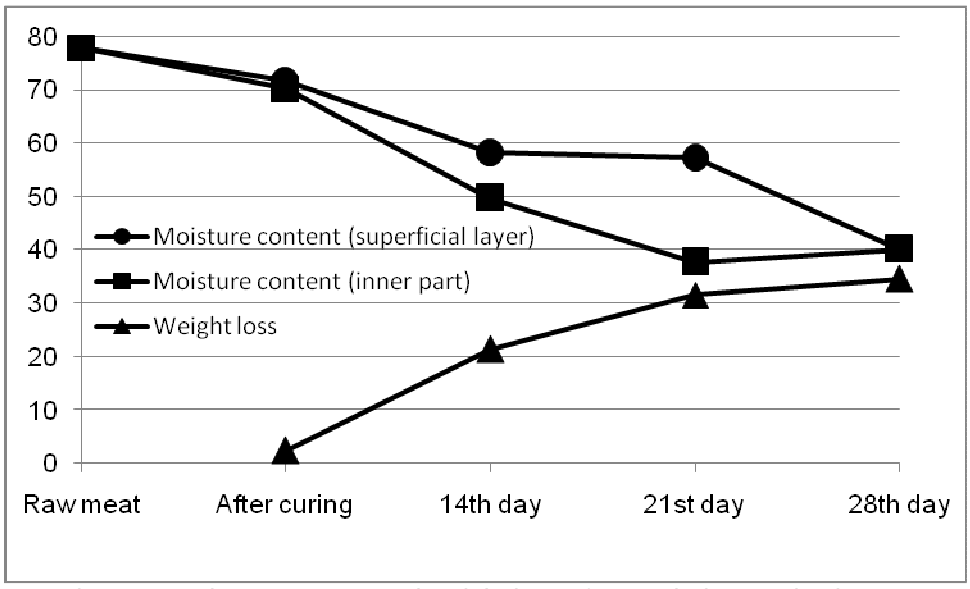

Figure 1. Moisture content and weight loss of meat during production, %

Results of pH value in meat in the different stages of the production are presented in Figure 2.
Value of pH in fresh meat was average 5.83 ± 0.06 and was similar on 7th, 14th and 21st day of production, 5.90 ± 0.09, 5.91 ± 0.07 and 5.86 ± 0.05, respectively. Obtained results for fresh meat are in the accordance with results of Dzierzynska and Pospiech (1989) which cited that pH value of fresh pork is 5.67-5.84 and with the results of Severini et al. (1989) which cited that pH value is 5.48-5.84 in fresh meat after 24 hours of slaughtering.
At the end of production, pH value was decreased up to 5.43 ± 0.01, mostly due to smoking and the influence of organic acid from the smoke. This result is in the accordance with results of Liepe and Porobic (1985) which stated that pH value is 5.30-6.25 in dry hams and with the results of Leon Crespo et al. (1982) that cited pH value of 5.30-5.95 in dry hams. Bellati et al. (1983) cited higher pH value in traditionally produced hams (6.00).
Average pH value in meat after 60 days of storage under vacuum conditions was 5.22 ± 0.05 and after 120 day of storage 5.11 ± 0.05. Lower pH values during the storage under vacuum conditions are the result of activity of lactic acid bacteria that are presented in dried meat in vacuum packaging due to their possibility to survive under microaerophylic and anaerobic conditions. Furthermore, in the curing mixture was added sucrose that was presented source for the growth of these bacteria.

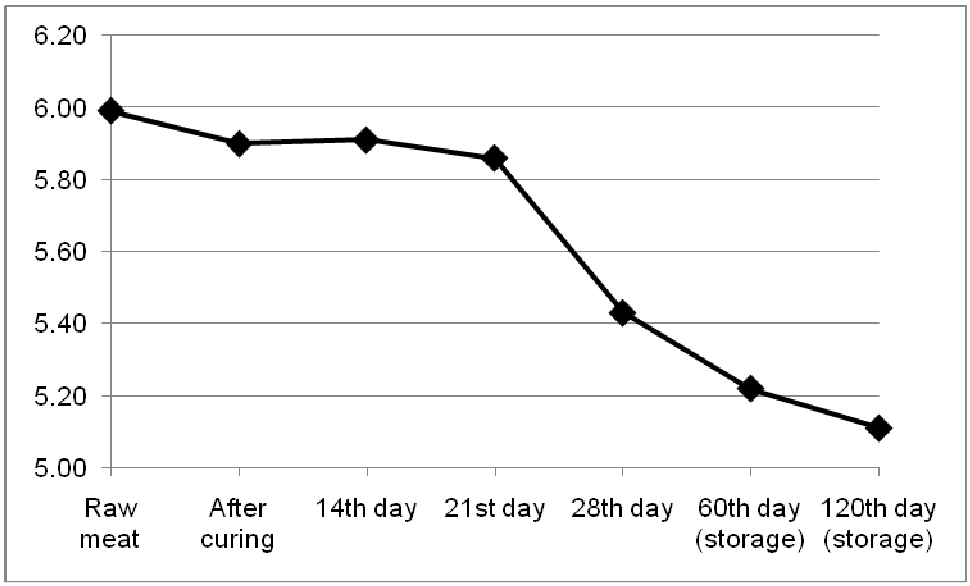

Figure 2. Changes of pH value during production and storage of dried pork

During the curing, smoking and drying, water activity in meat is decreased accordingly with physico-chemical processes (dehydration of meat). Results of the changes of water activity in meat during production are presented in the Figure 3. Average a_w value in fresh meat was 0.992 that decreased after curing (7th day of production) up to 0.985 ± 0.002. After smoking and drying (14th and 21st day of production), a_w value was decreased up to 0.950 ± 0.008 and 0.936 ± 0.009, respectively. At the end of production, a_w value was 0.899 ± 0.004. Obtained results are higher than the results of Leon Crespo et al. (1982) which cited that average a_w value in Jabugo ham of 0.83 (0.75-0.88), but in the accordance with results of Ventanas et al. (1989) which stated a_w value 0.90-0.96 and Molina et al. (1989) which cited that a_w value was 0.83-0.95 in the slow process and 0.87-0.93 in the fast process of the production of dry Iberian ham.

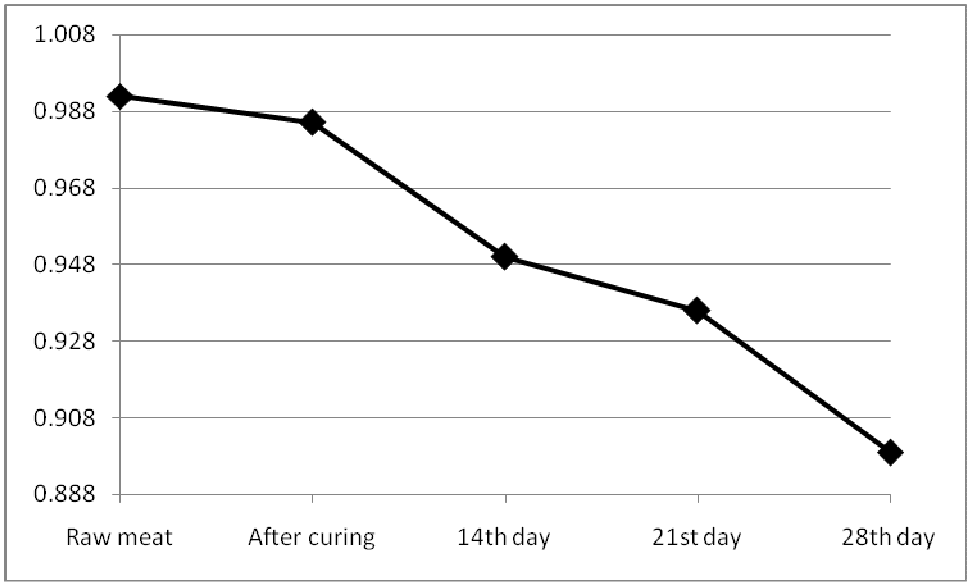

Figure 3. Water activity in dried pork during production

CONCLUSIONS

Moisture content of meat is decreased during the production, while weight loss is increased at the end drying, these values were similar (40.10% and 34.57%, respectively)
Water activity is decreased during drying up to 0.899 at the end of production.
Values of pH were similar during the production (approximately 6.00), but they are lower during the storage of products under vacuum conditions due to the activity of lactic acid bacteria that are presented in the first period of storage.
Lower salt content did not influence mentioned parameters in the comparison with the results of investigation of similar products produced with higher salt content.

ABSTRACT: Food and agricultural production often leads to generation of various types of by-products. The same is with sunflower oil production. Sunflower is a crop that is widely grown in Serbia, as well as in the world, mainly for edible oil production, and sunflower husk is a by-product which is generated through this production. It is in accordance with European regulative to find an ecologically friendly way of disposal for this kind of waste. Sunflower husk falls in the category of biomass and can be used for energy generation. The most common way to utilize biomass for energy generation is by combustion. In this study sunflower husk was investigated as an energy source, and it was pelleted in order to achieve better energy conversion and combustion characteristics. The optimal conditions of pelleting process were determined, that is optimal water content in the material for pelleting. When the material is well prepared less energy is consumed during pelleting process.
The aim was to analyze energy and combustion properties, as well as physical and chemical properties of pellets made from sunflower husk. Sunflower husk had satisfactory characteristic as a biomass fuel, although its pelleting required a lot of energy, and the pellets had poor abrasion characteristics (around 7-14%). The heating value was around 19.00 MJ/kg, and the volatile matter just above 70%. These values are mostly in accordance with European fuel pellets standards, with some aberrations for some of the properties. Since these standards are manly for wood, and wood-residue pellets, lower criteria could be applied for agricultural biomass pellets. Basic chemical and ultimate analyses of sunflower husk were in accordance with literature data for biomass samples, and low level of sulphur were detected (< 1.00%).
Key words: *sunflower husk, pelleting, fuel pellets, biomass*

INTRODUCTION

In food and agricultural production a substantial amounts of residues are generated, which are not exploited enough and are often treated as waste (Demirbas et al., 2009). They present valuable biomass and could be used as a renewable energy source, which presents an ecologically friendly way of utilization. These residues often have an unfavourable shape, therefore are often densified in pellets, which are easier to manage and transport. Most common way of generating energy from biomass is direct combustion, where pelleted material also presents benefits as pellets have more complete combustion and are easier to feed into the combustion chamber, in comparison to bulk material. The European biofuel pellet market is increasing over the last couple of years (Di Giacomo and Taglieri, 2009; Samuelsson et all., 2009), as pellets are becoming more popular for heating.
In order to produce quality pellets the material needs to be properly prepared in terms of granulation and moisture content (Kaliyan and Morey, 2009), therefore sometimes it is necessary to mill and condition the material. Conditioning is a process where material is exposed to water steam on elevated temperature and pressure, and thus becomes more suitable for densifiction. Too much water or too high temperatures can have a negative effect on production capacity and specific

energy consumption in the pelleting process, as well as on pellet quality (Thomas et al., 1997; Sredanović and Lević, 2000). Therefore it is necessary to determine the optimal pelleting parameters for every material.
Sunflower cultivation is taking up around 160 000 ha in Serbia, while around 90% of that production is in Vojvodina (Knežević and Popović, 2011). After the production of sunflower oil, a large quantity of husk remains, which could be used as biofuel. In order to do so the material should be analysed, and prepared (pelleted).
In this study four ways of material conditioning were investigated, and obtained pellets were analyzed for basic quality parameters. The sunflower husk was also analyzed to determine combustion properties and suitability of this material for biofuel.

MATERIAL AND METHODS

Material and processing

The sunflower husk was obtained from oil factory Victoria Oil, Šid, Serbia, in 2010, and all technological operation processing was performed at pilot-plant facility of Institute of food technology in Novi Sad, Serbia.
In order to achieve better granulation and more efficient pelleting process, material was milled using hammer mill (ABC inženjering, Serbia) equipped with sieve with 4 mm openings. To determine particle size distribution of milled material standard sieving was performed using sieves with following diameter of openings: 2500, 2000, 1250, 1000, 800, 630, 250, 125 and 63 μm.
Material was divided in four batches of 25 kg each and conditioned using a double-shaft pedal mixer/steam conditioner (Muyang SLHSJ0.2A, China). Two of the batches were conditioned by combined application of steam and water, with steam pressure of 2 bars, which was added to the material until it reached temperature of 80℃. Next two batches were conditioned only by add ition of water.
Pelleting was conducted on a flat die pellet press 14-175, AMANDUS KAHL GmbH & Co. KG (Germany), with die openings diameter of 6 mm and die thickness 30 mm. After pelleting, pellets were cooled and stored for 24 hours under room conditions, to reach equilibrium moisture.

Physical analysis

Abrasion of pellets was determined by “Pfost” abrasion test unit, Bühler, Switzerland (Pfost and Allen, 1962; Pfost, 1963). The test unit is a tumbling can device, where abrasion is induced by pellets shearing over each other and over the wall of drums, producing fines. The dimensions of the drum are specified, and a sample of 500 g of sieved pellets is inserted inside it. The device tumbles the pellets for 10 min at 50 rpm (rounds per minute), after what pellets are sieved through a sieve with a grid size of 0.8 x pellet diameter. The amount of fines passing through the sieve was determined and expressed in percentage.
Bulk density of grounded and pelletized material was measured with a bulk density tester, Tonindustrie, West und Goslar, Germany.

Chemical analysis

Starting material was analyzed for moisture content (NREL/TP-510-42621), crude ash (NREL/TP-510-42622), crude fat (AOAC 920.39), crude fibre (AOAC 962.10). In pellets, beside moisture and ash, were also analyzed volatile mater (CEN/TS 15148:2005), fixed carbon (calculated by difference between 100 and the sum of volatile matter, ash and moisture), content of C, H, N (CEN/TS 15104:2005) and S (CEN/TS 15289:2006) and higher heating value (HHV) (CEN/TS 14918:2005).

Statistical analysis

Statistical Analysis System (Statistical, Tulsa, Oklahoma, USA) was used for analyzing variations (analysis of variance – ANOVA) and least significant differences (LSD). The level of significance was set at $p<0.05$.

RESULTS AND DISCUSSION

Starting material

The analysis of the starting material is presented in table 1. The majority of chemical composition belongs to crude fibre, while the contents of protein and fat are around 4%. This content of fat was proved to be helpful in the process of pelleting.

Table 1. Chemical composition of milled sunflower husk

Component	Concentration (% (w/w))
Moisture	8.63
Crude ash	3.24
Crude protein	4.15
Crude fat	4.25
Crude fibre	52.53

After milling, geometric mean particle size of the material was 888.2 μm and geometric standard deviation was 1.84. Milling of the material is beneficial as decreasing particle size enables better absorption of water steam during conditioning. Smaller particle size also improves pellet quality by reducing air spaces between particles and weak spots in the pellets (Kaliyan and Morey, 2009).

In the process of conditioning, water can be added to the material in a form of liquid or steam. As steam conditioning requires more energy consumption, sometimes it can be replaced with liquid water conditioning. Energy is saved as water is added at room temperature, and it doesn't require heating and achieving elevated pressure. In this experiment both methods of water addition were investigated.

Batches conditioned by combined application of steam and water had final moisture content of 26.70% (s-1), and 23.25% (s-2) respectively. The moisture in s-2 batch was lowered in order to obtain pellets with satisfying quality and less energy consumption for drying of product. In the third (w-1) and fourth batch (w-2) that were conditioned only by water addition, water was added in order to reach similar moisture content to first and second batch, and achieved moisture contents were 26.05% (w-1) and 22.76% respectively (w-1).

Abrasion of pellets is shown in figure 1, where it is noticeable that each material had different abrasion. In general steam conditioning raises moisture content of the material, but at the same time it exposes it to elevated temperatures, which facilitates particle binding (Thomas et al., 1997). On the other hand water conditioned pellets in this case had the lowest abrasion, when a lower amount of water was applied (w-2). The highest abrasion was determined for water conditioned pellets with higher moisture content applied (w-1). Samuelson et al (2009) concluded that water has significant influence on particle binding in pellets, which results with influence on abrasion. They investigated wood pellets and found that higher moisture content (around 11,5%) resulted in lower abrasion (1-2%). But increasing moisture content can have a positive effect only to a certain point, while excessive moisture can cause the opposite effect (Fasina 2008; Kaliyan and Morey, 2009). Therefore it is necessary to discover the optimal moisture content for each raw material, depending on its

chemical composition and physical properties. When fuel pellets are considered, higher abrasion can cause malfunctioning of transporting and feeding systems, and causes larger dust emissions (Van Loo and Koppejan, 2008). All of the samples had significantly higher abrasion than proscribed by EU standards (< 2.3% in ÖNORM M 7135, and DIN 51731)

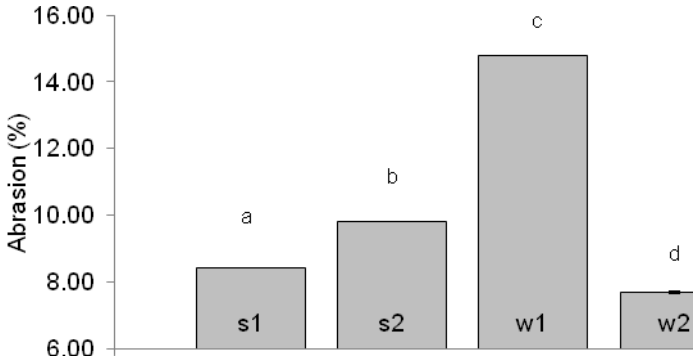

Figure 1. Abrasion of pellets

[abcd]Means with different letters in the same row are significantly different at the 5 % level

Bulk density was the highest for w-2 samples (figure 2), which were conditioned with water, and had final moisture of material 22.76%. The lowest density was measured for w-1 samples. In general all of the samples had poor bulk densities, comparing to other biomass samples (Samuelson et al, 2009; Mirnada et al, 2011; Zamorano et al, 2011), which have bulk densities above 500 kg/m^3.

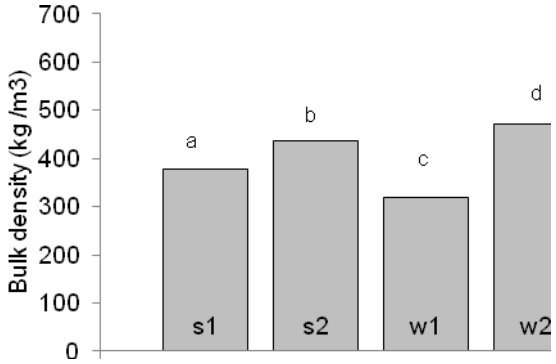

Figure 2. Bulk density of pellets

[abcd]Means with different letters in the same row are significantly different at the 5 % level

Chemical analyses of pellets are shown in table 2. Moisture content of the pellets was below 10%, as proscribed by ÖNORM M 7135 and DIN 51731, while ash content was around 3%, which is higher than proscribed, but in accordance with values typical for agricultural and food residues. Volatile mater and fixed carbon values are also in accordance with literature data (Zabaniotou et al, 2008; Khan et al, 2009; Raclavska et al, 2011). Ultimate analyses were characteristical for biomass, with emphases on sulphur and nitrogen levels which were low, and that is important for off gas emissions, when pellets are combusted. Heating values were around 19 MJ/kg, and proscribed values for fuel pellets are >18 MJ/kg (ÖNORM M 7135, DIN 51731).

*determined after 24 hours

CONCLUSIONS

Sunflower husk pellets had satisfactory characteristics, and high heating value, although their physical properties were somewhat poor. The results showed that steam conditioning can be replaced with water conditioning, which brings energy savings to the whole process. The pellets for which the material was conditioned with lower moisture content, proved to have the best physical characteristics.

ABSTRACT: Maltodextrin was subjected to spray drying to determine the effect of spray drying conditions on moisture content, water activity, particle properties (particle size distribution and particle density) and bulk properties (bulk and tapped densities, porosity, flowability) of the powder product. Experiments have been performed in a pilot scale spray-dryer (Mobile Minor Niro-Atomizer, Denmark) using a full-factorial design to provide data and correlations that predict the powder properties as a function of the main operational variables of the spray-dryer. The inlet (170-190℃) and outlet air temperatures (60-90℃) and the atomization pressure (196-392 kPa) were investigated as spray drying process variables. The effect of spray drying conditions on physical properties of powders was expressed with perturbation graphs. Perturbation graphs revealed that outlet air temperature and atomization pressure had more effect than inlet air temperature, on the physical properties of maltodextrin powder. The results showed that the Sauter mean diameter ($D_{3,2}$) was between 6.728 and 12.87 µm for maltodextrin powders . The bulk densities of samples were changed in the range of 476 and 568 kg/m^3. Maltodextrin powders had bad flowability due to their small particle size.

Key words: *Maltodextrin, spray drying, particle and bulk properties, particle size distribution*

INTRODUCTION

Spray drying is a well-established and widely used method for transforming a wide range of liquid food products into powder form. The process involves spraying finely atomized solutions into a chamber where hot and dry air rapidly evaporates the solution leaving the spray-dried particles. Spray-dried powders can be stored at ambient temperature for prolonged periods without compromising the powder stability. They are also cheaper to transport and easier to handle in manufacturing plants (Koç et al. 2010; Jayasundera et al., 2011; Koç et al. 2011).

However, caking or stickiness as one of the major degradation problems hindered the development of powders (Adhikari et al., 2007). The problem is mainly due to the existence of low molecular weight sugars with low glass transition temperatures. To produce food powders, using maltodextrins as a drying carrier is a popular method nowadays (Bhandari et al., 1997; Ersus and Yurdagel, 2007; Wang and Zhou, 2012). Maltodextrin can significantly increase the glass transition temperature and reduce the hygroscopicity of dried products (Goula and Adamopoulos, 2010).

Maltodextrin, a common encapsulating material used in the food industry, is made by the hydrolysis of starch, and comes in the form of a white powder and has a sweet taste. However, there have been very limited researches on the physical properties of maltodextrin, which can affect the resultant powder quality.

Physical properties of food powders including the particle shape, density and porosity, surface characteristics, diameter, and size (Kurozawa et al., 2009) can be affected by the spray drying temperatures and the type of atomizer, that are important in the storage, handling and final application of powder product (e.g. particle and bulk properties). One of the most important physical properties of

powders with regards to handling is particle size. Particle size can influence flow out of storage bins, the blending of different components, compaction, and the segregation of a mixture, in which smaller particles stay distributed on the bottom and larger particles on top. In addition, these properties significantly influence the essential properties of food products such as smell, texture, and appearance. The knowledge of food density is of fundamental use for material properties studies and for industrial processes in adjusting storage, processing, packaging, and distribution conditions. Bulk density includes the volumes of the solid and liquid materials and all pores and is generally used to characterize a final product obtained by drying (Kurozawa et al. 2009; Koç et al., 2012).
In this study, it was aimed to determine the influence of spray drying process, in terms of inlet and outlet air temperatures and the atomization pressure, on moisture content, water activity, particle properties (particle size distribution and particle density) and bulk properties (bulk and tapped densities, porosity, flowability) of maltodextrin.

MATERIAL AND METHODS

Maltodextrin (DE=18), used as the test material was supplied from Çağdaş Kimya, Turkey. Maltodextrin was dissolved in the distilled water and the solution containing 40% maltodextrin was used in the experiments.

Spray Drying

Experiments were conducted in a pilot scale spray dryer (Mobile Minor Niro-Atomizer, Denmark). Maltodextrin solution was atomized from nozzle into vertical, co-current drying chamber, 0.87m diameter and 1.2m height, under various operating conditions. Feed temperature of below 10℃ and hot air flow rate of 1.54 m^3/min were fixed for all experiments. Air inlet temperature (170-190℃), air outlet temperature (60-90℃) and atomization pressure (196-392 kPa) we re adjusted according to the full-factorial experimental design (Table 1). Air outlet temperature was controlled by regulating the feeding velocity. The dried powder was collected in a single cyclone separator and then packaged in ALPE packaging material until used for analysis.

Moisture content

Moisture content of maltodextrin powders was measured with a halogen moisture analyzer (Ohaus MB45, Switzerland) at 105℃.

Water activity (a_w)

The water activity (a_w) values of powders were measured with a water activity measurement device (Testo AG 400, Germany), with a ±0.001 sensitivity.

Particle Properties

Particle size distribution: The particle size distribution of the maltodextrin powders were measured using a laser light diffraction particle size analyser (MasterSizer model S 2000, Malvern Instruments Ltd., Worcestershire, U.K.) in which a small quantity of the powder was dispersed in water and the particle distribution was monitored during five successive trials. The particle size was expressed as mean volumetric size $D_{3,2}$ (Sauter mean diameter), and was calculated as follows:

$$D_{3,2} = \frac{\sum_{1}^{i} D_i^3 f_i}{\sum_{1}^{i} D_i^2 f_i} \quad (1)$$

where f_i is the frequency of particles of diameter D_i.

Particle density: Particle density (ρ_p) of the powder samples was analysed according to a study by Barbosa-Cánovas et al. (2005). The liquid (petroleum ether) pycnometry can be used to determine particle density depending on the volume of pycnometer bottle used.

Bulk Properties

Bulk and tapped densities: The bulk density (ρ_b) of the powders was determined by measuring the weight of the powder and the corresponding volume. Approximately 20 g of powder sample was placed in a 100 ml graduated cylinder. The bulk density was calculated by dividing the mass of the powder by the volume occupied in the cylinder. For the tapped density (ρ_t), the cylinder was tapped vigorously by hand until no further change in volume occurred (Jinapong et al., 2008).

Porosity: Porosity (ε) of the powder samples was calculated using the relationship between the tapped (ρ_t) and particle (ρ_p) densities of the powders as shown below (Jinapong et al., 2008):

$$\varepsilon = \frac{(\rho_p - \rho_t)}{\rho_t} \times 100 \quad (2)$$

Flowability: Flowability of the powders was evaluated in terms of Carr index (CI) (Carr, 1965) CI was calculated from the bulk (ρ_b) and tapped (ρ_t) densities of the powder as shown below:

$$CI = \frac{(\rho_t - \rho_b)}{\rho_t} \times 100 \quad (3)$$

Statistical Analysis

All samples were analyzed in triplicate. The analysis of variance (ANOVA) at a confidence level of 95% was performed. All the results that were obtained were analyzed using Design Expert–version 7.0 software (Statease Inc., MI, USA).

RESULTS AND DISCUSSION

Results of 11 different experiments (different runs of spray drying) performed according to full-factorial design were also given in Table 1.

Maximum moisture content (5.33%, wb) and water activity (0.216) values were recorded at the same spray drying conditions; outlet air temperature of 70℃, inlet air temperature of 190℃ and atomization pressure 392 k Pa. Moisture content and water activity of the maltodextrin powder increased with a decrease in the outlet air temperature since the feed flow rate to atomizer and also spray dryer is high to achieve lower outlet air temperatures, in which case the moisture removal rate gets lower. According to perturbation graphs (Figure 1a and 1b) moisture content and water activity were affected significantly by the outlet air temperature.

Table 1. Full Factorial Design with experimental values of response variables

T_{in} (℃)	T_{out} (℃)	P (kPa)	Moisture Content % (wet basis)	a_w	$D_{3,2}$ (μm)	ρ_b (kg/m^3)	ρ_t (kg/m^3)	ρ_p (kg/m^3)	ε (%)	CI (%)

190	90	196	3,330	0,115	11,02	490	788	1189	50,85	37,76
170	90	392	3,500	0,127	8,913	476	673	1173	74,31	29,24
190	90	392	2,880	0,107	9,502	504	695	1133	63,00	27,52

The particle size distribution of spray dried maltodextrin powders was shown in Figure 2. All powder particles had a narrower particle size range with relatively uniform distribution. The mean particle size of a material may greatly influence its reactivity and the quality of the end product (Baranauskiene et al., 2006). The results showed that spray drying does not produce larger particles. The Sauter mean diameter ($D_{3,2}$) of powders ranged from 6.728 to 12.87 µm. Perturbation plots (Figure 1c) showed that the Sauter mean diameter ($D_{3,2}$) of the maltodextrin powder significantly affected all the independent variables (outlet and inlet air temperatures and atomization pressure). Perturbation graphs revealed that outlet air temperature and atomization pressure had more effect than inlet air temperature, on the Sauter mean diameter ($D_{3,2}$).

The bulk properties (bulk and tapped densities, porosity, flowability) of a food powder are highly dependent on particle size and its distribution (Barbosa-Cánovas et al. 2005). Lower bulk densities of a product are not desirable, resulting in a greater volume of package. Moreover, lower the bulk density, more occluded air within the powders would be and a greater possibility for product oxidation resulting in reduced storage stability (Goula and Adamopoulos 2008; Kurozawa et al. 2009). The bulk densities of samples were changed in the range of 476 and 568 kg/m^3 (Table 1). Bulk density was affected by all the independent variables (Figure 1d) whereas tapped density and particle density was affected by only inlet air temperature and outlet air temperature, respectively (Figure 1e and 1f).

Minimum flowobility value (15.39%) and maximum porosity value (%82.63) were recorded at the same spray drying conditions; outlet air temperature of 70 ℃, inlet air temperature of 170℃ and atomization pressure 196 k Pa. Spherical particles pack the best and thus, have the highest bulk densities and porosity (Reineccius 2004). Maltodextrin powders have moderate-poor flowability due to their small particle size. Porosity was influenced by the outlet air temperature and atomization pressure. However, flowability was influenced by only inlet air temperature (Figure 1g and 1h).

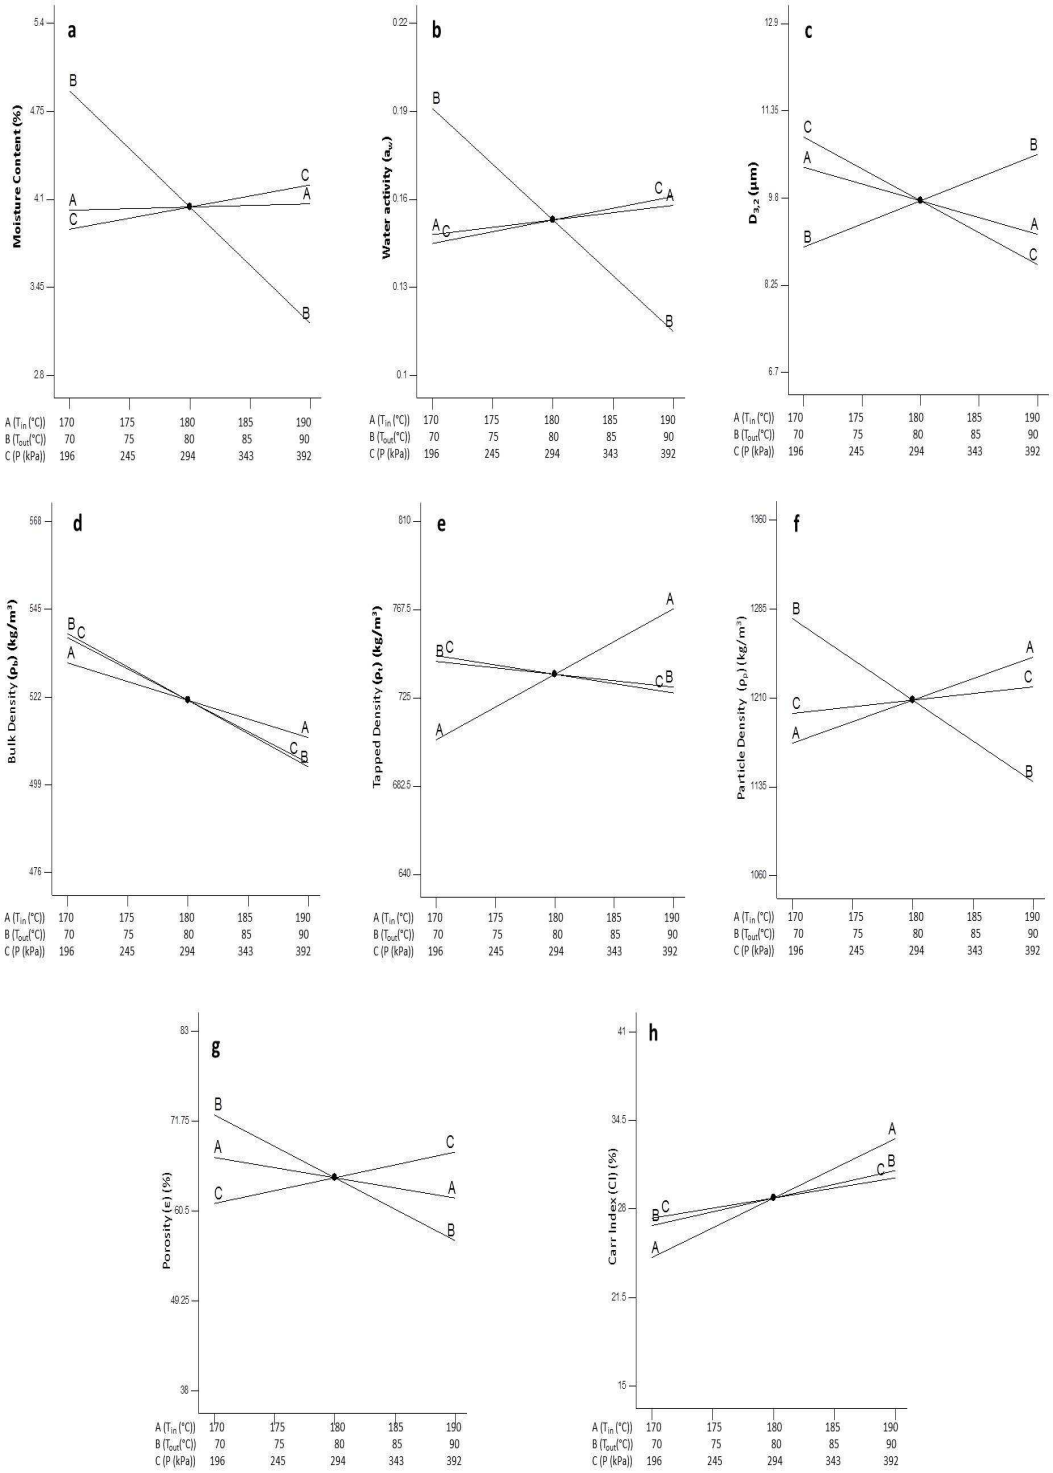

Figure 2. Perturbation plots. (A) Inlet air temperature, (B) Outlet air temperature, (C) Atomization pressure

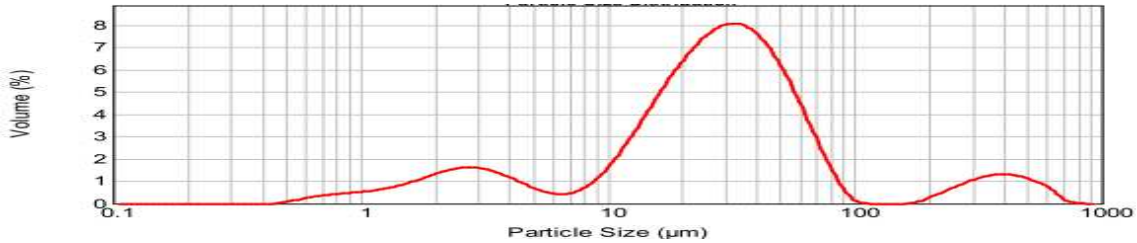

Figure 3. The particle size distribution of spray dried maltodextrin (inlet air temperature of 170℃, outlet air temperature of 70℃ and atomizati on pressure of 392 kPa)

CONCLUSIONS

In this study, physical properties of maltodextrin powders were investigated. The results showed that spray drying does not produce larger particles. Perturbation graphs revealed that outlet air temperature and atomization pressure had more effect than inlet air temperature, on the physical properties of maltodextrin powder. Maltodextrin powders had bad flowability due to their small particle size.

USING THE IMPACT DETACHERS AT THE HEAD OF THE REDUCTION SYSTEM IN THE WHEAT FLOUR MILLING PROCESS

ABSTRACT: In flour mills impact detachers are most commonly applied to support the grinding of clean middlings (clean endosperm with minimal bran contamination) at the head of the reduction system supplementing the roller mill before sifting. However, using the impact mills, the conditions for controlled milling are less favorable and could result in deterioration of the flour quality. The purpose of this work was to examine the effect that impact detachers have on the milling results on the front passages of the reduction system. The streams entering and leaving the impact detachers applied on the different reduction passages (1M, 2M and 3M) in the industrial mill were intercepted and employed in the experiments. The changes in the particle size distribution and ash content of the material were followed. Results show that impact detachers significantly increase the degree of particle size reduction of the feed. Under dominant impact forces both endosperm and bran particles are fractured limiting their use to the passages with the low ash content of the stock (<0,6%). Otherwise, the fractured bran particles would pass into the flour causing the deterioration of the flour quality.
Key words: *flour milling, reduction system, impact detacher, milling results*

INTRODUCTION

Wheat flour milling uses repeated breakage of the stocks and separation (by sifting) to achieve effective removal of bran and germ from endosperm, and appropriate size reduction of the endosperm to produce flour relatively free from bran contamination (Campbell and Webb, 2001; Sudgen and Osborne, 2001). During any comminution operation, both material properties and the design and operation of the milling equipment affect particle breakage [Scanlon and Lamb, 1995; Campbell et al., 2001). In flour milling, the predominant comminution tool is the roller mill (Haque, 1991) in which the feed material is passed between two counter-rotating rolls of usually 250 mm diameter and with either a corrugated or smooth finish. The rolls are separated by a small gap and rotate at different speeds. In a roller mill, particles are subjected to shear and compressive forces. Particle size reduction is achieved by passing cleaned and conditioned wheat through a series of break (fluted) and reduction (smooth) rolls (Posner and Hibbs, 2005).

The main goal of the flour milling industry is to produce a selection of flour of defined quality followed by low investment and energy costs (Fistes et. Al, 2008). For this reason flour mills are forced to rationalize their production facilities by reducing the equipment, operating and maintenance costs (Baltensperger, 1993; 2001). The trend in recent years has been to shorter mill flows, necessitating harsher grinding on both break passages and reduction passages which could have significant consequences to milling results (Dexter, 1996). Also, the grinding has been supported with impact milling of separate or together with roll passes making the shorter roll surface a reality (Wanzenried, 1991).

The main characteristic of the impact type of mills is the use of impact as the principal size-reducing force (Haque, 1991). The material is reduced by the loss of kinetic energy when the particle is struck by a high-velocity impeller or accelerated

and thrown against a wall to stress the particle beyond its elastic limits (Posner and Hibbs, 2005). Different types of impact machines are used in flour mills and, depending on their use, they are designated as impact detachers, sterilizers and entoleters. They are used: on wheat to break infested kernels and destroy insects and insect eggs, to support the grinding by supplementing the roller mills, or even to completely replace the rolls in both break and reduction systems in order to increase capacity and flour extraction. Most commonly, impact detachers are applied to support the grinding of clean middlings (clean endosperm with minimal bran contamination) at the head of the reduction system. These machines usually follow the rolls ahead of the plan sifter (Posner and Hibbs, 2005). The use of this machines increases flour yields and improves the sifting efficiency. It also prevents stock from over-tailing these sieves and loosing good quality stock to by-products.
However, under predominant impact forces both endosperm and bran particles are fractured making the conditions for controlled milling less favorable and could result in deterioration of the flour quality. The purpose of this work was to examine the effect that impact detachers have on the milling results on the front passages of the reduction system. The changes in the particle size distribution and ash content of the material were followed.

MATERIAL AND METHODS

The streams entering and leaving the impact detachers applied on the different reduction passages (1M, 2M and 3M) in the industrial mill were intercepted and employed in the experiments. Before sampling, the mill was checked for any kind of disturbances in the process and sampling was carried out with balanced load to machines. Since the impact detachers are used diagrammatically between the roller mill and the plan sifter the samples of the stock leaving the impact mills were taken after the air locks of the pneumatic conveying system before entering the appropriate section of the sifter. The mass of the each sample was around 2 kg.
Three set of batches of 100 g of the each sample (stocks entering and leaving the impact detachers applied on the mentioned passages) were sieved for 3 min on a Bühler laboratory sifter (gyratory in a horizontal plane), model MLU-300 (Uzwil, Switzerland). The sieve openings were 500, 350, 250 and 150 μm, and a bottom collecting pan was fitted.
Moisture and ash contents of the samples were determined according to ICC standard methods no. 110/1 and 104/1, respectively.
The significance of the differences in flour yield and flour ash content between the stocks that enter and leave the impact mills have been tested by the paired Student's *t*-test.

RESULTS AND DISCUSSION

Results show that impact detachers significantly increase the degree of particle size reduction of the feed (Table 1).

Table 1. Particle size distribution of the stocks entering (E) and leaving (L) the impact detachers

passage	stock	size fraction yield (%)				
		>500 μm	**500/350 μm**	**350/250 μm**	**250/150 μm**	**<150 μm**
1M	E	0,2	0,5	21,0	38,8	39,5
	L	0,1	0,3	9,5	25,9	64,2
2M	E	1,2	9,2	41,6	28,9	19,1
	L	0,5	3,6	28,2	28,7	39,0
3M	E	0,4	3,2	14,8	12,1	69,5
	L	0,4	1,1	11,2	8,1	79,2

The quantity of flour (<150 □m) increased while the quantity of the coarse (>500 and 350-500 □m) and especially medium sized stocks (150-350 □m) decreased, especially on the 1M and 2M. The difference in flour yield is statistically significant ($p<0.001$). The results confirm the role of the impact detacher in wheat flour milling process as a support to the roller mills for additional grinding of the stock before sifting.

Using the impact detachers the ash content of both the flour (<150 □m) and the rest of the stock (>250 □m) increases (Table 2). As it was mentioned earlier in paper, the nature of deformation during comminution operation depends not only on the applied stresses but as well on the particle components upon which the stresses act. The middlings are composed primarily of endosperm, but they also contain adhering bran and germ. Ash is concentrated in the bran and the ash content increases from the inner to the outer part of the wheat kernel (Pomeranz, 1988). Considering the present grinding conditions, under dominant impact forces both endosperm (brittle material) and bran particles (tough and fibrous) are fractured and the flour ash content increases. This increase in flour ash content follow the increase of the ash content of the feed material sent to the impact detachers, being 0,53, 0,76 and 1,03 $(\%)_{dm}$ for 1M, 2M and 3M respectively. On 1M and 2M, the difference in ash content of the flour before and after the impact detachers at the 0,05 level is not statistically significant but at the 0,01 level is statistically significant. On 3M this difference is statistically significant on both 0,05 and 0,01 level.

From the technological point of view, the increase of the flour ash content on 2M is already high while on 3M is not acceptable. Practically the use of impact detachers is limited to the passages with the low ash content of the stock (<0,6%) that is clean middlings with minimal bran contamination. Otherwise, the fractured bran particles would pass into the flour causing the deterioration of the flour quality.

Table 2. Moisture and ash content in the size fraction of the stocks entering (E) and leaving (L) the impact detachers

passage	stock	moisture content (%)		ash content $(\%)_{dm}$	
		>250 □m	<150 □m	>250 □m	<150 □m
1M	E	11,9	13,3	1,18	0,37
	L	11,3	13,2	1,44	0,42
2M	E	12,6	13,2	1,16	0,40
	L	11,8	13,0	1,55	0,48
3M	E	10,3	12,4	3,48	0,48
	L	10,0	12,0	3,92	0,61

The results also show a relatively small decrease in moisture content in the size fractions of the stock following the use of impact detachers (Table 2). However, it is expected considering that sampling was carried out after the air locks of the pneumatic conveying system and that the stock was in contact with the air from the pneumatic conveying system. In addition to that, impact detachers significantly increase the degree of particle size reduction of the stock and therefore its specific surface area practically increasing the drying effect of the pneumatic air.

CONCLUSIONS

Impact detachers significantly increase the degree of particle size reduction of the feed. Under intensive impact forces, as a predominant stress causing the comminution, both endosperm and bran particles are fractured. The fractured bran particles could pass into the flour and cause the deterioration of the flour quality (as determined by ash content). Considering that the aim of the wheat flour milling process, along with the size reduction, is to obtain the best possible dissociation of the starchy endosperm from the other parts of the grain, the application of impact

detachers as a grinding support to roller mills needs to be limited to the passages with the low ash content of the stock (<0,6%).

ABSTRACT: The aim of the work was to describe the impact of inert dusts as agents officially approved for use in the storage of crops from certified organic production system on the technological quality of wheat flour. In order to control storage insect pest *Sitophilus oryzae* (L.*)* in wheat, various inert dusts were used: natural zeolite, two products of diatomaceous earths originating from Serbia and a commercial **product** Protect-It®. Wheat samples, infested and non-infested, treated with the inert dusts were milled and the obtained flour samples were analyzed on rheological behaviour using Mixolab®. The nine parameters obtained were analyzed using the method of Principal Component Analysis (PCA). It was found that the two principal compounds accounted for 75.6% of total variance in the data. This research showed that dough stability (0.96) and water absorption (0.90) contributed most to the first principal component, starch gelatinization (0.83) and stability of the hot-formatted gel to the second one. Flour obtained from wheat treated with inert dusts showed higher water absorption and stability during mixing, and less protein weakening during heating in comparison to the control wheat non-treated with inert dusts. The component scores indicated the similarities among the treatments with inert dust. The outlier sample was the control with insect infestation and without inert dust protection.
Key words: *insect infested and non-infested wheat, inert dusts, Mixolab®, PCA*

INTRODUCTION

Natural zeolite (NZ) and diatomaceous earth (DE), commonly designated as inert dusts, are in some cases alternatives for conventional insecticides and fumigants. Codex Alimentarius Commission (1999) recommends control of insect pests in food commodities and lists zeolite and diatomaceous earth as permitted substances in organic food production and in plant pest control.

DE is a naturally occurring siliceous mineral compound from marine sediments which consists of microscopic skeletal remains of single-celled algae (phytoplankton) called diatoms. It is composed of amorphous silicon dioxide that is non-toxic to mammals (Korunić et al., 1998).

There are several research works dealing with the effectiveness of DE (Korunić et al., 1998; Fields and Korunić, 2000; Vardeman et al., 2007) and NZ (Kljajić et al., 2010) against stored-grain insects. Furthermore, few authors addressed the effects inert dusts treatments exert on the technological quality of grain and flour (Desmarchelier and Dines, 1987; Korunić et al. 1996).

The Mixolab® instrument measures the behaviour of wheat protein and starch when shear stress and temperature constraint are applied and seems to be a useful tool to evaluate quality of flour samples (Kahraman et al., 2008).

Principal components analysis (PCA) is a powerful tool for pattern recognition, classification, modelling, and other aspects of data evaluation (Csomos et al, 2002). Also, PCA is a projection method, and dimension reduction of the data can be achieved using a smaller number of principal components than original variables.

The aim of this research is to apply the PCA on a practical example related to treatment of various wheat lots characterized with insect infestation status with inert dust preparations and reveal which treatment showed produced statistically significant impact on the variability of technological Mixolab® parameters of wheat quality.

MATERIAL AND METHODS

In the experiment, wheat variety Danica (*Triticum aestivum* ssp. *vulgare*) were procured from a local producer.

Inert dusts

In the experiment, several types of inert dusts were used: 1) inert dust based on natural zeolite NZ; and 2) two dusts based on diatomaceous earth: DE-S1 and DE-S2, (all originating from Serbia and crudely refined and processed at the Institute for Technology of Nuclear and Other Mineral Raw Materials, Belgrade, Serbia); and 3) a registered product Protect-It® (Hedley Technologies Inc., Canada).

Inert dusts were applied on 0.5 kg wheat samples in five replications, in doses determined in preliminary trials: a) NZ- 1.0 g kg^{-1}; b) DE-S1 and DE-S2- 0.75 g kg^{-1}; and c) standard DE product registered worldwide (Protect-It®) 0.2 g kg^{-1}.

After 21 days of infestation by *S.oryzae* adults, the samples were sieved to separate insects. After total seven weeks of incubation, sieving was repeated to remove the progeny. The samples were than placed into plastic bags and put into refrigerator for 24 h. Next day, sieving was again repeated to remove the rest of possibly remained insects. Sieving was conducted using sieves 7/64'' for insect removal only whereas dust was returned to initial grain mass by mixing for one minute. The sieved samples were stored in plastic bags at room temperature until further examination.

Dough rheological investigation were determined by Mixolab® (Chopin,Tripette et Renaud, Paris, France) which gives dough characteristics during the process of mixing at constant temperature, as well as during the process of heating and cooling. All the measurements were performed using the Mixolab® „Chopin +“ protocol .

The algorithm of PCA can be found in standard chemometric material (Oto, 1999). Descriptive analysis of the data and the PCA were performed using the software package STATISTICA 10.0. In summary, PCA decomposes the original matrix into several products of multiplication into loading (parameters of quality) and score (different treatment with inert dusts) matrices.

Table 1. Experimental design and Mixolab® parameters

	Samples		Wat. abs. (%)	C2 (Nm)	Stab. (min)	α (Nm/ min)	C3 (Nm)	β (Nm/ min)	γ (Nm/ min)	C4 (Nm)	C5 (Nm)
Without insect infestation	1	Control	56,7	0.47	9,83	-0,056	1,79	0,424	-0,07	1,27	1,73
	2	DS S1	57,7	0.48	10,28	-0,082	1,82	0,388	-0,06	1,33	1,86
	3	DS S2	56,6	0.49	10,07	0,028	1,83	0,422	-0,068	1,32	1,83
	4	Prot®	56,5	0.49	10,55	-0,086	1,85	0,378	-0,08	1,38	1,91
	5	NZ	58,2	0.48	10,22	-0,088	1,79	0,398	-0,084	1,27	1,76
With insect infestation	6	I Control	61,2	0.26	4,37	-0,066	1,76	0,528	-0,046	1,44	2,06
	7	I DS S1	60.0	0.50	9,83	0	1,85	0,384	-0,064	1,45	2,03
	8	I DS S2	60,5	0.49	9,88	-0,06	1,83	0,428	-0,046	1,36	1,94
	9	I Prot®	62,4	0.47	7,95	-0,072	1,74	0,436	-0,06	1,25	1,76
	10	I NZ	61,3	0.50	8,33	-0,066	1,83	0,402	-0,058	1,41	1,97

Mixolab® parameters are taken as variables (column of the input matrix) and different treatments with inert dust as mathematical-statistical cases (rows of the matrix) (Table1).

RESULTS AND DISCUSSION

The ranges of average values for Mixolab® parameters for wheat sample were as follows: water absorption value, 56.5-62.4%; weakening of the protein (C2),0.26-0.50 Nm; dough stability, 4.37-10.55 min.; slope α, -0.088-0.028 Nm/min, starch gelatinization (C3), 1.74– 1.85; slope β, 0.378-0.528 Nm/ min; slope γ, -0.084- -0.046 Nm/ min; the stability of the hot-formed gel (C4), 1.25 - 1.45; the starch retrogradation (C5), 1.73 – 2.06 (Table 1).

The number of factors retained in the model for proper classification of the data from Table 2 was determined by application of Kaiser's and Rice's rule (1974). Therefore, two components having eigenvalues >1 were used for further analysis. PCA yields two PCs explaining 75.6% of the total variance in the data. Loading values (i.e. correlation coefficients) higher than 0.7 were marked throughout Table 2 in boldface type.

Table 2. Results of Principal Component Analysis for Mixolab® parameters in grain wheat sample treated with different inert dust

Parameters	**PC1**	**PC2**
Water absorption	**-0,905**	-0,017
C2	**0,863**	0,172
Stability	**0.961**	0,147
α	0,091	0,470
C3	0,516	**0,832**
β	**-0,885**	-0,275
γ	**-0,772**	0,213
C4	-0,466	**0,844**
C5	-0,592	**0,778**
Explained variance	***4,393***	***2,40***
Proportion of total variance %	***48,81***	***26,75***

Projection of the variables on the factorial plane (Fig.1) indicates that the variables dough stability (0.961); water absorption (-0.90), weakening of the protein (C2) (0.86) and slope β (-0.88) most contributed to the first PC indicator (which accounted for 48.81% of the variability), and thus to the total variability of the basic set. The second PC indicator (which accounted for 26.75 % of the variability) is contributed most by starch gelatinization, C3 (0.83) and stability of the hot-formed gel, C4 (0.84).
Parameters correlated with protein component contributed most to the first PC1, and parameters correlated with starch to the second PC2. Water absorption increase in flour from wheat with insect infestation could be attributed to the rise of relative proportion of protein and crude fibre in the damaged kernels as the consequence of insect feeding with starch. Similar was confirmed in the findings of Sanches-Marines et al. (1997). In the study of Korunić et al. (1996), it was found that water absorption of the sample treated with inert dust was raised but the variation was neither correlated to the dose nor was found significant. Although small amounts of inert dusts remain in the flour after wheat treatment (Desmarchelier and Dines, 1987), significant increases in water absorption were found in this study. This could be supported by the fact that inert dusts are known as substances with high moisture

absorption ability (Dakovic et al., 2007) which could contribute to the increase in flour water absorption.
Flour obtained from wheat treated with inert dusts showed higher water absorption and stability during mixing, and less protein weakening during heating in comparison to the control wheat sample non-treated with inert dusts. Changes in the dough rheological properties for flours treated with inert dusts might be partly due to presence of inert dust in the flour. In the study of Korunić et al. (1996), it was found from farinograph and extensigraph results that flour with added inert dust showed increased dough-mixing strength and extensigraph resistance in comparison with the control sample.

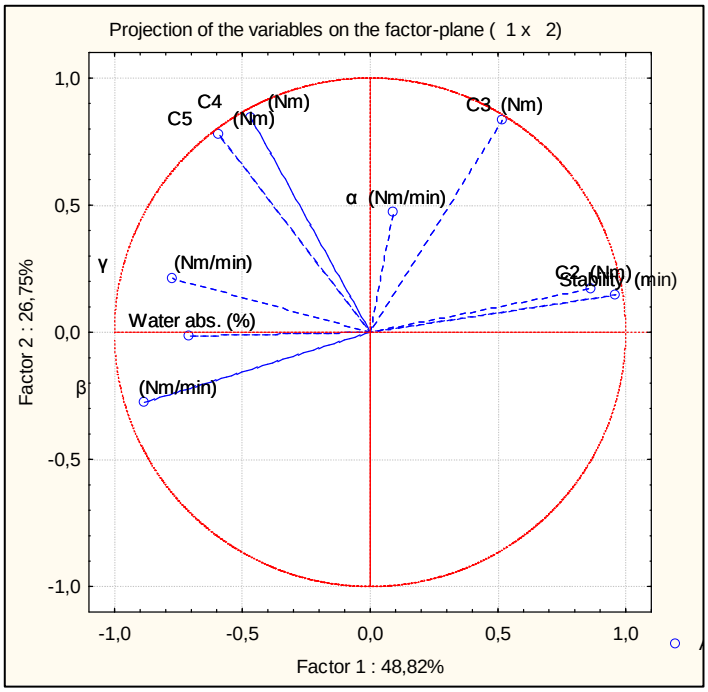

Fig.1. Projection of the variables on the factor-plane

Factor coordinates of individual observations (Fig. 2) indicate that the total variability of the first component is influenced mostly by the non-treated samples with insect infestation (Control) (-5.27). Flour obtained from insect infested wheat treated with inert dusts showed better stability during mixing, and less protein weakening during heating in comparison to the corresponding control wheat (infested, non-treated with inert dusts).The component scores indicated the similarities among the treatments with inert dust. The outlier point is sample Control with insect infestation and without inert dust protection (6).

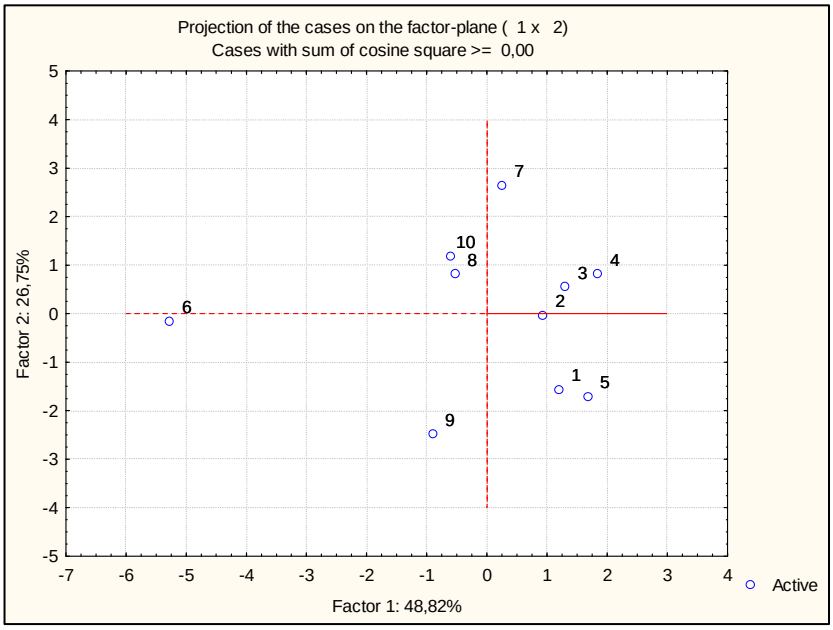

Fig.2. Projection of the cases on the factor-plane

This confirms that the presence of inert dusts may affect the rheological properties of wheat dough although significant changes were not detected by large-deformation tests in the non-infested samples.

CONCLUSION

It could be concluded that PCA is able to point out the outliers among the wheat samples with or without insect infestation and treated with different inert dust. This research showed that parameters correlated with protein component contributed mostly to the first PC1, and parameters correlated with starch to the second PC2. Flour obtained from wheat treated with inert dusts showed higher water absorption and stability during mixing, and less protein weakening during heating in comparison to the control wheat non-treated with inert dusts. The extreme outlier point is control sample with insect infestation and without inert dust protection. Use of inert dusts as protectants in stored wheat grains is reasonable, especially for grains produced in organic farming systems, primarily because the treatments do not compromise food safety.

ABSTRACT: Increasing need among human population for fresh vegetables has generated numerous investigations related to growing alternatives. This research aimed at evaluation of possibility to grow plants on treated wastewater. The growth of *Lactuca sativa* (lettuce) was tested in laboratory conditions, using treated communal and industrial wastewater inflowing from Subotica town into Palic Lake. This water is loaded with organic matter, and as such suitable for plant growth, containing plant nutrients phosphorus, nitrogen, and carbon. The objective was to assess the safety of examined lettuce for human consumption applying controlled conditions, among which most importantly-water aeration. The water used in the experiment contained human pathogens, which were found on the plant samples at the end of the examination period. Total coliform count was analyzed using 3M Petri film test at the beginning of the experiment and at the end of growing period of 30 days.
Results of the experiment indicated that lettuce could be used in ecoremediation technologies for water quality improvement (biomass has increased for 120%), but considering the presence of human pathogens in it, this lettuce would be a risk for human health.
Key words*: lettuce, Palic lake water, nitrogen, phosphorus, pathogenic microorganisms*

INTRODUCTION

Raw food is a main constituent of human diet, nevertheless in modern society nutritionists recommend it as the only constituent. Lettuce (*Lactuca sativa*) is the most widely consumed raw vegetable. It is an annual plant which is being grown worldwide, in different climates and conditions. Lettuce favors high soil humidity and moderately cold weather with temperatures below 24°C for proper growing. Final quality of lettuce is dependant on soil content, quality of irrigation water, ecological factors, and its convenience for human consumption. Natural, non pathogenic, epiphytic microflora is usually present on the lettuce surface after harvesting. But waterborne or soilborn pathogens in growing lettuce can lead to its contamination and consequently be an obstacle in producing safe food.
Nitrogen and phosphorus are necessary nutrients for growth of plants. But, crop production and excessive application of mineral fertilizers has given rise to leaching of these nutrients into the surface waters. High concentrations of nitrogen and phosphorus in surface waters promote the eutrophication and finally lead to perturbation of the ecosystem. There are numerous physical and chemical methods for nutrient removal, but when it comes to the big water systems they are mostly not feasible economically, and have other unfavorable side effects.
Ecoremediation is a biotechnological process that is based on the interaction of plants and microorganisms as an efficient procedure in reducing the consequences of accelerated eutrophication, i.e. degradation of environmental contaminants. Numerous authors emphasize the application of ecoremediation as very convenient

in dealing with organic and inorganic pollution (T. Toyama et. al. 2006, Xian-Ning Li et. al. 2010, L. Stout and K. Nu¨sslein 2010., M. Scholz and Å. Hedmark 2010).
Ecoremediation is economically favorable procedure being 60-80% cheaper than conventional physical and chemical procedures. It has been used to treat wide range of contaminants, especially in shallow waters and waters with low concentration of contaminants. Plant selection is very important, because it directly influences the efficiency of treatment with the high plant resistance, high yields and fast growth (R. P. Singh et. al., 2007.). Choosing the right plant, i.e. varieties with high accumulation potential, is also beneficial regarding the amount of nutrients that can be removed from the wastewater (since nitrogen and phosphorus are essential elements for plant growth) and get transferred into the plant biomass. Besides right plant selection, ecoremediation technologies also use biotechnological approach, i.e. introduction of different bacterial strains. Different researches have shown that certain bacterial strains in plant rhyzosphere promote plant growth and quality. Those are so called Plant Growth Promoting Bacteria (PGPB) and they involve geniuses like: *Acinetobacter, Alcaligenes, Arthrobacter, Azospirillium, Azotobacter, Bacillus, Beijerinckia, Burkholdria, Enterobacter, Erwinia, Flavobacterium, Rhizobium* and *Serrotia* (Bashan and de-Bashan, 2005). PGPB improve plant growth through nutrient supply and maintenance of environmental health. Inoculation of plant roots by PGPB also enhances water remediation.
This research aimed at evaluation of possibility to grow lettuce on treated wastewater, as well as its post usage in human diet. The effect of PGPB on lettuce growth was followed during the examination period of 30 days.

MATERIAL AND METHODS

This research was conducted in laboratory conditions with water sampled from Palic Lake, sector II. The water was analyzed previously to the setting of the experiment, to determine the total inorganic nitrogen, available phosphorus, and the presence of pathogens. Standardized detection methods of spectrophotometer (APHA-Method 4500-NO2-B, Drinking water P-V-2/B) and ionic chromatography (EN ISO 10304 – 1:1995) were used to determine total inorganic nitrogen content. 3M Petri film was used on 37℃ during 48 hours to determine total col iform count. The same method was used at the end of the experiment.
Lettuce seedlings were taken from the local greenhouse that has commercial growing of lettuce. The seedling samples were taken also prior to their planting and tested for total coliforms on 3M Petri film. Plant samples were made separately for lettuce root and above ground part of lettuce by using 20g of each and transferring it into 180ml flasks with peptone solution and homogenized in rotation mixer set at 250rpm for 20 minutes. These samples were tested both at the beginning of the experiment and at the end of examination period.
One of the tested pools with Palic lake water was different comparing to the others and set with lettuce seedlings inoculated with PGPB prior to setting into the water.
Pure cultures of *Azotobacter chroococcum*, *Bacillus circulans*, *Bacillus megaterium, Bacillus pumilus, Bacillus amyloliquefaciens,* and *Bacillus licheniformis* were made in concentration of 10^7 cfu/ml of inoculation medium and used.
Dry matter content was determined by drying the plants on the 80℃ during 3 hours.

RESULTS AND DISCUSSION

The study was intended to provide the assessment of lettuce seedlings' growth. During the experimental period the fresh biomass production was in a range of 45.7% - 182.8%, i.e. 121% on an average (Figure 1.). The experimental pool with PGPB didn't show higher biomass production rate comparing to the experimental

pools without PGPB and was ranging from 36.2%-166.6% of fresh biomass and average value of 122%.

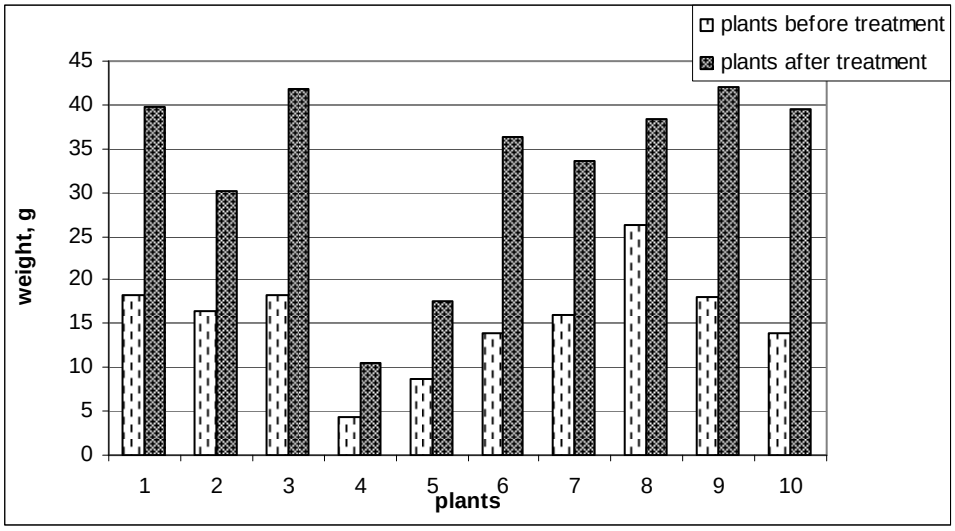

Figure 1. Plant biomass production during experimental period

The results of this research showed that wastewater treatment by lettuce has reduced the nutrient content in the tested water. Total inorganic nitrogen and soluble phosphorus, the essential nutrients for plant growth, were tested at the beginning of the experiment and were ranging from 3 mg/L to 0.11 mg/L, respectively. At the end of the experiment the decrease of nitrogen content was 73.1% and phosphorus content was 34.2% (Figure 2.).

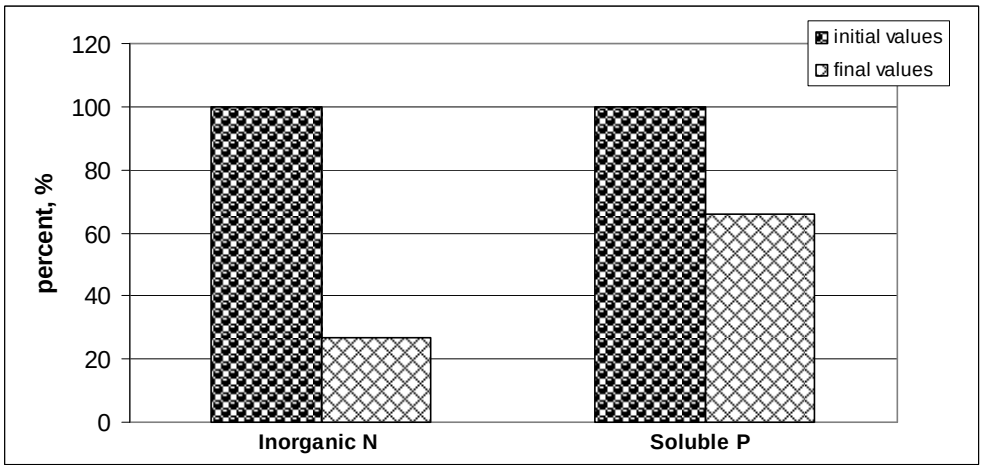

Figure 2. Total inorganic nitrogen content and soluble phosphorus in tested water

In the experimental pool with PGPB enrichment, the content of inorganic nitrogen was reduced by 71.6%, and soluble phosphorus was reduced by 70.7% (Figure 3.). The efficient removal of nitrogen and phosphorus from water was improved by usage of bacterial species that promote immobilization of nitrogen and phosphorus.

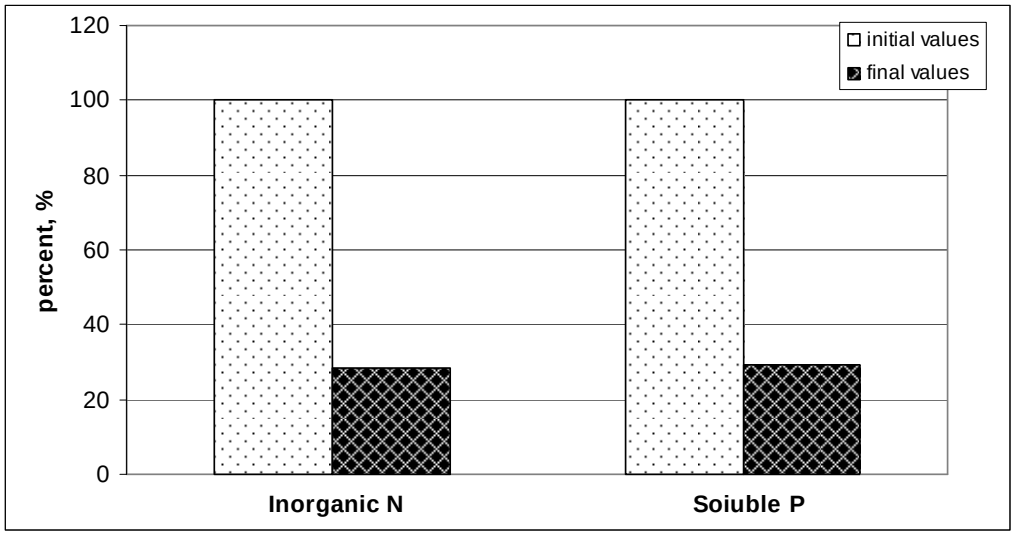

Figure 3. - The content of innorganic nitrogen and soluble phosphorus in the experimental pool with PGPB

Total coliform count in the water was ranging from 225 at the beginning of to 65cfu/ml at the end of experimental period. The lettuce seedlings from greenhouse had a significant count of coliform bacteria in both root and above ground plant. During the experimental period this number was significantly reduced (Table 1.).

Table 1. Total coliform bacteria count in water and plants (CFU/ml)

Tested period (days)	**Total coliforms, at 37℃**		
	water	**root**	**above plant**
0	225	TNTC	4760
15	439	3160	200
30	65	470	100

CONCLUSIONS

The presented study was intended to provide the proof of the possibility to grow lettuce on treated wastewater and its application in phytoremediation, all been proven by the results shown in the tables above and high level of generated biomass (Figure1). This experimental study also proved the benefits of introducing bacterial strains (PGPB) in terms of increased uptake of nitrogen and phosphorus from the water.

Considering the fact that lettuce is used in human diet without previous thermal treatment, i.e. raw, the presence of pathogens in lettuce after the treatment (Table1.) indicates its inconvenience for human consumption.

Further investigation need to be done in order to determine the transport mechanisms in lettuce of pathogen from its roots to above ground parts, as well as its total degradation by specific PGPB strains application and different plant selection.

ABSTRACT: L-ascorbic acid has good antioxidative properties but its efficiency in stabilizing fats and oils in products with high lipid content is negligible due to its hydrophilic characteristics. On the other hand, fatty acid ascorbyl esters are liposoluble, with even better antioxidative properties comparing to L-ascorbic acid. Therefore, developing of industrial process for lipase-catalyzed synthesis of vitamin C fatty acid esters, considering numerous advantages over conventional chemical methods (mild reaction conditions, high regioselectivity, and simplified downstream processing), is of great interest. In this study, L-ascorbyl oleate was synthesized in esterification reaction between vitamin C and oleic acid catalyzed by immobilized lipase from *Candida antarctica* in acetone as a reaction medium. Response surface methodology and 5-level-5-factor central composite rotatable design were employed in order to investigate interactions between experimental factors (initial water content, temperature, substrates molar ratio, vitamin C concentration, and enzyme amount), determine their individual influence on molar conversion, and eventually optimize the synthesis. Based on the experimental data, regression model, expressed with second order polynomial equation, was obtained. At values in the range of examination, enzyme amount had no influence on conversion so it was fixed at the minimum (0.2 % (w/v)). The maximum molar conversion of 91.3 % was predicted and corresponding, optimal reaction conditions were: temperature – 60 ºC, initial water content – 0 % (v/v), vitamin C concentration – 0.02 M, and substrate molar ratio – 1:15. Our system provided reaction conditions which enabled high conversions, thus obtained results may be used as a starting point for the process scale-up.

INTRODUCTION

Fats and oils are prone to autooxidation which causes shortening of the shelf life of food and cosmetics containing them. As additives in such products, synthetic antioxidants (BHT and BHA) are being used to prevent deterioration of lipids, but their potential toxicity is the matter of concern (Karmee, 2009). Therefore, natural, non-toxic antioxidants which have high free radical scavenging capacity and liposolubility, such as fatty acid ascorbyl esters, are preferable for this usage. Currently, ascorbyl palmitate is being industrially produced in process catalyzed by chemical means, despite disadvantages such as low yields and absence of regioselectivity, thus complicated downstream processing (Yan et al., 1999). Also, application of ascorbyl palmitate is limited due to its low solubility in oils which could be overcome by using unsaturated fatty acid esters of vitamin C. Nowadays, subject of many researches is development of industrial process for enzymatic synthesis of unsaturated fatty acid ascorbyl esters in which lipases would be used as a catalyst. Such production would provide avoidance of the main obstacles of chemically catalyzed synthesis and it would be classified as environmentally friendly.

Lipases (tryacylglycerol acylhydrolases, E.C. 3.1.1.3.), besides their application in hydrolysis of triglycerides, are widely used as a biocatalysts in esterification, transesterification, and interesterification reactions (Bezbradica et al., 2009). Fatty acid ascorbyl esters were so far synthesized by using several microbial lipases: *Candida antarctica* lipase, type B (Humeau et al., 1998a; Humeau et al., 1998b; Lerin et al., 2010; Viklund et al., 2003), lipase from *Thermomyces lanuginosus* (Reyes-Duarte et al., 2011), *Bacillus stearothermophylus* SB1 lipase (Bradoo et al., 1999), and lipase from *Rhizomucor miehei* (Burham et al., 2009). Oils, saturated and unsaturated fatty acids, and their methyl and vinyl esters were previously applied, whereas higher yields were achieved when more expensive, activated acyl donors were used (Karmee, 2009). Solvents with high log P values, which are most commonly used as a reaction medium in lipase catalyzed esterifications, have proved to be unsuitable for FA ascorbyl esters biosynthesis because of the high polarity of vitamin C (Song and Wei, 2002). Hence, reaction was mostly conducted in more polar solvents such as *t*-amyl alcohol, *t*-butanol, and acetone. Ionic liquids were also successfully applied, although its usage decreased enzyme stability and increased price of the process (Adamczak and Bornscheuer, 2009). In the majority of studies, it was reported that control of the initial water content, excessive amount of acyl donor, and water removal by molecular sieves were good tools for moving equilibrium towards the product (Karmee, 2009). Optimum temperature varied from 30 to 65 ºC in previous researches, indicating that this parameter is strongly affected by properties of substrates, product, and solvent (Song and Wei, 2002; Chang et al., 2009; Lv et al., 2008). At the present time, efforts are being made in order to optimize lipase-catalyzed synthesis of ascorbyl oleate since it has strong antioxidative effects (stronger then vitamin C and ascorbyl palmitate), its solubility in fats and oils is high, and oleic acid, as an acyl donor, can be classified as inexpensive and commercially available.

The main goal of this research was to optimize esterification of vitamin C and oleic acid catalyzed with immobilized lipase from *C. antarctica* in order to maximize limiting substrate molar conversion. Acetone was used as a reaction medium due to its low price, GRAS status, and high volatility. The effects of key experimental factors (enzyme loading, vitamin C concentration, temperature, initial water content, and substrate molar ratio) on reaction progress, as well as their interactions, were examined by applying response surface methodology (RSM) and 5-level-5-factor central composite rotatable design (CCRD).

MATERIAL AND METHODS

Enzyme and chemicals

Novozym® 435 (lipase from *C. antarctica*, type B immobilized on acrylic resin) was purchased from Novozymes (Bagsvaerd, Denmark). Substrates were L-ascorbic acid (99.7 %, Zorka, Šabac, Serbia) and oleic acid (Ph. Eur., NF pure) purchased from AppliChem, Darmstadt, Germany. As reaction media acetone (99.5 %, Zorka Pharma, Šabac, Serbia) was utilized. Substances used for the quantitative HPLC analyses were methanol obtained from JT Baker, USA and phosphoric acid purchased from Sigma-Aldrich Chemie Gmbh, both of HPLC grade.

Procedure for the enzymatic synthesis

Experiments were carried out in 100 ml capped vessels. The reaction mixture was composed of different amounts of vitamin C, oleic acid, enzyme, water, and acetone and the total volume was 10 ml. The reactions were carried out in a shaker at 250 rpm and at temperatures in range from 40 to 60 ℃. In control samples (lipase not added), which were prepared by exposure to the same temperature treatment, product was not detected. All experiments were conducted in duplicate and all

standard deviations were less than 5 %. In further calculations, average values were used.

Experimental design and statistical analysis

A 5-level-5-factor CCRD, including 32 experimental points of which 16 factorial, 10 axial, and 6 center, was employed in this study. Coded and actual levels of variables, experimental design, and obtained results are presented in Table 1.

*Central point

All 32 experiments were conducted randomly so that the possibility of systematic errors would be excluded. Response surface regression (RSREG) method was employed for analyzing of experimental data in order to fit them to the second-order polynomial equation

$$Y = \beta_{k0} + \sum_{i=1}^{5} \beta_{ki} X_i + \sum_{i=1}^{5} \beta_{kii} X_i^2 + \sum_{i=1}^{4} \sum_{j=i+1}^{5} \beta_{kij} X_i X_j \quad (1)$$

where Y is response (conversion), β_{k0}, β_{ki}, β_{kii}, and β_{kij} are constant regression coefficients, X_i and X_j are uncoded independent variables, and k is the number of single factor. MATLAB 7.0 (Mathworks Inc., Natick, MA, USA) was used when the least square method was applied for the response function coefficients calculation

and their statistical significance estimation. Into the final model, only significant terms with $p \leq 0.05$ were included. Fisher test was used in order to validate adequacy of the obtained model and student distribution was employed for the evaluation of the coefficients significance.

HPLC analysis

Quantitative analysis of reactants and products were conducted on Akta Purifier HPLC system. Waters Spherisorb ODS 2-C18, 250 mm × 4.6 mm, 5 µm reverse phase column was employed. Reaction mixture (10 µl), fifteen times diluted was injected and eluted with 1 ml min^{-1} of Methanol/H_3PO_4, 100/0.1 (v/v). Ascorbyl oleate was detected by UV detector at 235 nm.

RESULTS AND DISCUSSION

Adequacy of the model was confirmed by Fisher test (F_r value was 4.1 which is lower then theoretical (4.58) for significance level of 5 %). Student test was employed for determining the significance of the regression coeficients and based on it, β_0, β_1, β_2, β_4, β_5, β_{11}, β_{22}, β_{44}, β_{15}, β_{25}, and β_{45} were included in model. Following regression model was obtained:

$$Y = 26.17 - 3.17X_1 + 3.34X_2 + 0.45X_4 - 10.6X_5 + 0.737X_1^2 + 1.58X_2^2 - 1.47X_5^2 + 1.33X_1X_5 - 1.63X_2X_5 - 3.7X_4X_5 \quad (2)$$

It can be noticed that among linear terms, only the one describing effect of enzyme amount (β_3) was not significant, indicating that lipase loading, in the range from 0.2 to 1 % (w/v), was not affecting conversion degree. Positive quadratic regression coefficients β_{11} and β_{22} (functions with minimum) and negative, β_{44}, (function with maximum) were significant, as well as the terms that were describing negative interaction of vitamin C concentration with temperature (β_{25}) and substrates molar ratio (β_{45}) and positive interaction between ascorbic acid concentration and initial water content (β_{15}). From the Table 1, it can be observed that the highest conversion of 56.97 % was achieved in experiment No. 9. Response surface plots showing influence of pairs of factors on molar conversion are represented in figures.

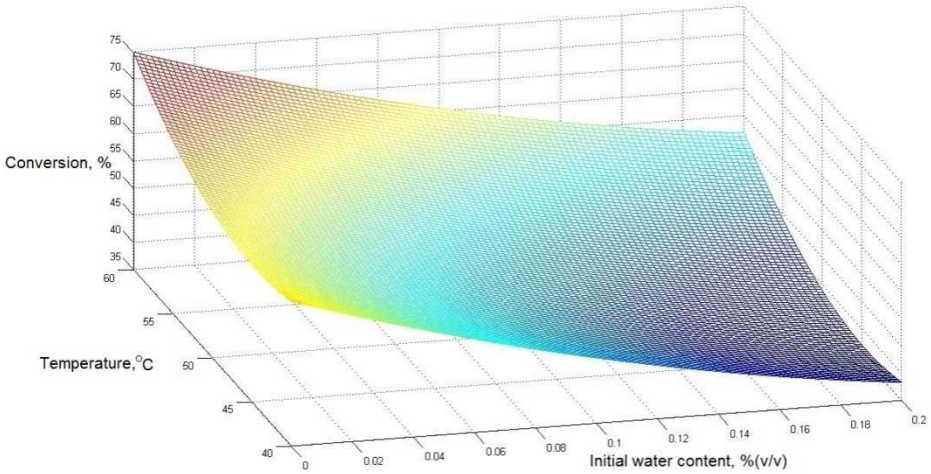

Figure 1. Response surface plot showing interactions between temperature and initial water content

Within the entire observed range, molar conversion increased with decrease of initial water content (minimum of this function was out of scope) reaching maximum when water was not added (Figs. 1 and 2). Obtained result indicated that additional water was not needed for keeping immobilized lipase in its active form. Influence of reaction temperature was also described by the function with minimum out of the monitored range (Fig. 1). Increase of temperature up to the 60 ºC (higher temperatures were not tested since they would cause boiling of reaction mixture) had positive effect on the conversion degree. Impact of vitamin C concentration was represented by linear function with negative slope. Hence, maximum conversions were achieved at lowest concentrations of L-ascorbic acid. From figure 2, in which mutual effect of initial water content and substrates molar ratio (parameters X_2, X_3, and X_5 were fixed at 0 levels) is represented, it can be noticed that maximum molar conversion was reached at 1:10 ratio. However, position of local maximums depends significantly on vitamin C concentration owing to strong negative interaction between factors X_4 (substrates molar ratio) and X_5 (ascorbic acid concentration), which is depicted in Fig. 3. At high initial ascorbic acid concentration, minimum substrates molar ratio (1:2) was optimal and *vice versa* (maximum molar ratio of 1:15 was optimal at low concentrations of vitamin C). Conversion decrease at highest oleic acid contents was probably induced by mass-transfer limitations caused by its high viscosity (Burham et al., 2009). Since best results were achieved at 0.02 mol dm^{-3} of limiting substrate, molar ratio 1:15 was set as optimal. Lipase loading was fixed at the minimum (0.2 % (w/v)) considering that it was not significant. Maximum molar conversion of 91.3 % was predicted by the model at optimized reaction conditions, which is significantly higher than highest conversion, accomplished in experiment No.9.

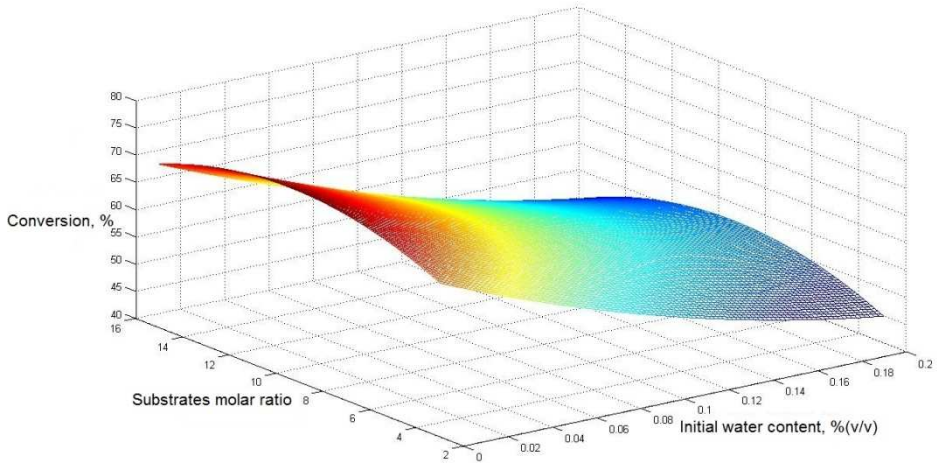

Figure 2. Response surface plot showing interactions between substrates molar ratio and initial water content

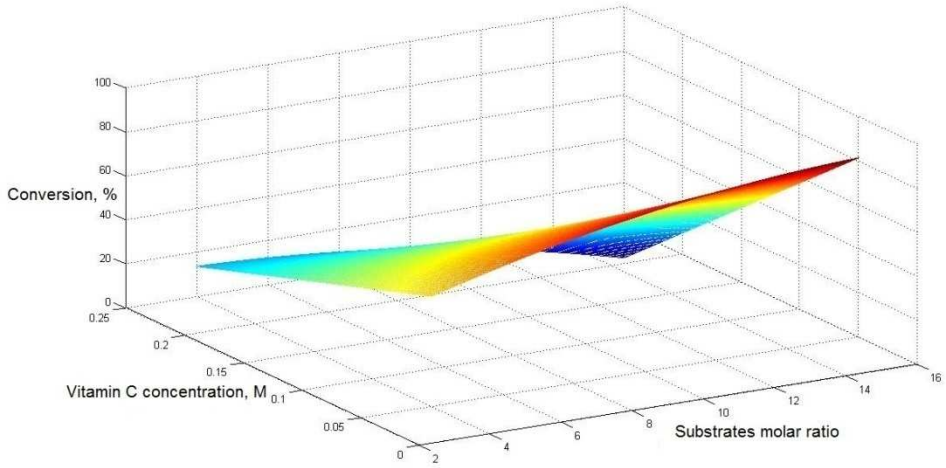

Figure 3. Response surface plot showing interactions between vitamin C concentration and substrates molar ratio

CONCLUSIONS

Aim of this study was to optimize enzymatic synthesis of ascorbyl oleate in acetone with vitamin C and oleic acid as substrates by applying response surface methodology (RSM) and 5-level-5-factor central composite rotatable design (CCRD). Results of the research are comparable with previously reported with more expensive solvents or activated acyl donors. Hence, it is possible to use them in a further process optimization on larger scales.

ABSTRACT: Enzymatic modification of starch provides a good solution for improving the processing behaviour and stability of starches. The composition of starch, especially in terms of amylose and amylopectin, is the most researched aspect of influence on functional behaviour of starch. Granular structure and extension of crystalline and amorphous zones have direct impact on starch properties. Using of amylolytic enzymes below the gelatinization temperature leads to a partial degradation of the suspended starch granules with retention of the grain structure.
In this study the influence of reaction conditions (type of starch, type of enzymes, reaction temperature and reaction time) on the grade of enzymatic hydrolysis of native corn, potato and pea starches, which differ according to the starch-type (A, B and C-type starches) was researched. The progress of the enzymatic reaction was followed by determination of glucose content in the supernatant (converted to starch) at specified reaction temperatures (30, 40, 50 and (55)60 ℃) and in specified time intervals (20, 44, 68, 92 h). It was found that the degree of hydrolysis of potato starch showed significantly lower values than that of corn and pea starch. The highest glucose values were determined after degradation with amyloglucosidase (Dextrozyme). By the hydrolysis of potato starch, glucose content in supernatant was below 10 %. Corn and pea starches were attacked most easily (to 60 %) in comparison to potato starch. Higher temperature and longer hydrolysis time led to a greater degradation of native starches.
Key words: *pea starch, corn starch, potato starch, enzymatic hydrolysis, enzymatic modification, hydrolysis conditions*

INTRODUCTION

Modified starch plays a significant role in rheological/texture properties of food and has significant industrial applications. In food processing modified starches are used as a thickener, stabilizer, gelling agent, bulking agent and water retention agent. Those properties can be improved by physical, chemical or enzymatic modification of starch granule. Traditional acid hydrolysis of starch to glucose is being superseded by enzymatic processes because acid processes leads to undesirable by-product. The fact that some enzymes have a particular capacity in transforming starch to shorter polymers inspired several researches in the recent years (Planchot, et al., 1994; Shariffa et al., 2009, Zieba et al., 2011; Gularte and Rosell, 2011). The importance of the enzymatic liquefaction of raw starch without heating has been well recognised, mainly due to energy savings which reduces the overall cost of starch processing (Robertson et al., 2006). This has generated a worldwide interest in the discovery amylases that directly hydrolyse raw starch in a single step at moderate temperature, much below the gelatinization temperature (Uthumporn et al., 2010). Many studies have shown that rate of hydrolysis of starch granules strongly depends on the botanical source from which they originated and that it mainly occurs in amorphous region of starch granule (Lacerda et al., 2008, Shariffa et al., 2009; Ahmed and Auras, 2011; You, S. and Izydorczyk, M.S., 2007).
The objective of this study was to investigate the influence of reaction conditions by the enzymatic hydrolysis of native corn, pea and potato starches in its native (raw)

granular state and compare the influence of two amylolytic enzymes and their ability to hydrolyse these starches.

MATERIALS AND METHODS

Materials: Raw corn and potato starch (Maisita 2100740 and Stärkina 20000-50) were obtained from the Agrana Group. Pea starch was isolated from peas at the Institute of Food Technology, University of Live Sciences, Vienna.
Enzymes: The commercial enzymes used in the present study, *Dextrozyme 225/75L* (*Aspergillus niger* glucoamylase and *Bacillus acidopullulyticus* pullulanase) and *Promozyme 200L* (*Bacillus acidopullulyticus* pullulanase) were products of Novo Industry (Novo, Denmark).
Determination of moisture content: The moisture content of starch samples were determined by using IR-30 Moisture Analyser (Sartorius thermo control DTC 01L, Haack, Vienna). Starch (5g) were spread uniformly on the pan and heated at 105℃.
Starch hydrolysis: Raw starch solution (20%) was prepared in distilled water (pH was adjusted to 4.5 with citric buffer) and incubated with Dextrozyme 225/75L or Promozyme 200L (10 times higher enzyme concentration as recommended by producer) at different temperatures (30, 40, 50 and 60(55) ℃). In the experiments with the potato starch were used temperatures no higher than 55 ℃, because the temperature of 60 ℃ leads to its gelatinization. A fter 20, 44, 68 and 92 hours 3 ml of suspension were removed from the water bath with a transfer pipette and centrifuged to obtain clear supernatant. Reducing sugars were analysed by 3,5-dinitrosalicylic acid (DNS) method (Sumner and Somers, 1949) using glucose as a standard. Each analysis was performed in duplicate. Suitable controls such as starch control (without enzyme) and enzyme control (without substrate) were determined. Degree of hydrolysis (%) was calculated as follows:

$$Glucose\ (\%) = \frac{\text{g reducing sugar expressed as glucose}}{\text{g total starch dry weight}}\ \text{x}\ 100$$

RESULTS AND DISCUSSION

Use of amylolytic enzymes below the gelatinization temperature of the starch results partial hydrolysis of the suspended starch granules with retention of the grain structure. The degree of starch hydrolysis was determined by measuring glucose content in supernatant at different time intervals. Figures 1 to 6 and Table 1 show the course of glucose production during enzymatic degradation of native corn, potato and pea starch with Dextrozyme and Promozyme at several reaction temperatures.

By corn starch (Figures 1 and 2, Table 1), after 92 h hydrolysis, glucose levels were 42.67% (measured at 40 ℃), 52.62% (at 50 ℃) and 5 2.52% (at 55 ℃). At 60 ℃ the glucose values were lower than at 40 or 55 ℃ (49.6 5%). The hydrolysis of corn starch with Promozym showed much lower values for the glucose content, which was after 92 h degradation between 0.09 to 0.22% .

Neither 40 ℃ nor 50 ℃ and 55 ℃ were sufficient t o raise the glucose level by potato starch above 10% in the hydrolysis with Dextrozyme (Figures 3 and 4, Table 1). The hydrolysis of potato starch with Promozym led to very low glucose levels at all reaction temperature, the glucose values were only 0.11 to 0.25%.

The pea starch hydrolysis showed a similar trend as the corn starch (Figures 5 and 6, Table 1). The higher values at 40℃ indicate a more intense hydrolyse of pea starch with Dextrozyme. After a 92-hour hydrolysis they amounted to 60.36%. A further

increase of reaction temperature to 50 or 60 ℃ gave lower values for the glucose content, and after 92 h hydrolysis it was 44.83% and 31.55% respectively. The effect of temperature on the degradation of pea starch with Promozym was similar to the degradation of Dextrozyme (the highest values were measured at 40 ℃), but with a much lower glucose content. The values after 92 h, were 1.35% (at 30 ℃), 2.66% (at 40 ℃) and only 0.54% glucose (at 60 ℃).

Table 1. Glucose content (% based on starch) after hydrolysis of corn (M), potato (K) and pea (E) starches

Sample	Starch type	Enzymes	Temperature (℃)	Glucose content[1) 2)] (%)

[1)] *Values are expressed as mean ± SD of four repeats*
[2)] *to the blank corrected glucose content*

Influence of reaction temperature: Lower degree of starch degradation at higher reaction temperature (50, 55 and 60 ℃) is related to adsorption of the enzyme on substrate (Karakatsanis et al., 1997). As indicated, enzymes adsorb better on substrate at lower temperatures, while higher temperatures accelerate desorption and assumption is that better adsorbed enzyme may develop a better effect. Another possible explanation for poorer starch hydrolysis at higher temperature (above 40℃) would be the binding of amylose in an amylose-lipid complex (Anger et al. 1994), wherefore the access of enzyme to amylase molecules is denied and it affects the final degree of hydrolysis.

Influence of the enzyme type: Numerous studies showed that the addition of pullulanase to glucoamylase or to α-amylase accelerated the degradation of native starch (Ueda and Marshall, 1980; Sprinat and Antranikian, 1992).
In this study Promozym 200L (pullulanase) and Dextrozyme 222/75L (pullulanase in combination with gluco-amylase) were used. These are two basic types of enzymes: (1) an endo enzyme (pullulanase), which cleaves the α-1, 6-glucosidic linkages of amylopectin, creating two smaller molecules, and (2) an exo-enzyme (gluco-amylase) which cleaved the α-1,4 - and α-1,6-glucosidic bonds, which resulted in the

glucose monomers. As expected, with Dextrozyme was achieved better starch degradation rate than with Promozym (pullulanase alone). It can be explained with a poor adsorption of pullulanase to starch granules (Wang et al., 1996).

Influence of starch type: In this study we used corn, potato and pea starch, which differ according to the starch-type (A, B, and C-type) (Imberty et al., 1988; Imberty and Pérez, 1988). It was found that the degree of hydrolysis of potato starch was significantly lower than that of maize or pea starch. Compared with pea starch, corn starch was attacked most easily. Only at a reaction temperature of 40 ℃ higher glucose values was obtained for pea starch than for the corn starch. Corn, pea and potato starch can be very slightly degraded with Promozym alone. Only in the pea starch slightly higher glucose content was observed.
From the literature is known that A-type starches are hydrolysed better than B-type (Gallant et al, 1982). The cereal starches, which have A-type crystallinity, have been degraded better than the legume starch having C-structure. The potato starch, which is a B-type, was hydrolysed the lowest. The differences between corn and pea starch can be explained that molecules of corn starch are packed in the less dense crystalline regions and therefore are more accessible to enzymatic attack, than in the starches with higher amylose content as is pea starch (Hoover and Sosulski, 1985a, Uthumporn et al., 2010). Poorer hydrolyse of potato starch in comparison to other types of starches could be explained by the size of potato starch granules which are relatively large and have smaller total surface area (Shariffa et al., 2009, Zieba et al., 2011). The results of starch hydrolysis confirmed that the susceptibility was affected by the botanical origin, and amylose/amylopectin ratio and degree of starch crystallinity.

CONCLUSION

Amylolitic enzymes, combination of gluco-amylase and pullulanase, are able to hydrolyse granular starch at a sub- gelatinization temperature in relatively high degree. Significant differences in a degradation of starches from corn, potato and pea were observed. The highest glucose values were determined after hydrolysis of corn starch and the lowest after hydrolysis of potato starch. Longer hydrolysis time and higher temperature (to 40℃) affects the hydrol ysis rate positively. This research clarified that hydrothermal enzymatic modification of starches was very strong affected by hydrolyse condition and that with their variation can be obtained modified starches which can have a specific application in the food industry.

ABSTRACT: Dimensions of individual biscuit pieces such as height, width and length thereof are a significant factor in the quality of hard biscuits. Provided that these dimensions are uniform, it would possible to apply an automatic packing of desired weights. Dimensions of hard biscuits largely depend on the quality of flour and dough, which is closely related to the content and quality of gluten in the flour. The object of this study was to analyze the impact of quantity and quality of wet gluten on the physical, chemical and on sensory properties of hard biscuits. Three white wheat flour samples containing 20, 22 and 24% of wet gluten were used in this study. The quality of flour samples in terms of granulation, ash content, moisture, acidity and amylolitic activity was equalized. Production of hard biscuits was carried out under industrial conditions according to a standard recipe. Physical parameters and chemical properties of the biscuit samples were measured. The sensory analysis of the samples was carried out, too. Statistical analysis of the results obtained has shown that the quantity and quality of wet gluten had no effect on length and width of biscuit samples. Differences among the samples were statistically significant however in terms of height and weight. The minimum deviation in dimensions and weight of the biscuits comparing to manufacturing specifications were noted in samples produced from flour with 22% of wet gluten. According to the results achieved, this content of wet gluten is optimal for production of hard biscuits.
Key words: *hard biscuits, wet gluten, rheological properties, physical and chemical parameters*

INTRODUCTION

Technology of flour-confectionary products is based on technological quality properties of flour as a basic raw material. When combined with other materials in a mechanical process, flour has the ability to produce dough of various consistencies. From the aspect of a product recipe, good quality flour implies the ability of flour to absorb higher sugar content and develop strong structural consistency without affecting the hardness of the product (Faridi et al. 2000).
Despite all the efforts to create different types of biscuits with higher nutritional values - e.g. biscuits with an addition of buckwheat flour (Shin, 2007; Šimurina et al. 2009; Filipičev et al. 2011), or use of soy product (Nikolić and Joka, 2003; Oluwamukomi et al. 2011) - the consumption of a standard hard biscuits from wheat flour is still widespread. Production of biscuits and related products in B&H over the past years has increased and in the period from 2007 to 2009 this increase was about 20% (SG/LJ, 2010).
Hard biscuits have certain properties that make them different from other baked products. They have provided geometric shape, slightly rounded sides, a flat, smooth and shiny upper surface with furrows and regular shape holes. Structure of the cross-

section is layered with tiny oval-spread shape and uniformly distributed pores. When chewing, the hard biscuit is crisp, firm, dry, and it softens slowly and it does not stick to the palate. During chewing, the biscuit softens and releases the aroma, flavor and taste (Gavrilović, 2003). Dimensions of hard biscuits are an important factor of quality when considering the packing and the net weight label. If the biscuits spread too much, it cannot be put in the box without breaking. If the spread is too little the box is not completely filled and the net weight is not correct (Hoseney, 1994).
Although the selection and production of soft wheat varieties intended for the production of biscuits is the focus of many studies (Labuscragne et al. 1996; Pajin et al. 2005), the quality of flour for production of hard biscuits is not always satisfactory or uniform. This is particularly reflected in the protein content. It is recommended that the flour with lower wet gluten (WG) content and lower sedimentation value be used for production of hard biscuits.
According to literature and production practice, WG content in flour intended for the production of hard biscuits allows a range of 20-24% and 9.5 to 11% of total proteins. However, even this, relatively narrow range of wet gluten content may lead to variations in quality, particularly in terms of width/ length ratio of the biscuits.
Given the importance of this problem in everyday practice, the aim of this paper was to investigate the optimum amount of WG content in the flour range of 20 to 24% in order to provide for the best quality hard biscuits.

MATERIAL AND METHODS

In this research we used samples of flour T-500 of uniform quality, except for WG content. The flour was purchased in the mill "Dukat", Tešanj, harvest 2009. The content of WG in the flour samples was 20%, 22% and 24%.
Production of hard biscuits was carried out under industrial conditions (Agrokomerc, Velika Kladuša), according to a standard recipe and the process known to the manufacturer. The experiment included the production of hard biscuits out of three samples with different content of WG (20%, 22% and 24%). The production was carried out in 10 replications, i.e. from each sample a total of 10 mixing were made.

Analysis of flour samples

Physical, chemical, farinograph (water absorption, dough development, stability, softening degree, quality number and quality group) and extensograph (area under curve, extensibility, resistance, max resistance and R/E) tests and amylolitic activity of flour samples and balancing thereof were carried out according to Kaluđerski and Filipović (1990) to determine the appropriateness of flour for hard biscuits production: water content (%), ash content (%dm), flour granulation, sifting the samples on the lab sieves according to Büchler (share of individual fractions is expressed in %), acidity according to Shulerd method, wet gluten content (%) was determined by manual washing, a total protein content N X 5,7 (%dm) was determined by Kjeldahl method, sedimentation by Zeleny, fat content by Soxhlet (%dm) and rheological analyses. Sample testing was performed in parallels, taking into account the allowable deviations between the measurements defined for each method. The results show mean values of the tested parameters.

Analysis of hard biscuit samples

To determine physical and chemical properties of hard biscuits it was analyzed the following (Trajković et al. 1983): moisture content in biscuit samples (%), ash content (%), crude protein content N x 5,7 (%) by Kjeldahl method (macro-method), fat content (%) by extraction of fat with an undetermined quantity of fresh solvent and acid pre-treatment of sample according to Weibl-Stoldt. Energy value of the final

product was calculated using the conversion factors for energy values.[1] Chemical parameters were determined on an average sample taken from each replication, i.e. from each mixing (10) in triplicates. The results show mean values.
Measuring the size of biscuit samples (length, width and height) was carried out using an electronic digital caliper (MIB Germany). There were 30 parallel measurements in 10 replications (N=10X30). Sensory evaluation of 10 hard biscuits samples was carried out according to Gavrilović's method (2003). The evaluation was performed by a panel of 5 skilled participants. Evaluation was carried out on an average sample taken from each individual mixing, from each replication. The results show mean values of the five evaluators for each individual parameter in all ten (10) replication.
Statistical processing included one-factorial analysis of variance (ANOVA-Microsoft Excel 2007). Determined differences were tested with Tukey test held at 0.05.

RESULTS AND DISCUSSION

Flour 1 had the lowest, while Flour 3 had the highest content of WG and proteins. Flour containing WG in the specified range is used in biscuits industry. The protein content suitable for producing hard biscuit ranges from 9.5 to 11% (Đaković, 1997). Observing this parameter, it can be concluded that sample 1 has insufficient flour protein content for the production of hard biscuits (Tab. 1).

Table 1. Physical and chemical properties of flour samples quality

	Flour 1	**Flour 2**	**Flour 3**
Moisture (%)	13,80	14,00	14,10
Ash content (%dm)	0,50	0.51	0,52
Wet gluten (%)	20,00	22,00	24,00
Fat content (%dm)	0.70	0.60	0.50
Proteins N x 5,7 (%dm)	8,00	9.50	11,00
Acidity	1,80	1,90	1,80
Sedimentation	25,00	27,00	29,00
Water absorption (%)	55.30	57,00	58,00
Dough development (min)	1,50	1.75	1,25
Stability (min)	1,50	1,50	2,75
Softening degree (BU)	80,00	70,00	60,00
Quality number	59,00	66,40	65,40
Quality group	B1	B1	B1
Area under curve (cm^2)	62,0	68,5	88,3
Extensibility (mm)	127,0	148,0	168,0
Resistance (BU)	340,0	360,0	360,0
Max resistance (BU)	380,0	443,0	470,0
R/E	2,7	2,4	2,1
Max viscosity (AU)	368	375	367

Sedimentation of tested samples ranged from 25 in samples 1 to 29 in sample 3. The higher the gluten content, the higher the sedimentation value. According to Bešlagić (2005) the sedimentation of flour for production of hard biscuits should be in the range of 25-30, so all flour samples are adequate for hard biscuits production according sedimentation value. Based on farionograpf measurements, all the samples belong to the quality group B1 (Tab. 1). Based on planimetric areas under

[1] Official Gazette of BiH No. 85/08

the extensograpf curve (62.0 to 88.3 cm2), extensibility (127-168 mm) and resistance (380-470 BU), the samples are classified as so-called "weak flours". According to Kovačević (1991) samples 2 and 3 would be more appropriate for hard biscuits production. Flour for biscuits should have a maximum value of viscosity of 300-400 AU (Manley, 2000). The values of this particular parameter in tested samples are within specified range. Based on overall analysis of flour samples it can be seen that the general quality of the samples is balanced in all quality parameters, except for content and quality of wet gluten, which again is in accordance with the set aim.

Table 2. Particle size distribution

Particle size (μm)	Share (%)		
	Flour 1	**Flour 2**	**Flour 3**
<37	12,0	12,4	12,6
37-55	9,0	9,2	9,3
55-75	19,9	20,0	20,5
75-120	30,5	30,8	31,0
120-150	26,7	25,7	24,7
150-190	1,4	1,3	1,5
190-250	0,3	0,4	0,2

More than 50% of flour particles are in the range up to 120 μm, and more than 20% of particles are in the range of 120-150 μm which, according to Gavrilović (2003) and Spasojević (2006) can be considered as optimal value for the production of biscuits (Tab. 2). Based on the classification of flour by particle size distribution by Gavrilović (2003), the examined samples are classified into the category of “weak sharply flour”

Table 3. Chemical content of biscuit samples and energy values (N=30)

	Hard biscuit sample 1	**Hard biscuit sample 2**	**Hard biscuit sample 3**
Moisture (%)	2,5	2,8	3,1
Fat (%)	13,5	13,0	12,3
Protein (%)	5,5	6,8	7,5
Ash content (%)	0,52	0,53	0,55
Carbohydrates (calculating %)	78,0	76,9	76,5
Energy value (KJ/100g)	1919,0	1903,9	1883,1

Higher content of WG in the flour ensures higher water content in the biscuits under the same baking conditions (Manley, 2000).

Based on one-factorial analysis of variance it was established that the amount of WG made no significant effect on the dimensions of the hard biscuits samples: width and length. However, in terms of height and weight of samples the effect of WG was statistically significant. Testing of differences has shown that the height and weight were the greatest in samples with WG of 24% (Fig. 1 and 4).

When compared to the values from manufacturing specification, there are differences in terms of height of biscuit samples – height of sample 1 is lower by 1.033 mm, while the height of sample 3 by 1.038 mm higher than defined values. The closest to the defined height value was sample 2, where mean deviation from the defined value was 0.025 mm. In practice, this deviation is considered insignificant, while deviations in samples 1 and 3 are considered significant. Given the height deviations, these samples would cause problems in the packing phase. Biscuits from sample 1, being of a lower height, would add to the weight of the packing as the package would include more pieces. In contrast, smaller number of biscuits from sample 3 could be fit into the package, which would lead to a lower weight than declared on the label.

Table 4. Sensory properties of biscuit samples

Properties	Scores		
	Hard biscuit sample 1	**Hard biscuit sample 2**	**Hard biscuit sample 3**
Shape	1,5	1,5	1,5
Upper surface	2,0	2,5	2,0
Lower surface	1,6	2,0	1,6
Fracture	2,0	2,0	2,0
Structure of fracture	2,4	3,0	2,4
Chewing	4,0	4,0	4,0
Odor, taste	5,6	5,0	5,0
Total evaluation	18,5	20,0	18,5

Biscuit samples made out of three different kinds of flour were rated descriptively as excellent. Sample 2, which was made of flour with 22.0% of WG scored maximum points, while samples 1 (with 20.0% WG content) and 3 (24.0% WG content) scored 18.5 points (Tab. 4). Of these three samples, the flour with 22.0% WG content proved to have the best sensory properties.

Differences in sensory properties of the samples were manifested in upper and lower surface and structure of the biscuits. Samples 1 and 3 scored lower points for these properties.

All samples scored maximum number of points for aroma and flavor. Accordingly, we can assume that quantity and quality of gluten in flour ranging between 20.0 – 24.0% do not affect the taste and aroma. This may be a partial confirmation of the quality of flour recommended for production of hard biscuits, although both increased or decreased level of gluten may cause practical problems in the packing phase. One could expect that improperly packed products will lose their favorable sensory properties due to cracking or breaking.

CONCLUSIONS

Based on these results, the best quality hard biscuits are made of flour with 22,0% of wet gluten and this can be considered the optimal value for production of hard biscuits, as it provides a uniform dimensions of final product, especially in terms of height, which is little or no different from the manufacturing specifications and therefore does not cause any delays and problems in packing phase. Using the flour with this gluten content enables uniform quality of hard biscuits, and corrections of the recipe or technological parameters are minimal.

ABSTRACT: Copper belongs to a group of essential elements, and needs to be replenished through food in certain quantities every day. But on the other hand, ingestion of large amounts of copper has an adverse effect on the human body, so that food should be subject of control in terms of copper content. In this work the copper content was determined in twelve different samples of kombucha fermented milk products using potentiometric stripping analysis, which was preceded by the determination of optimum conditions for carrying out the analysis. Fermentation liquid used as inoculum for the fermentation of milk is obtained by cultivation of kombucha on cooled tea. Four different kinds of tea were used for preparing tea: winter savory, peppermint, stinging nettle or wild thyme. Thus, four different kinds of fermentation liquids were obtained. The technique of potentiometric stripping analysis is applied with the dissolved oxygen as an oxidant, and the mercury film electrode as a working electrode. The copper content in samples was calculated using standard addition method. The contents of copper in the analysed kombucha fermented milk products were within the range from 0.016 mg/l to 0.036 mg/l, with a mean value of 0.25 mg/l. On the basis of the results of this study we can conclude that daily consumption of kombucha fermented milk products provides significant amount of copper to the human body in relation to milk, that is necessary for adults and children alike.
Key words: *copper, kombucha, fermented milk products, potentiometric stripping analysis*.

INTRODUCTION

Cooper belongs to the essential elements that are necessary for normal functioning of the human body. Copper is an integral cofactor for numerous enzymes that play key roles in various cell processes including oxidative metabolism, neurotransmitter synthesis, free radical detoxification, iron uptake and production of connective tissues (Copper in human health, 2012). Daily copper requirements for adults are 1.5-3 mg, and for children 1-2 mg (Švarc-Gajić, 2009). Copper deficit can cause thyroid problems, arthritis, and fragile bones (Švarc-Gajić, 2009). On the other hand, copper falls into the group of heavy metals. Ingestion of large amounts of copper can affect cardiovascular, gastrointestinal and nervous system. Due to its oxidant potential, copper can cause undesirable changes in processed food, related to browning reactions, lipid oxidation and consequently loss in nutritive value (Ferreira, 2005). Therefore, it is very important to monitor its content in food. Milk and fermented dairy products are very important human nutrients. They are known as an excellent source of calcium, magnesium and zinc, and provide small amount of iron and copper (Jigam et al., 2011). Consumption of milk and fermented dairy products is associated with beneficial health effects, beyond their pure nutritional value. Several reports indicated that dairy products could serve as carrier for other functional ingredients, such as phytosterols, fatty acids and various kinds of probiotic bacteria (Mattila-Sandholm et al., 2002).

Kombucha is a traditional fermented tea beverage that has gained popularity in the United States, as it is increasingly associated with health-promoting effects (Greenwalt et al., 1997). Kombucha was historically consumed in China, Russia and Germany, but today, it is a popular fermented tea beverage worldwide. Kombucha

colony is composed of two types of symbiotic microorganisms: yeasts and acetic acid bacteria (Vitas et al., 2011). Since kombucha is tea fungus, most often it is cultivated on black or green tea. After about 7-10 days incubation at room temperature, the mat, that consists of kombucha colonies, is transferred into a new fermentation, and the final product is acidic, slightly carbonated beverage, comprised of sugars, organic acids, tea components, vitamins and minerals, resembling cider (Greenwalt et al., 1997). The positive effects of these substances on the human body have long been known, and recent studies are described in the literature (Dufrense and Farnworth, 2000).
The objective of this study was to evaluate the optimal conditions for the performance of potentiometric stripping analysis (PSA), and to determine the copper level in kombucha fermented milk products, obtained by the addition of inoculums of kombucha cultivated on extracts prepared from winter savory, wild thyme and stinging nettle by potentiometric stripping analysis

MATERIAL AND METHODS

Samples

Samples of kombucha fermented milk products were obtained from the Laboratory of Analytical Chemistry at the Faculty of Technology Novi Sad. Fermentation liquid used as inoculums for the fermentation of milk is obtained by cultivation of kombucha on cooled tea. Tea was prepared by adding 70 g sucrose and 2.25 g of tea in 1 l of boiling tap water. Four different kinds of tea were used for preparing tea: winter savory, peppermint, stinging nettle or wild thyme. Thus, four different kinds of fermentation liquids were obtained. The prepared tea was cooled to room temperature, strained and then 100 cm^3 of inoculum from a previous fermentation was added. A glass jar was then covered with fabric bandwith for air, and kombucha incubation was performed at room temperature, for seven days.
For the production of kombucha fermented milk products, a pasteurized, homogenized milk with 2.8 % milk fat was used, from the manufacturer "AD IMLEK", Belgrade, department "Novosadska mlekara", Novi Sad. To the milk with 2.8 % milk fat, 10 % (v/v) of kombucha inoculums was added. Fermentation was performed at 37ºC, 40ºC and 43ºC, in 17 hours of duration, until a pH value of 4.5 was reached. Coagulated milk was then cooled and homogenized by mixer.

Instrumentation

An automatic system for potentiometric and chronopotentiometric stripping analysis used in this research was designed on the Faculty of Technology, Novi Sad as a result of cooperation with company Elektrouniverzal, Leskovac. Analyses were performed in a three-electrode cell consisting of a working electrode, a reference electrode and a counter electrode. Mercury film deposit at glassy carbon disc electrode was used as a working electrode. A platinum wire (φ = 0.7 mm, l = 7 mm) served the purpose of a counter electrode, and the reference was the Ag/AgCl, KCl (3.5 mol/dm^3) electrode. Mercury film was formed on the glassy carbon surface by galvanostatic deposition from the solution containing 0.2 g/dm^3 of mercury(II) and 0.02 mol/dm^3 of hydrochloric acid with the current of -50 µA for 240 s. Prior to each mercury film formation, the surface of the glassy carbon electrode was cleaned mechanically by filter paper wetted with acetone, and then, with doubly distilled water.
The technique of PSA (potentiometric stripping analysis) consists of several steps. The first phase includes a metal ion deposition from examined solutions on the thin mercury film of a working electrode. To maximize the amount of the concentrated metal the solution is stirred during this phase. After the second, calming phase, in the third phase the deposit is dissolved with the dissolved oxygen, and during this phase

relation between potential and time was measured. Oxidation potential is a qualitative characteristic, while the oxidation time is a quantitative one. Compared with other instrumental techniques such as the neutron-activation analysis, the atomic absorption spectrometry, that can be used for determination of copper, and other metal ions, PSA is the cheapest and the quickest method for carrying out a determination (Munoz et al., 2002, Švarc-Gajić et al., 2005).

Chemicals and solutions

All chemicals used in this work were of ultra pure grade ("Suprapur" – Merck). For all dilutions and dissolutions doubly distilled water was used. All vessels and cells were washed with nitric acid (1:1), distilled and doubly distilled water. These cautions were taken to prevent contamination from impurities in chemicals and dirty laboratory glassware.

Mercury stock solution (1 g/dm^3) was prepared by dissolving elemental mercury in nitric acid by heating and diluting with doubly distilled water. Copper stock solution (8.457 g/dm^3) was prepared by dissolving copper shavings in nitric acid (1:1). Working solution of copper was prepared by diluting stock solution with doubly distilled water.

RESULTS AND DISCUSSION

Potentiometric stripping analysis for determining the copper content was conducted on twelve samples of kombucha fermented milk products and a control sample. The control sample was a pasteurized, homogenized milk, with 2.8% milk fat, used for the production of kombucha fermented milk products. Each sample was analysed in five replicates.

Determination of the optimal conditions of the PSA

For determining the optimal conditions of the PSA, the effect of the solution stirring rate, the electrolysis potential, type and electrolyte concentration and electrolysis time were examined. All experimental parameters of the PSA were examined in the matrix of the sample, and were defined on the basis of five replicates for each examined parameter value.

To define the optimal stirring rate during preconcentration step, stirring rates from 1000 r.p.m. to 6000 r.p.m. were examined in the solution for the copper content of 20 µg/dm^3, applying the electrolysis time of 180 s. The stirring rate of 6000 r.p.m. resulted in the mechanical damage of the working electrode surface. At the stirring rate of 5000 r.p.m., analytical signal was higher, but the reproducibility was much lower. For further analysis stirring rate of 4000 r.p.m. was accepted, due to the best reproducibility and satisfactory height of the copper analytical signal (Results are shown in Table 1.).

Table 1. Influence of the stirring rate at copper analytical signal

Stirring rate (r.p.m.)	Oxidation time (s)	CV (%)
1000	1.09 ± 0.43*	19.7
2000	1.82 ± 0.26	7.1
4000	2.36 ± 0.30	6.3
5000	2.93 ± 0.65	11.1

*mean value ± 2SD (n = 5)
CV – coefficient of variation

In order to achieve greater sensitivity, selectivity and sharpness of the analytical signal, it is necessary to choose an appropriate electrolysis potential. Within that, electrolysis potential was examined in the range from -1.20 V to -0.51 V (Table 2.), with electrolysis time of 180 s, and stirring rate of 4000 r.p.m. for the copper content

of 20 µg/dm^3. The best reproducibility and satisfactory height of the analytical signal was obtained at the potential of -0.91 V, and it was applied in further investigations.

Table 2. Influence of the electrolysis potential at copper analytical signal

Electrolysis potential (V)	Oxidation time (s)	CV (%)
-1.20	1.76 ± 0.14*	7.9
-1.15	1.75 ± 0.08	4.4
-1.00	1.35 ± 0.06	4.6
-0.91	1.25 ± 0.03	2.6
-0.69	1.09 ± 0.04	4.1
-0.51	1.16 ± 0.05	4.3

*X_{mean} ± 2SD
CV – coefficient of variation

Hydrochloric, sulphuric, acetic and nitric acids were investigated as types of supporting electrolytes. Given that analytical signal in hydrochloric acid was sharp and reproductive, this electrolyte was accepted for further investigations.
Influence of the hydrochloric acid concentration was investigated in the range of 0.025 - 0.3 mol/dm^3, with electrolysis time of 180 s, and stirring rate of 4000 r.p.m. for the copper content of 20 µg/dm^3. The results are shown in Table 3.

Table 3. Influence of the hydrochloric acid concentration at copper analytical signal

c_{HCl} (mol/dm^3)	Oxidation time (s)	CV (%)
0.025	2.61 ± 0.67*	13.0
0.050	1.92 ± 0.28	7.3
0.100	2.62 ± 0.35	6.8
0.150	1.74 ± 0.55	16.1
0.200	1.77 ± 0.48	13.4
0.300	1.91 ± 0.14	3.6

*X_{mean} ± 2SD
CV – coefficient of variation

The best reproducibility of the determination was obtained in the 0.3 mol/dm^3 hydrochloric acid solution (CV = 6.8 %), but the concentration of 0.1 mol/dm^3 of hydrochloric acid was accepted as optimal, due to higher analytical signal. Influence of the electrolysis time was investigated in the range from 120-480 s in the solution of the copper content of 10 µg/dm^3, 20 µg/dm^3 and in the solution without added standard. The best reproducibility of the copper analytical signal was obtained for the electrolysis time of 180 s, and it was applied in further investigations. Limit of detection (LOD) and limit of quantitation (LOQ) are determined by applying the criteria 3 SD and 10 SD, and they were 0.006 mg/l and 0.020 mg/l, respectively. The copper content in samples was calculated using standard addition method.

Determination of the copper content in samples

Electrolysis was performed at the potential of - 0.91 V, for electrolysis time of 180 s. After the electrolysis step, which was performed under conditions of vigorous stirring (4000 r. p. m.), the solution was left quiescent for 15 s. Dissolution of deposited copper was performed in the conditions of diffusive mass transfer due to the oxidation with the dissolved oxygen. The determined copper contents in samples are shown in Table 4. The presented results represent the mean value ± 2 standard deviation of five replications of each sample. Samples were coded with letters following by number. Letters indicate kind of tea used for kombucha cultivation: winter savory tea – WS, peppermint tea – P; stinging nettle tea – SN; wild thyme tea – WT; while numbers 1, 2, 3 indicated fermentation at temperature: 37℃, 40℃ and 43℃, respectively.

Table 4. Determined copper content in samples of kombucha fermented milk products (kombucha cultivated on winter savory tea – WS; peppermint tea – P; stinging nettle tea – SN; wild thyme tea – WT)

Samples of kombucha fermented milk products	Temperature of fermentation (ºC)	Copper content (mg/l)*
WS1	37	0.022 ± 0.002
P1		0.033 ± 0.001
SN1		0.036 ± 0.010
WT1		0.031 ± 0.007
WS2	40	0.022 ± 0.002
P2		0.016 ± 0.001
SN2		0.019 ± 0.003
WT2		0.021 ± 0.005
WS3	43	0.023 ± 0.005
P3		0.028 ± 0.006
SN3		0.027 ± 0.002
WT3		0.025 ± 0.005
Milk		0.015 ± 0.003

**mean value ± 2SD (n = 5)*

The contents of copper in the analysed kombucha fermented milk products were within the range from 0.016 mg/l to 0.036 mg/l, with the mean value of 0.025 mg/l. The mean value of determined copper content in milk was 0.015 mg/l.
As can be seen from Table 4., kombucha fermented milk products contain higher concentrations of copper than milk. Given that samples were obtained in laboratory, increased copper content in samples most probably originate from the raw materials that were used in their preparation. According to the data from previous studies, kombucha beverage also contains certain amount of copper which is about 0.010 mg/l (Petrović et al., 1999). There are wide variations in the published data in terms of the copper concentrations of different kinds of tea, but there are no precise data about the copper content in the types of tea that were used for sample preparation.
Milk contains limited amount of copper. Foods especially rich in copper include bean, sea food products, cereal, vegetable and meat. (Zheng et al., 2007). Results showed that kombucha fermented milk products are richer source of copper compared to milk, so they consumption provide a higher amount of copper.

CONCLUSIONS

In this work copper content was determined in twelve different samples of kombucha fermented milk products using potentiometric stripping analysis, which was preceded by the determination of optimum conditions for carrying out the analysis. Obtained results showed that kombucha fermented milk products are richer source of copper compared to milk. Daily consumption of kombucha fermented milk products provides a certain amount of copper to human body, that is necessary for adults and children alike.

ABSTRACT: The aim of this study was to investigate effects of osmotic dehydration on microbiological profile of pork meat, in order to indicate the usefulness of this drying treatment. Samples of pork meat were dehydrated in sugar beet molasses and aqueous solution of sodium chloride and sucrose (AOS), at three different temperatures (20^0C, 35^0C and 50^0C). Also, a_w values of the fresh and processed meat were determined and the change of the microbiological profile between the fresh and dehydrated meat was examined. It was detected that the process of osmotic dehydration does not cause deterioration of the initial microbiological profile of the pork meat, but rather improve it due to increasing dry matter content and lowering a_w value of the processed meat. In all processed meat samples, decreased microbial load, was noticed. Better results of the reduction of the present microorganisms in pork meat were obtained in the process of osmotic dehydration of meat in molasses at the higher temperatures.
Key words: *Osmotic dehydration, pork meat, sugar beet molasses, microbiological profile*

INTRODUCTION

Meat is a very perishable foodstuff due to the high water content, so it represents an ideal environment for the growth of microorganisms, particularly bacteria (Modi, 2009). Microbial contamination of the meat is dependent on the microbial load of the host organism and the hygiene practices employed during slaughter, processing and distribution (Nollet and Toldrá, 2011).
Traditional drying process have been very successful in slowing the rate of microbial spoilage and extending the shelf life of meats (Toldrá, 2010). Preservation methods like drying, canning and freezing have been applied to prolong the shelf life of foods, but these methods produce food products that are low in quality compared to their original fresh state (Ratti, 2009). Compared to the other preservation treatments osmotic dehydration has a noticeable advantages providing shelf-stable and quality processed products, furthermore is environmentally acceptable and energy efficient process. (Abbas El-Aouar et al., 2006).
Osmotic dehydration (OD) is a process of the partial removal of water before further drying by direct contact of foods (fruit, vegetable, meat and fish) with a suitable hypertonic solution. Driving force for water removal is the concentration gradient between the surrounding solution and the intracellular fluid (Lević at al., 2008). Mass transfer process is caused by a difference in osmotic pressure and simultaneously three transfer process take place: water withdrawal from product to solution, solute diffusion from solution into the product, and leaching out of the products own solutes (Koprivica et al., 2010).
Concentrated sucrose solution, sodium chloride solutions and their combinations are usually used as hypertonic solution (Mišljenović at al., 2009). Sugar beet molasses emerges as an appropriate medium for osmotic dehydration. The application of sugar

beet molasses as osmotic agent has many advantages: it is nutritionally richer than sucrose and NaCl, sensory acceptable, always accessible and cheap raw material (Koprivica et al., 2008). High content of solids (around 80%) provide high osmotic pressure in the solution and allows greater loss of water during OD and enhances the efficiency of this process. On the other hand, specific chemical composition of molasses enriches chemical and nutritional composition of dehydrated products (Lević et al., 2005).
The objective of this research was to examine the influence of two different osmotic solutions at three different temperatures on the microbiological profile of the fresh pork meat after the process of OD as a confirmation of the process safety.

MATERIAL AND METHODS

Fresh pork meat from the shoulder blade, for the experiment was purchased on the local butcher shop in Novi Sad, shortly before use. Prior the treatment all working areas and tools were thoroughly washed, cleaned and disinfected with the pharmaceutical ethanol 70% vol. Fresh meat was cut into cubes of dimensions approximately 1x1x1cm. Aqueous osmotic solution (AOS) of sodium chloride and sucrose was prepared by mixing three components, commercial sugar in the quantity of 1200 g/kg water, NaCl in the quantity of 350 g/kg water and distilled water. The second osmotic solution was sugar beet molasses from the sugar factory in Pećinci, Serbia. The material to solution ratio of 1:5 was used in all experiments. The experiments were carried out under atmospheric pressure at the temperature of the process of 20^0C, 35^0C and 50^0C. The process was performed in laboratory jars. Samples of meat were dipped into AOS and sugar beet molasses, and the immersion lasted for 5 hours. On every 15 minutes meat samples in osmotic solutions were agitated to provide better homogenization of the osmotic solutions. After osmotic dehydration meat samples were washed with sterilised water and gently blotted with paper towels to remove excessive water from the surface.
Analysis of variance (ANOVA) was performed using StatSoft Statistica, for Windows, ver. 10 program.
Water activity (a_w) of the osmotically dehydrated samples was measured using a water activity measurement device (TESTO 650, Germany) with an accuracy of ±0.001 at 25^0C.
Determination of the *Salmonella* spp., *Escherichia coli*, **the** total number of bacteria and *Enterobacteriaceae* was done by the SRPS EN ISO 6579 ; SRPS ISO 16649-2 ; SRPS EN ISO 4833 and the SRPS ISO 21528-2, respectively.

RESULTS AND DISCUSSION

In the table 1. data of the average a_w values and standard deviation of the fresh and dehydrated meat in AOS and molasses at the temperatures of the process at 20^0C and 35^0C and 50^0C are shown. Fresh sample of meat in initial state had a_w of 0.940±0.01 which is close to the optimum growth level of most microorganisms (Modi, 2009). In all samples after the process of osmotic dehydration lowered a_w values were observed which should lead to the reduction of microbial load. All three samples of meat dehydrated in AOS as osmotic solution and at three different temperatures showed lower a_w values (0.843±0.03; 0.851±0.01 and 0.853±0.03 at 20^0C; 35^0C and 50^0C, respectively) in comparison to the meat dehydrated in molasses at the same temperatures (0.871±0.031; 0.887±0.021 and 0.868±0.021 at 20^0C; 35^0C and 50^0C, respectively). AOS was more effective in lowering water activities in meat regardless of the temperature. This is probably due to the higher values of solid gain in processed meat, because it is known that increased solute concentration means decreased a_w values (Vereš, 1991). Positive influence on the

reducing a_w value of the meat dehydrated in AOS was most expressed at 20^0C. When molasses was used as osmotic medium the lowest a_w value was obtained at 50^0C.

Considering that most meat spoiling bacteria do not grow below a_w value of 0.91(Vereš, 1991), achieved a_w values of the meat dehydrated in both osmotic solutions are lower than a_w values that inhibit bacterial growth. In addition, this a_w values prevents growth of the most microorganisms except moulds since the lowest water activity allowing moulds growth is 0.80 (Vereš, 1991). It may be concluded that process of osmotic dehydration ensure a_w values which are within a specified range for meat quality and safety.

Table 1. Average a_w values and standard deviation of the fresh and dehydrated meat at three temperatures

	Temperature of the OD process:		
	20^0C	35^0C	50^0C
a_w values of fresh meat	0.940 ± 0.01		
a_w values of meat dehydrated in AOS	0.843 ± 0.03	0.851 ± 0.01	0.853 ± 0.03
a_w values of meat dehydrated in molasses	0.871±0.031	0.887 ± 0.021	0.868±0.017

The results of the microbiological analysis of the fresh and dehydrated meat are presented in table 2. Pathogenic bacteria such as *Salmonella* spp. which are frequent contaminants of meat, in the neither of the analyzed samples were found.

The number of *Escherichia coli* is an important indicator of process hygiene. There was no observed presence of *Escherichia coli* in the meat before and after osmotic dehydration in both osmotic solutions and these results are in accordance with the hygiene production criteria of the Serbian National Regulation(72/2010).

Table 2. Microbiological analysis of the fresh and dehydrated meat at different temperatures

Microbiological analysis for:	Fresh meat cut in laboratory	Temperature of the OD process:	Dehydrated meat in AOS	Dehydrated meat in molasses
Salmonella spp. (negative/10 g)	0 ± 0^a	20^0C	0 ± 0^a	0 ± 0^a
		35^0C	0 ± 0^a	0 ± 0^a
		50^0C	0 ± 0^a	0 ± 0^a
Escherichia coli (CFU/g)	0 ± 0^a	20^0C	0 ± 0^a	0 ± 0^a
		35^0C	0 ± 0^a	0 ± 0^a
		50^0C	0 ± 0^a	0 ± 0^a
Total number of bacteria (CFU/g)	$(4.33\pm0.31)E+05^a$	20^0C	$(2.17\pm0.76)E+05^b$	$(1.17\pm0.29)E+05^b$

		50^0C	0 ± 0^b	0 ± 0^b

[abc] different letters in the superscript in the same row indicate significant statistical difference between the values, at level of significance $p<0.05$

Total number of bacteria in the fresh meat cut and prepared for the osmotic dehydration in laboratory was (4.33±0.31)E+05 CFU/g, table 2.

ANOVA has showed that there was significant statistical difference between the total number of bacteria in dehydrated samples and the fresh meat, in all cases, irrespective of the temperatures of dehydration and used osmotic solutions. This proves that the process of OD has a significant influence on reducing the total number of bacteria in the osmotically treated meat. The reductions of the total

number of bacteria in dehydrated samples in comparison to the initial total number of bacteria in the fresh meat were 50%, 91.77%, 95% for samples dehydrated in AOS at 20^0C, 35^0C and 50^0C respectively, and 73.08% , 92.85%, 96.54% for samples dehydrated in molasses at 20^0C, 35^0C and 50^0C respectively. These data point out that higher temperatures of the process positively contribute to higher reduction of bacterial load. Additionally, meat dehydrated in molasses has higher lowering of the total number of bacteria at the corresponding temperatures in comparison to the meat dehydrated in AOS. The most obvious reduction of bacterial load was at the highest temperature that was used in meat dehydrated in molasses, from initial (4.33±0.31)E+05 CFU/g to (1.50±0.26)E+04 CFU/g.

ANOVA has showed that there was no significant statistical difference between the total number of bacteria of the meat dehydrated in AOS at 20^0C and the meat dehydrated in molasses at 20^0C. Also there was no significant statistical difference between the total number of bacteria of the meat dehydrated in AOS at 35^0C and 50^0C and the meat dehydrated in molasses at 35^0C and 50^0C, but there was significant statistical difference in the total number of bacteria in meat dehydrated in the same osmotic solution but at the different temperatures. This indicates that temperature has a significant influence, while the nature of the osmotic solution does not have a significant influence on the reduction of total number of bacteria of the osmotically dehydrated meat.

Serbian National Regulation (72/2010) doesn't determine reference values for the total number of bacteria for the meat pieces, but tracking the change of this parameter can indicate the level of hygiene of the process and the sustainability of the produced semi product. The results of the reduction of total number of bacteria in any dehydrated meat in comparison to the fresh meat indicate that the proces of OD is hygienically safe.

Number of *Enterobacteriaceae* in the fresh meat was 193±25 CFU/g (table 2). After the process of OD number of *Enterobacteriaceae* in the dehydrated meat has lowered in samples dehydrated in both osmotic solutions at the all temperatures, except for the sample dehydrated in AOS at the 20^0C in which negligible increase of the number of *Enterobacteriaceae* was observed (3.5%). The reductions of the number of *Enterobacteriaceae* in dehydrated samples in comparison to the initial number of *Enterobacteriaceae* in the fresh meat were complete (100%) for samples dehydrated in both solutions at the higher temperatures of the process (35^0C and 50^0C), and 13.47% for sample dehydrated in molasses at the 20^0C.

ANOVA has showed that there was no significant statistical difference between the number of *Enterobacteriaceae* of the meat dehydrated either in AOS or in molasses at 20^0C and the fresh meat. Also there was no significant statistical difference between the number of *Enterobacteriaceae* of the meat dehydrated in AOS at 35^0C and 50^0C and the meat dehydrated in molasses at 35^0C and 50^0C, but there was significant statistical difference in the number of *Enterobacteriaceae* in meat dehydrated in the same osmotic solution but at the different temperatures. This indicates that temperature has a significant influence, while the nature of the osmotic solution does not have a significant influence on the reduction of the number of *Enterobacteriaceae* of the osmotically dehydrated meat. Data point out that higher temperatures of the process more effectively reduce the number of *Enterobacteriaceae*, and also the molasses has more sucess in it.

Although, Serbian National Regulation (72/2010) doesn't determine reference values for the total number of *Enterobacteriaceae* for the meat pieces, on the basis of the change of this parameter can be concluded that the level of hygiene of the process and the sustainability of the produced semi product is high enough and that the process of OD is hygienically safe.

CONCLUSIONS

Achieved a_w values of dehydrated meat indicate that growth of microorganisms in that environment would be inhibited. On the basis of measured a_w values can be assumed that OD of meat contribute to reduction of microbial load, providing products extended sustainability. The results of the microbiological analysis of the fresh and dehydrated pork confirmed the validity of this assumption.
Better reduction of the present microorganisms in pork meat were obtained in the process of OD of meat in molasses in comparison to the OD of meat in the AOS at the corresponding temperatures.
Higher temperatures contributed to higher reduction of the present microorganisms in fresh pork meat. The best results in reducing the number of the microorganisms was achieved after OD of meat in molasses at 50^0C.
OD of the fresh pork meat in both osmotic solutions at the temperature of 22℃ has given the satisfactory microbiological parameters which are in accordance with the requirements of Serbian National Regulation (72/2010). At this temperature, due to the absence of the need for extra input of energy, OD represents energy efficient process, which provides safe products.
The microbiological profile of the osmotically dehydrated meat has shown that the OD is hygienically safe process and semi products are microbiologically stable for further technological production.

ABSTRACT: High intensity ultrasound as novel food processing technology is promising in the field of drying of food products. Pretreatment of foodstuff using ultrasonics can significantly shorten drying time, which potentially have economical (electricity and time) and nutritional (lower drying temperatures, less impact on nutritional content) benefits. Cavitation produced by ultrasound increase number of pores and pore size which effectively impacts diffusion speed of water from core to the surface of fruits. However, changes in fruit matrix can have negative impact on textural properties of fruit. Main goal of this research is investigation of influence of ultrasonic pretreatment on drying time and texture of pears, and finding optimal processing parameters for drying. Experiments include pretreatment of pear samples using 20 to 100 % of maximal ultrasonic power (400 W) for 4 minutes. All samples were dried in the infrared dryer at 60 ^{o}C. Using instrumental texture analyzer samples were cut and hardness and elasticity were calculated based on obtained graphs. It is evident that ultrasound had significant impact on shortening of drying time (from 175 to 80 min). However this also mean that at the 80 % and 100 % of maximal power there are significant changes in textural properties, mainly in hardness and elasticity. Optimal amplitude was 60 %, which shortened drying time to 110 min, while retaining most of the hardness and elasticity compared to original untreated fruit.
Key words: *ultrasound, drying, pear, texture analysis*

INTRODUCTION

One of the main reasons for removal of moisture from pears and production of pear chips is longer shelf life, as lack of water inhibits growth of microorganisms and enzyme activity. Traditional sun drying of fruits has inherent hygienic and other problems, such as dependence on weather (Guiné, 2008). That process is also relatively expensive, and nowadays other methods of drying are commonly used. Infrared drying is one of methods which are effective for drying of thin slices. As well as conventional air drying, infrared drying is energy intensive, which can lead to high production cost (Fernandes et al, 2008). High drying temperatures required for removal of water from fruit damages nutritional characteristic of dried fruits, as well as flavor and colour (Velić et al, 2004.). Lowering of temperature significantly prolongs drying time which also negatively impacts fruit characteristics. Longer drying time also means higher costs for electricity and employees, and such method is not always economically viable (Brncic et al, 2010.).
High intensity ultrasound is effective method for shortening of drying time of various fruits (Fuente-Blanco et al, 2006). Cavitation bubbles which explosively collapse can produce microscopic channels (pores) in the fruit matrix, which influence internal and external transport of water from fruit (Carcel et al, 2007; Azoubel et al, 2010.). Besides shorter drying times which lead to significantly lower energy consumption, this also allows using lower temperatures. This in turn ensures higher vitamin and antioxidant content in the final product compared to standard drying processes. Ultrasonic cavitation which enlarge existing and create new pores in fruit tissue matrix could also negatively impact sensory properties, and lead to changes in

textural properties such as hardness and elasticity. Thus determining of optimal ultrasound and drying parameters is crucial to ensure consumer acceptance of final products and minimizing drying times.

MATERIALS AND METHODS

Pears (*p. communis* var. Williams, obtained from local market) were peeled and 5x5x0.5 mm slices were cut out. 15 g of pear slices were immersed in 100 mL of distilled water and treated with 24 kHz ultrasound (UP400s, Hielscher, Germany) with maximal power of 400 W. Each batch of samples was treated with amplitudes of 20, 40, 60, 80 and 100 % of full power, using full cycle during 4 minutes. After treatment samples were dried in infrared dryer (LJ16, Mettler-Toledo,UK) at 60 ^{o}C, until moisture content drops to 10 %. Instrumental analysis of texture was performed using TA.HDPlus (Stable Micro Systems, UK), and hardness and elasticity were calculated based on obtained TPA curves. Test was performed using blade set, with speed of 1 mm/s, until full cut through sample is evident. All samples were analyzed using 500x optical microscope. Statistical analysis of obtained data was performed using Statistica software package (Statsoft, USA).

RESULTS AND DISCUSSION

Drying time gradually drops with the increase of ultrasonic intensity, from 175 min for untreated samples to 80 min for samples treated with 100 % amplitude, as shown in figure 1. Using Tukey post hoc test it is determined that there are significant differences between drying times using various amplitudes, and $p_{100}>p_{80}>p_{60}>p_{40}>p_{20}$. It is evident that drying time is significantly shortened using ultrasound pretreatment, with minimal drying time achieved by using full power. This can be explained by influence of cavitation bubbles on cell walls and structure matrix of pear. Increase in pore dimension and creation of new microscopic channels allows for faster internal transport of water to the surface. Such enhancing of water diffusivity can shorten drying time, as presented by Azoubel et al (2010), but in turn can also have significant impact on textural properties. As shortening of drying time is less important than retaining of consumer acceptable properties, optimal ultrasonic amplitude was in the range from 20 to 60 %.

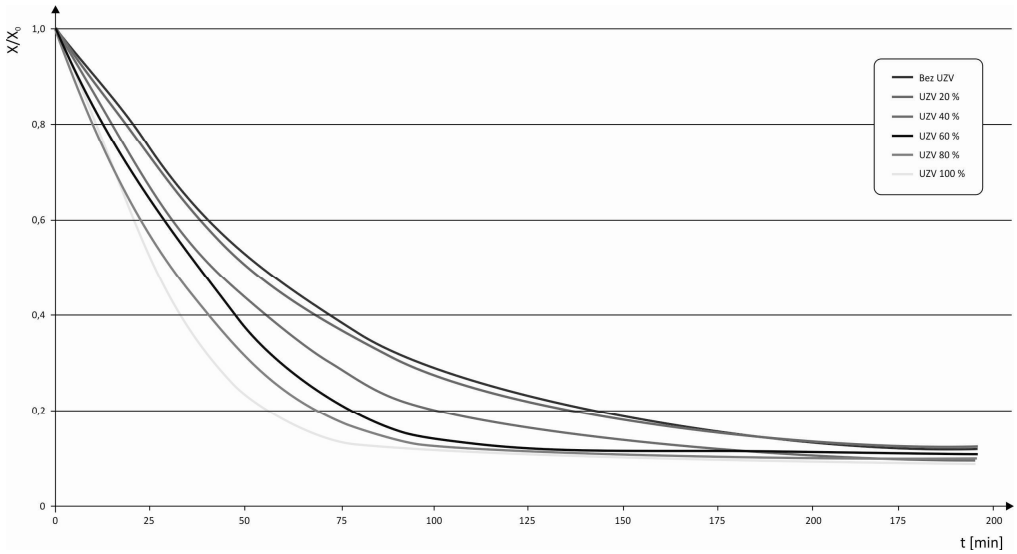

Figure 1. Drying time of untreated sample and samples treated using 2, 40, 60, 80 and 100 % of maximal ultrasonic power.

Hardness and elasticity of samples were also changing with the increases in ultrasonic intensity. This is main reason why samples treated with two of highest intensities have unacceptable sensory properties, and only those treated using amplitudes of 60 % and below appear to be acceptable from consumer perspective. Hardness, elasticity and work needed for the first bite in the sample, as shown in figures 2 and 3, increase with the increase in ultrasonic amplitude. Changes in matrix can be best seen in the figure 4. It is evident that cavitation bubbles damage cellular structure of treated samples, which confirms significant changes in textural properties.

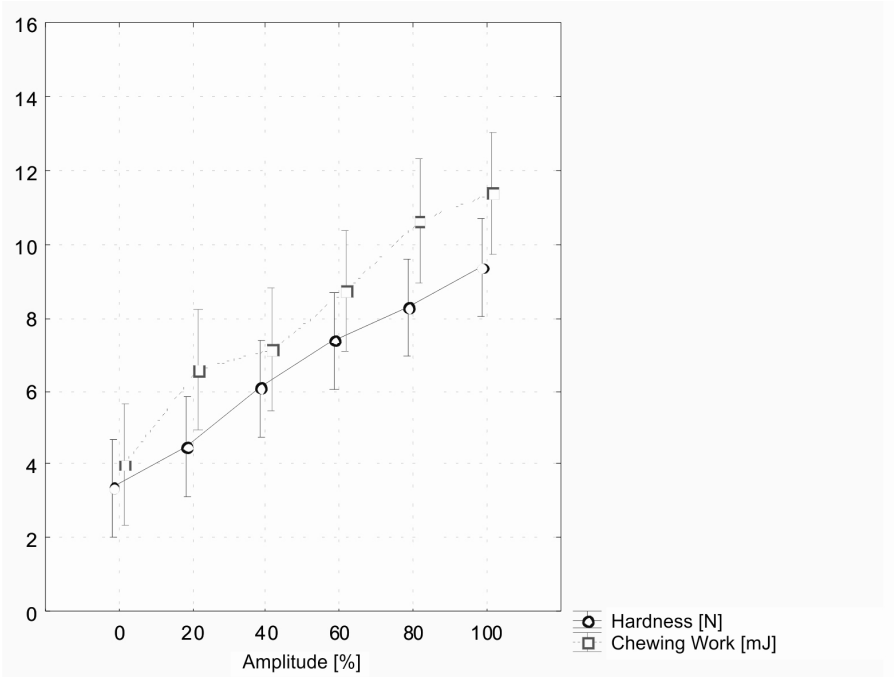

Figure 2. Influence of ultrasonic amplitude on hardness and chewing work of samples, using MANOVA method.

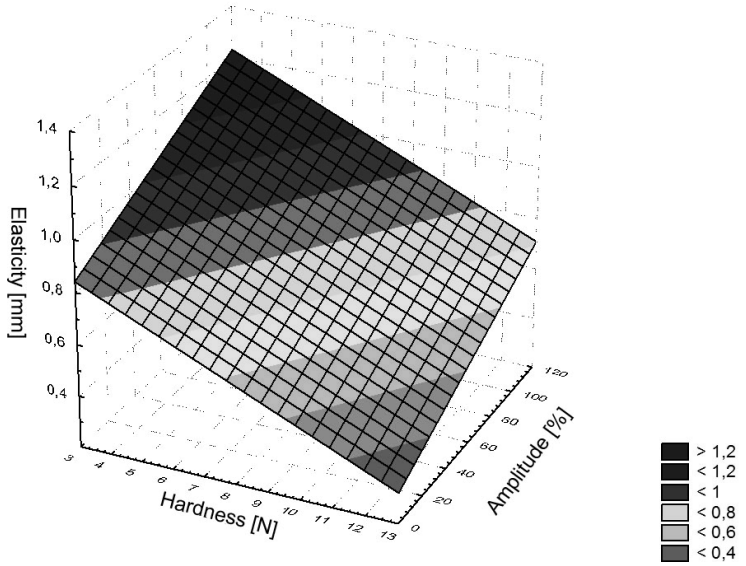

Figure 3. Influence of amplitude on elasticity and hardness of samples.

As main goal of this research is optimizing of process parameters (primarily ultrasonic amplitude) to minimize texture damage and drying time, it is evident that 100 % of amplitude leads to minimal drying time. However, as only 20, 40 and 60 % of amplitude satisfy second condition for minimizing of texture changes, optimal

ultrasound parameters for drying of fruits are 60 % of maximal power (240 W) during 4 minutes. Further increase in processing time would lead to more damages to structure.
Based on the obtained results, ultrasonic pre-treatment can be excellent addition to the conventional drying processes such as infrared or air drying. While texture changes must be minimized, drying time is still significantly shorter compared to drying of untreated samples. With calculation of energy consumption for the ultrasonic treatment, and energy savings obtained by shorter drying times, this kind of treatment can produce significant reduction in processing costs.

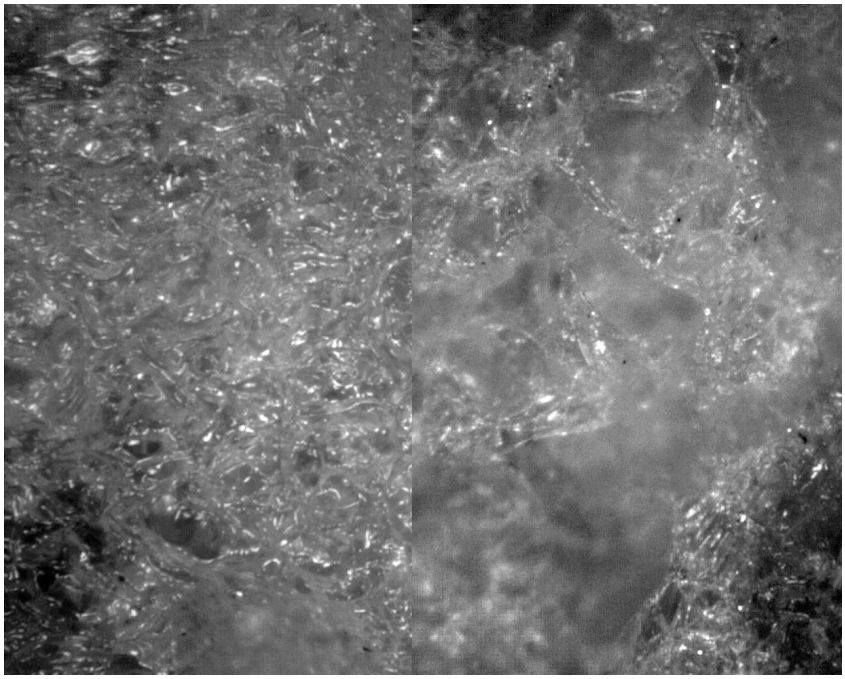

Figure 4. Side-by-side microscopic images of untreated sample, and sample treated with maximal intensity.

CONCLUSIONS

Ultrasonic pretreatment significantly shorten drying time, from 175 min (untreated) to 80 min (treated using full power). All amplitudes tested had influence on drying time, while maximal power consequently had maximal influence. At the same time, maximal power had largest influence on the hardness, elasticity and chewing work of samples. Optimal ultrasonic intensity was 60 Wcm^{-1} during 4 minutes, as this substantially shortens drying time, while retaining changes in the measured textural parameters in acceptable range. Loss of hardness and elasticity at larger intensities was too large, and despite shortest drying times, such samples were deemed unacceptable from consumer perspective. This research shows that ultrasonic pre-treatment is viable option for enhancing of drying process, as there is possibility for time and energy savings, as well as retaining of nutritional quality of raw fruits.

ABSTRACT

ABSTRACT: Particles size has important role as parameter for control and evaluation of food processing and quality characteristic of final product. In sugar cane or sugar beet processing the most important influences of particle size are evident in phase of juice purification and crystallization. Particle size of calcium carbonate has great effect to the nonsucrose compounds removal from raw juice and filterability of juices in the juice purification. Crystallization is the final stage in production of organic or nonorganic sugar.
The paper has dealt with applications of Coulter Counter technique in evaluation of crystallisation process in technical sucrose solutions under laboratory conditions. The crystal growth rate was determined by measuring crystal size and crystal size distribution. The Rosin-Rammler-Sperling-Bennet function was applied for evaluation of characteristic size and uniformity of crystals.
In sugar industry determination of crystal size distribution is applied in order to optimize production of crystal footing, evaporation and cooling crystallisation. Crystal size distribution has a significant influence on the processes of centrifugation, drying, sifting, storing and on the quality characteristics of the final product. The aim of crystallization is to produce a maximum amount of crystal sugar, sucrose crystals of best possible quality without any twin crystals, conglomerates or very fine grain and reduce energy consumption.
Key words: *nonsucrose compounds, sucrose crystallization, crystal size distribution, growrh rate dispersion*

INTRODUCTION

Sugar industry is one of the largest industries in the world, and crystallization is an important stage which determines the yield and quality of the sugar from sugar beet and sugar cane. White sugar, produced in modern sugar factory, easily meets the quality criteria according to the EU sugar market regime. Some industrial sugar consumers introduce additional requirements as content of insoluble matter, turbidity, creating floc, crystal mean size and size distribution, shape of crystals etc. (Clarke, 1995). Sugar is primarily a food, but it is also included in the formulation of many pharmaceuticals.
The kinetics of the growth of sucrose crystals usually represents reaction occuring on the surface of the different crystal faces and at the crystal-solution interface. Supersaturation is the driving force of the crystallization. It is known that minor changes in the supersaturation, temperature, the conditions of seeding, the hydrodynamic conditions, the amount of the crystals and purity of technical sucrose solution can have significant impact on the crystal growth kinetics. Nonsucroses can affect to the sucrose solubility, growth kinetics, morphology and quality of the crystals. The presence of nonsucroses inside the crystal lattice has important effect

on the sugar quality especially as colour, ash and water content. The various faces of sucrose crystal have different growth rates and the most rapid faces include mother liquor more rapidly than the others.
Two kinds of methods have application for measuring sucrose crystal growth rate: single and polycrystals (Hook, 1984). Single method is convenient and rapid but suffers from a variability of individual crystals growth (Bubnik et al.,1992; Sgualdino et al., 2005). Polycrystalline method is based on the measuring the size distribution of a crystals crop and can be adapted to simulate actual production process (Gros et al., 2001; Grbić, 2009).
The current work was targeted towards understanding sucrose cooling crystallization from technical solutions, which composition are similar to those in industrial crystallization of sugar beet processing.

MATERIAL AND METHODS

Growth rates of sucrose crystals were measured in presence of nonsucrose compounds, using $2.6 \cdot 10^{-3}$ m^3 batch cooling crystallizer at constant agitation speed. Concentration of nonsucrose compounds was increased by mixing different amounts of sugar beet molasses with beet white sugar and pure water. Technical sucrose solutions were kept for one hour undersaturated at 80 ℃ before cooling. Saturation state and point of seeding were calculated according to dry substance and sucrose content (Šušić et al., 1995). In analogy to the practice in industry, fixed amount of slurry was intoduced in the point of seeding. It was used in the amount of 1.0 % w/w. Slurry was prepared by wet-milling a sugar/isopropanol suspension in a ball mill. The experiments continued by lowering the solution temperature, following defined programme during the period of 3 hours. The supersaturation was reached by decreasing sucrose solubility.
The analyses of solutions were carried out according to the methods published in the Laboratory Handbook (Milić et al., 1992). The dry substance was measured by a digital automatic refractometer (ATR-ST plus, Schmidt + Haensch, Germany). The sucrose content was determined polarimetrically by a digital automatic saccharometer (Saccharomat IV, Schmidt + Haensch, Germany).
Crystal size distributions in slurry and solutions were obtained by off-line automated technique (Coulter Counter, model ZM, England). Coluter Counter determined number or volume distribution by direct crystal counting based on electrically conductivity measurement (Grbić et al., 2007). For evaluation of characteristic size and uniformity of crystals, the Rosin-Rammler-Sperling-Bennet (RRSB) function was applied (ICUMSA, 2003).

The crystal growth rate was determined as mass growth rate:

$$R_G = dm / A \cdot dt \quad (1)$$

Where is: R_G – mass growth rate, m – crystal mass (mg), A – crystal surface area (m^2), t – time (min).

RESULTS AND DISCUSSION

Parameters of technical sucrose solutions are presented in Table 1. The purity values in range from 90.55 to 92.30 % were based on the characteristics of the thick juice. Concentration of nonsucrose compounds ranged from 7.70 to 9.45 g/100DS. The points of solutions seeding showed the metastable zone of supersaturation.

Table 1. Parameters of technical sucrose solutions quality

Parameters	Experiments			
	A	B	C	D
Dry substance (°Bx)	80.40	80.00	80.40	80.00
Purity (%)	90.55	91.72	92.08	92.30
Nonsucrose compounds (g/100DS)	9.45	8.27	7.91	7.70
Seeding temperature (°C)	67	70	69	69
Seeding supersaturation	1.20	1.14	1.18	1.16
Final temperature (°C)	27	30	28	31

Figure 1 presents particles size distribution of slurry which was applied for the initial crystals formation. Diameters were divided in the intervals and the number of particles was counted in every interval (dual treshold technique). Mean particles size d_{RRSB} was 20 µm and uniformity coefficient 4.2.

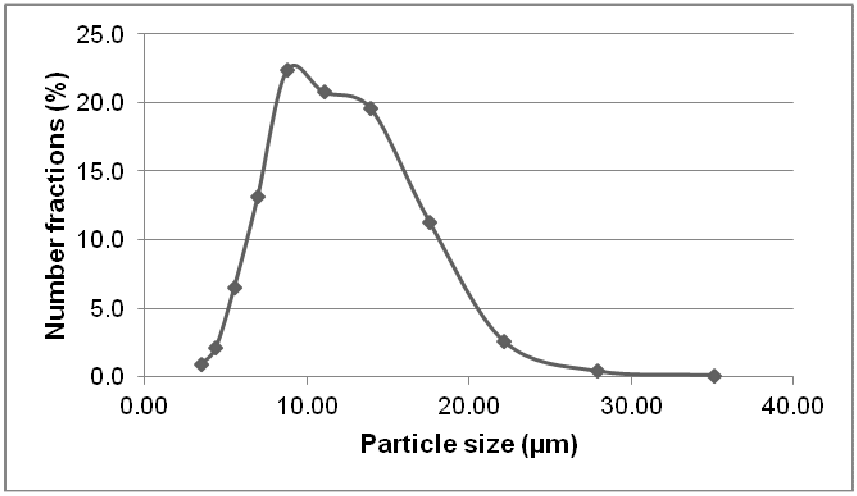

Figure 1**.** Histogram for number distribution of particles size in slurry

The changes of sucrose crystal mass growth rate and mean size d_{RRSB} as function of solutions purity are present in Figure 2.

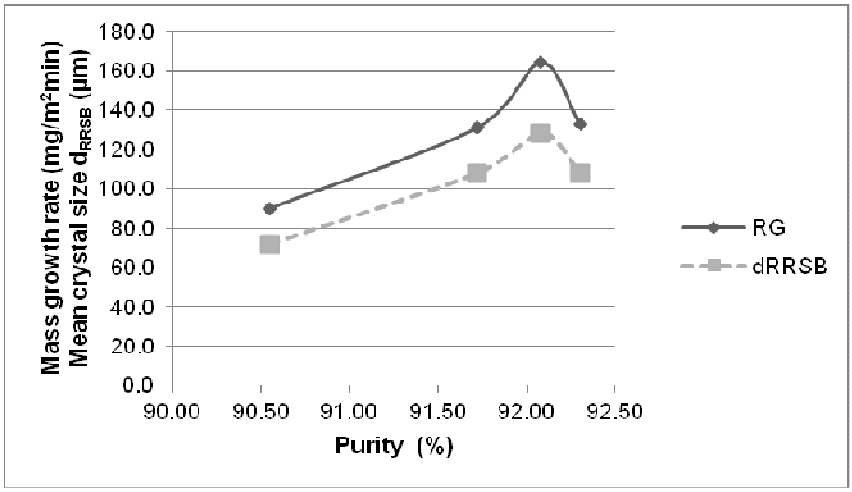

Figure 2. Sucrose crystal mass growth rate and mean size as function of solutions purity

The highest values were reached with solution purity of 92.08 %. Further increasing of purity decreased mass growth rate and mean size in the same conditions of experiments, because of secondary nucleation. In case of secondary nucleation a part of sucrose excess from supersaturation solution is also used for formation and growth of new nuclei and only the rest of sucrose excess is incorporated into the

crystal lattice originating from the slurry. Mechanism of the nonsucrose compounds influence on crystal growth rate is complex and should be understood as a result of their impact on sucrose solubility, diffusion of sucrose in solution and on surface reaction (Sgualdino et al., 1996).
The crystal size distribution is determined by number and mass distribution, mean crystal size, uniformity coefficient, spread of crystal sizes. In the crystallizer, the crystal size distribution is formed by a complex series of strongly interrelated processes referred to as the mechanism of the crystal size distribution formation. Studies on crystal growth dispersion, secondary nucleation and agglomeration can be made from crystal size distribution. Mass distributions of sucrose crystal size for different systems are present in Figure 3. By increasing of solutions purity from 90.55 to 92.08 % maximums of mass distributions were shifted to higher values of crystal size. The next increasing of purity over 92.08 % led to decreasing of crystal size for mass distribution maximum. Increase of distributions spread were obtained from higher purity solutions. The uniformity coefficients of crystal were very good in all experiments, and varied from 5.0 to 5.8.

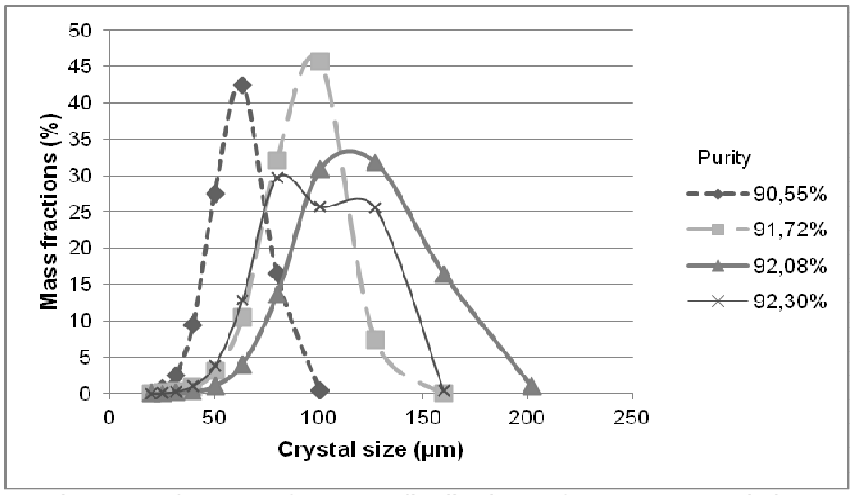

Figure 3. Histogram for mass distributions of sucrose crystal size

The change of number fraction of crystals smaller than 50 µm as function of solutions purity is presented in Table 2.

Table 2. Number fraction smaller than 50 µm in sucrose crystal mass of technical solutions

Purity (%)	90.55	91.72	92.08	92.30
Number fraction of crystal size < 50 µm	70.24	21.83	17.64	31.28

Growth rate dispersion is an important factor that influences crystal size distribution. Small crystals grow slowly than larger in the same hydrodinamic conditions, because the higher supersaturation is required for their growth. Figure 4 presents mass growth rate of particular fractions in the experiment C. The results shows that growth rates increase with crystal size (Martins and Rocha, 2007).

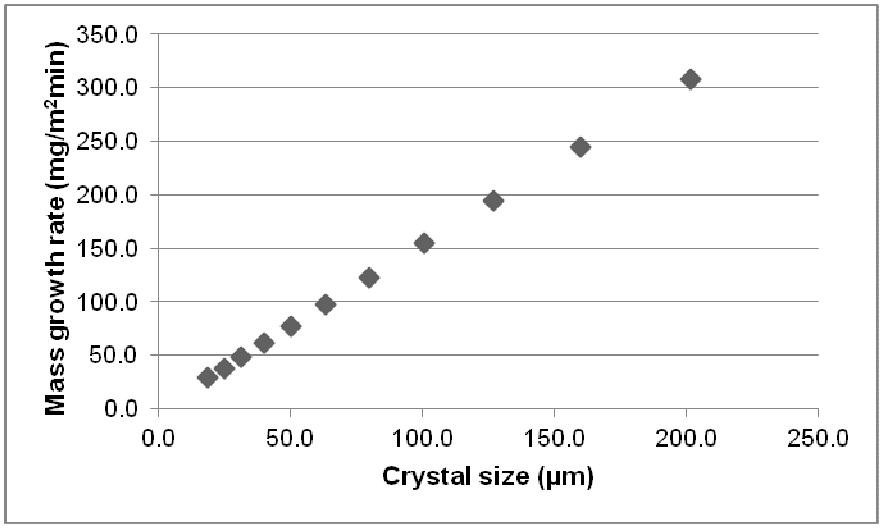

Figure 4. Mass growth rate of sucrose for different crystal sizes in the solution of 92.08 % purity

In all experiments, crystal size distributions during crystal growth satisfied the Rosin-Rammler-Sperling-Bennet (RRSB) function.

CONCLUSIONS

Based on the results of this study , the following conclusions can be made:

- Nonsucrose compounds led to reduction of growth kinetics and mean crystal size of sucrose.
- The highest values of sucrose crystal growth rate and mean size were reached with solution purity of 92.08 %. Further increasing of purity decreased mass growth rate and mean size in the same conditions of experiments, because of secondary nucleation.
- Maximums of mass distributions were shifted to higher values of crystal size by increasing of solutions purity from 90.55 to 92.08 % The next increasing of purity over 92.08 % led to decreasing of crystal size for mass distribution maximum.
- Small crystals grew slowly than larger. Dispersion of growth rate is one of the important factors that influenced the crystal size distribution.
- Uniformity coefficients from 5.0 to 5.8 presents very good values, that pointed to satisfied conditions of cooling crystallization.
- Crystal size distributions during crystal growth satisfied the Rosin-Rammler-Sperling-Bennet (RRSB) function.
- Coulter Counter technique is important tool to describe the crystal size distribution during crystallization and can contribute to a better understanding of the process.

ABSTRACT: Osmotic dehydration is a water removal process involving soaking food in a hypertonic solution. Process of osmotic dehydration is typically used as a pre-treatment for many processes in order to improve the sensory and functional properties of food, without a significant decrease in nutritive values of the product. This paper analyzes the effects of different hypertonic solutions, after the process of osmotic dehydration of pork meat under atmospheric pressure at room temperature of 22^{o}C, to determine the nutritive quality of the final product. As osmotic agents sugar beet molasses and aqueous solution of sodium chloride and sucrose and sugar beet molasses in the ratio 1:1, were used. The ratio of raw material and hypertonic solution was 1:5, and immersion time was set to 5 hours. Fundamental chemical composition was determined by *SRPS ISO* methods, and mineral content was determined using AAS method. The results indicate that during the process of dehydration significant changes occur in water loss and growth dry matter content. The initial dry matter content of meat was 26.21% and after the immersion in molasses increases to 68.52%, while in aqueous solution of sodium chloride and sucrose and sugar beet molasses in the ratio 1:1 increases to 63.70%. Also, after the process of dehydration meat was enriched in some minerals Na, K, Ca and Fe, while the content of Mg was slightly reduced. Based on the results, it can be concluded that the applied solutions significantly improve quality of semi-products and that osmotic dehydration represent a suitable pre-treatment for meat drying. Water loss was slightly higher when sugar beet molasses was used as osmotic agent. Using sugar beet molasses as an alternative medium for the process of osmotic dehydration opens new opportunities for innovation in dehydrated products.
Key words: *osmotic dehydration, pork meat, osmotic solution, molasses*

INTRODUCTION

Osmotic dehydration is a useful process for obtaining products with moderate moisture content, which has been in recent years used in the preparation of different types of meat product. In the case of meat, water removal is combined with mild salting and liquid smoking to effectively replace long and costly salting/smoking operations (Mitrakas et al., 2008).It is frequently used as a pre-tretman (preparation) for many processes to improve sensory and functional properties of food without significantly altering the nutritional composition of the product (Beuchat, 1996). According to Rastogi et al., osmotic dehydration is becoming popular as pre-treatment in the processing of foods specifically because of the advantages of energy savings (occurs without a change in physical state of water) (Tortoe et al., 2007).
As hypertonic solutions commonly are used combined solutions of sodium chloride and sucrose with different concentration levels and ratios, and driving force for the water removal process is concentration gradient between the solution and the fluid inside the cell. During the osmotic dehydration kinetics of water removal depends

primarily on the type of osmotic agent, its concentration and temperature of osmotic solution, and the size of the matrix (Khan et al., 2011).
Osmotic dehydration is the most intense at the beginning of the process, as a result of the major difference in osmotic pressure between the osmotic solution and cell fluid of dehydrated material and a small mass transfer resistance (Salvatori et al., 1999; Mazza, 1983). Traditionally, meat was considered a highly nutritious food (Higgs, 2000). Meat is an important source of high biologically valued protein, macro and micro elements, vitamins B and vitamin D (Lombardi et al., 2005).
Treatment of soaking meat in a concentrated solution of salt/sugar provides great dehydration of product, allowing the elimination of the operation of salting and dehydration, which is commonly practiced in traditional meat processing, limiting the immersion of high salt content in muscle tissue, which causes a high salt content in the final product. Moreover, the presence of another solution besides salt, such as sucrose and/or sugar beet molasses maintained a high potential for achieving high dry matter content, or significant loss of water. At the same time large quantities of salt impregnation in muscle tissue, are interfered by the presence of sucrose. Sucrose has the “barrier effect”, forming a layer on the periphery of the product which is caused by difference in the transport of water and solutes in meat. The barrier effect is stronger if a high molecular weight sugar is being used. (Santchurn et al., 2007).
The aim of this study was to investigate the possibilities and effects of concentrated solution sodium chloride/sucrose/molasses and pure sugar beet molasses as two hypertonic solutions for osmotic dehydration on the nutritional value of fresh pork.

MATERIAL AND METHODS

For the experiment, fresh pork meat from shoulder blade, without skin, bones, fat or connective tissue, was purchased at local market 48 hours after slaughter. For the preparation of osmotic solutions were used commercially available sodium chloride and sucrose, and sugar beet molasses from sugar factory Bač.
The meat, from which the remains of fat and connective tissue were removed, was cut into cubes, dimension of nearly 1x1x1cm, using a sharp knife. After grinding, the samples were immersed in hypertonic solution R_1 (sugar beet molasses) and R_2 solution (NaCl + sucrose+ sugar beet molasses in the ratio 1:1).
The ratio of raw material and hypertonic solution was 1:5, and the immersion time of 5 hours. Osmotic dehydration was carried out at atmospheric pressure and temperature of 22℃. After the treatment, samples were taken out from osmotic solutions to be lightly washed with water and gently blotted with absorbent paper to remove excessive water.
The basic chemical composition of fresh and dehydrated meat was determined by examining:
-Moisture content (dry matter*)* (SRPS ISO 1442, 1997),
-Protein-nitrogen content (TruSpec CHN(S), LECO, metod AOAC 992.15.)
-Free fat content (JUS ISO 1443, 1997)
-Chloride content (SRPS ISO 1841-1,1999).
-Total phosphorus content (SRPS:ISO 1443,1997)
-Sugar content by Luff-Schoorl-u (Baras et al.,1983)
-Metal content (AAS- Manuals of Food Quality Control, 2. Additives Contaminents Techniques. FAO Food and Nutrition Paper, Rome, 1980.)

RESULTS AND DISCUSSION

Table 1 provides an overview of the general chemical composition of sugar beet molasses and sodium chloride, sucrose and sugar beet molasses solutions, which

were used in this experiment. The results of the basic chemical composition of fresh pork meat from shoulder blade are shown in Table 2.

Table 1. Chemical characteristics of sugar beet molasses (R_1) and the mixture solution (sodium chloride, sucrose and sugar beet molasses (R_2)

Characteristics	Sugar beet molasses- R_1	mixture solution R_2

Results are given as mean ± standard deviation (n = 3)

Based on the results of tables 2 and 3, the value of dry matter in dehydrated meat is increased, indicating that there was a diffusion of sucrose and other nutrients from

the solution R_1 and R_2 in to the flesh. The ratio of water loss and solid gain is an indicator of osmotic dehydration efficiency. The increase in dry matter content of fresh meat from 26.21% after dehydration was two and a half times in the meat samples M_1 (68.52%) dehydrated in molasses. Smaller increase in dry matter content (63.70%) was obtained in the meat samples dehydrated in osmotic solution R_2. Since the water loss is affected linearly by the temperature of osmotic solution, working temperature was set to 22℃, which pursued the redu ced viscosity of solution, primarily sugar beet molasses and facilitating the penetration of substances into the muscle tissue. Molasses is a poly component system and has a high density; thereby the diffusion of molasses components in muscle tissue is more difficult at lower temperatures.

By increasing the dry matter content an increase in the share of total protein and fat occurred in dehydrated meat. Protein content in meat M_1 reached 36.60% and 32.60% in M2, which helped to preserve the most important nutritional component of the meat. As for sugar, dehydrated meat has a higher content of both sucrose and invert sugar comparing fresh meat, regardless of the type of solution for dehydration. The increase in sugar content was moderate and ranged from 6.68% to 7.81% for sucrose and from 7.04% to 8.23% for invert in dehydrated meat M_1 and M_2. The amount of NaCl in meat after osmotic dehydration in R_1 was 3.57%. Since sucrose is a compound that is normally present in animal tissue, the permeability of sucrose in the muscle cell may be lower compared to NaCl (Vivanco et al., 2004). Rapid formation of a concentrated sugar solution layer on the surface of meat as well as faster impregnation salt than sugar can be explained by a lower molecular weight of salt and greater potential for mass transfer (Santchurn et al., 2007).

Sugar beet molasses represents a significant source of many minerals, especially potassium, calcium, iron and magnesium. Particularly significant is the fact that all the mineral components in the molasses are in dissolved state and the potassium is in much greater quantities than all other cations with a share of about 75% (Šušić et al., 1989). Osmotic dehydration of pork meat M_1 in sugar beet molasses R_1 lead to significant increase of K content from 234mg/100g to 1307 mg/100g, while in samples M_2 dehydrated in solution (salt/sugar/molasses) R_2, content of K was 508 mg/kg. After five hours of immersion content of Na increased five times 5 in meat M_1, and ten times in meat M_2. Increase of Ca is less expressed in sample M_1 36mg/100g compared to M_2 113mg/100g. The content of Mg decreased slightly during the osmotic dehydration of meat in a solution of molasses R_1, while larger losses were obtained during immersion in R_2, where the Mg content of fresh meat from 28mg/100g decreased to13mg/100g. The increase of Fe content in final products M_1 and M_2 is about two times higher than the same quantity before dehydration, regardless of the type of hypertonic solution. This increase of Fe in dehydrated meat is very significant, if it is known that the absorption of Fe from meat is usually 15-20%, which significantly improved functional and nutritional value of meat as food (Higgs, 2000).

CONCLUSIONS

The most significant changes in water loss took place during osmotic dehydration. Rate of water loss was two and a half times in meat dehydrated in sugar beet molasses, a slightly lower in meat dehydrated in mixture solution (sodium chloride, sucrose and sugar beet molasses). Increasing dry matter increases concentration of total protein, fat, K, Na, Ca and Fe. The content of Mg decreased slightly during the osmotic dehydration of meat in both solutions.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR 31055 “Osmotska dehidratacija hrane-energetski i ekološki aspekti održive proizvodnje (Osmotic dehydration of food-energy and environmental aspects of sustainable production)”, financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT: Production of food with lower amount of common salt (sodium) is challenge for food industry. Particularly problematic is the production of dried meat with lower amount of common salt because these products are not preserved by high temperature.
In this paper is presented the microbial profile of dried pork produced with lower amount of salt during production and storage under vacuum conditions for 120 days. Total plate count is determined during processing, in the raw meat, after curing and on 14th, 21st and 28th day of production by standard method ISO 4833:2003. During storage under vacuum conditions on the 1st day, 60th day and 120th, count of halotolerant bacteria is determined using Manitol salty agar and count of lactic acid bacteria by standard method ISO 15214:1998.
Maximum total plate count was after curing, average 5.04 cfu/g and after that it is decreased up to the end of production, average 2.68 cfu/g. Average count of halotolerant bacteria was 2.19 cfu/g in the final product in superficial layer of meat and 1.41 cfu/g in inner layer of meat, but after 60 and 120 days of storage halotolerant bacteria were not presented. Lactic acid bacteria were presented only at the beginning of storage, 2.17 cfu/g in the superficial layer of meat and 1.98 cfu/g in the inner parts of dried meat. Maximum total plate count after curing is presented due to handling with meat and it is under positive influence of added salt.
Vacuum conditions had negative influence on presence of halotolerant and lactic acid bacteria which are not presented during longer storage, because of anaerobic conditions in the vacuum packing.
Key words: *microbial profile, dried pork, lower salt content*

INTRODUCTION

Common salt (NaCl) is an ingredient that has been used since ancient time for the preservation and flavouring of meat. Sodium chloride contributes functional properties in meat products. It activates proteins to increase hydration and water holding capacity; it increases the binding properties of proteins to improve the texture; it increases viscosity of meat batters, facilitating the incorporation of fat to form stable batters; and it has essential flavouring and antimicrobial effects (Terell, 1983). In the 20th century, human nutrition becomes mostly based on consumption of meat products and snacks that contain high content of sodium chloride. Even sodium chloride is GRAS substance (generally recognized as safe), excessive daily intake of sodium has linked to essential hypertension and correlated with mortality and risk of coronary heart diseases, independent of other cardiovascular risks, including hypertension (Tuomilehto et al., 2001). Large amount of sodium originated from meat products (Wirth, 1991).
Present trends in nutrition is reducing the sodium content in meat products, as reported by Ruusunen and Puolanne (2005) and Desmond (2006), can be achieved in the following way: (1) by reducing the amount of sodium chloride added (Sofos, 1983; Lilić, 2000); (2) by substituting part of NaCl with other salts (Sofos, 1983; Terell, 1983; Guàrdia et al., 2006; Lilić et al., 2008).; (3) by using flavour/aroma enhancers and masking agents (Desmond, 2006); (4) combination of mentioned procedures (Sofos, 1983; Terell, 1983); (5) adding of spice herbs and spice extracts to meat products (Lilić

and MatekaloSverak, 2007; Matekalo-Sverak et al., 2007); (6) optimisation of the physical form of salt (Angus et al., 2005); and (7) alternative process techniques (Claus and Sørheim, 2006).
The aim of this paper was to investigate microflora of dried pork produced with lower content of sodium chloride.

MATERIAL AND METHODS

The material in this paper was pork (*m. longissimus dorsi pars thoracis*) originated from white pigs, six months old, with live average weight of 100 kg. After chilling the meat was treated with following mixture: 950 g of nitrite curing salt and 50 g of sucrose, in the amount of 300 g per 10 kg of meat. Curing lasted for 7 days and after that meat was smoked for next 7 days. Process of drying and ripening lasted for 14 days. Final products were packed in PA/PE bags under vacuum conditions and stored at room temperature for 120 days.
Samples for microbial examination were taken on the first day of production (raw meat), after curing (7^{th} day of production) and on 14^{th}, 21^{st} and 28^{th} day of production (final product). In these samples were determined the total plate count by standard method ISO 4833:2003. Samples were taken also on the 60^{th} and 120^{th} days of storage under vacuum conditions in the aim of determination of number of halotolerant bacteria using Manitol salty agar and lactic acid bacteria count that determined by standard method ISO 15214:1998.
Results of microbiological examinations are presented as average count of bacteria (log cfu/g) with standard deviation.
Sensory characteristics of dried meat were evaluated by six trained assessors (SRPS ISO 6658:2002).

RESULTS AND DISCUSSION

The total plate count (aerobic mesophylic bacteria) during the production of dried pork is presented in Figure 1. Average number of aerobic mesophylic bacteria in raw meat was 3.99 ± 1.09 cfu/g in superficial layer of meat and 2.00 ± 0.57 cfu/g in inner part of meat. After curing total plate count increased up to 5.04 ± 0.86 cfu/g in superficial part and up to 2.16 ± 1.04 cfu/g in inner part of meat. Smoking had negative influence on aerobic mesophylic bacteria which average number was 3.18 ± 0.26 cfu/g in superficial and 1.92 ± 0.98 cfu/g inner part of meat. During drying and ripening the number of bacteria was also decreased up to 2.75 ± 0.19 cfu/g on 21^{st} day of production and 2.68 ± 0.30 cfu/g at the end of production in superficial layer of meat and 1.23 ± 0.87 cfu/g in inner part of meat on 21^{st} day of production, while these bacteria were not presented in inner parts of meat at the end of production. Obtained results are in accordance with results of Sinell (1977) who found 10^2-10^7 cfu/g and with results of Ockerman and Kuo (1982) which found 2.66-2.67 log cfu/g.

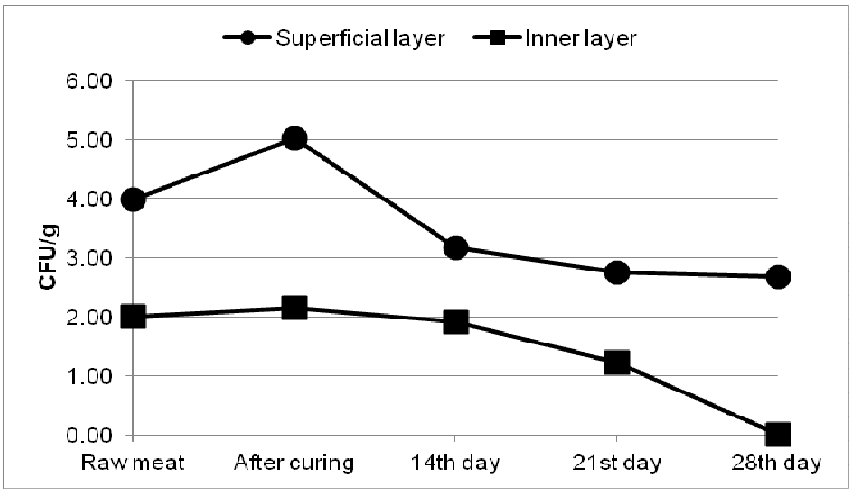

Figure 1. Total plate count in meat during production

Number of halotolerant and lactic acid bacteria is presented in Figure 2. Average number of halotolerant bacteria was 2.19 ± 0.18 cfu/g in the superficial layer of meat and 1.41 ± 1.00 cfu/g in inner part of meat, while average number of lactic acid bacteria was 2.17 ± 0.20 cfu/g in superficial layer of meat and 1.98 ± 0.33 cfu/g in inner part of meat. On 60th and 120th day of storage under vacuum conditions these bacteria were not determined. Halotolerant and lactic acid bacteria were not presented at 60th and 120th day of storage due to low amount of oxygen or total absence of oxygen under vacuum conditions. Obtained results for halotolerant bacteria are in accordance with results of Silla et al. (1990) that determined 10^2-10^6 cfu/g and with results cited by Giolitti et al. (1971) that found less than 500 cfu/g. Number of lactic acid bacteria in dried pork is 10^2-10^7 cfu/g according to results of Sinell (1977) and to results of Silla et al. (1990) that cited number of lactic acid bacteria up to 10^3 cfu/g in dry ham.

Molina et al. (1989) cited that microflora of dry ham consisted from *Pediococcus pentosaceus*, while other lactic acid bacteria are *Lactobacillus alimentarius*, *Lactobacillus curvatus* and *Lactobacillus casei* var. Rhamnosus and *Lactobacillus divergens*. Cornejo and Carracosa (1991) determined in 96% of all halotolerant bacteria belong to family *Micrococcaceae*. Both halotolerant and lactic acid bacteria have role in ripening and fermentation during the production of dried meat due to activity of lypolitic and proteolitic enzyme activity. Toldrá and Conceptión Aristoy (2010) cited that natural flora of dry ham is consisted from *L. sakei*, *L. curvatus* and *P. pentosaceus* but their number is less than 10^4 cfu/g.

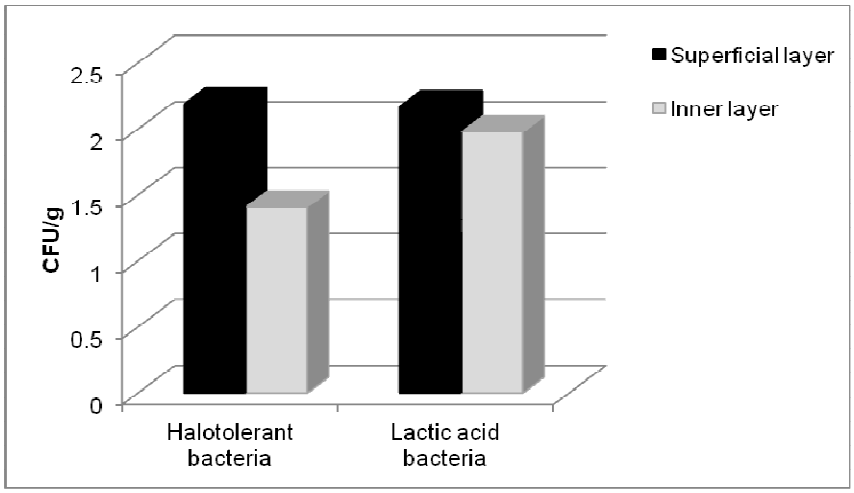

Figure 2. Halotolerant and lactic acid bacteria count in vacuum packed dried pork

CONCLUSIONS

Total plate count is higher in superficial layer of meat after curing that could be explained by meat handling during curing; but it decreased to the end of the production in both superficial and inner part, particularly in inner part it was not detectable at the end of production.
Halotolerant and lactic acid bacteria are presented in dried pork at the end of production, approximately 2 cfu/g for both groups of bacteria in the superficial layer of meat. In the inner part of meat, the number of halotolerant bacteria was average 1.41 cfu/g and number of lactic acid bacteria was 1.98 cfu/g.
Due to microaerophylic condition in the first period and anaerobic conditions in the next period of storage, halotolerant and lactic acid bacteria could not be detected in dried pork.

ABSTRACT: Colour is very important quality factor for fruit juices which affects consumers' preferences. Sour cherry juice colour is mainly due to the presence of anthocyanins. Fruit maceration with enzymes improves extraction of anthocyanins, while pasteurization can cause their degradation. Therefore, the aim of this study was to investigate the effect of different duration of the maceration and pasteurization on colour stability of cloudy Marasca juice. Sour cherries Marasca were used to produce cloudy juices on small scale equipment with hydraulic press.Processing included thawing (without depitting), maceration, pressing and pasteurization. Duration of maceration varyied (30-150 minutes) and juices were sampled after pressing and after pasteurization. Obtained juices were analyzed by colour measuring, total content of anthocyanins, phenols and antioxidant activity. All samples were sensory evaluated using Quantitative Descriptive Analysis. Duration of maceration and pasteurization had significant effect on colour parameters in Marasca cloudy juice. Anthocyanins were present in the highest concentrations in juices with 0.5 h of maceration. Furthermore, pasteurization affected positively on its amounts, as well as on the content of total phenols and antioxidant activity. Maceration enzymes treatment significantly affected taste attributes of Marasca cloudy juice. Maceration of 0.5h is sufficient for producing well coloured Marasca cloudy juice with good sensory attributes. Pasteurization doesn't negatively affect juice colour as well as the content anthocyanins, total phenols and antioxidant activity.
Key words: *sour cherry Marasca, juice, enzyme treatment, colour, anthocyanins, sensory evaluation*

INTRODUCTION

Sour cherry Marasca is an autochthonous Croatian cultivar, with great amount of biologically active compounds, high content of dry matter, dark red colour and intensive agreeable aroma (Pedisic *et al*., 2007, Levaj *et al*., 2010). Although Marasca sour cherry is fruit with great benefits and large number of processing possibilities, it is insufficiently used.Interestingly, sour cherry products have had an increased utilization in the food market in the past decade because of their potential health benefit (Khoo *et al.*, 2011; Kyrakosian *et al*., 2009). Belibağli and Dalgic (2007) mentioned extensively use of sour cherry juices in the food industry, as constituents of juices, jellies, marmalades, jams, wines beverages, etc. what generates a consumer market with increasing demand. Also, sour cherry juices are characterized by pronounced sweet-sour flavour which makes them very popular and preffered to other fruit juices by various customers. Marasca cherry is fruit suitable for processing into cloudy juice, containing more antioxidants and fibre than clear juices (Mieszczakowska-Frąc*et al.*, 2012). Anthocyanins are highly concentrated in the epidermal tissue of fruit and several studies conducted in recent years have shown that anthocyanins display a wide range of biological activities including antioxidant, anti-inflammatory, antimicrobial and anti-carcinogenic activities (Obón *et al.*, 2011). Process of juices separation from fruit cells in cloudy juice production is usually obtained by pressing and provides juices with nice colour, which is very important

quality factor and affects consumers preferences. Maceration of pulp with enzymes in juice production is widely used to enhance the yield of juice and to increase the contents of various compounds in the juice (Laaksonen *et al*., 2012; Pap *et al*., 2010). Its effectiveness depend on type of applied enzyme and treatment conditions (pectinolytic enzyme dose, maceration time, and reaction temperature). Most of commercial enzyme preparations contain pectinases, cellulases and hemicellulases in various ratio, which act in different way, but it is important that the enzyme doesn't degrade pectin completely, while pectin and other components of cell wall transferred to pressed juice contribute to cloudiness (Will and Dietrich, 2006; Mieszczakowska-Frąc*et al.*, 2012). To prolong shelf life of juices, pasteurization is the necessary and integral process in juice production and the thermal pasteurization is the most widely applied technique, successfully inactivating vegetative microorganisms and enzymes (Kimball, 1999). As the anthocyanins are found to be sensitive for higher processing temperature, pasteurization can cause colour degradation of sour cherry juices (Patras *et al.*, 2010). The objective of the present work was to investigate the effect of different duration of maceration and pasteurization on colour stability, chemical composition and sensory profile of cloudy sour cherry Marasca juices in order to elaborate suitable enzyme treatment to obtain juice with nice colour, health benefits and excellent sensorial characteristics.

MATERIAL AND METHODS

Juice production

Juices were produced from sour cherries Marasca grown near Zadar (Škabrnja). Fruits were harvested in June 2011, packed in polyethylene bags and kept at -18 ºC till juice production. After thawing overnight at +4 ºC and without depitting, samples were used to produce cloudy juices on small scale equipment with hydraulic press (Euclid Ltd., Croatia). Prior to pressing, fruits were warmed up in a water bath to the incubation temperature (48 ºC) and treated with Endozym Pectofruit PR (AEB group, Italy) in concentration of 40 µL/kg. Every half an hour, batch of 2 kg of sour cherries Marasca was excluded for pressing, concluding with 2.5 hour of maceration (juice code: 0.5, 1, 1.5, 2, 2.5). Control juice (0) was produced without pre-treatment. Juices were glass bottled after pressing and after pasteurization (85ºC/10 min) (juice code: 0P, 0.5P, 1P, 1.5P, 2P, 2.5P) and kept at -18 ºC until all analysis.

Methods

Soluble solids were determined by measuring the ºBrix (Atago refractometer, Japan). Total acidity (expressed as g malic acid/100 mL juice) and pH-value were determined in accordance with methods in literature (Tanner and Brunner, 1979).

Colour (CIE L*, a*, b*) analysis was performed using Konica Minolta CH-3500 D spectrophotometric colorimeter. Color of sour cherry juice was presented as L*, a*, b*, C* and H° values. C and H° values were calculat ed according to the formula $C^* = (a^{*2} + b^{*2})^{1/2}$, H° = arctan (b*/ a*) (Konica Minolta Tehnical Ins tructions, 1998).

The content of anthocyanins (TAC) in juices was determined by bisulfite bleaching method (Ough and Amerine, 1988). The molar absorption coefficient for cyanidin-3,5-diglucoside was used as a standard value. Results were expressed as mg of cyanidin-3,5-diglucoside equivalents (Cy-3,5-DG) per 1 mL of juice.Total phenols (TP) were extracted according to Coseteng and Lee (1987) and spectrofotometricaly determined using Folin-Ciocalteu colorimetric method (Ough and Amerine, 1988) and the results were expressed as mg gallic acid equivalent (GAE)/1 mL of juice.FRAP method was used for the antioxidant activity (AA) determination (Connor et al, 2002). FRAP values were calculated according to the calibration curve for trolox, and they were expressed as mmol of trolox equivalents (TE) per 1 mL of juice. All

spectrophotometric measurements were performed by UV-VIS spectrophotometer UV-Vis Unicam β.
All analyses were done in triplicate and data are presented as mean value.
The sensory evaluation (SE) of the juice samples was conducted using Quantitative Descriptive Analysis (QDA). The panel consisting of eight trained members evaluated juice samples according to the corresponding list of descriptive terms for colour (intensity), taste (sour, sweet, sour cherry taste, astringent, harmony taste, taste fullness), odour (sour cherry odour) and texture (viscosity, homogeneity). Attributes were rated on a 10-point intensity scale, in which 10 indicated the highest intensity of evaluated sensory attribute.The procedure was performed according to methods described in ISO 6564, ISO 8587, ISO 11036 and the reports of Bursać *et al.* (2007) and Bursać Kovačević *et al.* (2008) in a sensory laboratory equipped according to ISO 8589.

Statistical data analysis
All obtained results were subjected to statistical analysis using ANOVA (Statistica v. 10, Statsoft Inc, Tulsa, OK, USA) to investigate the statistical significance of maceration and pasteurization. Differences were considered significant at $p \leq 0.05$.
Principal component analysis (PCA) was applied for general assessment of similarity-dissimilarity of the evaluated sour cherry juice samples. Statistical analyses were gained by Statistica v. 10 (Statsoft Inc, Tulsa, OK, USA).

RESULTS AND DISCUSSION

Soluble solids, pH value and total acidity values (Table 1.) of control juice (0) were in accordance with previously reported results for fresh Marasca sour cherry by Pedisic *et al.* (2007). Generally, soluble solids increased with duration of maceration (24.40 – 29.95 ^{o}Brix). Pasteurized juices mostly had higher soluble solids than unpasteurized ones. According to ANOVA ($p \leq 0.05$) it was observed that the duration of maceration significantly effected on pH value ($F=7.95$, $p=0.02002$), which decreased with longer duration of maceration (3.51 – 3.36). Although, the total acidity values (2.0 – 2.50) showed opposite trend to pH values, maceration and pasteurization had no significant effect on juices total acidity or their soluble solids. ^{o}Brix/Acid ratio in all samples was in range of 11.4 – 12.5, which was similar to results in Pedisic *et al.* (2007) report (11.8) and higher in comparison to the results of Konopacka *et al.* (2009) for untreated sour cherry sample (9.3). The highest ratio was observed in 1.5 and 2 juices and higher ratio means more acceptable juice (Fellers *et al*., 1988.).

Table 1. Physico – chemical and colour parameters of Marasca juices

Juice code	pH	Soluble solids	Total acidity	°Brix/ Acid ratio	L* (light ness)	a* (red ness)	b* (yellow ness)	C* (chroma)	H° (hue angle)
		°Brix	g malic acid/100mL						
0	3.45	25.30	2.21	11.4	2.94	20.41	5.05	21.03	13.91
0P	3.51	24.40	2.00	12.2	1.80	12.47	3.05	12.84	13.76

2P	3.36	27.30	2.30	11.9	0.34	2.39	0.59	2.46	13.78
2,5	3.37	27.00	2.20	12.3	0.66	4.68	1.13	4.82	13.50
2,5P	3.36	29.95	2.50	12.0	0.26	1.81	0.45	1.87	13.88

Colour of Marasca juices were presented with parameters L*, a*, b*, C*, H°(Table 1). With increasing duration of maceration, a significantly decreasing trend in L*, a*, b* and C* values was observed in all samples. Decreased lightness (L*) in juice is mainly attributed to increased anthocyanin content as a result of enzyme treatment (Khandare *et al*., 2011), which was confirmed, in spite of falling direction of the line, with high correlation (r=0.83) between L* values and the amounts of anthocyanins in Marasca juices. The same correlation was obtained with a* and C* values. Expectedly, pasteurization caused colour degradation in obtained juices, while thermal treatment affected anthocyanins stability. Values of a* parameter, which represent the redness of Marasca juices, were almost double lower in pasteurized juices than in unpasteurized juices.

The results of total anthocyanins (TAC), total phenols (TP) and antioxidant activity (AA) of Marasca juices are shown in Figure 1. Enzyme treatment affected positively on TAC content, causing it's initially increase in all obtained juices. Among treated juices, TAC slightly decreased with duration of maceration. The highest value (2.654 mg cy-3,5-DG/mL) was obtained in sample exposed to 0.5 h of maceration. Pap *et al*. (2010) reported that enzymatic treatment resulted in the increase of anthocyanin and flavonol content of the black currant juice, what is similar to our results. According to ANOVA ($p \leq 0.05$), there were not significant effects of duration of maceration on TAC, opposite to pasteurization, which significantly affected on TAC in Marasca juices ($F=7.69$, $p=0.03924$). TAC content increased during pasteurization probably because all anthocyanins present in cloudness cells in unpasteurized juice might not react with bisulfite reagent, but after pasteurization they could be liberated in juice and could be more available for reaction. Total phenols (TP) and antioxidant activity (AA) results showed similar trend as TAC results. TP and AA amounts were the highest between 0.5 and 1.5h of maceration. Pasteurization had not caused their degradation. Correlation between TAC and AA was good (r=0.69), but there were no correlation between TP and AA. The enzyme treatment was more effective to TAC increase of Marasca juice samples than TP. The increase was about 20 - 40% in the TAC case, while the maximum TP increase was 15%.

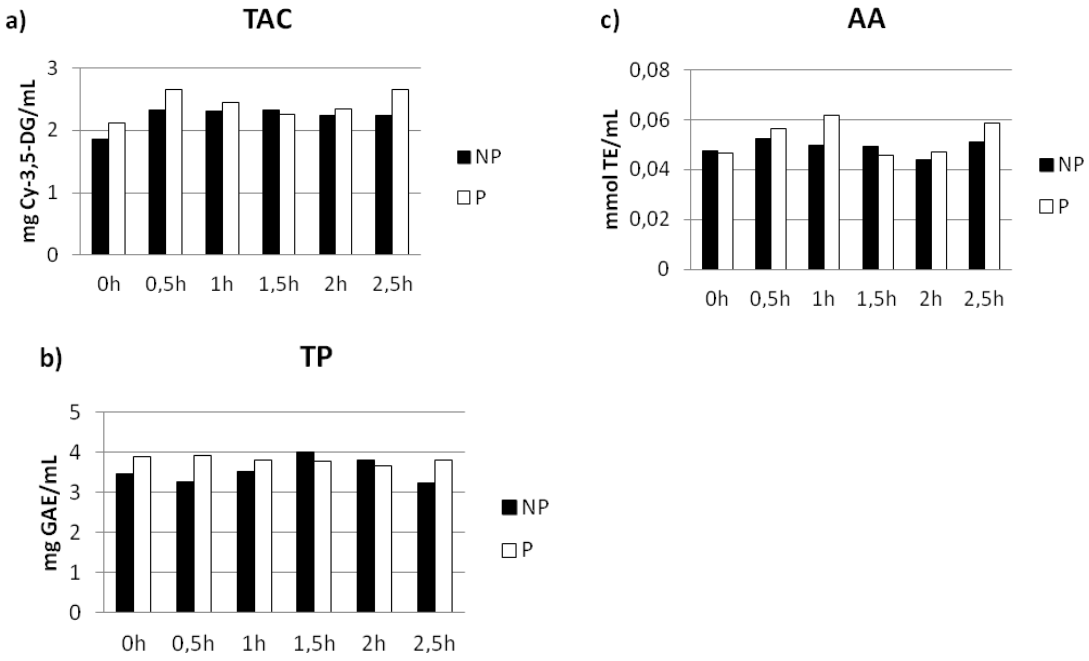

Figure 1. Total anthocyanins (TAC), total phenols (TP) and antioxidant activity (AA) of Marasca juices

Main observations of SE were that duration of maceration caused significantly increase of sweetness ($F=8.29$, $p=0.01831$) and decrease of sourness ($F=47.72$, $p=0.0.00032$) what is in accordance with increase of soluble solids ($r=0.68$) and ^{o}Brix/Acid ratio in juices (for unpasteurized juices $r=0.82$, pasteurized juices $r=0.65$). Additionaly, astringency ($F=6.30$, $p=0.03239$), and sour cherry odour ($F=13.64$, $p=0.00615$) of juices significantly decrease with duration of maceration. Pasteurization didn't negatively affect on sensory attributes, especially on colour intensity, which remained constant in all samples.

PCA was performed on all samples and variables to determine whether the different kinds of samples (sour cherry juices produced with or without different enzyme pre-treatment before and after pasteurization) had an effect on different sensory attributes. In this context, ten sensory attributes of sour cherry juice were the investigated variables.

The PCA results were two graphs (projections of variables, loading plots and cases-score plots), but the interpretation also mentioned eigenvalues of the correlation matrix, factor variable correlation (factor loadings) and case contributions, which are not discussed here.

The first two factors (PC1 and PC2) represented 64.2 % of the initial variability of the data. This was a good result, but some information might be hidden in the next factors. So, first and third factors PC3 (11.30 %) are also observed, but not shown here.

Figure 2. gives a visual representation of the differences between sour cherry juices produced with or without different enzyme pre-treatment before and after pasteurization. Regardless of pasteurization effect, sour cherry juices without enzyme treatment were positioned on the right side of the PC1 while sour cherry juices with enzyme treatment at 0.5, 1.0 and 1.5 h were positioned in the middle. Sour cherry juices with enzyme treatment at 2 and 2.5 h were positioned on the left side of the PC1, without considerable effect of pasteurization.

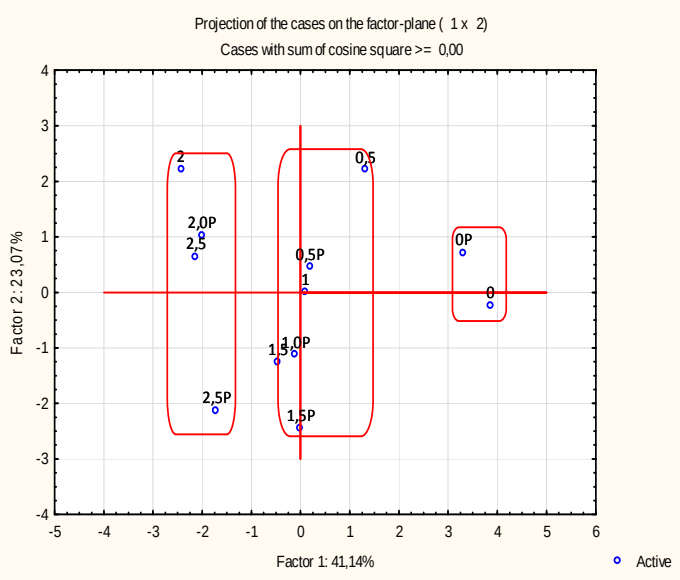

Figure 2. Principal component analysis (PC1 vs. PC2) of Marasca juices, taking into account all relevant variables. Sample labels for the score plot: P – samples with pasteurization, 0 – samples without enzyme treatment, 0.5, 1.0, 1.5, 2.0 and 2.5 – samples with duration time of maceration

Without effect of pasteurization, sour cherry juices without enzyme treatment were characterized by sensory variables such as sour taste, flavour fullness and sour cherry odour. These sensory attributes strongly correlated with the PC1. According to correlation with PC2 it can be assumed that sour cherry juices with enzyme treatment (1.5h and 2.5 h) and pasteurization are characterized by harmony taste. Due to correlation with PC3, it can be observed that sour cherry juice with enzyme treatment (0.5 h) and without pasteurization is characterized by homogeneity.

CONCLUSIONS

Presented study showed that conditions of enzyme treatment 0.5h/48 ºC prior to pressing remarkably improved the quality of sour cherry Marasca cloudy juice, resulting in enhanced anthocyanins and total phenolic content and their antioxidant activity, as well as nice colour and good sensory attributes. In addition, all mentioned components and attributes remained preserved after pasteurization (85 ^{o}C/10 min).

ABSTRACT: Plantain, a member of the banana family is an important staple food in the tropics. It is edible when fully ripe but in most cases it is cooked before consumption. Despite its abundance in the diet of many populations, quantitative and qualitative data on various starch fractions are scarce. *In vitro* digestibility of starch for processed and unprocessed samples was determined using pancreatic α-amylase and amyloglucosidase (Englyst & Englyst, 2004), and D-glucose was measured using glucose oxidase/peroxide reagent. Resistant starch in content in uncooked samples was 36.6±1.5g/100g and 62.7±2.9g/100g for ripe and unripe samples respectively. These values were reduced in the processes samples, with figures ranging between 3.5-6.5 g/100g in the ripe samples and 15.0 - 19.9 g/100g in the unripe samples. Slowly digestible starch (SDS) values were between 0.6 and 9.2 g/100g, while rapidly digestible starch (RDS) ranged between 25.6 – 56.6 g/100g for processed samples. Starch digestibility index (SDI), which is the ratio of the rapidly released glucose to the total starch content was lowest in the grilled samples (60.0). It is concluded that processing techniques affect the type and content of nutritional starches and therefore it will be essential to optimize processing techniques to maximize the RS and SDS which are known to have positive effect on postprandial glucose response.
Keywords: Plantain, resistant starch, slowly digestible starch, rapidly digestible starch, processing

INTRODUCTION

Plantain (*Musa AAB*), a member of the banana family, serves as a major staple food in many parts of the African subcontinent. Starch is the main component of plantains, reaching up to about 80% on dry weight basis, depending on the stage of ripeness. (Da Mota *et al*, 2000; Zhang *et al*, 2005). Plantain is low in protein but relatively high in carbohydrate, minerals, and vitamins (Southgate *et al*, 1969; Best *et al*, 1984). Ripe plantain contains 66% starch and 17% sugars compared with 5% starch and 80% sugars for bananas (Ketiku, 1973). A high level of dietary fibre and resistant starch in unripe plantain and banana flours was reported by Da Mota *et al*. (2000).
Plantain is cooked in different ways before consumption in Nigeria and is believed to have therapeutic properties. The results of a recent study supports the fact that green plantain has a favorable function in the dietary management of persistent diarrhoea in hospitalized children, in relation to diarrheal duration, weight gain and costs (Alvarez-Acost *et al.,* 2009).“A plantain-based diet can be designed for diabetic people based on its low glycaemic index.”(Mohapatra *et al*, 2009). In an ileostomy study by Englyst and Cummings (1986) on the digestion and absorption of banana carbohydrates, up to 90% of the starch could be accounted for in the effluent; also, complete recovery of non-starch polysaccharides (NSP) was attained. They inferred that the amount of banana starch not hydrolyzed and absorbed from the human small intestine and therefore passing into the colon may be up to eight times more than the NSP present in the food and depends on the state of ripeness of the fruit.
Although the physiological effect of RS has been investigated in relation to reduction of the glycemic and insulinemic responses to food. (Jenkins *et al*, 1987; Asp *et al*, 1996), recent studies have indicated that there are other nutritional starch fractions

which have an impact on glycemic response. Englyst *et al*, (1992) classified starch fractions into resistant starch (RS) which are undigested starch fractions, slowly digestible starch (SDS) which are completely but slowly digested and rapidly digestible starch (RDS) which are rapidly and completely digested (table 1). Studying the impact of processing on these nutritional fractions is quite important because during processing, starch undergoes many and varied significant changes which can alter both physical and chemical properties of food as well as the food form. Starch gelatinization, pasting and retrogradation which underlie starch functionality are the three most significant phenomena in starch applications and play a very significant role in determining starch digestibility and the relative quantities of starch fractions in processed foods (Liu, 2005).
In this work we aimed at determining the proportions of various starch fractions in ripe and unripe plantains and how theses are affected by various processing methods used before they are consumed. The cooking methods (boiling, boiling with skin, grilling and frying) used in this work reflect the major ways in which plantains are consumed in a typical African diet.

MATERIALS AND METHOD

Sample collection and preparation: Cultivars of ripe and unripe plantains were purchased from Leeds city market. Unripe plantains selected were full green (stage 2) while ripe plantains used were in fully ripe stage (yellow) in colour (stage 6) on the colour index scale (Aurorea, 2009). Both ripe and unripe plantains were divided into five portions each. The peel was removed from all five portions except portion two. Portion one was and boiled, two was boiled with the skin on, three was fried while four was grilled, five was used raw. Each process was conducted three times for the four cooking methods. The samples were cut into thin slices of 2mm in diameter, freeze dried and blended into fine flour and stored way in clean plastic containers for future analysis.

Cooking processes

Boiling: 150gram of sample was boiled in 300ml distilled water for 10 minutes in a clean pot with a lid.
Grilling: 150 gram of sample was grilled at high/medium heat in a grill for 30 minutes.
Frying: 150g portion of samples were cut into slices of 2mm in diameter and deep fried in vegetable cooking oil for approximately 5 minutes.
Digestion: Total starch (TS), free glucose (FG) and the different starch fractions – RDS (rapidly digestible starch), RS (resistant starch) and RAG (rapidly available glucose) were measured in triplicate by the method of Englyst and Englyst (2004). Efficiency of starch hydrolysis and speed of water bath were first standardized using wheat flour, cornflakes and raw potato starch. Briefly, samples were first incubated with pepsin for 30 minutes at 37℃ to disrupt starch –protein interactions. The contents of the various starch fractions were measured in samples after a further incubation with pancreatin and amyloglucosidase at 37℃ in capped tubes, horizontally immersed in a shaking water bath. The incubation tubes contained glass balls for disrupting the food particles and guar gum was added to standardize the viscosity of the incubation mixture. A value for rapidly available glucose (RAG) was obtained as the glucose released after 20 min (G20). A second measurement (G120) was obtained as glucose released after further 100 minutes incubation. A third measurement (total glucose; TG) was obtained by gelatinization of the starch in boiling water and treatment with 7M aqueous KOH under ice, followed by complete enzymatic hydrolysis with amyloglucosidase. Free glucose (FG) was also determined by treating the sample with acetate buffer and placing the tube in a water bath at 100℃ for 30 min.

A blank tube containing buffer, glass balls and guar gum was also included to correct for the glucose present in the enzyme mixture. Glucose was determined in all the samples using a glucose oxidase–peroxidase diagnostic kit from Megazyme international, Ireland.

Table 1: Nutritional classification of starch in foods (adapted from Englyst et al,1992)

STARCH TYPE	DEFINITION
Rapidly digestible starch (RDS)	The fraction of starch that is digested completely in the human small intestine, and is measured as the starch digested within 20 minutes of enzyme hydrolysis
Slowly digestible starch (SDS)	The fraction of starch that is digested completely in the human small intestine, but more slowly than RDS, and is measured as the starch digested between 20 and 120 minutes of enzyme hydrolysis
Resistant starch (RS)	The sum of starch and starch degradation products not digested in the human small intestine and is the difference between starch hydrolysed by 120min and total starch.

CALCULATIONS

RAG=G20
SAG=G120-G20
TS=TG x 0.9
RDS = (G20-FG) x 0.9
SDS = (G120-G20) X 0.9
RS = TS-SDS
SDI = RDS/TS X 100

RESULTS AND DISCUSSION

Table 2 presents the starch fractions obtained from raw and processed plantain as derived *in vitro* from the glucose fractions. Resistant starch (RS) content in uncooked samples was 36.6±1.1g/100g and 62.7±0.9g/100g for ripe and unripe samples respectively. RS reduced dramatically in the processed samples ranging between 3.5-6.5 g/100g in the ripe samples and 15.0 - 19.9 g/100g in the unripe samples. Dramatic changes observed in the levels of resistant starch in the processed samples is not unconnected with gelatinisation of starch granules which affects starch digestion, however, many other factors such as botanic origin, food form, composition, starch retrogradation and ripeness also have an impact on the levels of resistant starch (Bello-Perez, 2009, Englyst & Cummings, 1986).
Slowly digestible starch (SDS) values were between 0.6 and 9.2 g/100g and did not record the same trend as observed for the levels of resistant starch but varied between the ripe and unripe samples. SDS has been associated with the advantage of a slow increase in postprandial blood glucose levels and sustained blood glucose level over time as well as moderate impact on glycemic index, but the effect of hydrothermal treatment in the generation of slowly digestible starches are quite complex and its structural properties are still being studied (Lehmann, 2007).

TABLE 2: Glucose fractions and starch fractions for ripe and unripe plantain (g/100 dry weight basis)

sample	FG	RAG	SAG	RDS	SDS	RS	TS
Unripe raw	0.7^{d}±0.0	4.5^{g}±0.2	11.6^{a}±1.3	3.4^{f}±0.2	10.4^{a}±1.2	62.7^{a}±0.9	76.5^{bc}±0.1
Unripe boiled	0.5^{d}±0.0	58.5^{b}±1.5	7.0^{c}±1.5	52.2^{b}±1.3	6.3^{c}±1.3	16.7^{e}±2.6	75.2^{d}±0.1
Unripe boiled S	0.5^{d}±0.0	59.3^{b}±2.0	10.3^{ab}±1.3	52.9^{b}±1.8	9.2^{b}±1.1	15.0d^{e}±2.4	77.1^{b}±0.1
Unripe grilled	0.7^{d}±0.0	53.9^{c}±2.3	10.6^{b}±1.6	47.9^{c}±2.1	9.1^{ab}±1.4	19.3^{c}±2.2	76.2^{c}±0.2
Unripe fried	0.5^{d}±0.0	63.4^{a}±1.7	5.4^{d}±0.1	56.6^{a}±1.5	4.9^{d}±0.1	17.3^{cd}±1.6	78.7^{a}±0.0
Ripe raw	7.6^{a}±0.3	9.3^{t}±0.3	5.5^{d}±1.1	1.5^{t}±0.4	5.0^{d}±1.0	36.6^{b}±1.1	43.1^{e}±0.4
Ripe boiled	5.4^{c}±0.2	42.3^{d}±1.6	0.7^{f}±0.1	33.2^{d}±1.7	0.6^{f}±0.1	3.4^{g}±0.3	37.3^{f}±0.3
Ripe boiled S	5.2^{c}±0.3	40.4^{d}±2.5	3.2^{e}±0.3	31.7^{d}±2.4	2.9^{e}±0.3	3.4^{g}±0.5	38.0^{f}±1.1
Ripe grilled	5.7^{b}±0.3	35.1^{e}±2.5	3.8^{e}±0.3	26.5^{e}±1.6	3.4^{e}±0.2	6.5^{f}±0.4	36.4^{g}±0.8
Ripe fried	5.8^{b}±0.3	34.2^{e}±1.6	6.2^{cd}±0.4	25.6^{e}±1.7	5.5^{cd}±0.4	6.2^{f}±0.2	37.3^{f}±0.4

Values are means of triplicate
Boiled S- plantain boiled with skin
Values with different superscripts in the same column are significantly different while values with the same superscript in the same column are not significantly different (at 95% confidence level).

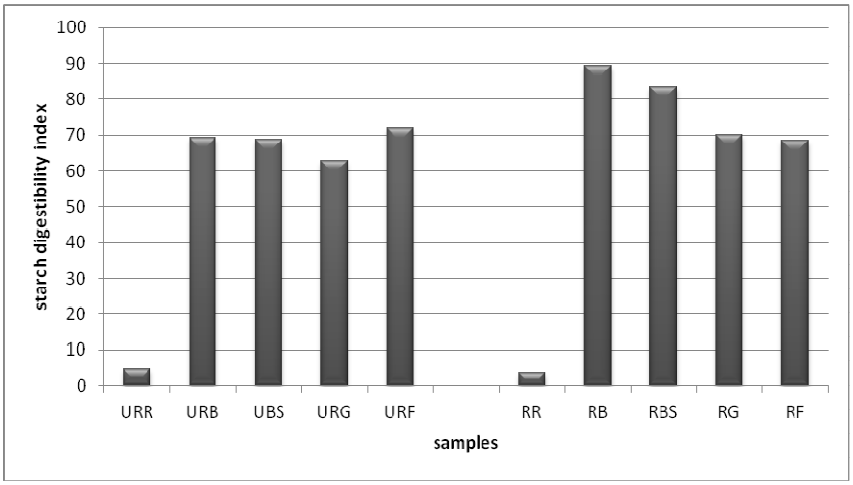

Figure 1 Effect of processing starch digestibility indices for ripe and unripe plantains
Abbreviations: UR-unripe, R-ripe, B-boiled, BS-boiled with skin, G-grilled, F-fried

Starch digestibility index (SDI), is the ratio of the rapidly digested starch (RDS) to the total starch content. Higher starch digestibility index (SDI) in processed samples (figure 1), which implies higher digestibility, may be an indication of the extent of starch gelatinization. Amongst the processed samples, the highest SDI value was recorded in the ripe boiled sample (90) while the lowest value was in the grilled unripe sample (60). This can be attributed to the dry-heat processing conditions of grilling and lower moisture involved during grilling as compared with boiling. Starch gelatinisation is dependent on several factors amongst which the starch-moisture content plays a significant role.

Rapidly available glucose (RAG) represents the quantity of glucose that is available quickly for absorption after a meal. The RAG is the sum of rapidly digestible starch (RDS) and free glucose present in the food. Hence, it is useful in predicting the glycemic response to carbohydrate foods as proposed by Englyst *et al* (1999).

CONCLUSION

Ripe plantain contained significantly lower amounts of all nutritional starches which further decreased with processing when compared with unripe plantains. This information will be useful in developing food processing conditions that positively affect starch resistance to digestion in order to optimize its nutritional quality and to improve the physiological benefits.To maximize resistant starch (RS) and slowly digestible starch (SDS) contents in plantains, it would be important to identify the stage of ripening and the processing techniques needed to develop desired products which are fit for consumption, and for delivering optimum benefits required.

ABSTRACT: Croatia in the Neretva valley produces remarkable quantities of mandarins but, as always, one part of yield, according to fruit characteristics, are not suitable for consumption as fresh. At the same time those fruit are suitable for processing industry e.g. for juice production. In Croatia, mandarin juice is not industrially produced, and generally is rare on market. The current study is contribution to mandarin juice processing with the aim to investigate influence of different pre-treatment on yield, quality, biological and sensorial attributes of obtained juices.
Mandarin from Neretva valley was used to produce cloudy juices on small scale equipment. Before pressing, fruits were peeled and treated (i) with maceration enzymes at various temperature and duration (EPT) (ii) by ultrasound (USPT) with different amplitude and duration. Control juices were produced without enzymes or USPT. In juices biologically active compounds (BAS) total carotenoids (TC), total phenolics (TP), and vitamin C were determined. All juices were sensory evaluated (SE) by quantitative descriptive method. The results were statistically analyzed. Considering the investigated parameters there are no remarkable differences among juices produced by enzyme treatments independent of enzyme concentration, temperature (20 or 50 ^{o}C) and duration of 30 or 60 min. regarding to BAS and SE. Also, different US treatment conditions did not show any remarkable influence on investigated parameters. But in comparison of these two types of treatment better yield and SE were obtained by US and higher content of TC was obtained by enzyme treatment. Treatment by US could be recommended to produce mandarin juice due to high yield and SE but also further investigations are needed to optimize US conditions due to better preservation of BAS.
Key words: *mandarin juice, ultrasound, enzyme maceration, biologically active compounds*

INTRODUCTION

Croatia in the Neretva valley produces remarkable quantities of mandarins but, as usual, one part of yield, are not suitable for consumption as fresh. At the same time those fruit are suitable for processing industry e.g. for juice production. In Croatia, mandarin juice is not industrially manufactured, and generally is rare on the market. Looking on juices from citrus fruit, on Croatian market, as well as on world market, orange juice is predominant. In comparison to orange juice mandarin juice has higher intensity of orange colour and may be added to orange juice to improve its colour (Perez-Lopez et al., 2006). Citrus juice production usually is based on extraction from unpeeled fruit and peel constituents which may pass into the juice later in technological process it should be removed (Bates et al., 2012). Since, mandarin is easy-to-peel fruit, mandarin juice could be produced with previous peeling (Tietel et al., 2010) what is convenient for SMEs (Bates et al., 2012) because peel constituents are not present in fresh juice after extraction which technologically simplifies finalization of juice. Yield of juices obtained by pressing is in dependence on pectin structure and content therefore pectolitic enzymes usually are used. To obtain higher yield certain enzyme treatment before pressing is desirable for many fruit (Chang et

al., 1994, Levaj et al, 2010, Levaj et al., 2011). Recently in juice production, ultrasound technology has been investigated mostly as an substitution to common thermal treatment e.g. pasteurization in order to inactivate enzymes and microorganisms at mild temperature conditions (Tiwari et al., 2008; Dubrović et al., 2011; Rawson et al., 2011; Chandrapala et al., 2012; Fonteles et al., 2012) but in laboratory ultrasound is well-established as method for cell disintegration to extract intracellular components (Skauen, 1976, Valero et al., 2007). High-intensity cavitation punctures the cell walls and releases the cell content. Mandarin as other citrus fruit contain high valuable nutrients such as vitamin C, folate, dietary fiber, minerals (potassium) and biological active comounds (BACs), the terpenes and phenolic compounds, which synergistic action with vitamin C contribute to citrus antioxidant capacity (Codoner-Franch and Valls-Belles, 2010; Unno et al., 2011). Mandarin is rich in hesperidin, flavanon specific for citrus fruit, and with carotenoid, β-chryptoxanthin, which possess anti-inflammatory and anti-carcinogenic activity (Codoner-Franch and Valls-Belles, 2010; Kohno et al., 2001). Flavonoids also have a role in cardiovascular protection, (Codoner-Franch and Valls-Belles, 2010). Consquently, better releasing of hesperidin and β- chriptoxanthin, generally speaking, phenolics and carotenoids, in the processing of juice are desirable in order to better quality as well as health reasons. The current study is contribution to mandarin juice processing with the aim to investigate influence of ultrasound in comparison to thermal and enzyme treatment on yield, quality, biological and sensorial attributes of obtained juices.

MATERIAL AND METHODS

Mandarin fruit (*Citrus unshiu* Markovich), were harvested, twice with an interval of two weeks, in the Neretva Valley in 2010 and transported at 4 ℃ to Faculty of Food Technology and Biotechnology in Zagreb, hand peeled and frozen at -18 ℃ till juice manufacturing.

Juice manufacturing

After defrosting fruit was chopped by knife or homogenized in blender (Mixy Zepter, International) and was used to produce cloudy juices on small scale equipment according to scheme (Figure 1).

Ultrasonic pre-treatment (USPT)

Homogenized fruit (round 400 mL) was placed in a glass beaker (1000 mL), which served as the treatment chamber. An ultrasonic processor (S-4000, Misonix Sonicators, Newtown, CT, USA), set at 600 W, 20 kHz and 12–260 μm with a 19-mm diameter probe, was introduced into the vessel. Ultrasonication was carried out with 60 and 120 μm amplitude. Samples were treated ultrasonically for 5 and 10 min at 25 ℃ (table 1). Each experiment was conducted at least in duplicate.

Thermal (TPT) and enzyme pre- treatment (EPT)

Chopped fruit for was treated at 20 or 50 ^{o}C for 30 minutes (TPT) and for EPT with 50 or 150 ppm maceration enzymes (Endozym Pectofruit PR, AEB group, Italy) at 20 or 50 ^{o}C for 30 or 60 minutes (table 2). These concentrations and temperatures were selected according to the manufacturer's instructions.

Pressing was done on hydraulic pack press (Euclid Ltd., Croatia). Juices were kept in refrigeration at 8^{o}C until analysis. Juices were produced separately with the mandarin from the first harvest and with the mandarin from the second harvest. Each juice was separately analyzed.

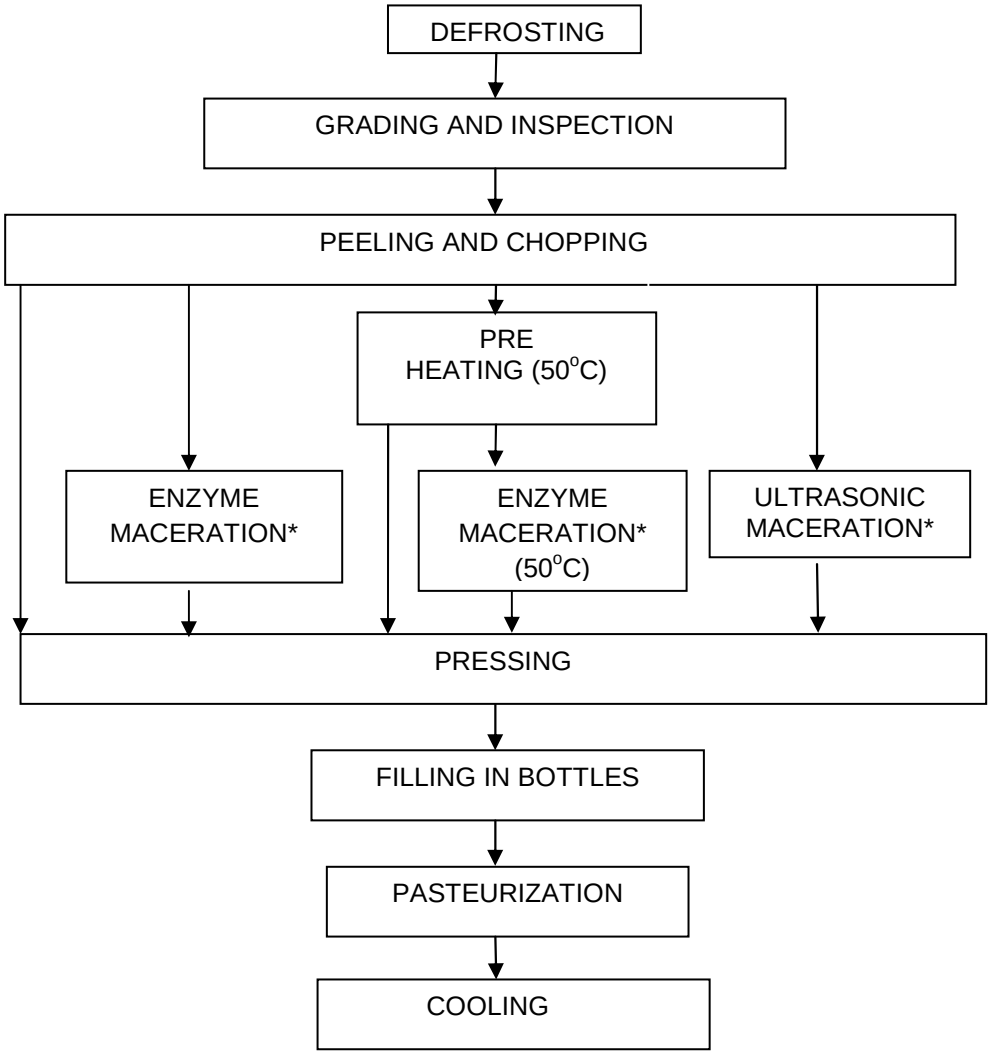
Table 1. Conditions of USPT and the code of produced juices

Code of sample	Amplitude/μm	Duration (min)
US/60/5	60	5
US/60/10	60	10
US/120/5	120	5
US/120/10	120	10

Table 2. Conditions of TPT and EPT and the code of produced juices

Code of sample	T (℃)	Enzyme (ppm)	Duration (min)
20/0/30	20	-	30
20/50/30	20	50	30
20/150/30	20	150	30
20/50/60	20	50	60
20/150/60	20	150	60
50/0/30	50	-	30
50/50/30	50	50	30
50/150/30	50	150	30

After pressing juice was filled in glass bottles of 200 mL and closed. Pasteurization of juices was done after filling at 85 ^{o}C/15 min. Cooling was done by immersing in cold water.
Yields were calculated on fruit pulp, after peeling.



*-see table 1 and 2

Figure 1. Scheme of juice manufacturing

Biologically active compounds determination and sensory evaluation

Total phenolics (TP) were extracted according to Coseteng and Lee (1987) and determined by spectrophotometer using Folin-Ciocalteu reagent (Ough and Amerine, 1988) based on gallic acid calibration so results are presented as equivalent of gallic acid (GAE).

Carotenoids were extracted by petroleum ether (V_u=total volume of extract (mL)), absorbance (λ=450 nm) ($A_{\lambda max}$) was measured by spectrophotometer and concentration was calculated by using extinction coefficient $E^{\%}_{1\ cm}$ (extinction coefficient in petroleum ether for β-carotene=2500) and formula (Vuelleumier, 1967):

$$\text{Total carotenoids (as β-carotene) (mg/100 g)} = \frac{A_{\lambda max} \cdot 1000 \cdot V_u}{m(g) \cdot E^{\%}_{1\ cm}}$$

Vitamin C were determined by titration with 2,6-diclorphenolindophenol (AOAC, 2002).

All analyses were done in duplicates.

Obtained juices were conducted to sensory evaluation by Quantitative descriptive analysis which was very comprehensive. The panellists were requested to list the terms appropriate to describe the colour, odour, taste, consistency and overall

sensory impression whereas a total of 10 descriptive terms for all major sensory attribute categories were generated. The panellists scored the samples using a suitable line intensity scale, with scores awarded on a scale of 0 – 10 in which 10 indicated the highest intensity of evaluated sensory attribute. Sensory analysis was carried out by a trained panel consisting of fifteen members per session. The procedure was performed according to ISO 6564, ISO 8587 and ISO 11036 (in a sensory laboratory equipped according to ISO 8589) and in consistence with method from literature (Bursać et al., 2007; Bursać Kovačević et al., 2008).

Statistical data analysis

Statistical analysis was performed via analysis of variance (ANOVA) by Kruskal-Wallis test using SPSS (ver. 17) in order to investigate influence of pre-treatment (temperature, enzyme – temperature, and ultrasonic) on each determined parameter. Differences were considered significant at $p \leq 0.05$.

RESULTS AND DISCUSSION

All treatments were grouped as follow: (i) thermal pre-treatment (TPT) in order to investigate influence of temperature, (ii) enzyme pre-treatment (EPT) in order to investigate influence of enzyme concentration, temperature and duration of maceration, and (iii) ultrasonic pre-treatment (USPT) in order to investigate amplitude and duration of ultrasonic treatment.

Within each treatment there was not significant influence of temperature or enzyme concentration, temperature and duration of maceration or amplitude and duration of ultrasonic treatment on juice yield. However, USPT ranked highest yield followed by EPT and TPR (χ^2=11.60, p<0.01). Average values of juice yield are shown in table 3. Lieu and Le (2010) investigated US in grape mash treatment and also concluded that sonication treatment increased extraction yield.

Table 3. Average values of each treatment for yield, TP, TC and vitamin C

Treatment	Yield (%)	TP (mg/100 g)	TC (mg/100g)	Vitamin C (mg/100 mL)
TPT	65.27±6.09	76.45 ±26.98	0.75±0.26	17.18±4.16
EPT	75.55±6.75	73.36±37.55	0.75±0.11	17.81±2.11
USPT	83.16±5.97	71.07±11.38	0.44± 0.11	19.66±2.83

Influence of all treatments on BACs (TC, TP and vitamin C) was investigated. Content of TP were a little lower than previously determined in fresh mandarin (114.09 mg/100g) (Levaj et al., 2008) which may be due to a difference in the mandarin cultivars and the processing. According to average values for each treatment (table 3) the highest TP content was obtained by TPT and retention in USPT was 93 %. With prolonged time and higher amplitude loss of BACs was higher although the differences were not significant (table 4). Rawson et al. (2011) had similar observation for watermelon. TP content was not much affected at lower processing times of 0 to 6 min in comparison to higher processing times of 10 min where significant degradation of TP content was observed. Fonteles et al. (2012) also conclude that ultrasound caused reduction of TP content. In our study significant influence of pre-treatment was observed only for TC content (χ^2= 14.14, p=0.01). The average value for USPT was 40 % lower when compared to the highest average value of TC content determined for EPT (table 3). Although between all treatments there was no significant influence on vitamin C content, its average value of USPTs slight increased in comparison to other two treatments (table 4). Rawson et al. (2011) reported about degradation of vitamin C as processing time was increased from 0 to 10 min for an amplitude level of 24.1 μm at 25 ℃. In our study at lower amplitude was achieved higher vitamin C content which decreased with the higher amplitude but the differences were not significant (table 4).

Table 4. Average values of each USPT for TP, TC and vitamin C

USPT	TP (mg/100 g)	TC (mg/100g)	Vitamin C (mg/100 mL)
US/60/5	76.66±4.72	0.42±0.01	22.26±0.49
US/60/10	72.78±18.07	0.45±0.19	21.92±0.98
US/120/5	75.37±1.84	0.44±0.16	16.70±2.45
US/120/10	59.45±13.36	0.47±0.13	17.74±0.0

Additionally, within each treatment there was no significant influence of temperature or enzyme concentration, temperature and duration of maceration or amplitude and duration of ultrasonic treatment on TC, TP or vitamin C content.

(a) (b)

Figure 2. Results of sensory evaluation: (a) desirable attributes; (b) undesirable attributes

All sensory attributes are divided in two main evaluation blocs: first one include desirable attributes (see Fig. 1a) and the second one undesirable attributes (see Fig. 2b). Total sum of scores for desirable attributes and total sum of scores for undesirable attributes were calculated and mathematically adjusted that both blocks had the same share in total sensory score regardless of number of grades in blocs and than were subtracted. For desirable attributes (χ^2= 37.84, $p<0.01$) as for TSG (χ^2=54.53, $p<0.01$) the best ranking treatment was USPT, while TPT has the largest rank for undesirable attributes (χ^2=53.78, $p<0.01$).

CONCLUSIONS

Ultrasound is promising method in juice processing as a pre-treatment method to ensure alternative of thermal or enzymatic method according to results of sensory evaluation and yield. Additionally, better yield in this study was obtained in much shorter time when compared to conventional methods. Further investigations are needed to improve content of BAC in juices.

ABSTRACT: Osmotic drying of quince is used as the first step in combined drying. The removal of moisture during osmotic drying ensures less time for convective drying. Osmotic treatment reduces water activity, provides microbiological stability and extended shelf life of products. In addition, osmotic pre-treatment has a positive effect on the mechanical properties of the final product. The impact of osmotic drying on the change of quince color and volume was examined. Quince cubes of dimensions 15x15x15 mm were used in the experiment. Osmotic drying was carried out with the following combinations of temperature and concentration of sucrose solution in water: 40°C,50°Bx; 60°C,50°Bx; 40°C,65°Bx and 60°C,65°Bx. Drying time was 180 minutes. The samples were tested every 20 minutes. The samples, treated by osmotic drying, were air dried convectively at the temperature 40°C for 20 hours. Color measurement was performed by Konica Minolta colorimeter CR-400. CIE L*a*b * values were used for color parameters. During osmotic drying significant changes in parameter b* were measured, while the parameters L* and a* did not change significantly. At high values of temperature and concentration of osmotic solution less color change occurs after convective drying. The biggest changes in volume were measured again at the highest values of temperature and concentration of osmotic solution.
Keywords*: quince, osmotic drying, color, volume, dimensions*

INTRODUCTION

Quince is a fruit species that is highly appreciated for its aroma. It is typically used in the production of brandy and compotes, while it is rarely used in the fresh state. This is because of the hardness and firmness of the fruit (Babić et al, 2008). Dried quince is used as an ingredient in muesli and tea blends. At the Faculty of Agriculture in Novi Sad a new quince product has been developed to be used for direct consumption as a delicacy. This product is a result of combined methods of drying. Combined drying consists of osmotic and convective drying. The advantages of combined drying, apart from the improvement of mechanical properties, are reflected in preserving the quality of dried fruit (color, flavor, aroma and taste), prolonged periods of storage with higher final humidity and shorter drying to final moisture content (Babić, Ljiljana and Babić, M., 2003). During the drying process the physical properties of materials change. The aim of this study was to determine the effect of different parameters of osmotic drying on the change of the color, size and volume of quince. Food drying is one of the most common ways of protecting and preserving the stability of food (Mayor and Sereno, 2004). However, during drying, the material is exposed to high temperatures which can have adverse effects on the quality (Barreiro et al, 1997; Ibarz and Lozano, 1997; Avila and Silva, 1999; Ibarz et al, 1999). However, some authors reported that osmotic drying reduces these changes. The first indicator of product quality is its color and shape. Change of the color of fruit may be due to chemical, biochemical and physico-chemical mechanisms: degradation of cells, changes of natural pigments (chlorophylls, carotenoids and anthocyanins) and development of enzymatic browning. Drying and water loss cause changes of cell microstructure and volume (Koc et al., 2008). The size of these

changes depends on the moisture transport mechanism. That is the method and drying conditions affect the intensity of volume changes. Convective drying is the most commonly applied method of drying. During this drying method the volumes of material significantly change and the rate of rehydration is reduced. Osmotic pre-treatment has the positive influence on preservation of shapes and sizes.

MATERIALS AND METHODS

A variety of quince Leskovačka was used in the experiment. On the basis of previous research results this variety is very suitable from the aspect of size and shape. The final products, dried quince quarters, have a satisfactory shape and dimensions. These properties are important because the research has been focused on developing products for direct consumption (Radojčin et al., 2010). Color measurement was performed on quince cubes of the dimensions 15x15x15 mm. The cubes are formed in quarters and treated with sulfur dioxide. The measurement was carried out on three samples, each time on the same area. The values, shown in Figures 1, 2 and 3, represent the average of the three measurements. Magdić and Dobričević (2007) reported that color measurement can be nonobjective because it is not possible to capture the same area. The shape and dimensions of the samples enabled the recording of quince colors always on the same place. The measurement was performed on the beginning of the process and after every 20 minutes during osmotic drying. Before each measurement the excess of osmotic solution was removed from the samples. Osmotic drying was carried out in a solution of water and sucrose. Drying time was 180 minutes. Osmotic drying was carried out at the following combinations of temperature and sucrose solution concentration: 50^{o}Bx and 40^{o}C, 60^{o}C and 50^{o}Bx, 40^{o}C and 60^{o}C and 65^{o}Bx and 65^{o}Bx. After osmotic drying, convective drying was carried out in an experimental dryer with trays. Convective drying time was 20 hours at the temperature of 40^{o}C, for all samples.
Color measurement was performed by Konica Minolta colorimeter CR-400. The value of the colors is shown in the CIE L*a*b* color system. This way of representing the color is suitable because the measured value of the color is shown in three-coordinate system. In this system L* indicates lightness (brightness, light), a negative value a* is green, and positive a* is red. Negative b* is yellow, a positive b* is blue (Alvarez-Fernandez et al, 2003).
For presentation of color change the value ΔE*ab is also used. This value represents the total color change. This is the difference between the color at the beginning of measurements and at appropriate moment during the experiment.

$$\Delta E^{*}ab = \sqrt{\left(L_o^{*} - L^{*}\right)^2 + \left(a_o^{*} - a^{*}\right)^2 + \left(b_o^{*} - b^{*}\right)^2}$$

where: L_o*, a_o* b_o* are the initial values measured on fresh fruit samples, and L*, a*, b* are values measured after drying process (osmotic, convective or combined).
After convective drying, the color of samples was measured, too. The color measurement was conducted on the samples which were not osmotically treated. The color of these samples was measured after sulphuring and after convective drying.
Based on Archimedes' law the sample volume was determined. In order to measure the volume it is necessary to have a scale, glass gauge and a thin metal wire (Babić, M., and Ljiljana Babić, 2007). To calculate the volume it is necessary to measure the mass glass gauge with distilled water before and after the sample is submerged in water. The volume of the sample is calculated using the following equation:

$$V = \frac{M_{II} - M_I}{\rho}$$

where: V - quince cube volume [m^3], M_I - mass of glass with liquid [kg], M_{II} - mass after immersing the sample in glass [kg], ρ - the density of distilled water [kg/m^3]
Shrinkage is the relation between the changes in volume of the sample at a certain moment during drying and the volume at the beginning of drying.

$$SV = \frac{V_0 - V_i}{V_0} \cdot 100(\%)$$

where: - SV [%] – shrinkage, relative change in volume, V_o - initial volume [m^3], V_i - volume at a certain moment during drying [m^3].

RESULTS AND DISCUSSION

During osmotic drying the color parameter b*, which means yellow color, changed during all 180 minutes. There is a constant increase in the value of this parameter. Somewhat larger change of this parameter was measured at the concentration of 65^0Bx. The values of parameters L^* and a^* have not significantly changed. Smaller decline and growth of these values is noticeable. The value of parameter L^* is in the range from 70 to 80, while the value of the parameter a* ranged from -6 to -4. Osmotic drying provides the color of the final product very similar to fresh fruits, what was also confirmed by Rodrigues et al. (2003).

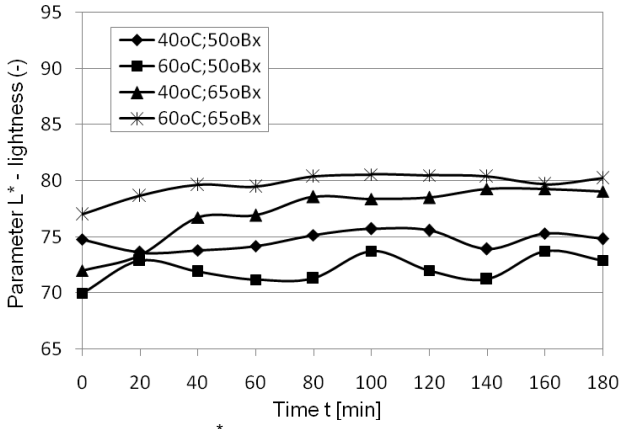

Figure 1. Change of color parameter L^* during osmotic drying for different osmotic parameters

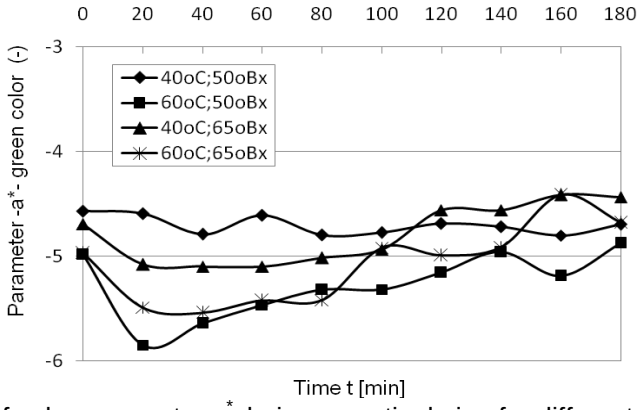

Figure 2. Change of color parameter a^* during osmotic drying for different osmotic parameters

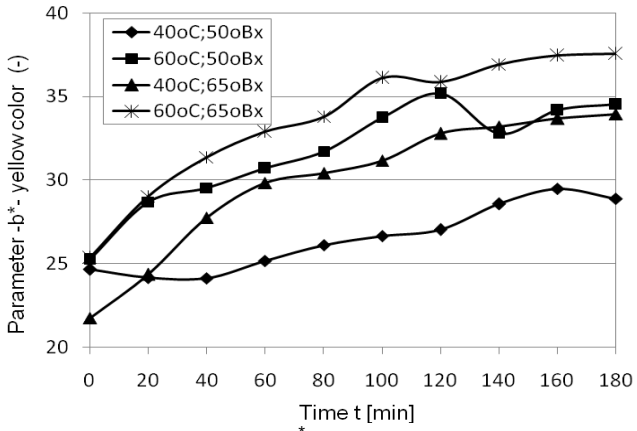

Figure 3. Change of color parameter b^* during osmotic drying for different osmotic parameters

The mean values of color parameters L^*, a^* and b^* in the quince samples which were not osmotically dried are shown in Figure 4. L^* and a^* parameters did not change significantly. These measured values changed only for 2 or 4 units. The more significant change of parameter b^* was measured. The difference between parameter b^*, for fresh and convectively dried samples, was 10. It can be said that this difference is significant.

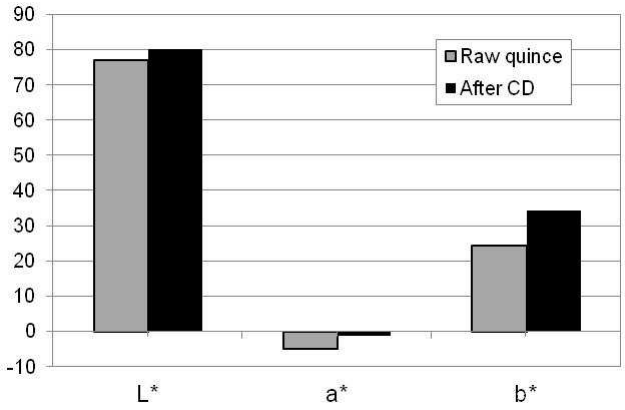

Figure 4. Values of color parameters (L*,a*,b*) of raw quince and after convective drying (CD)

The total color change ΔE*ab is a parameter that is often used to evaluate color changes in food products. In all the experiments the total color change was recorded (Figure 5). Somewhat larger changes were measured at the solution concentration of 65°Bx. Some authors suggest that less moisture in the product is favorable for the progress of the tanning process. This could explain such a result. However, an unexpected result was the greatest color change at the temperature of 40°C and the solution concentration of 65°Bx. After convective drying, smallest differences of total color were measured at the temperature of 60°C and the solution concentration of 65°Bx. The formation of the sugar layer on the surface of the sample prevents any chemical reaction with the surrounding air which results in browning of fruit tissues (Rahman and Mujumdar, 2007). Less change in total color was measured in quince samples which were not osmotically dried. One of the goals during food processing is to preserve the color. However, the total color change in the experiments with osmotic drying was caused by changing of the parameter b^* (Table 1). There was no significant change in the parameter L^*, the lightness was preserved. The result is a product of intense and purer yellow color.

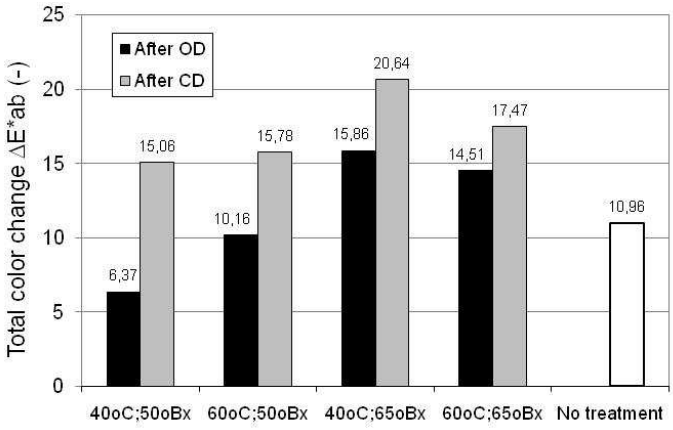

Figure 5. Total color change after osmotic and combined drying (■ ■ osmotic treated quince, □ convectively dried quince-without osmotic treatment)

Table 1. Color parameters of raw quince, after OD, after CD (combined drying) for different osmotic parameters

Material	Color parameters	40°C; 50°Bx	60°C; 50°Bx	40°C; 65°Bx	60°C; 65°Bx
Raw		74.80	70.15	72.05	77.08
After OD	L^*	74.81	72.92	79.05	80.22
After CD		77.72	69.94	77.79	78.03
Raw		-4.57	-4.99	-4.69	-4.97
After OD	a^*	-4.69	-4.87	-4.43	-4.68
After CD		-2.24	-1.08	-1.61	-2.14
Raw		24.66	25.24	21.74	25.35
After OD	b^*	28.89	34.52	33.94	37.56
After CD		39.08	42.25	40.19	41.64

OD-osmotic drying, CD-combined drying

Volume change during drying is an important indicator of product quality. It depends on the type of materials, cell properties and structures and drying conditions. Experimental data published in some studies show that the volumetric shrinkage is dependent on the moisture content in the material (Lozano, Rotstein, & Urbicain, 1983; Suzuki, Kubota, Hasegawa, & Hosaka, 1976). Lozano et al. (1980) describe the shrinkage of apples in the function of moisture content as a linear model. However, non-linear models adequately describe the volumetric shrinkage of fruits and vegetables. The values of shrinkage during osmotic drying are given in the diagram (Figure 6). The biggest changes were measured for the solution concentration of 65°Bx. The change intensity is the greatest at the beginning and it decreases during drying. The change of the moisture content is similarly changed during drying, which indicates the relationship between changes in volume and moisture. This relationship between volumetric shrinkage and moisture content is not linear. This dependence is best described by the nonlinear model. These results are reported Babić et al. (2008). Volumetric shrinkage ranges from 33% to 53% for different parameters of osmotic drying.

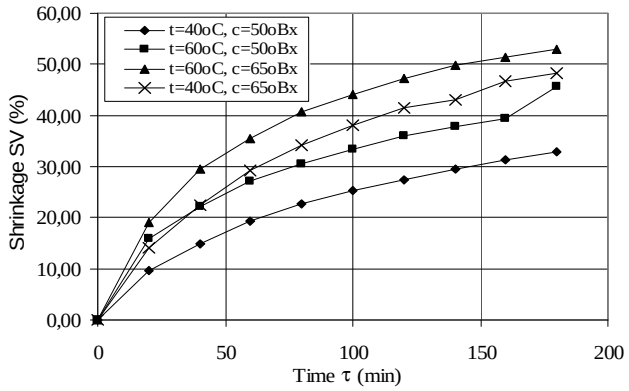

Figure 6. Volumetric shrinkage during osmotic drying

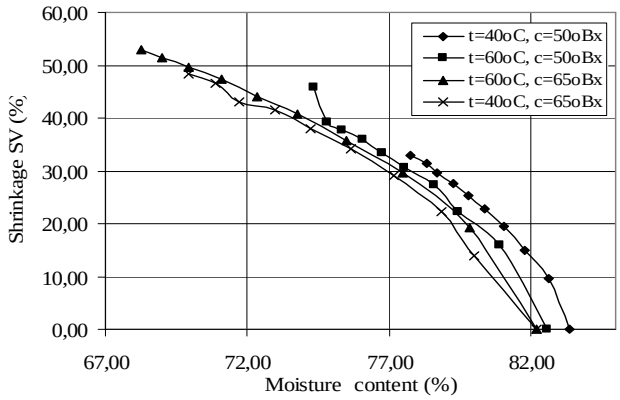

Figure 7. Shrinkage as a function of moisture content during osmotic drying

CONCLUSION

The physical properties of food products are the first indicator of quality. Preserving these properties is one of the goals to be achieved during the drying process. The change of the total color of quince occurs during osmotic drying. Less change of color after convective drying occurs at high values of temperature and osmotic solution concentration. A layer of sugar on the surface of the sample has a protective role in preserving the color of products. The biggest change in volume and dimensions were measured again at the highest values of temperature and concentration of osmotic solution. Changing the volume and dimensions, depending on moisture content and drying time of material, is best described by the nonlinear model. Further research should be directed towards the search for dependencies between the studied parameters and other parameters that affect their behavior.

ABSTRACT: The experimental research of the osmotic drying kinetics of nectarine tissue in a sucrose solution has been conducted. As the research material, the mesocarp tissue of the nectarine variety *Fantasia* has been used in the shape of fruit halves. Based on the data obtained by a dispersion analysis of this two-factor experiment (with the statistical probability of 99%), it can be concluded that there are impacts of the selected factor levels on the drying speed of the nectarine tissue and the dry matter increase. The most significant moisture decrease, dry matter increase, and ***volume shrinkage*** has been noted in the combination t_r=60^{o}C and C_r = 65^{o}Bx, (2.27 kg_w/kg_{sm}; 3.78%, 0.3449, successively), whereas the least significant changes have been noted in the combination t_r = 40^{o}C and C_r = 50^{o}Bx (1.45 kg_w/kg_{sm}, 2.45%, 0.174, successively).Using a regression analysis, a mathematical modelling of moisture change (compared to the dry base) and dry matter increase of the nectarine tissue was conducted during the osmotic drying. Three empirical models, enhanced with factors of non-dimensional osmotic drying, have been selected for every modelled value. Based on the statistical indicators such as the correlation coefficient (*R*), the chi-square test (χ^2), the ***mean bias error*** (MBE), and the mean squared error (MSE), models have been assessed and the most precise models have been selected. Ultimately obtained mathematical models have high correlation coefficients (R = 0.9886 and R = 0.9936).
Keywords: *osmotic drying, drying kinetics, nectarines.*

INTRODUCTION

The research subject of this paper was the osmotic drying (mesocarp) of nectarine tissue in the form of fruit halves in a sucrose solution. In scientific literature the pieces of information on the influence of parameters of osmotic drying on changes in physical characteristics of fruit tissues of different fruit types are numerous. When it comes to the fruit type which is the subject of this research, the results are few and they refer to the tissue dried in the form of regular geometrical shapes (cube, prism, cylinder, sphere) (*Fernandez el al., 2004, Kingsly, 2007*). In production of dried fruit, as a final product, the above mentioned geometrical shapes are rarely used, except for certain types of food supplements. The results of this kind of research, apart from the scientific purpose, are rarely applicable in the design process of drying of the fruit tissue where the completely natural fruit shape is used, or a part of it (one half of the whole fruit, one quarter of the whole fruit).

The aim of the research as a part of this paper is to determine the changes of the basic physical characteristics of nectarine halves during the osmotic drying in a sucrose solution depending on process parameters. Based on the measured values, mathematical models of the changes of fruit tissue moisture in relation to the dry base and dry matter increase will be established. Mathematical models will be in function from analyzed parameters of the working fluid from osmotic drying. The established mathematical models should be as correct as possible, but at the same time simple enough for the practical usage.

MATERIAL AND METHOD

In the experimental part of the research fresh fruit of the nectarine variety Fantasia has been used. Nectarines were obtained from orchards in Srem, near Čerević, Serbia. Until the beginning of the processing, fruit was stored in a locker on the temperature of 4^{o}C and 75% relative air humidity. The stage of fruit ripeness was the beginning of technological maturity with the average values of pH = 2.99±0.14 and fruit strength of 5.55± 0.42 kg/cm^2. The measured values of the basic physical characteristics of the fruit were: moisture in relation to the dry base 4.51± 0.13 $kg_w/kg_{sm,}$ fruit mass 113.51± 15.66 g, length 60.60±2.78 mm, width 58.24±3,45 mm, and thickness 56.50±2.98 mm. All average values were measured on a random sample of 20 fresh fruit.

The preparation of fresh fruit for the drying implied washing, cutting in halves and the removal of the seeds. With this type of preparation, the usable mass of tissue was 103.75±15.78g which makes 91.25±1.84% of the whole fruit mass. Prepared halves had the following mean value of physical characteristics: tissue moisture in relation to the dry base 4.58±0.274 $kg_w/kg_{sm;}$ length of one half 56.20±3.178 mm; width of a half 54.34±2.427 mm; thickness of a half 25.37±1.686 mm; volume of a half 41.73±4.30 cm^3. After cutting in halves the prevention of tissue darkening was conducted. With the dry process of sulphuring, 2g of technical sumphur in powder per 1 kg of prepared halves was burnt. The exposure time of the halves to the sulphur dioxide in the sulphuring chamber was 8 h. Upon completing of the preparation, the samples were placed in the experimental semi-industrial osmotic dryer, with the capacity of 0.039 m^3 (Babić, M., et al., 2004, Pavkov et al., 2007). When planning the experiment one of the main criteria was to achieve the simulation of real processes of osmotic drying in the experimental dryer. For this reason, the experiment was conducted in a semi-industrial osmotic dryer.

Previous studies on the process of osmotic drying of fruit tissues and influential factors emphasize the following statement: temperature and osmotic solution concentration are the two most influential factors on the rate of mass transfer during osmotic drying (Park et al., 2002, Babić, Lj., 2007, Khoy and Hesari, 2007, Pavkov, 2007; Pavkov et al 2009). Based on these findings, the experiment was performed with two factors. Osmotic solution temperature was varied at two levels, 40℃ and 60° C and two levels of concentration of osmotic so lution, 50^{o}Bx i 65^{o}Bx. The duration of the process of osmotic drying was 180 minutes. The mass ratio of osmotic solution and nectarine halves of the sample was 10:1. Velocity of solution in front of the layer of the material 0.00913 m/s. Porous of a layer of the nectarine halves at the beginning of osmotic dehydration was 33.79 ± 1.47%. To obtain osmotic sucrose solution was used in the form of confectionery sugar crystal as solute and distilled water as a solvent. For each combination of selected levels of influencing factors of osmotic drying three repetitions were carried out.

During the experiment of osmotic drying every twenty minutes, from the start of the process until the expiry of the stipulated time, three halves were taken from the osmotic dryer. It is assumed that these samples represent the mean changes in physical properties of fruit tissue during osmotic drying in the observed time period. Their moisture content, increase in dry matter and the volume were measured.

Samples and increased moisture content of dry matter was measured by thermogravimetric method, using a laboratory dryer, Sterimatic ST-11, “Instrumentaria”, Zagreb and analytical scales KERN 440-33N (0 - 200 g, 0.01g, ±0.02) in three repetitions (Službeni list, 1983). Calculation of dry matter increase was based on the equation (*Bchir et al., 2009; Togrul and Ispir, 2007; Park et al. 2002*):

$$SG = \frac{m_{dm(i)} - m_{dm(0)}}{m_0} \quad (1)$$

where is: *SG* – solid gain (kg_{dm}/kg); m_0 – mass of fresh sample (kg); $m_{dm(0)}$, $m_{dm(i)}$ – mass of sample dry matter: at the beginning of the process, at the *i* - moment of drying process (kg_{sm});
Volume of the sample (half or quarter) was measured using the analytical scale KERN 440-47N (0 -2000 g; 0.1 g, ±0.2 g), glass cylinders and thin metal wires (*Babić, M. et al., 2007, Mohssenin, 1980; Rahman, 2009*). Measured values of the volume of individual pieces of fruit tissue before osmotic drying and in the moment of osmotic drying were used to calculate the shrinkage in volume according to the equation (*Babić, M., et al., 2008*):

$$SV = \frac{V_{(0)} - V_{(i)}}{V_{(0)}} \quad (2)$$

whre is: *SV* – volumetric shrinkage (-); $V_{(0)}$ $V_{(i)}$ – volume of halves: before drying, at the i-moment of drying process (cm^3).

Measuring the temperature of the solution during the experiment was carried out every 20 minutes using a mercury thermometer (0 - 110^{o}C, 0.1^{o}C, ±0.05^{o}C), and solution concentration using a digital refractometer ATAGO– Japan, model PAL – α (0-85^{o}Bx, 0.1 ^{o}Bx, ±0.1^{o}Bx). Velocity of osmotic solution was measured using an ultrasonic flowmeter, Krohne UMF 600P, sensor A, USA (0.03 – 13.47 m/s, 0.01 m/s, ±0.02 m/s). Dimensions were measured using the fruit floating measure TMA INOX, D-6-1, Nemačka (0 - 200 mm, 0.1 mm, ±0.05 mm).
The influence of the chosen levels of temperature and osmotic solution concentration on the rate of nectarine halves moisture change and dry matter increase was checked by the dispersive analysis of the double-factor experiment with a statistical probability of 99%. The influence of the chosen factor levels was analyzed on the basis of the calculated mean speed of drying of nectarine halves and the mean speed at which dry matter increases for the drying period of 180 minutes. Dispersion analysis was performed in the program package Statistica 10 (*StatSoft, Inc., 2010*).
Based on the results of the experiment, what was carried out was modeling of changes in moisture with regard to the dry base during osmotic drying, and modeling of increase in dry matter in comparison to the wet base during the drying time. For both sizes that were modeled three mathematical models were adopted as a starting point based on the literature review, theoretical, half-theoretical and empirical models of fruit drying kinetics. (Henderson and, Perry, 1976; Yagcioglu et al., 1999, Wang and Singh, 1978; *Panagiotou, et al, 1998*). In accordance with the aim of this research, the initial models were expanded in the function of influencing factors of the experiment in dimensionless form, namely as the ratio of the selected factor levels and its reference value (*Babić, Lj., et al., 2004*; *Panagiotou, et al., 1998;Pavkov, 2007*). The proposed equations for the change of moisture of nectarine halves in relation to the dry base are: 3, 4, 5; and the equation for the increase in dry matter are: 6, 7 i 8. The values of osmotic solution concentration and temperature of osmotic solution as a reference value were adopted, and those amounts are: $t_{r(ref)}$ = 60^o*C* i $C_{r(ref)}$ = 65^o*Bx.*

- $$\omega = a \cdot \exp(-k \cdot \tau) \cdot \left(\frac{t_r}{t_{r(ref)}}\right)^{n_1} \cdot \left(\frac{C_r}{C_{r(ref)}}\right)^{n_2} \quad (3)$$

- $$\omega = a \cdot \exp(-k \cdot \tau) \cdot \left(\frac{t_r}{t_{r(ref)}} \right)^{n_1} \cdot \left(\frac{C_r}{C_{r(ref)}} \right)^{n_2} + c \quad (4)$$

- $$\omega = a + \left(b \cdot \tau + c \cdot \tau^2 \right) \cdot \left(\frac{t_r}{t_{r(ref)}} \right)^{n_1} \cdot \left(\frac{C_r}{C_{r(ref)}} \right)^{n_2} \quad (5)$$

- $$SG = a \cdot \tau^{n_1} \cdot \left(\frac{t_r}{t_{r(ref)}} \right)^{n_2} \cdot \left(\frac{C_r}{C_{(r)ref}} \right)^{n_3} \quad (6)$$

- $$SG = \exp(k \cdot \tau) \cdot \left(\frac{t_r}{t_{r(ref)}} \right)^{n_1} \cdot \left(\frac{C_r}{C_{r(ref)}} \right)^{n_2} \quad (7)$$

- $$SG = a + (b \cdot \tau + c \cdot \tau^2) \cdot \left(\frac{t_r}{t_{r(ref)}} \right)^{n_1} \cdot \left(\frac{C_r}{C_{r(ref)}} \right)^{n_2} \quad (8)$$

where is: ω –moisture content on the dry basis (kg_w/kg_{dm}); *SG* – solid gain (%), τ – time (min); t_r – solution temperature (°C); $t_{r(ref)}$ – referent solution temperature (°C); C_r – solution concentration (°C); $C_{r(ref)}$ – referent solution concentration (°C); *a, b, c* – function constants (-); *k* – drying constant (min^{-1}); n_1, n_2 – exponents of function (-).

Calculation of unknown constants, coefficients and exponents of the proposed mathematical models was performed by regression analysis that was done in the program package Statistica 10 (*StatSoft, Inc., 2010*). An assessment of the accuracy of the agreement of the tested models with the results of the experiment and the choice of the most suitable model were done through the correlation coefficient (R) as the basic criteria. And the statistical parameters were applied: chi - square (χ^2), mean bias error (*MBE*) and root mean square error (*RMSE*). Larger values of R accurate model and smaller values χ^2, *MBE i RMSE* indicate a greater precision of the model.

RESULTS AND DISCUSSION

Based on the results of dispersion analysis (Table 1 and 2) with the statistical probability of 99% can be concluded that there are statistically significant differences ($F > F_{crit}$) between the chosen levels of solution temperature and concentration compared to an average speed of drying nectarine halves and the increase of dry matter.

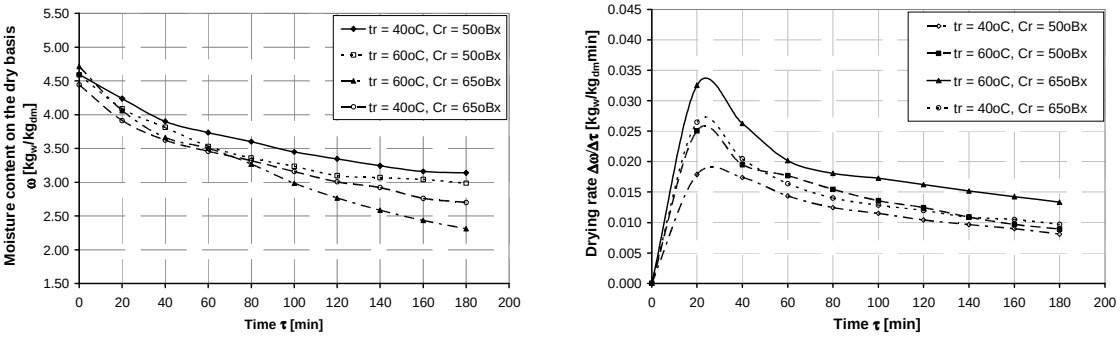
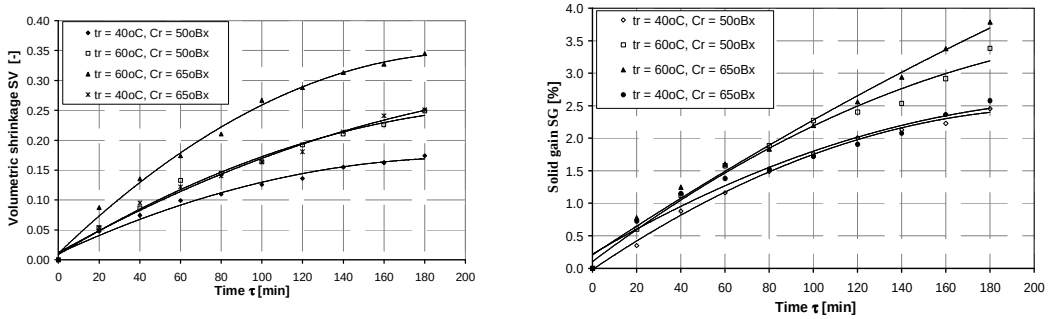
Figure 1a shows the kinetic curves of changes in mean moisture of nectarine halves with relation to dry base, and in figure 1b the mean drying rate compared to the dry base during osmosis.



a) b)

Figure 1. Kinetic curves of changes in mean moisture of nectarine halves with relation to dry base (a) and drying rate (b) during the osmotic drying time depending on temperature and concentration of osmotic solution

The largest decrease in moisture with relation to dry base was observed in the combination of temperature of osmotic solution at 60 °C and concentration of 65 °Bx, $\Delta\omega$ = 2.402 kg_w/kg_{sm}, and the smallest at the osmotic solution temperature of 40°C and concentration of 50°Bx, $\Delta\omega$ = 1.272 $kg_w/kg_{sm,}$ (Figure 1a). Drying rate increased intensively in the period of heating of the material at all combinations of temperature and solute concentration. After that, during the combining of factor levels t_r = 60°C and C_r = 65°Bx, mean drying rate is still significantly higher than the other combinations. For other combinations of factor levels, differences in mean speed of drying gradually reduce and equalize (Figure 1b). In Figure 2 increase in dry matter of nectarine halves is expressed in percentage with relation to the wet base(SG). Measured values (points in the diagram) are for the easier visual analysis of approximated second-order polynomial.



a) b)

Figure 2. Curves of mean increase in dry matter of nectarine halves with relation to wet base (a) and volumetric shrinkage (b) over time, depending on temperature and concentration of osmotic solution

The greatest increase in dry matter after 180 minutes in nectarine tissue was observed in combination of temperature of osmotic solution of 60℃ and concentration of 65°Bx, SG = 3.78 kg_{sm}/kg. The smallest increase of dry matter was observed in the combinations of osmotic solution concentration with lower values of temperature of osmotic solution, SG = 2,45 kg_{sm}/kg.

Figure 2b shows the results of volumetric shrinkage of nectarine halves during osmotic drying depending on the temperature and concentration of osmotic solution. The highest shrinkage was observed at osmotic solution temperature of 60°C and concentration 65°Bx, SV = 0.344. At osmotic solution temperature of 40°C and concentration 50°Bx recorded the least shrinkage SV = 0.174. The combination of solution temperature of 60°C and concentration of 50°Bx shrinkage is the same as during osmotic drying, where the temperature of the solution is 40°C and concentration 65°Bx SV = 0.25.

Influence of osmotic solution temperature factor is explained by high temperature solution lead to changes in the structure of cell membranes. The membrane becomes more permeable for water molecules, which diffuse through the tissue more intensively towards the interface, lowers the resistance of the tissue diffusion of moisture. Also, changing of the cell membrane partial permeability, solute molecules diffuse intensively from the osmotic solution into the inner layers of the fruit tissue. Higher concentrations of solution have resulted in the appearance of large concentration gradient of water and solute molecules, the interface between the fruit tissue and osmotic solution. The influence factors of osmotic drying are discussed in the same way by the authors: *Khoyi, and Hesari,* (2007) the apricot tissue in the form of thin sheets, *Park, et al.,* (2002) for osmotic drying of pear tissue in a cubic form.

Results of regression analysis of the kinetics of osmotic drying of nectarines in the studied form are given in Table 3.

Table 3. Results of regression analysis

Number of equation of mathematical model	Coefficients of the Model				Exponents of Model			*R*	χ^2	*MBE*	*RMSE*

(8)	0.11539	0.02322	-0.00002		-2.10990	-0.45632	-	0.9889	0.02285	3.85E-09	0.14141

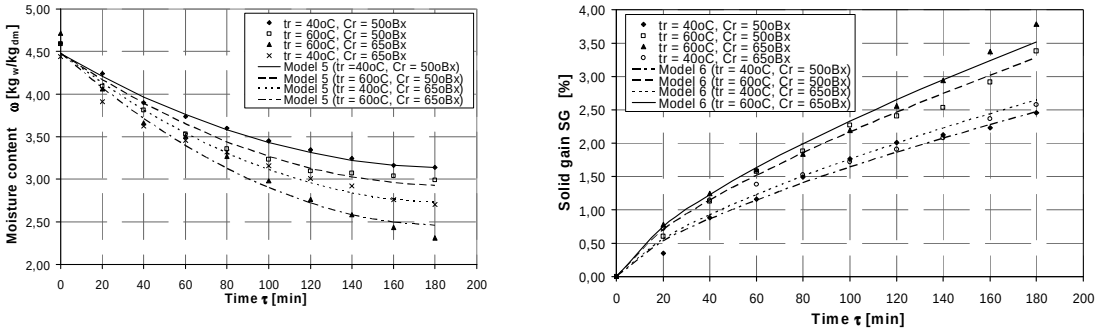
The highest coefficient of correlation (R), for mathematical models of moisture changes in relation to dry base during osmotic drying time has extended model *Wang & Singh* (equation 5). This model shows good agreement with the results of the experiment for the nectarine tissue, which is further confirmed by additional statistical indicators (χ^2*, MBE, RMSE).* The highest coefficient of correlation (R), for mathematical models of the kinetics of increase in dry matter compared to the initial mass during the osmotic drying time has extended *Degree model* (equation 6). This model shows good agreement with the results of the experiment for all three types of fruit tissue, which is further confirmed by additional statistical indicators (χ^2*, MBE, RMSE).*

When the final mathematical models for the change of moisture nectarine halves in relation to the dry base and increase in dry matter during osmotic drying are included, the calculated coefficients and exponents are:

$$\omega = 4{,}480 + \left(-0{,}0215\tau + 0{,}000057\tau^2\right)\cdot\left(\frac{t_r}{60}\right)^{0{,}3562}\cdot\left(\frac{C_r}{65}\right)^{1{,}0069} \quad (9)$$

$$SG = 0{,}0932\cdot\tau^{0{,}6990}\cdot\left(\frac{t_r}{60}\right)^{0{,}6948}\cdot\left(\frac{C_r}{65}\right)^{0{,}2676} \quad (10)$$

The derived mathematical models for nectarine tissue are applicable in a range of factors that they are derived for. Figure 3a shows the graphical comparison of changes in humidity of nectarine halves in relation to the dry base (ω) during osmotic drying time (τ) with the derived mathematical model 5, in figure 3b shows the graphical comparison of the increase in dry matter compared to the wet base (SG) during osmotic drying time (τ) with derived model 6.



a) b)

Figure 3. Comparison of measured values of change in moisture of nectarine halves in relation to dry base (a) with derived model 5 and increase of dry matter (b) with the derived model 6

CONCLUSION

Regression analysis of the measurement results of the osmotic drying experiment resulted in empirical models which describe the kinetics of osmotic drying of nectarine halves in sucrose. Two mathematical models were established, which describe: the change of moisture and increase in dry matter. The models are extended by influential factors in the dimensionless form. The derived models are with satisfactory correlation coefficients (R = 0.9886 and R = 0.9936) and as such may be useful in practice. The presented models are specific in their comprehensiveness. Using the derived model allows the calculation of the changes of modeled component over time in the range of factors in which the osmotic drying experiment is performed. At the same time, the models are sufficiently simple for the practical usage. With the help of standard computers it is possible to quickly calculate all modeled sizes, but also their application in control computers.

ACKNOWLEDGMENT

The results are a part of the project of the Ministry of Education and Science, the Republic of Serbia, No. TR – 03158, entitled “Combined Technology of Integrated and Organic Fruit and Vegetable Drying”.

ABSTRACT: In this study, gluten free breads (GFBs) made from rice and carob flour in different proportions were investigated. Water added changed in response to the carob amount. Structural and textural parameters of the samples such as viscoelastic properties of the dough, porosity, firmness, relative elasticity and microstrucure of crumb, were measured. Simple mathematical models were developed to correlate the measured properties with carob flour and water content. The simplest and most convenient mathematical model developed was a power model, indicating a significant water influence on GFBs characteristics . Carob flour addition enhanced the protein, fiber and minerals amount of the produced samples, and improved their functional properties as well, when water amount used was adequate. Rheological tests made, confirmed a shift towards a more elastic character when water content was low, typical for stiffer dough. .
Key words: *gluten-free, carob flour, structure, rheology, mathematical model*.

Nomenclature

A_o	surface of the compressed sample (cm^2)
a_1, b_1, a_{o1}, x_1, z_1 , a_2, b_2, a_{o2}, x_2, z_2, C_o, W_{to}	constants of the models (-), (-), (-), (-), (-), (-), (-), (-), (-), (-), (-), (%), (%)
C	percentage concentration of carob flour (%)
F,F_{max}, F_{res}	firmness of bread, maximum force for 25% compression of the crumb, residual force after 240s of relaxation phase (N)
h_o, h_t	initial and final height of the slice after compression (cm)
$REL\%$	relative elasticity of bread crumb

INTRODUCTION

Celiac disease is considered to be a gastrointestinal disease, where genetically predisposed individuals exhibit intolerance in peptides released from wheat gluten. Cereals such as wheat, rye, barley, and probably oat are toxic for celiac patients. The only, up to now known treatment for celiac disease is strict adherence to gluten free diet. Rice flour can be a safe substitute of wheat for celiacs due to its bland taste, white colour, ease of digestion, and hypoallergenic properties (Gujral and Rosell, 2004). Furthermore gluten free products lack many important nutrients, such as proteins, vitamins, minerals and last but not least dietary fibres. (Lazaridou et al., 2007). For increasing the nutritional value of GFBs, pseudocereals like carob could be also used as protein source, enhancing also the overall nutritional value of the

gluten-free products, including their fiber amount. Carob germ flour can be used as dietetic human food (Dakia et al., 2007) or as a potential ingredient in cereal-derived foods for celiac people (Feillet & Roulland, 1998).
The objective of this study is the development of gluten-free bread formulations using carob and rice flour in different ratios changing also water content. Thus for a specific carob flour amount, water content has been changed in a broad range in order to find out the best combinations. Mathematical models correlating structural and textural characteristics of the final gluten-free breads to water/carob amount are developed and quantitative data are discussed. Micrographs were also taken using a Scanning Electron Microscope (SEM). Viscoelastic behavior of doughs was also evaluated performing frequency sweep tests.

MATERIALS AND METHODS

Materials

The materials used in this study were rice flour, moist yeast (L'hirondelle, S.I. Lesaffre, France), sugar, salt (iodised sea salt, Kallas, Greece), shortening (Vitam, Unilever S.A, Greece), egg white powder (Laffort S.A., Bordeaux, France), whey protein concentrate (Nutrilac®DR-7015, Arla Foods Ingredients Amba-Denmark) with 65% minimum protein content, emulsifier (DATEM:Diacetyl-tartaric esters of mono- and diglycerides, Danisco, Copenhagen), locust bean gum (LBG) (Sigma-Aldrich Chemie GmbH, Germany), enzyme of alpha-amylase with additional transglutaminase and hemicullolase activity (VERON CLX AB Enzymes, Darmstadt, Germany) and tap water. Moreover carob flour from the seed meal was partially integrated in the dough.

Bread making procedure

The basic dough preparation included the mixing of dry ingredients in a Hobart mixer (Hobart N50, Hobart Co., Troy, OH, USA) (carob flour, rice flour, sugar, salt, albumen powder, whey protein powder, Datem, LBG gum and enzyme) was followed by addition of melted shortening. The yeast was progressively mixed with the water amount and added to the final blend. The water amount added varied from 70-150% (on total flour basis) according to the carob flour content added. The water content range for each formulation was determined by conducting preliminary experiments, due to problems during farinograph measurements, in an attempt to find out the best combinations of water and carob content in gluten free breads. As it is known that dietary fibres addition absorb considerable amounts of water, it was seen that during these experiments carob flour formed a rigid structure that could not flow under gravity, requiring high amount of water to form bread with high quality, After complete mixing, the dough was fermented at 35^{o}C, 85% RH for 50 min. Following fermentation, samples were baked at 170^{o} C for 30 min in a convection oven. The loaves were cooled to room temperature and placed in polyethylene bags for 24 h before determination of their physical properties.

Bread analyses

Chemical analysis

Protein content was determined by Kjeldahl method for Nitrogen determination (ISO 937-1978). Total fat content was determined by the combination of acid hydrolysis with NaCl and the Soxhlet method using petroleum ether as a solvent according to Pearson's Chemical Analysis of Food (1981). The fiber content was determined using AOAC (1990) method 985.29. Total carbohydrates were determined by difference subtracting 100 g minus the sum of protein, dietary fiber, ash and fat expressed in g/100 g. The ash content was determined according to Pearson's

Chemical Analysis of Food (1981) and the NaCl content was determined according to Volharol method (Pearson's Chemical Analysis of Food, 1981).

Crumb texture

The firmness of bread's crumb was estimated with the 74-09 method of the American Association of Cereal Chemists (2000) in a Universal Testing Machine, equipped with a 50 N load cell. A slice of 2.5 cm (thickness) from the center of the loaf was compressed to 40% of its initial height with a 4 cm diameter probe coming down with a speed of 101mm/s.

The crumb's relative elasticity testing was carried out in crumb cubes of 2 x 2 x 2 cm (length x width x height). A uniaxial compression test with subsequent relaxation phase that lasted 4 min was applied in order to determine the textural and viscoelastic properties of the bread crumb. The relative elasticity of the crumb (the force with which the crumb resisted the defined mechanical stress during compression) was derived from the recorded force–time diagram. The calculation was done according to Equation 1:

$$REL\% = (F_{res}/F_{max}) \times 100 \qquad (1)$$

The measurements were done in triplicates.

Porosity determination

For porosity measurements, samples of 1.5 x 1.5 x 1.5 cm (length x width x height) of the geometric centre of the crumb were taken from all breads. The volume of solids (V_S, m^3) was measured with gas pycnometer (Stereopycnometer SPY-3, Quantachrome, Syosset, N.Y., USA) using helium as the displacement fluid for volume measurements. For each measurement three different samples were used, each measured three times.

SEM analysis

The structure of the crumb bread was analysed by scanning electron microscopy (SEM). Samples were freeze-dried and then mounted on metal stubs and sputter-coated with gold. Analysis of the samples was performed at an accelerating voltage of 10 kV with a SEM Jeol 6360 (Jeol USA Inc., Peabody, MA).

Dough rheology properties

The rheological properties of gluten-free dough were studied by a rotational rheometer (Rheometric Scientific SR5, United States) using a parallel plate geometry (mm diameter and 1 mm gap); the temperature was regulated at 25 ^oC by a RTE-130M circulating bath (Neslab, USA). The tests performed on the dough samples were: (a) strain sweep test in order to establish the viscoelastic region of dough samples and (b) dynamic oscillatory tests for a frequency sweep from 0.1 to 20 Hz at 0.5% strain. Each test was performed on different dough sample, at least in triplicates.

Mathematical Modelling

Various mathematical models were developed in order to determine the effect of the two independent parameters (the concentration of carob flour and water) in the total porosity, bread firmness and crumb's relative elasticity. The simplest and most convenient model according to the regression analysis was the power function.

RESULTS AND DISCUSSION

Chemical analysis

Table 1 shows the results of chemical analysis for breads with 15% carob content. Compared to a typical wheat bread this GFB has a high amount of dietary fiber and protein content; additionally it is a good source of microelements. According to Segura & Rosell (2011) the protein content of GFBs found in the Spanish market ranged from 0.91-15.05g/100g, with only one that contained soy protein had 15g/100g protein content. Thus, GFB with 15g carob flour/100 g flour can be considered a fibers' enriched product, rich also in proteins.

Table 1. Macronutrients and minerals amount of a gluten-free bread containing 15% carob flour

Macronutrients (g/100g bread)										
Protein		Dietary fibres		Fat		Ash		Carbohydrates		
8.37		6.10		2.04		1.76		38.70		
Minerals' concentration (mg/100g bread)										
Ca	K	Mg	Na	P	Al	B	Cu	Fe	Mn	Zn
75.93	112.02	51.72	381.89	99.58	1.01	0.15	0.19	1.65	0.69	1.17

Dough rheological characteristics

The viscoelastic region for the gluten-free dough formulations, measured by strain sweep experiments, was limited up to a strain of 1%; above this level, drop of elastic and loss modulus, G', G'' , respectively occur, indicating the breakdown of the gluten-free dough structure. Other researchers found 1% strain as the end of the viscoelastic region for gluten free formulations as well (Lazaridou et al., 2007; Sivaramakrishnan et al., 2004). Dynamic oscillation tests data concerning G' (f), G'' (f) and tan δ(f) for 5%, 10 and 15% carob content and for different water content are presented in Fig 1a, 1b, 1c, 1d.

All gluten-free dough formulations presented an elastic (or storage) modulus, G', greater than the viscous (or loss) modulus, G'' (f), in the frequency range. Tan δ values are always greater than 0.1 typical for weak gels. Concerning the impact of water content in dough formulations containing constant amount 5% of carob flour, the value of both moduli increased and that of tanδ decreased with a decrease in water content. This increase might be attributed to the fact that dough becomes stiffer since carob flour was not fully hydrated at low water content (Fig 1a, b).

The increase in carob content caused a shift of G' (f) and G''(f) towards higher values, while curve tan δ(f) exhibited lower values. Furthermore, frequency dependence on viscoelastic parameters was lower. The data indicate that carob addition caused an increase in bread dough elastic character e.g. led to a more pronounced solid elastic-like behaviour. Since both moduli increased with frequency, the gluten-free doughs exhibited a solid elastic-like behaviour. Therefore, tanδ (=G''/G') values for all dough formulations were lower than 1 (Fig 1 c,d). Similar observations on dynamic rheological studies have been previous reported for wheat dough supplemented with carob fiber (Mis´, 2011) and for rice flour dough (Lazaridou et al., 2007; Sivaramakrishnan et al., 2004).

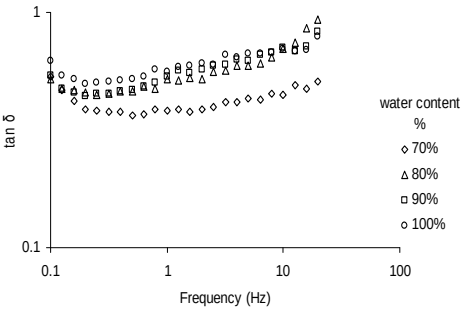

Figure 1b. tan δ(f) values for 5% carob content and different water content.

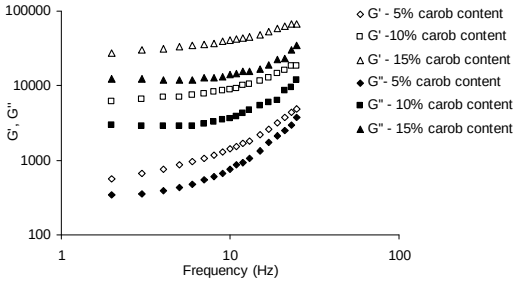

Figure 1c. G' (f), G'' (f) values for 100% water content for the three carob concentrations.

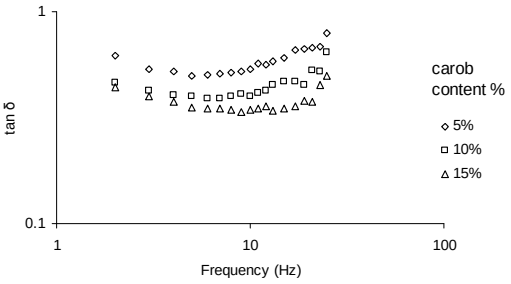

Figure 1d. tan δ(f) values for 100% water content for the three carob concentrations.

Crumb structural characteristics

Total porosity is influenced by both carob flour and water amount. As shown in Figure 2 and Table 2 porosity increases with increase in water but simultaneously is reduced with an increase in carob flour in an exponential relationship. However the influence of water is more pronounced that that of carob flour as shown by both figure 2 and mathematical model (Eq. 2 and Table 2). By changing carob amount from 5 to 15% in final GFBs, a reduction in maximum porosity values is observed that can be ascribed to fibers amount that may disrupt protein network and reduce bread volume.

Table 2. Mathematical model for Total porosity.

Total Porosity Model					
$\varepsilon=\varepsilon_o \cdot (C/C_o)^{n1} \cdot (W_t/W_{to})^{m1}$ (2)					
C_o	W_{to}	εo	n_1	m_1	R^2
10	100	44.41	-0.43	0.79	0.971

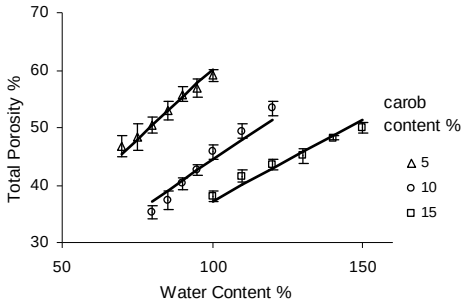

Figure 2. Influence of the carob and water content of GFBs on total porosity. Values are the averages of three replicates and error bars represent standard deviation. Solid lines represent theoretical values of the mathematical model (Eq 2).

SEM techniques were used to investigate the structural integrity of carob enriched gluten free bread's crumb. The addition of higher amounts of carob flour containing higher amounts of dietary fibers showed a large number of very small gas cells in an interrupted protein matrix, presenting a dense structure (Fig 3a. and 3b respectively). If the proportion of water is too low, the dough becomes brittle, not consistent leading to small or no development of the porous bread structure. In figures 3c and 3d GFB with 15% constant carob flour addition in different water contents is presented. In figure 3c with low amount of water content a coalescence of the gas cells may occur, evidenced by the small amount of gas cells presented. On the other hand sufficient water leads to a stabilized more aerated structure.

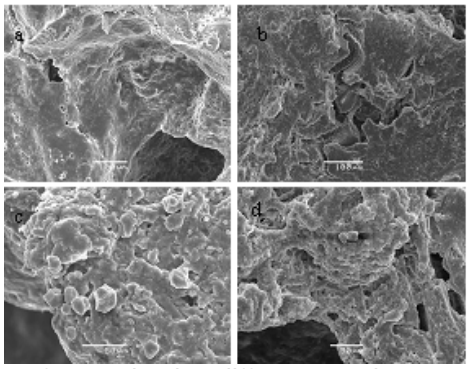

Figure 3. SEM micrographs of GFBs having different carob content /water ratios: 10/120 (a), 15/120 (b), 15/100 (c), 15/150 (d)

Texture analysis

Figure 4a shows that an increase in the water and carob flour content leads to a softening of the crumb. The greatest crumb firmness values were noticed in breads with 5% carob content (F_{max} = 48.7 N). Wang et al. (2002) indicate that the addition of carob fiber gives a softer bread crumb. However, firmness is mainly influenced by water content and in a much lesser extent by carob flour as shown in Table 3. Regarding relative elasticity, increasing the water there is a reduction in values observed (Fig. 4b). Carob flour can lead to a more elastic crumb as was found in the visoelastic tests of the dough

Table 3. Mathematical model for crumb's Firmness and Relative elasticity.

Firmness Model					
$F=F_o \cdot (C/C_o)^{n2} \cdot (W_t/W_{to})^{m2}$ (3)

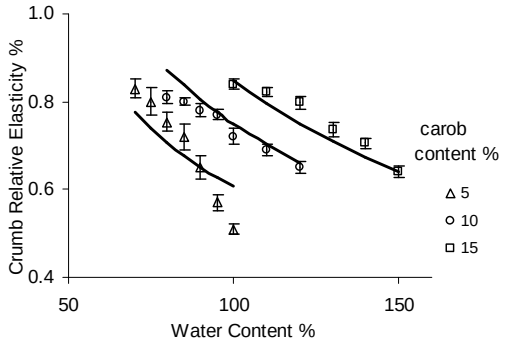

Figure 4b Influence of the carob and water content of GFBs on crumb relative elasticity. Values are the averages of three replicates and error bars represent standard deviation. Solid lines represent theoretical values of the mathematical model (Eq 4).

CONCLUSIONS

Based on the experimental results GFBs with carob flour / water ratio 10/110, 15/130 and 15/140, presented accepted quality parameters, with adequate dough proofing
crumb expansion and low firmness. The incorporation of carob flour as gluten substitute in breads results in bakery products with good functional attributes and improved nutritional value and can be proposed for a gluten-free diet.

ACKNOWLEDGEMENTS

This work was co-funded by the European Regional Development Fund and the Republic of Cyprus through the Research Promotion Foundation (Project ΥΓΕΙΑ/ΤΡΟΦΗ/0609(BIE)/08). The authors wish to thank the mills Kaplanides S.A. Serres- Greece for providing rice flour. We would like to thank the laboratory of Microscopy in AUA and specifically Dr. C. Fasseas for performing SEM analysis and for valuable discussions.

ABSTRACT: Given the overall demand for savings and quality improvement of beer, this study aimed optimizing of the production technology based on the evaluation of malts produced in Europe being reflected in the improvement of properties of beer in the factory "Birra Peja". The comprehensive study was carried out for the entire beer production chain, in close cooperation with the factory’s production and laboratory staff. The study was focused on malts produced in three European countries, Ukraine, Croatia and Serbia, as well as beer produced by these malts. These malts were analyzed in all stages of production, including chemical and microbiological analysis, as well as sensorial evaluation. Beer tasting for this study was done by two taster panels; panel of "Birra Peja" and the panel of Agricultural University of Tirana. We consulted with the working and laboratory staff at the "Union" brewery. Chemical and microbiological tests have been conducted based on European Beer Convention and MEBAK methods.Based on the conducted analysis and assessments of the beer quality, it was concluded that the beer produced with malts from Croatian origin, corresponds to a better quality of beer, which already is under production
Key words: Malt, Beer, production technology, EBC, MEBAK.

INTRODUCTION

The production of the beers was based on the a consistent formula at all stages of production, the same quantity and quality of water, the same amount of malt, the same generation *Saccharomyces carlsbergensis* type of yeast.
Starting from the first stage of beer production, one may observe various differences between the product and final product, such as saccharification time and rate, the apparent degree of fermentation, and the amount of polyphenols. An important factor is the amount of wort obtained at the end of the process or the degree of utilization of raw materials (malt) that is different from one type to another. Another very important factor is the presence of secondary products, such as high alcohols, which move from beer to beer.
In all cases of beer production technological parameters were the same, starting from the first stage in the domestication of the malt with water (quantity of malt, water quantity and water temperature).

MATERIAL AND METHODS

For this study, malts originating from Ukraine, Croatia, and Serbia are used. The first raw material used for the production of the beer: malts with the quantity of 4,500 kg, originally from Ukraine, Croatia and Serbia, water from the source of strong white Drin of 9ºDGH. In this case hops used on type originating from Slovenia Aurora (bitter) and Golding (aromatic) in report 70:30%. In all three cases there was 6.1gr α-acids/hl. Yeast which is used for production of these beers was *Saccharomyces carlsbergensis* with a concentration of about 20 million yeast cells per ml, or about 0.7 litres of a dense yeast hectoliter of wort. The processes and parameters in the phases of obtaining the wort were the same in all three cases.
The manufacturing process of the sweet solution was made with two decoctions. Cooling temperatures during the transfer to primary fermentation were the same (8 ℃ at the

beginning of the process). The temperature and pressure during the primary fermentation and complement was the same (8 ℃ - 15 ℃ and 0.5 b ar) for the three cases.
For the decomposition of β-glycan and the assistance of fermentation and decomposition of diacetyl enzymes used (α + β-glycan as amylase + protease, fungal-α-amylase, α-acetolactat decarboxylase).
At maturity, the beers stayed for 23 days at temperatures 0- (-1) ℃ and 0.5 bar pressure.
The beer was filtered with the same parameters and the same vehicle expense for filtering, (0.117030 kg / hl). The temperature was the same (25 min at 68 ℃) for pasteurization as well. At every stage of the production process of technological process is followed by microbiological tests which have been all time to level. Official methods for deriving the abovementioned results and analyzes are the following: the European Brewery Convention (EBC) and The Central European and Technical Analysis Commission "Methodensammlung der Mitteleeuropäischen Brautechnischen Analysenkommission" (MEBAK) .

CONCLUSIONS

Based on work done in the period March 2010 - December 2010, has come to the conclusion that beer produced from malts originating from Croatia fulfills best conditions. On the basis of chemical and microbiological analysis beers, malts produced by Croatian origin were more qualitative compare to others. Beer stability is high; it is drinkable and shows the colloidal stability of high level.

These beers were evaluated by two tasting panels: panel test of the Agricultural University of Tirana as well as the panel test of JSC "Birra Peja". It is tested to Beer: taste, aroma, color, clarity, and foam. During these tasting beers that both groups have scored as follows: to taste (2.00; 2:45; 2.20), for flavor (1.57, 1:22, 1:35), for color (3.80, 4:45, 4:11) to light (3:42 ; 4:00; 4.00), and foam (3.10, 4.28, 4.44) Both panels evaluated with higher grade the beer produced from selected malts from Croatia.

EFFECT OF ELECTROMAGNETIC WAVES (MICROWAVE) ON STORAGE ABILITY OF YOLK LIQUID

F. Lotfian[1], A. Mousavi Khaneghah[*2,] , E. Jahed[3], S. H. Khabbazi [4]

ABSTRACT:Microwave energy inactivates micro-organisms. In this study yolk liquid was pasteurized by using electromagnetic method in 3 different frequencies (2950-3950-4500 MHz) for constant time of 12 sec (6 sec of second pulse) and then results were compared with samples which were pasteurized at 65°C for 120 sec and control samples, after different times of storage(1,3,5,8,10 and 15 days). Results showed that used electromagnetic waves had significant effect on reduction of logarithmic count of aerobic mesophilic bacteria. According to results, however thermal pasteurization had a greater bactericide effect at zero time than cold pasteurization, but, a great increase was occurred in the number of aerobic mesophilic bacteria after passing time, in comparison with non- thermal pasteurized product. According to Iranian National Standard, in electromagnetic method liquid yolk shelf life has been defined 14 days which it is very ideal in comparison with thermal pasteurization (7d max) and control sample (2d max)
Key words: *electromagnetic waves (microwave), Yolk liquid, mesophilic bacteria, Non thermal methods.*

INTRODUCTION

Pasteurization inactivates some of undesirable enzymes; this method extends shelf life of liquid egg yolk around 7 days, 10 days, 14 days and even 16 days. It depends on relation between thermal processing temperature and length of time (Schlegel, 1992). Pasteurization is defined as “a process of heating food for the purpose of killing harmful organisms such as bacteria, viruses, protozoa, molds, and yeasts.” (Lewis and Heppell, 2000). A process has been developed for the non-thermal treatment of liquid food products which results in a significant reduction in the microbial population, thus reducing spoilage and extending shelf life. In egg yolk because of low pH and higher solids content, Egg yolk is an excellent media for the growth and multiplication of bacteria and bacteria are able to grow faster than whole egg and albumen, so egg yolk pasteurization temperature must be higher than pasteurization temperature for egg and albumen (Stadelman *et al.,* 1995). Proteins are highly heat sensitive components of the egg. The functional properties like whip ability, foam ability, foam stability etc. which make the eggs an inevitable ingredient of various food products are severely affected by high temperatures. Also experimentally it is found that the egg yolk needs to be heated to a higher temperature than the albumen (Dev *et al.,* 2008). Since yolk pasteurization changes the amount of solid substances, it is effect on stability and resistance of the emulsifier, also in consequence of thermal process, proteins will be denaturised and formed disulfide bonds that will cause to release sulphur gas and make a bad smell (Hanson *et al.,* 1946). Heating leads to death in foodstuff bacteria, either it is effect on aroma, flavor, texture and nutritional value of processed food. Among different methods of antisepticising of food, because of protection nutritional value of product, improve the quality of food and decrease of its cost that it is important for customer the non -thermal methods which results in significant reduction in microbial count, and decreasing of spoilage and increasing shelf life of food products these methods have been received more attentions (Hasanzade, 2008;

Huang, 1989). This study examined the effect of cold pasteurization by electromagnetic waves (microwave) on liquid egg yolk and reduction of logarithmic amount of present aerobic mesophilic micro-organisms in samples, and compared them with current thermal methods (regular pasteurization).

MATERIAL AND METHODS

Sample preparation

Samples were selected from a fresh and healthy batch of egg and it was broken by egg breaker equipment, and was separated (yolk and white egg), was filtered (to separate crust and small particles) and was homogenized. These was performed by selecting fifty 100 g samples from 100kg liquid yolk randomly and they were filled in special poly ethylene bags automatically after filtering and they were stored at 0 to 4ºC until experiments.

Instrumentals specifications

Electromagnetic pasteurizer was used (model SCP150, Afra Sanat Kimia Mashhad co, Mashhad, Iran). This device was able to work in variety of temperature, times and frequencies.

Method

Four Samples were selected randomly, then, one of them was retained as control sample and other three samples were treated under 3 frequencies (2950, 3950 and 4500 MHz). Each experiment replicated 10 times. Prepared packaged samples placed in the device chamber and it was set turn on and turn off magnetrons at specific times. It was considered 2 pulses, 6 sec ON and 8 sec OFF it means that the total exposure period was defined 12 sec and total procedure period was 20 sec. The storage time was defined accordingly to avoid of egg yolk coagulation that it is the maximum time which 100 g liquid egg yolk could expose to electromagnetic waves at max 40 ºC without any damages or changes in its physical properties in comparison with fresh (control) sample. After setting pulses and time switch the magnetron1 (frequency 1 ON and turn the system ON, and has taken out the sample, after the set time has finished and system turned OFF, second and third samples exposure to higher frequency by defined method respectively, then all samples were treated under the same pasteurization method. In this method temperature of product center was below 40°C. Also egg yolk liquid samples were pasteurized at 65°C by regular pasteurizer and then automatically filled in airproof packages by filler and placed in refrigeration room. Then samples transferred to laboratory for cultivation with culture medium of plate count agar in 2 repeat, and cultivated in 30 °C for 72 hours according to national standard NO. 5272, and Total Aerobic Mesophilic Count (TAMC) were determined. Results were compared with those which they are as control and thermal treated samples. After that treated samples which stored in suitable condition (0°C to 4°C) for 1, 3, 5, 8, 10, 15 days for studying the effect of storage time on TAMC, then cultivated and TAMC was determined again. Results were compared with permitted total count of mesophilic bacteria's in pasteurized egg, with consider to Iranian national standard (13248) (Institute of Iran Standard and Industrial Researches, 2007; Institute of Iran Standard and Industrial Researches, 2010)

Statistical analysis

Each treatment was analyzed as randomized complete block design with ten replications and the data were assessed by analysis of variance (ANOVA) and Duncan s multiple range test using MSTAT-C software program. Differences among treatments were tested with least significant difference (LSD) test ($P<0.05$). Besides, correlation analyses were performed to clarify the relations among parameters considered in this study. Microsoft Excel 2007 was used to plot apparent.

RESULTS AND DISCUSSION

Effect of different electromagnetic frequencies (microwave) and different storage time on logarithmic count of aerobic mesophilic bacteria

Results showed that pasteurization by electromagnetic waves had reduced count of aerobic mesophilic bacteria in egg yolk liquid at least 0.30 to 0.46 logarithmic cycles instantly after cold pasteurization in comparison with control samples. Microwaves have the ability to generate heat from within the substance that is exposed to it. The shell egg appears ideally suited for pasteurization in a microwave environment (Fleischman, 2004; Rehkopf, 2005). The results confirmed with results of kozempel et al. (1999) which reported microwave energy has a significant effect on reduction of microbial population in egg yolk liquid (Kozempel *et al.,* 1999). Results also agreed with results of Dev et al. (2008) which showed, in this study, microwave heating has been considered for in-shell egg pasteurization. First of all, the effects of temperature (0-62^{o}C) and frequency (200 MHz to 10 GHz) on the dielectric properties of egg components were investigated. Laboratory trials on microwave heating of in-shell eggs indicated that the heating rates of both albumen and yolk were similar. Therefore, microwave heating appeared perfectly suited for in-shell egg pasteurization (Dev *et al.,* 2008). According to results, that obtained from statistical analyzes, effect of adding frequency variants ($P<0.05$) and pasteurized product durability ($P<0.01$) on reduction of total aerobic mesophilic count in liquid egg yolk in α level was 0.05 (95% probability) and it was statistically significant, but no interaction was observed between studied variants in cold pasteurization process. Storage time which was studied up to 15 days has a higher effect on TAMC than various frequencies applied so the value of increasing TAMC was higher than reduction of it during yolk liquid pasteurization process by different electromagnetic waves. Comparing averages of three types frequencies used in liquid egg yolk cold pasteurization and reduction of TAMC, experiments showed that killing ability of waves has decreased by increasing frequency from 2950 MHz to 3950 MHz, and then by increasing frequency to 4500 MHz efficiency of electromagnetic method in reduction of microbial population in pasteurized product significantly increased (figure. 1). As shown in figure 1. Minimum TAMC was in samples which were treated by frequency 4500 MHz and it was 3.68 cfu/mL, that a reduction was found around 1.2 logarithmic cycles in comparison with control samples. The least lethal effect was at 3950 MHz that it has a decline around 0.97 logarithmic cycles comparing with control sample. Lethal ability of microbial population at 2950 MHz frequency was medium, however it was better than 3950 MHz frequency (by reduction around 1.1 logarithmic cycles) but it was not statistically significant.

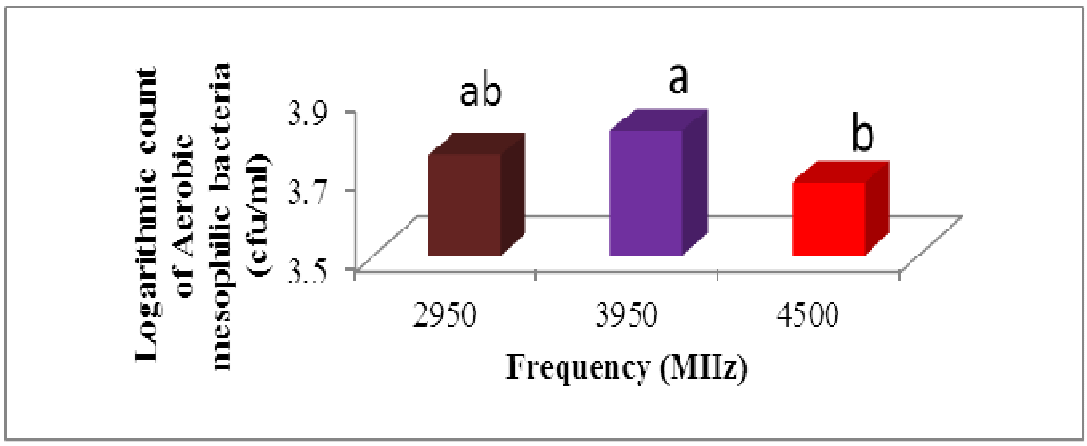

Figure 1.Effects of different frequencies on TAMC in liquid egg yolk cold pasteurization procedure

Therefore it has been confirmed that in a way of better functionality and higher lethal ability frequencies are in this order: 3950 MHz <2950 MHz <4500 MHz but 3950 was an exception which it has a lower killing effects. Results show that by increasing storage time of pasteurized product from 0 days to 15 days, TAMC rise rapidly, depend on intensity of

treatments, increased by different growth rates (Figure 2.). TAMC immediately after pasteurization at 4500 MHz was 3.17 cfu/mL and went up to 4.38 cfu/mL in 15th day. TAMC instantly after pasteurization (zero time) at 2950 MHz and 3950 MHz were 3.27 cfu/mL and 3.33 cfu/mL, respectively while in 15th day it reached 4.42 cfu/mL and 4.50 cfu/mL respectively. This agreed with Sevcan et.al. Studies on variation in dielectric content of fresh egg in storage period and relation of it with egg freshness and either confirming that ε' (dielectric properties rate) and ε" (dielectric lose factor rate) in egg yolk, will increase during storage (Unluturk *et al.,*2008).

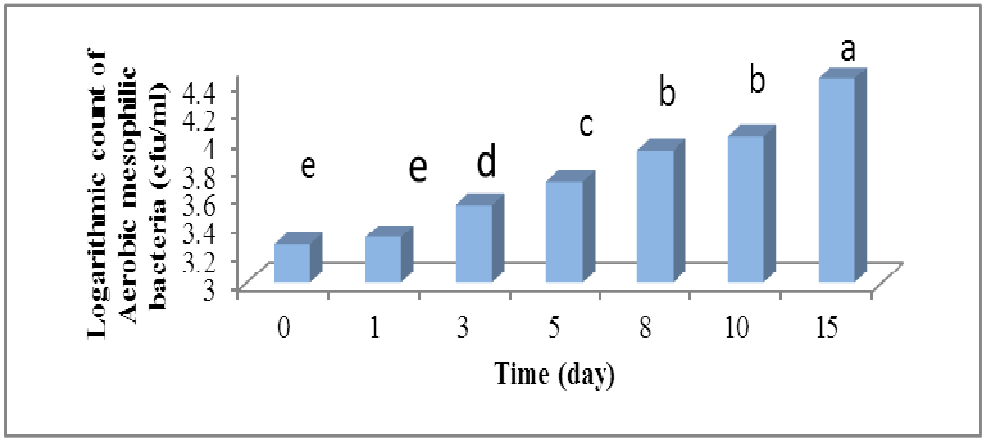

Figure 2. Effect of different storage time on logarithmic amount of aerobic mesophilic bacteria's in yolk liquid cold pasteurization procedure

Comparison between liquid egg yolk cold pasteurization, electromagnetic method and pasteurization by thermal treatment

Results showed that in zero time (immediately after treatment), thermal pasteurization can decline TAMC around 0.52 and pasteurization by electromagnetic method can decrease TAMC nearly 0.3 to 0.46 logarithmic cycle comparing with initial control samples (Table 1). Thermal pasteurization method was more effective in destroying bacteria in comparison with cold pasteurization in zero time, but because of high advantages of non -thermal methods, this difference is connive. Therefore, results of this study, confirmed different studies, include Goldblith and Wang (1967), Mudgett (1982) and Fujikawa et al. (1992) welt et al. (1993) showed that there isn't a significant difference between microwave heating and regular heating (Goldblith and Wang 1967, Mudgett 1982, Fujikawa *et al.,* 1992, welt *et al.*, 1993). Results generally showed that both treatment, include thermal and electromagnetic have significantly decreased microbial amount in comparison with blank samples, and this difference was observed during product storage days. According to results, cold pasteurization by electromagnetic waves decreased mesophilic bacteria population more than regular methods, especially during storage days, product which had been treated by waves, had less increasing microbial amount (Figure 3.). As it could be observed, even worst electromagnetic treatment (in 3950 MHz) has better worked in comparison with thermal treatment (thermal treatment<3950 MHz<2950 MHz<4500 MHz). Results of this research showed that usage of both heat and waves could have stronger effect on lethal factor and it confirmed results of Kozmpel et al. which demonstrated that microwave energy may complete or strength thermal effects (Kozmpel *et al.,* 1999). Sanvo co. (2010) used microwave method combined with 65°C heating and claimed that product heated to only coagulation and coacolation point and consequently the product was completely like fresh egg. This process decreases total amount of bacteria 10 times more than regular pasteurization methods. Studies showed that the method will protect egg functional properties 20% more than regular methods (Colavitti *et al.,* 2010). There is significant reduction in process time which is important in results of other studies, also in this study confirmed total time of process is only 20 sec that it is very short comparing with 120 sec time of thermal pasteurization. In comparison with regular methods for heating foodstuffs,

pasteurization by microwave potentially could improve organoleptic properties, appearance and nutritional value. During storage time minimum amount of aerobic mesophilic bacteria was determined in samples treated by waves and since first day it was observed that increased amount of aerobic mesophlic bacteria in thermal treatment. It was much higher than treatments by waves, for example in 4500 MHz frequency logarithmic number of bacteria increased from 3.17 at the first moment after process to 4.38 in 15th day, (i.e it has increased 1.21 logarithmic cycle), whereas in thermal treatment from 3.11 immediately after process reached to 4.99 in 15th day (i.e. it has increased 1,88 logarithmic cycle). As it has shown in Figure 3. Logarithmic number of bacteria in 4500 frequency which was equal to 3.68 cfu/mL during storage days as it showed reduction around 1.2 logarithmic cycles in comparison with control sample. Minimum killing effect was in 3950 MHz which had a reduction around 0.97 logarithmic cycles. Killing effect of 2950 MHz was halfway and it was almost 1.1 logarithmic cycles and in thermal treated samples, total aerobic mesophilic bacteria was equal to 4 cfu/mL and killing effect was around 0.74 logarithmic cycle. Results showed that, however thermal pasteurization was better on destroying bacteria than cold pasteurization at the first time, microbial amount increase more rapidly during storage time.

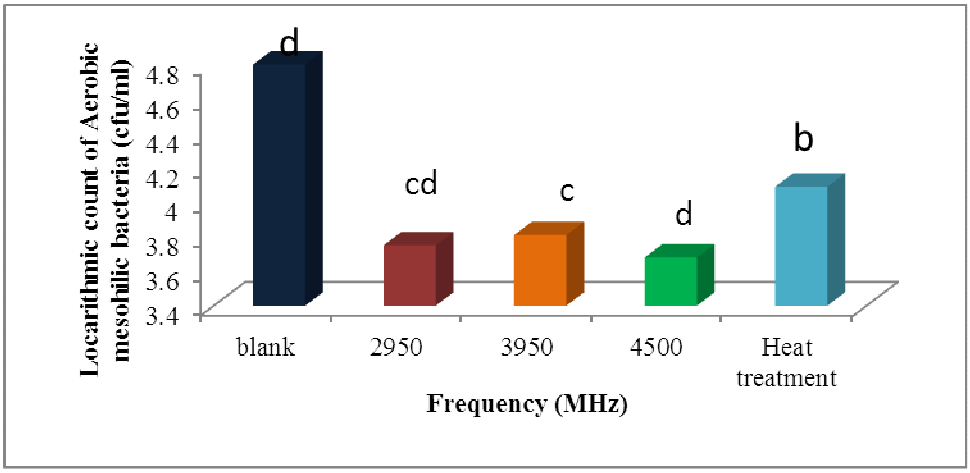

Figure 3. Comparison of yolk liquid cold pasteurization procedure using different frequencies with blank samples and thermal pasteurization procedure

Table1. Average aerobic mesophilic bacteria's population, under different treatments and different storage days

Blank	Heat treatment	4500MHz	3950MHz	2950MHz	Storage day
3.63	3. 11	3.17	3.33	3.27	0
4. 3	3. 55	3.25	3.38	3.34	1
4. 72	3. 75	3.49	3.59	3.55	2
4. 92	4. 12	3.66	3.77	3.71	3
5 .07	4. 45	3.87	4	3.93	8
5. 24	4. 69	3.97	4.10	4	10
5. 96	4.99	4.38	4.5	4.42	15

Determination pasteurized sample's storage time according to Iranian national standard limit

Microwave energy inactivates micro-organisms through thermal kill. It also has the potential to cause biological damage as well as alteration of the cell membrane and metabolic functions. (Huang, 1989). Maximum authorized logarithmic amount of liquid egg pasteurized mesophilic bacteria at 0°C – 4°C is 4.47cfu/mL and it was defined 30000 pcs/mL according to Iranian national standard. At the end of third day, results showed that logarithmic amount of mesophilic bacteria in control samples (non- pasteurized) is 4.72 cfu/mL (Table 1). Therefore, maximum storage time of non-pasteurized liquid egg is two days. At the end of 8th day, results confirmed that total aerobic mesophilic count in thermal treated samples is

4.45 cfu/mL (Table 1). Therefore, maximum storage time of liquid egg pasteurizing by regular thermal method is 7 days. At the end of 15th day results showed that number of aerobic mesophilic bacteria in cold pasteurized samples is 4.38- 4.5 cfu/mL (Table 1). Therefore, maximum storage time of liquid egg which pasteurized by waves method is 14 days. Finally it was observed that the rate of increasing total aerobic mesophilic count in product that was pasteurized by this method (cold pasteurization in electromagnetic method) was much slower than regular thermal method. Tang et al. (2002) by similar studies on bean showed that the product processed by microwave had better color and taste than those pasteurizing by regular method in cans and shelf life of sterile product by microwave will increase (Tang *et al.,* 2002). Consequently, shelf life of pasteurized liquid egg yolk in electromagnetic method defined maximum 14 days which is more ideal comparing with shelf life of it in regular methods, 7 days, and control sample (non-pasteurized yolk liquid), 2 days.

CONCLUSIONS

Liquid egg yolk cold pasteurization significantly decreased total aerobic mesophilic count of samples. Therefore this method can be used in liquid egg yolk manufacturing industry. Meanwhile present obstacles in use of pasteurized yolk liquid in the country (because of changes in quality and functional properties comparing with fresh egg) will be eliminated and like other modern countries in the world, national legal organizations can persist on obligation of using pasteurized liquid egg in egg consumer units. Because raw egg consumption that includes a huge risk, will reduce in products such as mayonnaise sauce and therefore could effect on the usage of chemical preservative substances in these products. Also it was observed that product shelf life in this method has increased two times comparing with regular thermal method. It shows that in spite of initial amount of vegetative bacteria in regular thermal method was lower at the first time, it wasn't able to terminate bacteria spores equal to wave method, that this is very important for consumers and makes higher assurance for shopping and storage of product.

ABSTRACT: With the objective to replace mayonnaise as the basis of a ready-to-eat traditional Greek deli salad, corn, carrots, cucumbers, peas, capers and Aloe Vera and lemon juices were combined into an emulsion like homogenized avocado puree. All ingredients were of Greek organic agriculture. The product was vacuum packaged in transparent, polypropylene containers. The objective was to achieve a commercially viable product fresh-like quality and extended shelf life. High Pressure (HP) processing, targeting on microorganisms and enzymes inactivation while maintaining the sensorial quality of the food was used. After refining the formula of the product for final texture, flavour and quality, it was HP processed at pressures ranging from 100-800MPa and process times from 2 to 30min to allow for optimal HP conditions selection. The main quality deterioration factor for avocado-based products is the enzymatic browning attributed to polyphenoloxidase (PPO). Control of PPO activity is prerequisite for product stability through time. Based on sensory evaluation and colour degradation of the processed samples, the conditions selected were 600 MPa for 15 min. Adequate microbial and enzyme inactivation was measured at these conditions, while texture and flavour were maintained. Shelf-life experiments were conducted at temperatures from 0 to 15 ºC. Based on the quality indices monitored and modeled with time, the shelf life of this product was estimated as 72, 45, 20 and 7 days for storage at 0, 5, 10 and 15 ºC, respectively.
Key words: *High pressure, extended shelf-life, avocado-based products, stability*

INTRODUCTION

Several traditional Greek deli salads are based on a mayonnaise emulsion with a variety of ingredients mixed in, including vegetables such as eggplant, carrots, potatoes, traditional pasta components and herbs and spices. The aim of food producers is to extend the line of such products, strengthening the healthy image, by replacing the mayonnaise basis with a no egg, no added fat vegetable based matrix. Avocado puree, rich in nutrients, and unsaturated fats could be used as a substitute of mayonnaise. However, a major fraction of avocado protein content has been reported to be composed of oxidative enzymes such as polyphenol oxidase (PPO) (Kahn 1977; Elez-Martinez et al, 2005). When avocado pulp is processed from the intact fruit, the tissue undergoes partial disruption of cellular organelles releasing PPO enzyme that reacts with its substrates (phenolic compounds), causing the formation of *o*-quinones. These compounds undergo further polymerization producing brown pigments, undesirable flavors, and nutritional losses (Weemaes et al, 1999; Tomas- Barberan and Espın 2001). Consequently, the main quality deterioration factor for avocado-based products is the enzymatic browning attributed to PPO. Control of PPO activity is prerequisite for product stability through time.

Conventional thermal processing (thermal pasteurization) could be used to inactivate PPO from avocado products, but the temperature has negative effect on sensory (development of bitter taste) and nutritional characteristics. On the other hand, High pressure (HP) could be used in commercial-scale operations as a non thermal processing technology in order to inactivate the spoilage microorganisms and endogenous enzymes (Lopez-Malo et al,1998;

Palou et al,1999;2000; Katsaros et al 2010) as well as to extend the shelf-life without affecting their quality characteristics. Application of HP processing on acidified avocado puree (addition of lemon juice) could minimize the detrimental quality modifications induced by residual PPO activity and assure product safety. The objective of this work was to study the quality and shelf-life extension of a commercially viable non mayonnaise based, vegetable (avocado based) deli salad.

MATERIAL AND METHODS

Product formula refining

The developed 'Green Mediterranean Deli Salad' composition is similar to the widely known Russian salad, substituting the mayonnaise with avocado puree and adding some health promoting ingredients. The product composition can be characterized by two parts; the avocado base and the rest vegetable based ingredients:

Base: Avocado puree (54%) was used as a base for the production of this salad. Avocadoes are rich in nutrients such as dietary fibres, vitamin B6, vitamin C, folates, vitamin E, potassium and magnesium. They have a mild fresh flavour and the texture of their puree can be similar to the mayonnaise emulsions. *Aloe Vera* juice (3%) was added to avocado puree targeting in the desired textural characteristics of the final product, while simultaneously strengthening its nutritional-functional characteristics.

Vegetables: Whole vegetables or vegetables cut in cubes were added to the base (avocado puree) adding nutritional value to the product. The addition of different vegetables of different colours made the final product more attractive to the consumers and contributed to the desired flavour and taste. The ingredients - all products of Greek organic cultivation - that were added for the formula refining are: corn (11%), cucumber (9%), carrot (8%), caper (3%), peas (2%), salt, pepper and lemon juice for pH adjustment equal to 4.

A number of steps using appropriate equipment that consists of vegetable processing units, packaging equipment, High Pressure Unit for cold pasteurization and cold chambers for the storage of products are necessary for the final product production (Figure 1).

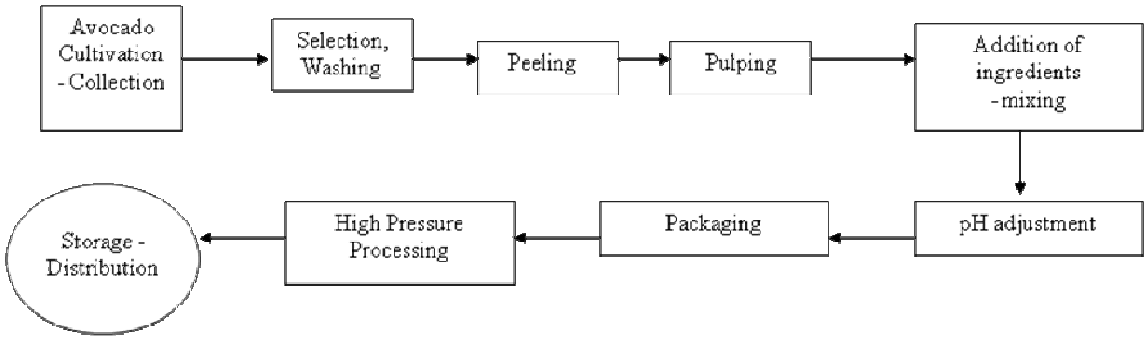

Figure1. Flow chart for the production of Green Mediterranean Deli Salad

For the experiments, samples (200 g) were packed into multilayered bags (PP-aluminium leaf-PE) for HP processing. High pressure treatments were achieved using a 1.5 L volume HHP equipment with a maximum operating pressure of 1000 MPa and temperature control (Food Pressure Unit FPU 1.01, Resato International BV, Roden, Holland) by a liquid circulating jacket connected to a heating-cooling system. Pressure was released after preset time interval by opening the pressure valve. Pressure and temperature were constantly monitored and recorded (in 1 s intervals) during the process. HP processed and untreated samples were stored at 0, 5, 10 and 15 ºC for over a period of 72 days. Selected quality indices such as sensory evaluation, microbiological analysis and colour were measured through time for the determination of Green Mediterranean Deli Salad shelf-life. Evaluation of the selected quality indices for all the samples was performed at specific time intervals. The shelf-life determining factors were browning and bitter taste.

Polyphenoloxidase activity
The PPO activity was measured as described by Pizzocaro et al. (1993). For HP treated and untreated samples, 10 g were mixed and homogenized with 10 ml of citric-phosphate buffer solution (pH 6.5). The homogenate was centrifuged (4000xg) at 4 ºC for 30 min and the supernatant was filtered and analyzed for PPO activity at 420 nm and 25 ºC. One milliliter of catechol solution (0.175 M) and 2 ml of buffer solution pH 6.5 were added to 0.5 ml of PPO extract. PPO activity was assayed in triplicate in a Spectrophotometer (Helios Unicam, USA) and calculated on the basis of the slope from the linear portion of the curve plotted with ΔA_{420} versus time up to 2 min for both fresh and HP treated avocado purees. One unit of PPO activity was defined as 0.001 ΔA_{420} min^{-1} (ml of extract)$^{-1}$. Residual PPO activity was expressed as the ratio between treated and fresh avocado purees.

Color measurement of avocado-based salad
Quantification of the colour change was based on measurement of CIELab values with a CR-200 Minolta Chromatometer (Minolta Co., Chuo-Ku, Osaka, Japan) with an 8 mm measuring area. At predetermined times of isothermal storage, according to the design, measurements were conducted and values of ΔC and ΔE were determined.

Microbiological analysis
Microbiological analysis was conducted in HP-treated and untreated samples of Green Mediterranean Deli Salad. Using the spread-plate technique, total plate count (PCA) and yeasts and moulds (RBC) were measured in all samples after incubation at 25 ºC for 72h and 120h, respectively. All received data were estimated as $\log_{10}$ values.

Sensory evaluation
For the sensory evaluation all the samples were removed from the storage cabinets and stored at 15 ºC until temperature equilibrium (approximately 30 min). The colour, taste and general impression of each sample were scored by a 9-member organoleptic panel, using a nine-grade hedonic scale. The value equal to 5 was set as the acceptance/non-acceptance limit.

RESULTS AND DISCUSSION

After refining the formula, the final product was HP processed at pressures ranging from 400-600 MPa and process times from 5 to 15 min at 20℃, to allow for optimal HP conditions selection. Based on minimum sensory and colour degradation and microbial (total microflora) and enzyme (PPO) inactivation, the process conditions selected were 600 MPa for 15 min. Figure 2 presents the residual PPO activities for the studied high pressure treatments. For treatment at 600 MPa and process times 5, 10 and 15 min, the residual PPO activity in avocado puree was estimated as 68, 36 and 5% of the initial activity, respectively. Pressure treatment of the avocado puree at a pH value 4, significantly affects its PPO activity. This is in agreement with the study of Eshtiaghi and Knorr (1993) who reported that reducing the pH of the immersion medium by addition of citric acid combined with high pressure treatments could lead to increased PPO inactivation.

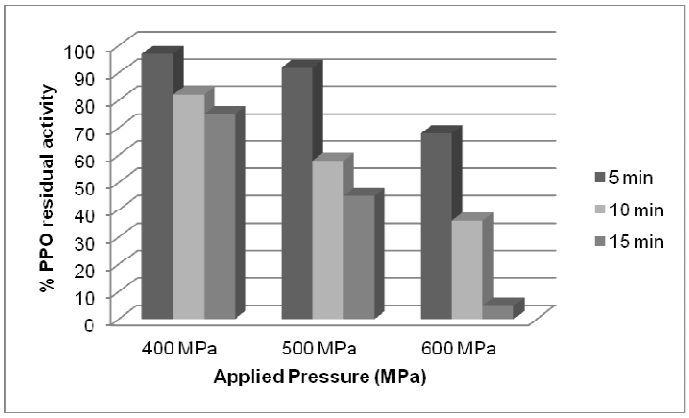

Fig. 2. Effect of high hydrostatic pressure treatments on PPO activity of avocado puree

Microbiological analysis

HHP treatment (600MPa, for 15 min at 20 ºC) of avocado-based salad prepared with a reduced pH (4.0) yielded microbiologically stable products during storage at 0, 5, 10 and 15 ºC. For all HHP treated samples stored at all temperatures, the measured colonies for total plate count and yeasts and moulds were below the detection limit, throughout the whole studied storage period. On the other hand, the untreated samples were spoiled within the first 5 days of storage at 5 ºC (total microflora higher than 10^7 CFU/g).

Colour change

Colour is considered to be the most deteriorative quality index for that kind of products. During storage, the colour of all samples was measured using appropriate equipment. The initial color parameters of the untreated (L=62.4, a=-7.02, b=35.18) and pressure-treated samples (L=61.59, a=-7.80, b=34.66) at 600 MPa for 15 min were not significantly different. During storage, only the a-value of the color parameters was altered significantly. The b value (yellow-blue parameter) and the L-parameter of the colour (higher L-value corresponds to brighter sample) of samples stored at 0, 5,10 and 15 ºC did not change significantly (Figure 3a). On the other hand, the a-value parameter (negative a-values represent green colour, while positive values represent red colour) appeared to be more sensitive to temperature and time. Storage at 15 ºC resulted in an increase of a-value from -8 to -1 within 7 days. At that time (when a-value equal to -1), the product was considered to be unacceptable. The effect of storage time and temperature on the a-values of all samples is depicted in Fig. 3b.

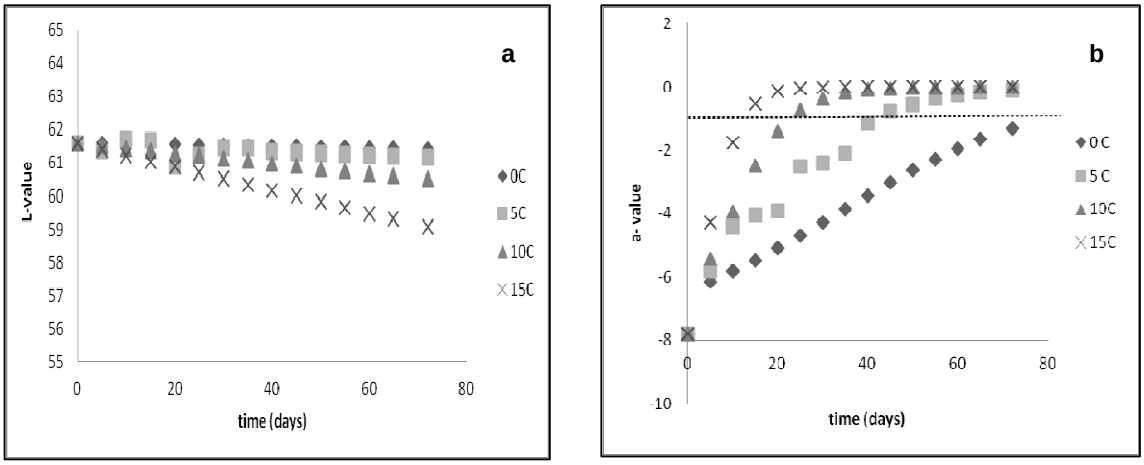

Figure 3. Colour parameters alteration: **a.** lightness (L-value) and **b.** red-green parameter (a-value) for the HP treated (600 MPa, 15 min, 20℃) product during storage at 0, 5, 10 and 15°C.

Sensory evaluation

All the samples were sensory evaluated by the sensory panel. According to their evaluation, HP-treatment did not significantly affect the overall impression of the samples compared to the untreated samples. For samples stored at 15 ºC, the degradation was fast, resulting in a non-acceptable product after storage of 7 days. When the samples were stored at lower temperatures the degradation was significantly slower. All the results of the samples scoring are depicted in Figure 4. The dot line represents the limit (score equal to 5) under which the samples are considered to be not appropriate for consumption. The limit was defined by the colour degradation of the samples (brown pigments appeared on the surface) and by the bitter taste that was developed to these samples.

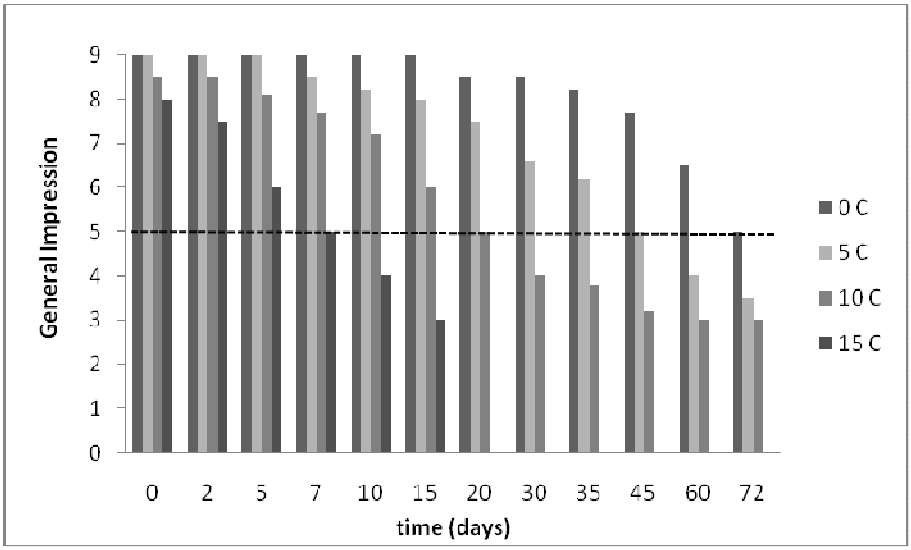

Figure 4. Sensory evaluation of high pressure-treated samples of "Green Mediterranean Deli Salad" during storage at 0,5,10 and 15 ºC

Shelf-life determination

The quality degradation and the shelf-life estimation of the developed product can be correlated to the development of bitterness in the product and by the colour alteration due to enzymatic browning. Taking into consideration all the received results from our study, the shelf-life can be determined based on colour alteration (a-value equal to -1) or the sensory evaluation (scoring equal to 5). The shelf life of this product is estimated as 72, 45, 20 and 7 days, after storage at 0, 5, 10 and 15 ºC, respectively. Comparing the obtained results with corresponding results for untreated samples stored at 5 ºC (shelf-life estimated as 5 days), a 9-fold increase is achieved when processing at 600 MPa at 20 ºC for 15 min.

CONCLUSIONS

The shelf-life study of a developed deli salad ready-to-eat product, HP treated at 600 MPA for 15 min, was studied. The HP treatment was used for the pasteurization of this product, in which mayonnaise emulsion was substituted by homogenized avocado puree which is very sensitive to enzymatic browning. The quality degradation and the shelf-life estimation of the developed product can be correlated to the development of bitterness in the product and by the colour alteration due to enzymatic browning. In general, the shelf-life was estimated as 72, 45, 20 and 7 days, after storage at 0, 5, 10 and 15 ºC, respectively.

The development of a commercially viable non mayonnaise based, vegetable deli salad with fresh-like quality and extended shelf life, named "Green Mediterranean Deli-salad", was achieved. The in pack non-thermal High Pressure (HP) processing, targeting on microorganisms and enzymes inactivation, while maintaining the sensorial quality of the food,

can be efficiently used. A superior product with commercial stability addressed to local and export markets was developed, based on the healthy image of avocado and Aloe Vera and other organically grown Mediterranean ingredients.

ABSTRACT: Smoking is a traditional method for preserving fish due to the synergistic action of salt incorporation, the preservative effect of smoke compounds and dehydration, creating a product with a characteristic flavour and an extended shelf life. The aim of the study was to model and comparatively assess changes in quality characteristics of smoked eel, mackerel and salmon, during refrigerated storage. Hot smoked eel (*Anguilla anguilla*) fillets, whole smoked mackerel (*Scomber japonicus*) and cold smoked salmon (*Salmo salar*) slices were provided by a Greek farming and processing unit. Eel fillets were stored isothermally at 0, 5, 10, 15℃ and at variable temperature conditions (T_{eff}=7.5℃) and mackerel and salmon slices were stored at 5 and 10℃. Quality assessment was based on microbiological analysis, colour, lipid oxidation (TBARs), TVB-N and sensory scoring. Quality indices were kinetically modelled and temperature dependence of quality loss rates was modelled by the Arrhenius equation. According to sensory evaluation, the shelf life was 7-9 weeks at 5℃ and 3-5 weeks at 10℃. The limiting TBARs value for sensory acceptability was 2 mg·kg^{-1} flesh for mackerel and salmon. Eel fillets exhibited higher TBARs values due to their significantly higher lipid content (23.9% crude lipids). TVB-N value of 10 mg N·100g^{-1} was used as the limit of acceptability for smoked eel. Results from variable temperature experiment were in good agreement with the prediction of the shelf life models developed from the isothermal experiments validating their applicability at the fluctuating storage conditions that usually occur in the cold chain.
Key words: *smoked fish, eel, mackerel, salmon, kinetic modelling*

INTRODUCTION

Smoking is one of the oldest means of preserving fish and meat. The long shelf life of smoked products is due to the low water activity, resulting from the added salt and slight dehydration, the processing temperature, which may be as high as 80-90℃ and the contribution of smoke components. In lightly smoked products, containing less salt and smoke components and more moisture, refrigeration and vacuum packaging contribute to preservation. Smoked seafood may contain up to 0.5 g/100 g of tissue of smoke components, mainly carboxylic acids and phenols, which have a distinct antimicrobial action. More susceptible to the action of smoke components are the vegetative forms of bacteria, while spores and moulds are usually more resistant.

Cold smoked fish is of considerable economic importance worldwide, particularly in Europe. These food products are produced by a light salting and smoking process (containing about 5.5% salt in the water phase and exposed at least 6-7 h to the action of smoke) and are typically consumed as ready-to-eat with no additional heat treatment. It is usually stored at chilled temperatures, is more sensitive than the hot smoked products and based on sensory evaluation have a limited shelf life of 2 to 6 weeks.

The process of smoking affects the sensory attributes of seafood by inducing desirable protein changes, resulting from the salt curing as in cold smoked products, or from heat treatment, e.g. in hot smoked eel. It imparts an appealing smoked colour and flavour to the fish. The colour of smoked fish depends mainly on the pigmentation of the skin, but is also affected by the amount and composition of the deposited smoke components and their interactions with the product. The kind of wood used for smoke generation has also a significant effect (Sikorski and Sun Pan, 1994).

European eel (*Anguilla anguilla*) is an economically important fish. The top three producing countries of farmed European eel are the Netherlands, Italy, and Denmark. Spain, Greece, Sweden and Germany are also centres of eel farming activity. The market demand for fresh eel has increased markedly due to its aroma and high yield. Eels are usually hot-smoked after brining or dry-salting, but the method differs considerably from country to country to suit local preferences. In Europe, eels are sold almost exclusively as skinned hot-smoked fillets.
Mackerel *(Scomber japonicus*) demonstrates an exceptional nutritional value in the human diet being rich in minerals, vitamins and polyunsaturated fatty acids. Mackerel is usually hot smoked to give a ready-to-eat delicatessen product. In Greece, mackerel is usually marketed as fresh chilled in ice or as processed, i.e. salted-smoked or canned. The smoked product can be whole gutted fish, with or without the head on, or fillets.
Salmon is a fish that is frequently consumed smoked (60% of total salmon produced). Vacuum packed cold smoked salmon is of considerable economic importance worldwide, and particularly in Europe. This product is produced by a light salting and smoking process and is typically consumed as ready-to-eat with no subsequent heat treatment. Thus, the salt concentration in the water phase of the product and proper refrigeration (below 5℃) along the whole chill chain are critical factors for product safety. The minimum salt concentration in the water phase of the product should be 3.5% (w/w), as measured in the thickest part of the fillet (FAO, 2005-2012).
The aim of the study was to model and comparatively assess changes in quality characteristics of hot smoked European eel (*Anguilla anguilla*) fillets, whole hot smoked mackerel *(Scomber japonicus*) and cold smoked salmon (*Salmo salar*) slices, during refrigerated storage.

MATERIAL AND METHODS

Hot smoked eel (*Anguilla anguilla*) fillets, whole smoked mackerel (*Scomber japonicus*) and cold smoked salmon (*Salmo salar*) slices were provided by a Greek farming and processing unit in their commercial (vacuum) packages. Samples were transported directly to the laboratory in polystyrene boxes with appropriate quantity of flaked ice (0℃) within 4–6 h. Eel fillets were stored isothermally at 0, 5, 10, 15℃ and mackerel and salmon slices were stored at 5 and 10℃ in high-precision (±0.2℃) low-temper ature incubators (Sanyo MIR 153; Sanyo Electric, Ora-Gun, Gunma, Japan), and their shelf lives were studied. Temperature in the incubators was constantly monitored with electronic, programmable, miniature dataloggers (Cox Tracer®, Belmont, NC, USA). Samples were taken in appropriate time intervals to allow for efficient kinetic analysis of quality deterioration.
In order to validate the applicability of the models from the isothermal experiments to real conditions, a variable temperature experiment was carried out on a separate batch of smoked eel fillets. A time-temperature scenario was applied, which consisted of several repeated cycles of three isothermal steps, 8 h at 3℃, 8 h at 10℃ and 8 h at 6℃. T_{eff}, the constant temperature that results in the same quality value as the variable temperature distribution over the same period, was calculated based on the Arrhenius model and the equivalent value was 7.5℃. Samples were taken at a ppropriate time intervals and the rates of the quality deterioration measured during the nonisothermal experiment were compared with the values calculated for T_{eff} by the models based on the isothermal experiments.
Quality assessment was based on microbiological analysis (total viable count, *Pseudomonas* spp., *Brochothrix thermosphacta*, *Lactobacilli*), colour, lipid oxidation (TBARs) and sensory scoring. Total aerobic viable count was enumerated on Plate Count Agar (PCA, Merck) after incubation at 25℃ for 72 h. *Pseudomonas* spp. were enumerated on Cetrimide Agar (CFC, Merck) after incubation at 25℃ for 48 h. *Brochothrix thermosphacta* was enumerated on STAA Agar (CM 881, Oxoid, Cambridge, UK) supplemented with SR 151 (Oxoid), which was incubated at 25℃ for 48 h. Lactic acid bacteria we re enumerated on De Man-Rogosa-Sharpe Agar (MRS, Merck) followed by incubation at 25℃ for 96 h. The microbial growth was modelled using the Baranyi growth model (Baranyi and Roberts 1995). For curve fitting, the in-house program DMfit of Institute of Food Research (IFR, Reading, UK) was used,

kindly provided by Dr J. Baranyi. Kinetic parameters such as the rate (k) of the microbial growth were estimated.

To evaluate lipid oxidation, 2-thiobarbituric acid reactive substances (TBARs) assay was performed according to the method of Loovas (1992). The absorbance was measured at 532 nm with a digital spectrophotometer (Unicam Helios; Spectronic Unicam EMEA, Cambridge, UK). The concentration of TBARs as calculated from a standard curve prepared by 1,1,3,3-tetraethoxypropane and expressed as mg malonaldehyde (MDA) per kg.

Total volatile basic nitrogen (TVB-N) and trimethylamine nitrogen (TMA-N) analyses were conducted on a single TCA extraction by distillation in a Kjeldahl rapid distillation unit (Buchi 321 Distillation unit, Flawwil, Switzerland) and titration with sulphuric acid (Pivarnik et al. 2001). For the determination of TMA-N, 20 ml formaldehyde 37% was added in the distillation tube to block the primary and secondary amines.

The sensory parameters (appearance, odour, texture, taste) of smoked fish were evaluated by a trained sensory panel of eight and sensory scores were recorded in appropriate forms, reflecting the organoleptic evolution of quality deterioration. Additionally, panellists were asked to score the overall impression and acceptability. Rating was assigned separately for each parameter on a 1–9 descriptive hedonic scale (9 = like extremely and 1 = dislike extremely). A sensory score of 5 was taken as the average score for minimum acceptability.

Values of the different measured indices were plotted against time for all temperatures studied, and the apparent order of quality loss was determined based on the least-square fit. Temperature dependence of the deterioration rate constants, k, was modelled by the Arrhenius equation (Eq. 1)

$$\ln(k) = \ln(k_{ref}) - \left(\frac{E_a}{R}\right)\left[\frac{1}{T} - \frac{1}{T_{ref}}\right] \quad (1)$$

where k_{ref} is the rate constant of the degradation of the respective quality index at a reference temperature, T_{ref} (e.g. 4℃ for refrigerated foods), T is the temperature in K, E_a is the activation energy of the studied action and R is the universal gas constant.

RESULTS AND DISCUSSION

Table 1 shows the composition (nutrition information) of hot smoked eel, hot smoked mackerel and cold smoked salmon. These fish products are excellent sources of high biological value protein and omega-3 fatty acids (ω3-FA).

Table 1. Nutrition information per 100g of fish product

	Hot smoked eel	Hot smoked mackerel	Cold smoked salmon
Energy	1258kJ/301kcal	668kJ/159kcal	885kJ/212kcal
Protein	21.4 g	28.0 g	27.9 g
Fat	23.9 g	5.3 g	11.1 g
SFA	6.4 g	1.6 g	1.7 g
ω3 fatty acids	4.1 g	1.8 g	1.9 g
20:5 ω3 EPA	1441 mg	294 mg	379 mg
22:6 ω3 DHA	1404 mg	1215 mg	556 mg
Na	0.9 g	0.7 g	0.3 g

Results are given as mean ± standard deviation (n = 3); SFA - saturated fatty acid; EPA - eicosapentaenoic acid; DHA - Docosahexaenoic acid

Hot smoked eel

Total plate count and lactic acid bacteria counts showed a slow increase during refrigerated storage reaching a plateau at 4 logcfu/g after 50 days at 0 and 30 days at 5℃. *Pseudomonas* spp. and *Brochothrix thermosphacta* were not detected (<100 cfu/g) at all storage temperatures. Sensory scorings and TBA values were modelled with apparent zero order equations. TVBN values increased with storage time and were modelled with apparent first order equations. The E_a values for the rates of TVBN, total plate count, lactic acid bacteria growth and TBA increase were 136.3, 51.0, 81.2 and 74.4 kJ/mol, respectively

(Figure 1a). Overall impression scores showed high correlation with TBA and TVB-N values. At all temperatures studied, the time of sensory rejection coincided with TBA concentration of 15 mg MDA/kg. TVB-N level of 10 mg·100g^{-1} flesh could be regarded as the limit of acceptability for smoked eel. This is in agreement with Özogul et al. (2005) who reported the limit of 10 mg N·100g^{-1} for European eel stored in ice. The shelf life of smoked European eel determined by sensory evaluation was 82, 54, 20 and 12 days at 0, 5, 10 and 15℃, respectively.

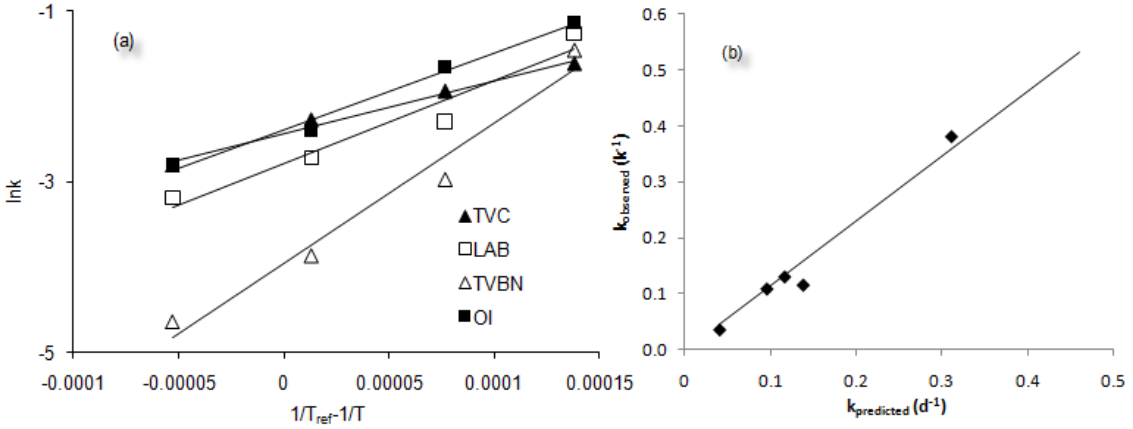

Figure 1. (a) Arrhenius plots of the rates of quality deterioration (TVC - total viable count, LAB – lactic acid bacteria, TVBN – total volatile basic nitrogen, OI – overall impression (sensory scoring), (b) Rates of chemical and sensory changes determined by the non-isothermal experiment ($k_{observed}$) and calculated by the models from the isothermal experiments ($k_{predicted}$)

Results from variable temperature experiments were in good agreement with the prediction of the shelf life models developed from the isothermal experiments, validating their acceptability at the fluctuating storage conditions that usually occur in the cold chain (Figure 1b). Relative errors averaged at ±13% (the highest value was -19.2%) for all the indices measures, which is below the 20% limit used in the literature as criterion of acceptability (Gougouli et al., 2008).

Hot smoked mackerel and cold smoked salmon

Slow microbial growth was observed at 10℃, with total viable count reaching a value of 5 logcfu/g after 50 days for both fish products. Sensory scorings for mackerel and salmon were modelled with apparent zero order equations. According to sensory evaluation, the shelf life was 8-9 weeks at 5℃ and 3-5 weeks at 10 ℃. TVB-N values showed small changes and remained in low levels for mackerel and salmon stored isothermally at 5 and 10℃ (<10 mg·100g^{-1} sample). Organoleptic degradation was well correlated with lipid oxidation. The limit TBARs value for sensory acceptability was 2 mg·kg^{-1} flesh for mackerel and salmon. This value is lower than the respective TBARs values reported by Nishimoto et al (1985) for high and low quality mackerel (i.e. 4 and 27 mg MDA·kg^{-1}, respectively).

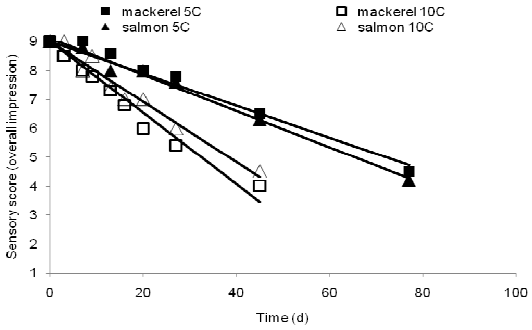

Table 2. Shelf life (in days) of hot smoked mackerel and cold smoked salmon stored isothermally at 5 and 10℃, calculated based on TBARs value[1]

	Hot smoked mackerel	Cold smoked salmon
5℃	72	64
10℃	32	38

CONCLUSIONS

The objective of the study was to model and comparatively assess changes in quality of hot smoked European eel and mackerel and cold smoked salmon, during refrigerated storage. According to sensory evaluation, the shelf life was 7-9 weeks at 5℃ and 3-5 weeks at 10℃. Eel fillets exhibited higher TBARs values due to their significantly higher lipid content (i.e. 24% crude lipids compared to 5.3 and 11.1% for mackerel and salmon, respectively). The results from the non-isothermal experiment showed a satisfactory agreement with the prediction based on the kinetic models developed from the isothermal experiment and the rates of change of the quality indices are not dependent on the temperature history. Of course the starting value of any indice will affect the time to reach the upper acceptable level, i.e. shelf life, and this parameter is taken into account in the developed models.
If the temperature conditions of the products could be continuously monitored, e.g. by inexpensive Time-Temperature Integrators, reliable estimation of the quality status and the remaining shelf life of the products could be performed based on the presented modelling of the quality indices. This could allow better management and optimization of the cold chain from manufacture to consumption (Taoukis et al., 2012).

ABSTRACT: Alterations in quality of food during storage in most cases have negative effects on sensory and biological values of products.
Packaging must maintain the quality of a product unchanged from the moment of packing until consumption. Barrier properties of packaging materials are very important for this purpose. These properties must protect the products from the effects of the environment such as air, especially oxygen, which may cause oxidation of some product components when exposed to light.
Depending on the moisture content, bakery products show various signs of aging. Products with higher initial content of moisture, with soft crumb when fresh, lose elasticity and harden during aging with undesirable changes of odor and taste. Flour products with low initial content of moisture absorb the ambient moisture during aging; they soften, become sinewy and stale. The problem is also microbiological contamination of bakery products, particularly molds which are most often causes of deterioration of this group of products.
The paper gives a review of the research results on grain milling and bakery products shelf-life. Wheat flour T-500, wheat semolina, toast bread and croissants were tested, i.e. shelf-life of these products was controlled in their standard packaging. The obtained results indicate that packaging used in this research did not affect the shelf-life of the tested products. They also showed that the right selection of packaging and determination of optimal procedure of packaging and bagging of grain milling and bakery products assured optimal period of shelf-life of these products and did not shorten it.
Key word: *containers, packaging, wheat flour, wheat semolina, toast bread, croissants.*

INTRODUCTION

Bakery products are very sensitive organic origin substrate of organic origin which undergo physical and chemical processes causing the change in quality and sensory, chemical and nutritional values during the period of storage (Gvozdenović, 2010).
During storage certain alterations in texture of bakery products or their taste may occur. Bread becomes dry and hard due to starch retrogradation. Variety of grain milling and bakery products as well as their complex composition are both a specific problem of their preservation. Both their appropriate production and preservation of product quality are important. To achieve this it is necessary to wrap and pack the products in appropriate wrappings and packaging which will protect the products from scattering and changes caused by external environmental effects.
To reduce the undesirable changes in quality of these products to the lowest possible level and thus provide good quality for appropriate storage period, it is necessary to know qualitative properties of material and wrapping along with qualitative properties of the wrapped content.
The packaging must maintain the quality of the product unchanged from the moment of packing until the moment of consumption. Barrier properties are very important for this purpose since they must protect the product from effects of environment, such as air and especially oxygen, which may cause oxidation of some product components when exposed to light (Gvozdenović et al.,1999).

The purpose of this paper is to test effects of certain types of grain milling and bakery products packaging on alterations in physical, chemical and sensory properties of tested samples.
Packaging material used for packaging of fresh bread, sliced bread and pastry with extended shelf-life should be with as little water vapor permeability as possible in order to prevent drying. Besides, the occurrence of moisture condensation should be considered. Apparently, vapor condensation on the inner side of the foil has a direct effect on quality alteration due to temperature reduction – it causes crust softening and favors mold growth.
Oxidation, specific aroma loss and stale odor and taste may occur with products having higher fat content (Crnčević,1980).

MATERIAL AND METHODS

The bakery products, being wheat flour T-500, wheat semolina, toast bread and croissants, produced in A.D. Žitoprodukt Zrenjanin were tested.
Physical and chemical analysis and sensory assessment of grain milling and bakery products were performed in accordance with Regulation on methods of physical and chemical analysis for quality control of wheat, grain milling and bakery products 1988, their freshness i.e. the shelf-life of these products in their standard packaging was tested. Unlike bakery products whose quality was controlled for several days (in accordance with the product label), the quality of grain milling products was controlled during a one-year period of time.
Wheat flour T-500 was sacked in two-layer 25 kg kraft paper sacks sewed up, wheat semolina T-400 in one-layer 1 kg kraft paper bags, toast bread and croissants were wrapped in polypropylene foil. Five sacks of flour and three samples from each wheat semolina, toast bread and croissants were analyzed.

RESULTS AND DISCUSSION

The results of physical and chemical and sensory assessment of wheat flour T-500 are shown in table 1 and figure 1.

Table 1. Shelf-life testing of wheat flour T – 500

Date	25/01/2010	22/04/2010	20/07/2010	20/10/2010	20/01/2011
Moisture content %	14.85	14.38	14.07	13.82	13.62
Gluten content % in dry substance	25.5	25.1	24.9	24.1	23.2
Sensory assessment	5	5	4	4	3

The obtained results show that in sacked wheat flour T – 500 the moisture content was slowly reduced. The change in moisture of flour depends on both the protection properties of packaging material and relative moisture and air tepmerature in the storehouse. When flour is stored in sacks arranged in rows, mositure will change at a slower rate.
The content of moist gluten was also reduced, which indicates that there are changes of certain components of protein-proteinase complex of flour during storage (physical properties of gluten change leading to reduction of flexibility) (Đaković, 1997). Reduction of gluten content results in lower technological quality of flour.
As for the sensory assessment, the characteristic flour odour weakened and small lumps in the last analysed sample were visually detected.
In wheat semolina, Table 2, the moisture content was lower, acid level was higher between the second and the third test.

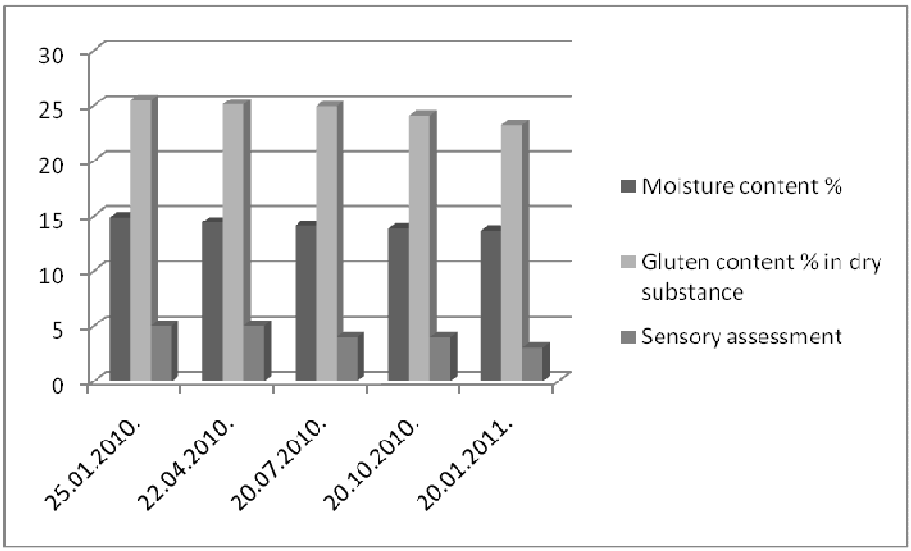

Figure 1. Diagram of wheat flour T – 500 shelf-life

Acid level increases due to amassing of free unsaturated fatty acids (Auerman, 1988). According to the Regulation on quality of wheat, grain milling and bakery products, 2004, the level of acide with wheat semolina T-400 is considered regular if lower than 2.5.
A brighter shade of the last analysed sample was noticed. The color of flour comes from pigment and depends on the color of grain endosperm and quantity of peripheral parts of the grain (Kaluđerski et al.,1998). Since the tested samples were packed in bags, wheat semolina bleaching is slow and practically may be noticed only when stored for a longer period of time.

Table 2. Shelf-life testing of wheat semolina T-400

Date	20/07/2010	20/10/2010	20/01/2011
Moisture content %	14.98	13.98	13.19
Acid level	1	1.11	1.44
Sensory assessment	5	5	4

The results presented in Table 3 containing data about physical and chemical analysis and sensory assessment of toast bread show that there were aroma loss and changes in texture of bread. Decrease in total content of water due to water diffusion from the inner part to external crust was also noticed.
The odor of the first analyzed sample is very intense, pleasant, characteristic for this type of bread as well as the taste which is intense, solubility of crust and crumb is excellent, the crumb is sticky and does not crumb.

Table3. Shelf-life testing of toast bread

Date	20/01/2011	22/01/2011	24/01/2011
Moisture content of toast bread crumb %	41.96	40.21	39.34
Acid level of crumb	1.56	1.56	1.58
Sensory assessment	5	4	3

The change in quality of croissants, Table 4, is a result of freshness loss. The increased content of fat may cause changes in quality due to fat oxidation during longer storage period. Temperature, presence of air i.e. oxygen, light and lipolytic enzymes have effects on oxidative stability of the product (Gvozdenović et al., 2010).

Table 4. Shelf-life testing of croissants

Date	20/01/2011	22/01/2011	24/01/2011
Moisture content of croissants %	23.80	23.20	22.90

CONCLUSION

The results of the performed tests lead to the following conclusions:

- analyses of flour quality indicate the necessity to undertake laboratory analyses of raw material and consideration of flour quality prior to its use in bakery production
- since the grain milling products are very sensitive to changes of moisture and gluten content, the selection of packaging material is of utmost importance
- due to sensitivity to moisture, bakery products need wrapping which could provide optimal protection of wrapped product from mechanical effects and changes of nutritional quality of the product
- in order to obtain more reliable results of the quality of bakery products and to provide their shelf-life it is necessary to select adequate types and combinations of packaging materials and undertake control of all parameters of technological process
- the right selection of packaging material and determination of optimal packaging and bagging procedure of grain milling and bakery products also provide optimal shelf-life period of those products and does not shorten it.

ABSTRACT: The influence of two packaging methods, under vacuum and modified atmosphere packaging, (MAP) and of storage time (45 and 270 days of production) on lipolytic and oxidative reactions and on fatty acid composition of the serbian traditional *Petrovská klobása* sausage were compared. Sausages were household produced and subjected to smoking, drying and ripening processes for 45 days. They were then divided in three experimental groups. The first group consisted of unpackaged sausages, while the second and third groups consisted of sausages packaged under vacuum and in MAP (80% N_2 and 20% $C0_2$), respectively. Intensity of lipolysis in sausages was estimated by the value of acid number (KOH/g lipids) and oxidative changes were monitored through the concentration of malondialdehyde (MDA). These parameters were examined at the end of the drying process (45^{th} day of production) and at the end of the storage period (270^{th} day of production). Acid number at the end of drying process was significantly ($P<0.05$) lower, while MDA content and fatty acid composition of total lipids did not differ significantly compared to that of unpackaged sausages after 270 d storage. At the end of the storage time, acid number for unpackaged sausages (21.83 mg KOH/g lipids) was significantly ($P<0.05$) higher than for sausages packaged under vacuum (15.03 mg KOH/g lipids) and in MAP (16.90 mg KOH/g lipids). Based on MDA content at the end of the storage period, lipid peroxidation intensity was significantly ($P<0.05$) higher in unpackaged sausages (0.85 mg MDA/kg fresh sausage), whereas fatty acid composition did not differ significantly comparing to that of sausages packaged under vacuum (0.38 mg MDA/kg) or in MAP (0.53 mg MDA/kg). Thus, it can be concluded that traditional *Petrovská klobása* sausage can be successfully stored using vacuum or MAP packaging without any significant alterations in terms of sensitivity of their lipids to lipolysis and of their fatty acids to peroxidation.
Key words: *traditional sausage, packaging, vacuum, modified atmosphere, lipolysis, peroxidation, fatty acids*

INTRODUCTION

Nowadays in many european countries, the demand for traditional food products has increased. Moreover, food and gastronomy form an inherent link with tourism in Europe, with a renewed interest of consumers for typical and regional foods (Talon et al., 2007). Traditional fermented food products of meat origin are produced by numerous small-scale and family sized processing units in Europe. Their fermentation relies on natural contamination by environmental flora. This contamination occurs during animal slaughtering and increases during manufacturing. Fermentation is not controlled (Tasić et al., 2012). Petrovská Klobása (Petrovac Sausage) is a traditional dry fermented sausage from Bački Petrovac (province Vojvodina, Serbia), which has been gained much popularity in last years in Serbia and in near by countries, even further. Due to its specific and recognizable sensorial qualities (texture, flavour and taste), this product is protected with the mark of geographic origin under Serbian law (Petrović et al., 2007). It is produced exclusively from pork meat and fat, red hot paprika powder, salt, crushed garlic, caraway and sugar leading to specific hot taste, aromatic and spicy flavors, a dark red color and a firm consistency (Ikonić et al., 2010). Dry fermented sausages are meat products with a high fat content (20-40%).

Fat influences the nutritional and health values of dry fermented sausages. It acts as a source of essential polyunsaturated fatty acids (PUFA) and fat soluble vitamins and constitutes a very concentrated source of energy in the human diet (9 kcal/g) (Olivares et al., 2010). However, fermented sausages show some negative aspects as a consequence of their high animal fat content. Namely, events that altered fat structural stability during processing fermented sausages, such as lipolysis and lipid oxidation, have a major impact, both desirable and deleterious for the final product quality of meat products. Lipid oxidation can altered sensorial properties of food products, since fat contributes to flavour, texture, mouth feel, juiciness and overall sensation of lubricity of the product (Muguerza et al., 2002). Besides, oxidation can affect the nutritional value of food by decomposition of vitamins, oxidation of essential PUFA leading to production of peroxides (malondialdehyde, hydroxy-alkenals,..) very toxic compounds for consumers (Ansorena and Astiasarán., 2004).
Retail storage of dry fermented sausages is usually done in aerobic conditions, the product being exposed to oxygen and, in consequence, to a potential risk of lipid oxidation. Furthermore, an excessive dehydration can also ocur using traditional storage conditions, leading to economic loss because of weight loss. Consequently, industrial trends are to extend the shelf life of this type of product by adopting improved storage practices (Ansorena and Astiasarán., 2004). Both modified-atmosphere and vacuum packaging are a commercial way for the retail selling of dry fermented sausages. Valencia et al., 2006 and Rubio et al., 2008 have reported the effect of the packaging conditions (vacuum and modified atmosphere) of dry fermented sausages on oxidation of their lipids.
Taking into account all negative effects of drying and storage on lipid structure of fermented sausages , our present study was designed to determine the effect of different conditions of packaging and storage time on theintensity of lipolytic and oxidative reactions occuring in traditional *Petrovská klobása* sausages produced in industrial conditions.

MATERIAL AND METHODS

Petrovská klobása sausages were prepared according to the procedure described by Tasić et al. (2012). They were elaborated in industrial conditions of smoking (a sequence of 12 treatments of 30 min each) during 3 days followed by a drying (temperature: 10^0C; relative humidity: 75-90%) for 45 days (% moisture: < 35%), Sausages were then divided in three experimental groups. The first group consisted of unpackaged sausages, whereas sausages of the second and third groups were packaged under vacuum and in MAP (80% N_2 and 20% $C0_2$), respectively. After packaging, sausages were stored in a chamber with a controlled temperature (15℃) and relative humidity (75%) for 225 days. Analyses of fatty acid composition of total lipids and of lipolytic level as well of oxidative level were conducted after 45 days of drying and 225 days of storage. All determinations were made in duplicate for three samples of each batch. Means were compared by Duncan's multiple range test, using the STATISTIKA 8.0 computer programme (2008).
Fatty acids were determined from total lipids extracted from sausages. The Folch et al. (1957) method was used for lipid extraction. Boron trifluoride/methanol was used for the preparation of fatty acid methyl esters (FAME) (Bannon et al., 1982) for the fatty acid composition of total lipids determined by gas chromatography with the Perkin–Elmer Autosystem XL gas chromatograph fitted with a capillary column Omegawax 320 and flame ionization detection. The injector and detector temperatures were both of 260^0C. The carrier gas was helium, at the pressure of 11 psi. The sample volume was 0.5µl. FAME was identified by their retention time in comparison with those of FAME standards separated in same chromatographic conditions. Centesimal distribution of fatty acids was calculated as a weight percentage of total FAME.
Acid number of total lipids (mg KOH/g lipids) was quantified according *SRPS ISO* (2000). The TBARs test was used for determination content of malonaldehyde (MDA) (Botsoglou et al., 1994).

RESULTS AND DISCUSSION

In this work, the fatty acid profile did not show significant changes after storage in all conditions tested (Table 1). After 270 days of production, no significant differences in lauric (C12:0), stearic (C14:0), palmitoleic (C16:1) and oleic (C18:1) acids were observed among batches (P>0.05). All sausages of three batches maintained lower values comparing to sausages at the end of the drying process after 45 days. Therefore, content of linoleic (C18:2 n-6) and linolenic (C18:3 n-3) acids ranged between 13.94-14.15% and 0.32-0.37%, respectively, these values being not significantly changed even after 225 days of storage (P>0.05). Level of total saturated fatty acids (SFA) was stable and similar in all batches, ranging between 35.27-35.96%. Also, no significant differences were found among batches for total unsaturated (UFA) and polyunsaturated fatty acids (PUFA) (P>0.05) (Table 1).

Table 1. Effects of packaging treatment and of storage time on fatty acid composition in total lipids of serbian traditional *Petrovská klobása* sausage.

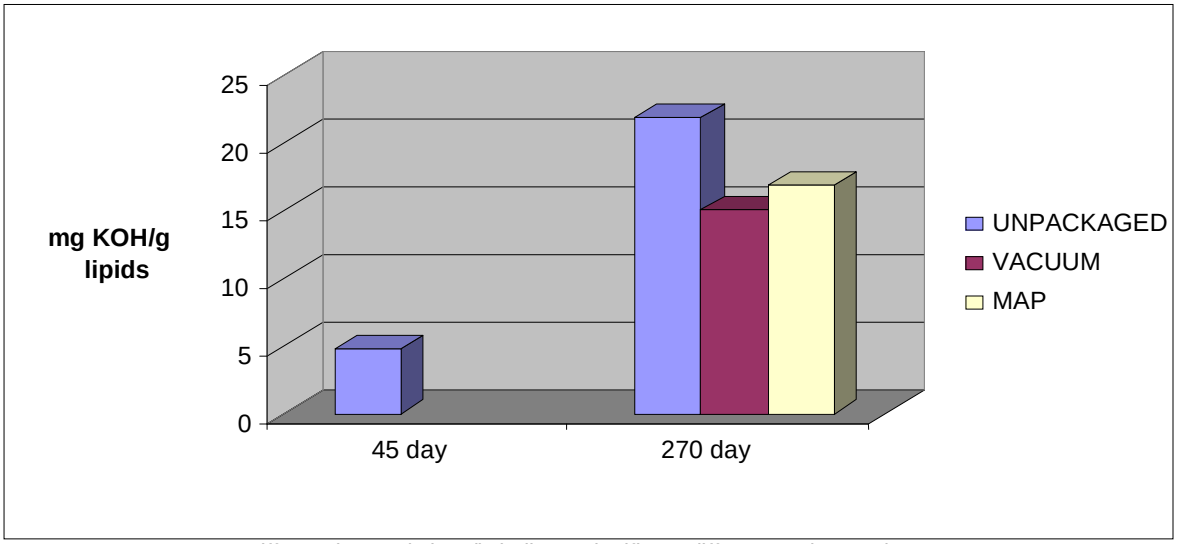
UFA/SFA	1.72 ± 0.02	1.72 ± 0.00	1.73 ± 0.00	1.73 ± 0.00

SFA- saturated fatty acids; UFA- unsaturated fatty acids; PUFA-polyunsaturated fatty acids. Results are expressed as mean ± standard deviations. Values in the same row bearing different letters are significantly different (P< 0.05).

These results pointed out the high stability of fatty acid distribution in total lipids of sausages in these storage conditions. Similar results were already reported by Rubio et al., 2008 and Valencia et al. 2006. Also, in dry fermented sausages, Valencia et al. (2007) did not find any differences for FA distribution at the end of drying and those obtained after 30 and 90 days of storage under vacuum.

Lipids are associated to many aromatic substances generated by lipolytic and oxidative phenomena taking place during the ripening process (Navarro et al., 1997). The intensity of lipolytic and oxidative phenomena in the studied batches was determined by parameters related to lipid stability such as acid number (Graph 1). Lipolysis of sausage lipids led to the increase of free fatty acid content attributed at the beginning of fermentation to both microbial and muscle lipases acting in the sausages (Visessanguan et al., 2006).

The acid number of the lipids in Petrovska klobasa sausages ranged from 4.79 to 16.90 mg KOH/g of lipids (Figure 1) in accordance with literature data (Vuković et al., 2011). At the end of drying process, the acid number in sausages (unpacked sausage - 45 day) had significantly (P<0.05) lower values than those of all batches at the end of storage. Similar results for this type of sausage were reported (Sumo et al., 2010, Visessanguan et al., 2006).

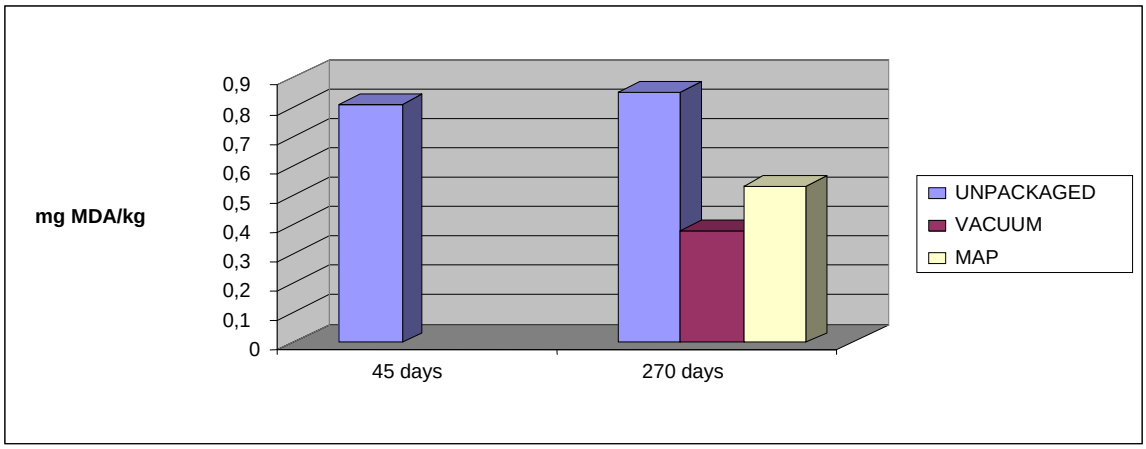


Different letters (a,b,c,d), indicate significant differences (P<0.05).

Figure 1. The effect of packaging treatment and storage time on of acid number values (mg KOH/g lipids) in serbian traditional *Petrovská klobása* sausage

Additionaly, differences in the acid number values were found between packaging methods (P<0.05). Namely, vacuum packed sausage had significant lower acid number (15.03 mg KOH/g lipids) comparing to those of unpackaged (21.83 mg KOH/g lipids) and MAP (16.90 mg KOH/g lipids) packaged sausages. These results showed the lowest hydrolytic changes in vacuum packaged sausage, but this observation was in contrast with a literature data (Visessanguan et al., 2006).

Malonaldehyde (MDA), the main degradation product of lipoperoxidation, was used as the marker for lipid peroxidation intensity. In contrast to acid number values, TBA values decreased during storage in accordance with literature data. Namely, Janero et al., (1990) pointed out that a decrease in TBA values during storage could be attributed to MDA reaction with amino acids, sugars and nitrite in complex formulations. The results of TBARS test, expressed as MDA content (mg/kg), are presented in Figure 2. Our TBA values were in accordance with those of Ansorena and Astiasarán (2004), but much lower than those of others for the same type of product reported by Nassu et al., (2003) and Rubio et al.(2008). At the end of drying process, (45th day), values of MDA in unpackaged sausage amounted to 0.81 mg/kg fresh product to values not significantly different (P>0.05) compared to those of unpackaged sausage (270days) (0.85 mg/kg), but significantly higher than those in vacuum (0.38mg/kg) and MAP (0.53mg/kg) packaged sausages at the end of storage.



Different letters (a,b,c,), indicate significant differences (P<0.05).

Figure 2. The effect of packaging and storage times on TBARs values (mg/kg) in serbian traditional *Petrovská klobása* sausage

Considering storage conditions, differences were found in the TBA values between packaging methods. Namely, batch packaged under vacuum shown lower TBA values (P <0.05) than those found in gas packaged samples. Similar results for this type of sausages were already reported by Zanardi et al. (2002).

CONCLUSIONS

Sausages packaged under vacuum or MAP indicated a significant lower (P<0.05) of lipolytic and oxidative changes during storage, comparing to that with unpackaged sausages. Therefore, it can be concluded that the *Petrovská klobása* sausage can be stored for a long period using either vacuum or modified atmosphere packaging without any defavorable effects on the nutritional and health values properties.

ABSTRACT: The Effects of polyethylene terephthalate (PET) pieces and different storage conditions on fatty acids profile and some quality factors in three types of commercial oils, namely sunflower oil, canola oil, and blended oil containing sunflower oil, soy bean oil, and cottonseed oil were studied. Quality factors such as peroxide value, free fatty acids, and iodine value and induction period before and after storage of samples at 25 and 45℃ for 20 and 60 days in the presence or absence of PET pieces were investigated. It was concluded that the stability of vegetable oils is dependent on the type of oil and its initial physical and chemical properties, time and temperature of storage and the type of employed packaging material (PET and glass). This study showed that storing oils at low temperatures (T<25 ℃) may be recommended in order to extend the shelf life and maintenance quality of commercial oils which are packaged in PET containers.
Key words: *canola oil, fatty acid profile, blended oil, PET pieces, sunflower oil, quality factors*

INTRODUCTION

Oils play a crucial role in the human diet. More than 90% of the world oil production from vegetable, animal and marine sources is used in foods or as part of it (Tawfik and Huyghebaret, 1999). Different kinds of oil have various uses in the food industry, among them canola and sunflower oils are used extensively for cooking. The blended oil (which contains sunflower oil, soy bean oil, and cottonseed oil) is considered as one of the current oils in Iran's market. The materials which are used for packaging have a large variety. Glass, metal and different kinds of plastics are used in oil packaging (Tsimis and Karakasides, 2002; Tawfik and Huyghebaret, 1999). The kinds of packaging have significant affect on shelf life of the oils as the carefully processed oil may be damaged by inelegant selection of packaging materials (Ramazani, 2007). PET is one of the most commonly used plastics in food packaging covering a wide range of packaging material. PET satisfies many important requirements such as good aesthetic aspect (brilliance and transparency); suitability for coloring; good mechanical, thermal, and chemical resistance; low production cost; suitability for short storage, easy recyclability, and low weight with respect to glass bottles (Tsimis and Karakasides, 2002). The trend toward incorporating modifier compounds into PET packaging resins has grown in order to produce containers with a high degree of clarity, in a wide variety of custom shapes, and free from residual acetaldehyde. In addition, incorporation of antioxidant stabilizers in PET increases its application in the food area, particularly for vegetable oil storage (Piergiovanni and Limbo, 2010; Tsimis and Karakasides, 2002). Important characteristics such as barrier properties of packaging materials against moisture, oxygen and the interaction between foodstuff and packaging materials have an important effect on the quality and shelf life of oils in foodstuff (Sharma *et al*., 1990). Hence, the major function of packaging is to minimize the reaction which has direct effect on stability of the contained product. The studies published about the effect of packaging on oil quality have concluded that stability can be enhanced by suitable selection of packaging material (Leo,

1983; Kaya *et al*., 1993; Kucuk and Caner, 2005; Ramazani, 2007; Coutelieris and Kanavouras, 2005; Tsimis and Karakasides, 2002; Tawfik, 2005).
One of the additives, fat soluble phenolic antioxidants, present in the compounded polymer may migrate at an appreciable rate into the oil during storage which then effect its stability (Cinquanta *et al*., 2001). Numerous studies have shown the release of antioxidants from the packaging materials into oil-containing foodstuff (Baner *et al*., 1992; Niebergall *et al*., 1993). The extension of shelf life of some products due to the presence of such compounds has been reported (Miltz *et al*., 1988). The shelf life and oxidative stability of olive oil stored in glass and polyethylene (PE) bottles were examined (Kiritsakis, 1984). Due to this research, glass bottles which prevent oxygen from entering the oil were more protective against oxidation in comparison with plastic bottles (PE). Kaya *et al.* (1993) studied the effect of permeability and transparency of the packaging materials (glass and PET bottles) on the shelf life and also stability of sunflower and olive oils. In this research, oxidative stability of the oil was studied by measuring the peroxide values. The results demonstrated that storage stability of oil increased in the order which depended on packaging material, colored glass > transparent glass > PET..Satue *et al.* (1995) reported that the extent of oil oxidation is often specified by measuring the peroxide value (PV). Since this index is related to the hydroperoxides, the primary oxidation products which cause rancid flavor because of their instability and hence conversion to secondary oxidation products (Kaya *et al.,* 1993; Satue *et al.,* 1995). Kucuk and Caner (2005) studied the effect of PET packaging materials and the various keeping conditions on storage stability of sunflower oil. The results showed that PET packaging, presence of oxygen, light and storage period increased the peroxide value, free fatty acids and iodine value in addition to soap content compared with glass packing in the above mentioned conditions (Kucuk and Caner, 2005), in this case they leave a great impression on decreasing the oil storage stability.
The effect of different type of plastics (polyethylene terephthalate (PET), polyvinylchloride (PVC), polypropylene (PP) and polystyrene (PS) on the stability of olive, sunflower and palm oil were studied (Tawfik and Huyghebaret, 1999). The authors have concluded that the period and temperature of storage as well as packaging materials have significant effects on the stability of the above mentioned oils (Tawfik and Huyghebaret, 1999). Tawfik (2005) studied the oil absorption and the global migration of different types of plastic material (PET, PVC, PP and PS) into different vegetable oils (olive, sunflower and palm oil). The findings showed that the amount of overall migration from plastic packaging into a vegetable oil is determined by the type of plastic packaging and the kind of oil considered. Tawfik concluded that the chain length of the fatty acids and the degree of saturation clearly influence the oil absorption by polymers whereas the migration of components from plastic was not influnced that much (Tawfik, 2005).
The present study examined the effects of PET plastic pieces and various storage conditions on fatty acid profile and some quality factors. Hence, Fatty acid profile and quality factors such as peroxide value, free fatty acids and iodine value and induction period before and after storage of samples at 25 and 45℃ for 20 and 60 days in presence or absence of PET pieces in three types of common oils from Iran's market were investigated.

MATERIALS AND METHODS

Oils and PET bottles : Commercial sunflower, canola and blended oils (contains sunflower, soy and cotton seed oils)(amount of added B.H.T as antioxidant 100 mg/kg in all of the oils) and PET bottles were obtained from Savola Behshahr Co., Tehran. Iran. Chemicals solvents were purchased from Merck Co., Germany.

Sample preparation

After measuring a specific surface on the bottles, they were cut to14 pieces with the same size (surface of them are 6 cm^2). Pieces were placed in 250ml Glass vessels, the glass vessels were poured with oil up to 150ml volume of container, so that the test pieces were always remained well apart from one to another and immersed completely in each type of oil.

The glass vessels that contain tests pieces were stored at 25 and 45℃ for 20 and 60 days (Tawfik, 2005). Since all of the samples have been stored in a dark place and in sealed container (in glass vessels 250 ml) the effect of light and oxygen parameters in all specimens were similar. The temperature were controlled and the data recorded by data logger (LASCAR, England). Glass vessels containing oils only were placed in the same conditions and served as blank samples. Every treatment was performed in four replicates.

Chemical tests

By using rancimat system (Metrohm model 734, Switzerland) and AOCS (Cd 12b-92) the induction period test was done at 110 ℃ (Firestone , 1994).

The iodine value was calculated based on mathematical formula which presented in AOCS (Cd 1c-85), which directly calculated from the oil fatty acid profile (Firestone, 1994). In oxidative rancidity oxygen is taken by the oil with the formation of peroxide. The degree of peroxide formation (Peroxide Value) was calculated according to the AOCS (Cd 8-63) (Firestone, 1994). Determination of free fatty acids was done by AOCS (Cd 3d-63) (Firestone, 1994).

Statistical analysis

Experiments on each of samples were performed at four times. Two analyses were taken from the test samples at each specific time interval. Statistical analysis (Mean values and standard division were calculated at each time interval, so were analyzed by SPSS ver. 17 (SPSS Inc. Michigan Avenue., Chicago, USA) and Minitab ver. 11.12 (Minitab Inc., USA).

RESULTS AND DISCUSSION

Effects of time passing and raising of temperature caused breaking 2 cis double bonds and converting them to single double bond and without double bonds, Also, the conversations between different shape of geometrical isomerization such as Cis or Trans and local isomerization such Iso caused above mentioned alteration (Tarzi *et al*., 2006).

Since all of the samples have been stored in a dark place and in sealed container (in glass vessels 250 ml) the effect of light and oxygen parameters in all specimens were similar. Presence or absence of plastic pieces has no significant effect on fatty acids profile

According the results which is shown in Fig. 1, significant decrease ($P \leq 0.05$) was observed at induction period (IP) in the mentioned oils after storage for 20 and 60 days at 25 and 45℃. Among the oils, canola has maximum induction period because this oil contain a large amount of oleic fatty acid (mono unsaturated) and the blended oil has the minimum induction period because the oil contains different types of fatty acids such as poly unsaturated fatty acids. A significant difference ($P \leq 0.05$) at induction period was observed in the presence or absence of plastic pieces. These differences indicate the effect of plastic pieces on decreasing induction period and correlates with previous investigations (Huang *et al*., 1981; Kucuk and Caner, 2005). In the case of the blended oil, the significant decreasing in induction period after 60 days at 45°C has made the oil useless, with consider to blended oil standard (maximum authorized of induction period is 8 hours) (Institute of Iran Standard and Industrial Researches, 1981; Institute of Iran Standard and Industrial Researches, 1999; Institute of Iran Standard and Industrial Researches, 2007). The result shows that the canola oil has the maximum induction period in comparison with other oils.

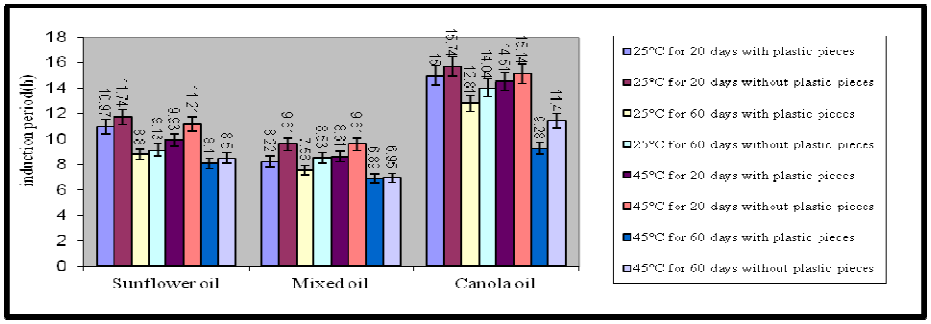

Figure 1. The induction periods of sunflower, blended (Mixed) and canola oils during different storage conditions

As shown in Fig. 2, sunflower and blended oils have increased significantly (P≤0.05) in peroxide value(PV) after 20 and 60 days at 25 and 45℃ and in the presence or absence of PET pieces but in canola oil only period and temperature has affected significantly (P≤0.05) in peroxide value. In blended oil that contains different types of fatty acids; peroxide value was formed quickly because of the large amount of poly unsaturated fatty acids. Peroxides in sunflower and canola oil was formed slower than blended oil due to the presence of high amount of natural antioxidants and mono unsaturated fatty acids like oleic acid, respectively (Kucuk and Caner, 2005; Kadivar *et al*., 2010; Cinquanta *et al*., 2001) but during storing and after decreasing efficiency of natural antioxidants and decreasing amount of mono unsaturated fatty acids the amount of peroxide value has increased in sunflower and canola oil in comparison with the initial oils. In presence and absence of plastic pieces, the sunflower and canola oil has increased significantly (p≤0.05) in peroxide value after 20 and 60 days at 45℃. Relatively, the PVs have been alte red at the end of storage period, and have been increased as a result of releasing pro oxidant compounds such as aldehydes from plastic pieces. Moreover, it has been stimulated by increasing temperature. This result was confirmed by previous investigations (Huang *et al*., 1981; Frankel, 1991; Kucuk and Caner, 2005; Ghasemnezhad and Honermeier, 2007). Maximum authorized value of peroxide in National standard of Iran for sunflower, canola and blended oils are 2.5, 2.0 and 5.0 meq/kg, respectively, so based on these values, sunflower oil which stored at 45℃ in both of storage periods, canola oil which stored at 45℃ for 60 day s and blended oil that stored at 45℃ for 20 days with plastic pieces, 60 days with and also without plastic pieces became useless (Institute of Iran Standard and Industrial Researches, 1981; Institute of Iran Standard and Industrial Researches, 1999; Institute of Iran Standard and Industrial Researches, 2007). Results show that canola oil has the minimum PV in comparison with other oils at the end of storage period.

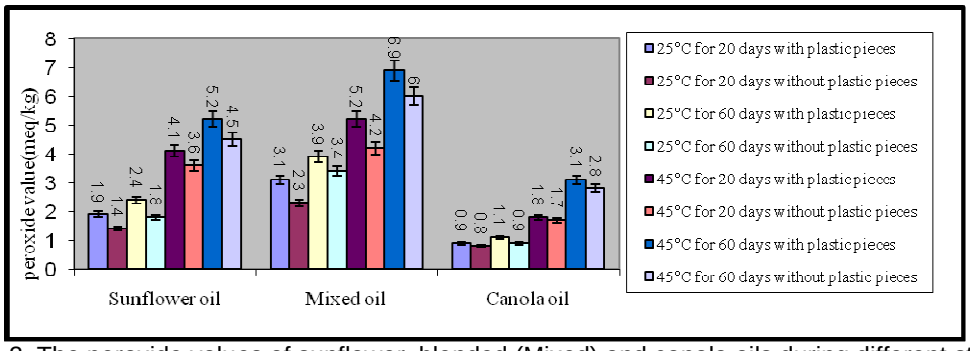

Figure 2. The peroxide values of sunflower, blended (Mixed) and canola oils during different storage conditions

The Iodine value (IV) is decreased during the storage period as shown in Fig. 3. The amount of unsaturated fatty acid has a direct effect on IVs. As the result existence of poly unsaturated fatty acids in the blended and sunflower oil, The IVs in sunflower and blended oil significantly declined (P≤0.05) after 60 days at 45℃ and in presence or abse nce of PET

pieces. Slight changes after decreasing of iodine value in canola oil were observed. The Results correlates with the previous investigations (Tawfik and Huyghebaret, 1999).

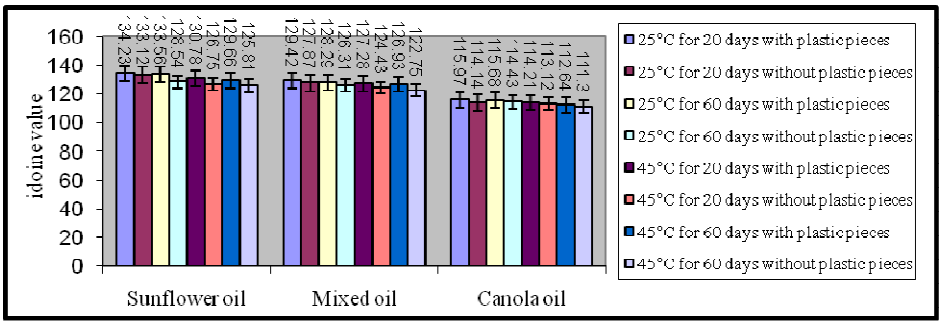

Figure3. The iodine values of sunflower, blended (Mixed) and canola oils during different storage conditions

Amounts of free fatty acids (FFA%) during different conditions of storage were shown in Fig. 4. It is well accepted that during storage period, partial hydrolysis of oils has taken place, thus free fatty acid content were increased. There was a significant increase (P≤0.05) in the FFA% among the storage for 20 and 60 days at 25,45℃ in mentioned oils which shows the effect of temperature and time on forming free fatty acids, and also confirm the previous investigations (Sharma *et al*., 1990; Frankel, 1991; Ghasemnezhad and Honermeier 2007). FFA% had increased significantly (P≤0.05) in presence or absence of the plastic pieces in the oils. Releasing lower molecular acids from plastic pieces which are stimulated by increasing temperature cause the Increasing of FFA %. In National standard of Iran, the maximum permissible level of free fatty acids in sunflower, canola and blended oil are 0.2, 0.2 and 0.1%, respectively, thus the blended oil which had been stored at 45^0C for 20 and 60 days with and without plastic pieces was deteriorated (Institute of Iran Standard and Industrial Researches, 1981; Institute of Iran Standard and Industrial Researches, 1999; Institute of Iran Standard and Industrial Researches, 2007). It is necessary to be noticed that the presence of free fatty acids increases the hydrolysis which leads deterioration of oils and make them unsuitable for human consumption. Results show that the canola oil has the maximum level of free fatty acids in comparison with the other oils.

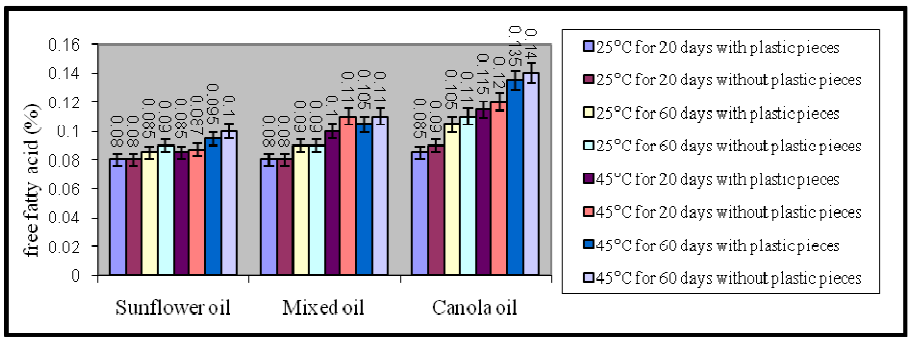

Figure 4. The amount of free fatty acids of sunflower, blended (Mixed) and canola oils during different storage conditions

CONCLUSION

On the examination of quality factors such as free fatty acids, peroxide value, induction period and iodine value, some results clearly emerged. Increasing storage period and temperature and presence of PET pieces has some effects on FFA%, PV, induction period and Iodine value. It is concluded from this study that the stability of vegetable oils is dependent on the type of oil and its initial physical and chemical properties, time and temperature of storage and the type of packaging (PET and Glass). In addition increasing

storage temperature and time accelerated the deterioration and limited the stability of vegetable oils. Results show the quality of oil has been decreased after the storage at high temperature (45℃) and long time of storage. So for preventing of deterioration, the oils which were packed in PET bottles should be stored at a temperature lower than 25℃. If the temperature is raised (T<45℃) the shelf life of pr oduct should be limited. Difference between these effects in the mentioned oils can be explained by their nature, initial physical and chemical properties of oils. Oil stability can be enhanced by selection of a suitable package.

ABSTRACT: Bisphenol A diglycidyl ether (BADGE) and its derivatives are determined in canned oily foods from Iran's market using a new simplified extraction method. Samples are extracted with methanol, back extracted with methanol, and were analyzed by using reversed –phase high performance liquid chromatography (RP-HPLC) with fluorescence detection (FLD) and excellent validation data were obtained. Whereas detection limit for BADGE.2H2O was detected in 0.04 ppm. Also the present of recovery for BADE and its derivatives in comparison to previous investigations is suitable. This method can detect the amount of BADGE and its derivatives in low concentration. From 57 analyzed cans, containing various fatty tuna fish products, BADGE.HCL, BADGE.H_2O.HCL and BADGE.H_2O were not detected in any samples. However, BADGE, BADGE.2H2O and BADGE.2HCL were detected in samples but the amounts of specific migration of BADGE and its derivatives from metal cans into the samples conform to European Community legislation (EC 1895/2005 that determined specific migration limits (SML) for sum of the BADGE and its hydrolyzed derivatives is 9 mg/kg and Sum of chlorinated derivatives is, 1 mg/kg), which confirm the safety of these cans container that were used for packaging oily foods in Iran.
Key words: *BADGE, HPLC, Specific Migration, canned oily food*

INTRODUCTION

Nowadays food packaging is one of the most important fields in food industry and also has certain effect on food safety issue. Most of cans which use for preserving food are coated by interior lacquer based on epoxy resins to have a barriers role between the food or beverage and the metal surface of the cans for presenting good condition for products.
Bisphenol A diglycidyl ether (BADGE) is the condensation reaction product of one mole of Bisphenol A (BPA) with two moles of epichlorohydrin. BADGE was used as a starting substance or stabilising components for epoxy resins (Suarez, *et al*., 2000).
BADGE hydrolyses occurs in contact with aqueous and acidic food and it may be convert to forms of mono- and dihydrolysed products (BADGE.H2O and BADGE.2H2O) of BADGE or chlorinated products (BADGE. HCL, BADGE.2HCL) or BADGE H_2O HCL, that can be migrate from can lacquers into food stuff (Fig .1) (Hammarling, *et al*., 2000; Forrest, *et al*., 2005; Satoh, *et al*., 2004). BADGE may break down and stability of BADGE depended on condition and environment of storage. Also the natural of food has effect of this stability (Poustkova, *et al*., 2004).
The epoxy resins are alkylating bifunctional agents and they have specific cytotoxic actions in tissues with high rates of cell division vitro assays using different endpoints. In the case of hydrolysis products and BADGE chlorohydrin no data exists about their genotoxicity (Suarez, *et al*., 2000). BADGE cause disfunctionality of sex (female) hormones and also is of concern due to its teratogenicity and carcinogenicity (Rauter, *et al*., 1999; Peterson, *et al*., 2003; Kang, *et al*., 2006; Rykowska, *et al*., 2006). With consider to this issue there is a lack of

information concerning BADGE and its derivatives migration from can coatings into canned sea food in oil which has a high level of consumption in Iran market.
In 1996 in Switzerland market, BADGE was detected in oil that extracted canned fish. They had a higher level of the maximum permissible amount of Switzerland legislation and removed of the consumption market (Shafagh Gilani, *et al*., 2007).
Rauter, *et al*. in 1999 determined bisphenol A diglycidyl ether (BADGE) and its hydrolysis products in canned oily foods from the Austrian market by using a new simplified HPLC method. Samples are extracted with pentane, back extracted with methanol, and finally dissolved in the mobile phase (cyclohexane/*tert*–butyl methyl ether). Separation is performed on a normal phase HPLC column using fluorescence detection. Results showed that from 67 analyzed cans, containing various fatty meat or Fish products, 16% were above the maximum quantity of 1 mg/kg tolerated by the European Community, 45% were in the range between 0.1–1 mg/kg, 24% between 0.02 and 0.1 mg/kg, and in 15% the BADGE concentrations were below the detection limit of 0.02 mg/kg. The hydrolysis product BADGE.H2O was not detected in any sample, whereas BADGE.2H2O was found in some samples up to a concentration of 0.5 mg/kg (Rauter, *et al*., 1999). BADGE has been examined in canned fish in oil. Cans and lids were extracted by acetonitryl separately. BADGE extracted of fish with hexane and re-extracted with acetonitryl. The method of analysis was by RP-HPLC with fluorescence detector. Finally BADGE was detected in 12% of fishes, 24% of the cans and 18% of the lids (Theobald, *et al*., 2000). Migration of BADGE and its derivatives in canned foods have been determined by Hammarling, *et al*. in 2000. In this research the greatest amount of BADGE was found in canned fish in oil (5.1 mg/kg). BADGE was also found up to 1.1 mg/kg in the fish in tomato sauce (Hammarling, *et al*., 2000) Leepipatpiboon, *et al*. in 2005 determined bisphenol-A-diglycidyl ether,bisphenol-F-Diglycidyl ether, and their derivatives in oil-in-water and aqueous-based simultaneously in canned foods which was applied by high-performance liquid chromatography with fluorescence detection. The method detection limits range 0.72–4.20 ppb and the method quantitation limits range 2.40–14.85 ppb, respectively (Leepipatpiboon, *et al*., 2005). Cabado, *et al*. in 2008 evaluated kinetics migration of BADGE and BFDGE from varnish into canned products (sardines, tuna fish, mackerel, mussels, cod and mackerel eggs) by HPLC in 70 samples after 6, 12 or 18 months of storage. Results of this research showed that there is no migration of BADGE in tuna fish, sardines, mussels or cod. However, migration of BFDGE occurs in all species, in a storage time-dependent way and content of fat, although migration of these compounds is not affected by sterilization conditions (Cabado, *et al*., 2008).
Specific migration limit (SML) for sum of BADGE, BADGE. H_2O and BADGE.$2H_2O$ is set to 9 mg/kg and for sum of BADGE. HCl, BADGE .2HCl and BADGE H_20 HCl is set to 1mg/kg in the legislation (European Standard, 2005).
The main purpose of this study is determination of migrated BADGE and its derivatives in canned oily foods by simplified extraction and HPLC Method.Also, comparison of final result with European legislation has been done for confirmation safety of used lacquer in can.

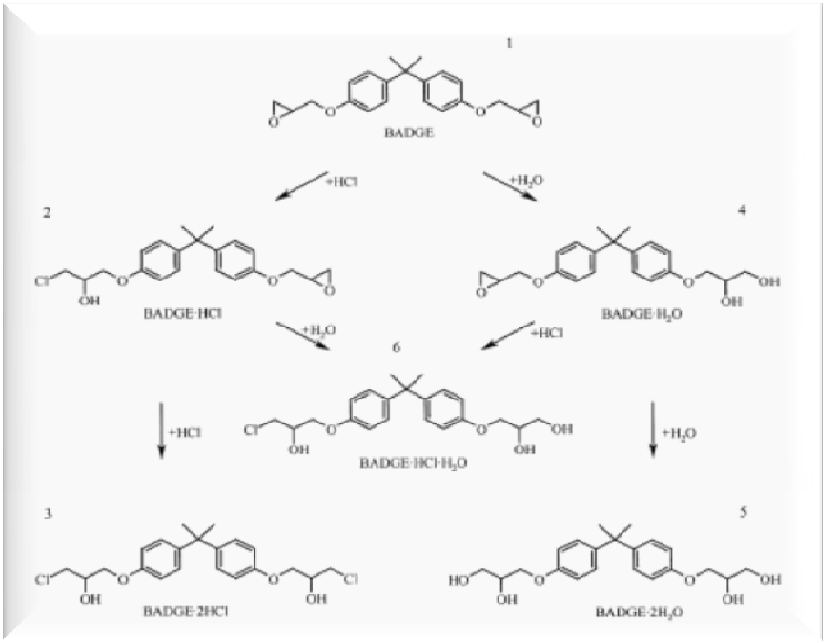

Fig 1. Bisphenol A diglycidy ether (*BADGE*) and its reaction products (Peterson, *et al*., 2003)

MATERIAL AND METHODS

Materials: Standards and reagents

All standards of BADGE and its derivatives (BADGE.H20, BADGE.2H_2O, BADGE.HCL, BADGE.2HCL, and BADGE.H_2OHCL) were purchased from Fluka chemical Co., Swiss. Stock solutions of BADGE and its derivatives were made in methanol at a concentration of 100µg/ml and were stored at 4 $^{\circ}C$ .Intermediate solutions of BADGE and its derivatives were prepared at a concentration of 10 µg/ml in methanol. HPLC-gradient grade water and methanol solvents were purchased from Merck Co., Germany

Samples

The experiments have performed on 57 canned oily foods (tuna fish in oil) that purchased and analyzed at least 6 months after producing.

Extraction process

The whole content of each can include the solid material and the oil, was homogenized using a laboratory Mixer. 2.5 g of this homogenate was weighted accurately into a 15 ml CellStar Tube, 5 ml methanol was added and the tube was sealed and properly shaken on a Vortex mixer. Afterwards centrifuged and the supernatant was transferred into a second tube. The extraction was repeated twice. The collected methanol fraction was evaporated under nitrogen stream up to approximately 4ml, after adding 1ml distillated water Centrifuged in refrigerate at 3500 rpm in -2 ℃ for 10 min in orde r to separation, extracted samples were filtered through a micro filter (whatman, diameter 13 mm, pore size 0.45µm) then analyzed by HPLC with Fluorescence detector for determination of migrants.

Measurements of BADGE and its derivatives by HPLC

Standards and the content of these monomers in samples were separated and quantified by using a HPLC system (Agilent 1200, Germany) equipped with an Agilent G1311A quaternary pump , an Agilent G1315A Florescence Detector (FLD) and C18 Agilent column (150mm, 5 µm particle diameter, and 4.6mm internal diameter was used). The column temperature was kept at 30℃ by using a column oven . The used wavelengths for detection of monomers were 225 nm (excitation wavelength) and 305 nm (emission wavelength). The

binary gradient conditions were used: H2O / Acetonitrile (60:40v/v) to H2O / Acetonitrile (40:60 v/v) and Flow Rate: 0.75 to 1.5 ml/min were established. The volume of injection was 5 µl as illustrated in table 1. (Mousavi Khaneghah, *et al.,* 2012).
A mix stock standard solution (10 ppm) were prepared from BADGE and its derivatives in methanol and stored in the dark place at refrigerator temperature. Calibration standards solutions were prepared on the day of use at levels 5, 2, 1, 0.5, 0.25; 0.125and 0.0625µg/ml of stock standards solution and 5 µl of each standard were injected to HPLC at three times**.** Standard curves for all standards were plotted by injection 7 concentration of standard and peak area responses are obtained. A standard graph was prepared by plotting concentration versus area (Mousavi Khaneghah, *et al.,* 2012).

RESULTS AND DISCUSSION

Results from method validation

Recovery studies were carried out by spiking selected samples of homogenized Tuna Fish with mixed standard solution (mix of BADGE and its derivatives) at four different concentrations (0.25, 0.5, 2 and 4ppm). The spiked samples as well as controls were analyzed in 3 replicate experiments. The recoveries were calculated by using standard calibration curves. The detection limit (LOD) and quantitation limit (LOQ) are defined as the amount of analyte in standard solutions that yields an instrumental signal significantly different from the blank or background signal which equals to 3 and 9, respectively. Depending on the spiked concentration, the recovery rates were between 70% and 120% and the reproducibility for the whole determination procedure was less than 20%.The correlation coefficient for the linear regression curve was found more than 0.994 in the range of 0.0625 – 5 µg/ml. Table 2 summarizes R^2, Recovery, LOD and LOQ values of individual compounds and clearly indicates that the analytical method has excellent sensitivity.

Results from various samples

Altogether, 57 canned oily food, were analyzed for their content of hydrolyzed and chlorinated derivatives of BADGE. Result shows that the amount of migrated Compounds (hydrolyzed and chlorinated derivatives) into fish from Can metal coating during this experiment were lower than EC Nº1895/2005 legislation (with maintained specific migration limits for sum of the BADGE and its hydrolysis derivatives is 9 mg/kg and Sum of chlorinated derivatives is, 1 mg/kg) as observed in Table 3, so can containers can be considered to be in compliance with EC regulation. No BADGE.HCL, BADGE.H_2O.HCL and BADGE.H_2O were detected in any samples whereas BADGE.$2H_2O$ was found up to 41.22% in samples. Also BADGE up to 31.57% and BADGE.2HCL up to 5.26% were detected in samples. From all samples were analyzed 67.5 % of hydrolyzed derivatives and 5.2 % chlorinated derivatives of BADGE were above quantification limit. Also the chromatograms of HPLC for one of the samples and standards have been shown in fig 2 and fig 3.

Table 3. The average of migrated derivatives in all samples

Analytes	Amount (mg/kg)
Hydrolyzed Derivatives	0.7619
Chlorinated Derivatives	0.0301

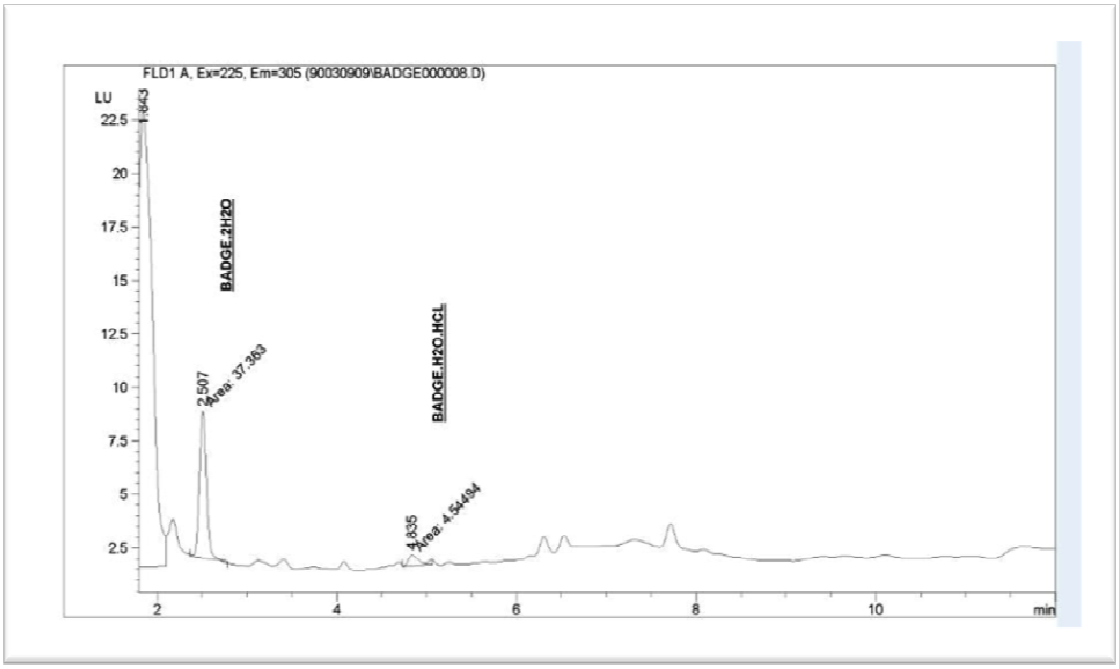

Fig 2. HPLC chromatogram for one of the samples

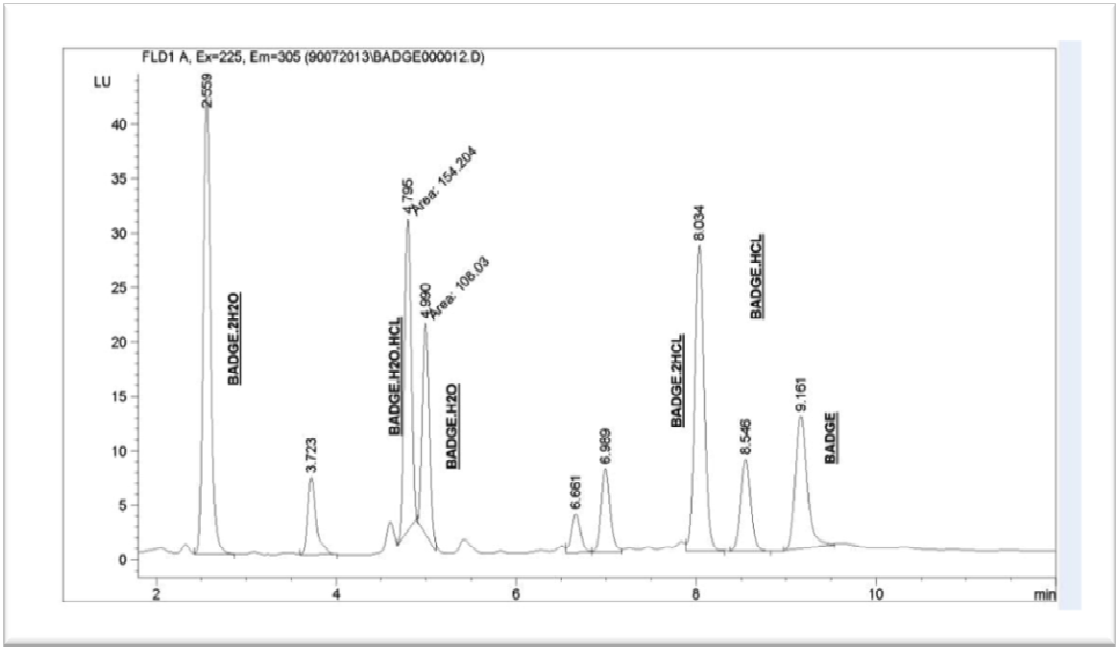

Fig 3. HPLC standard chromatogram for mixture of BADGE and its derivatives in concentration of 1 ppm

CONCLUSIONS

HPLC method with Fluorescence detector was used for determination of migration of BADGE and derivatives from can containers into canned oily food. This study was carried out for investigation of quantify migration of hydrolyzed and chlorinated derivatives of BADGE in canned oily food. Extraction with centrifuge under cold condition (-2 °C) provides a rapid and accurate method for determination of BADGE and its derivatives by HPLC with fluorescence detection especially decreased run time in comparison with previous investigations that have been performed on canned food (Rauter, *et al*., 1999;Hammarling, *et al*., 2000;Cabado, *et al*., 2008).

More studies should be done on migration of BADGE and its derivatives at different types of canned food. It is necessary to control and improve the distribution chains and the conditions of storage to ensure the safety of products.

This method in this study can detect the amount of BADGE and its derivatives in low concentration. Whereas detection limit for BADGE.$2H_2O$ was detected in 0.04 ppm. Also the limit of recovery for BADE and its derivatives in comparison to previous investigations is suitable (Rauter, *et al*., 1999; Hammarling, *et al*., 2000; Cabado, *et al*., 2008).

Results showed that the BADGE.HCL, BADGE.H_2O.HCL and BADGE.H_2O were not detected in any samples. However, BADGE, BADGE.2H2O and BADGE.2HCL were detected in samples but the amounts of specific migration of BADGE and its derivatives from metal cans into the samples conform to EU legislation (EC 1895/2005 that determined specific migration limits (SML) for sum of the BADGE and its hydrolyzed derivatives is 9 mg/kg and Sum of chlorinated derivatives is, 1 mg/kg), which confirm the safety of these cans container that were used for packaging of canned oily food in Iran's market.

ACKNOWLEDGEMENTS

This study was supported by Food and Drug Control Labs, Ministry of Health of Iran. The Authors are grateful staff of Packaging and Toxicology Labs, Food and Drug Control Labs for their helpful cooperative during this project.

Authors have special thanks to Dr Nemati and Mrs Fathi as their helpful guides.

ABSTRACT: Fresh-cut shredded carrot processing involves wounding operations (peeling and cut) which lead to fast quality deterioration (physiological and microbiological). However, advantages can be drawn from the use of wounding due to the related effect of phenolic synthesis induction. Phenolic compounds are known to be present in higher concentrations in carrot peripheral tissues (peels) than in the internal ones. In view of the processing diagram to fresh-cut carrot production it is of utmost importance to characterize the peeling operation effects in regard to the balance between phenolic losses and synthesis during storage. This study aimed to evaluate the effects of wounding intensity (peeling and shredding) on the total phenolic content (TPC) of *cv*. Navajo carrot during storage (7 days/5 °C). Higher phenolic contents were observed (≈40%, $p<0.05$) in unpeeled carrot samples, demonstrating the significant contribution of peels to the carrots total phenolic content. Wound-induced responses were dependent on wounding intensity and storage time. By the end of storage, TPC levels of 246.4 and 155.3 mg CAE/100 g were found in unpeeled and peeled shredded samples, respectively, corresponding to increases in TPC when compared to raw material ($p<0.05$; 128.6 mg CAE/100 g). Peel removal did not compromise wound-induced responses. These results are of great importance to the fresh-cut technology since peel removal prevents accelerated microbial decay while allowing the production of high quality products with expectable longer shelf-lives.
Key words: *Shredded carrot; Wounding intensity; Stress; Phenolic content*

INTRODUCTION

The fresh-cut fruits and vegetables (F&V) (washed, cut, packaged and refrigerated products) market is the fastest growing segment on the F&V market in the European Union (EU) and its success is mainly due to their convenience, freshness and associated health benefits (Ragaert *et al.*, 2004). Shredded carrot is an important fresh-cut commodity due to its pleasant flavour and nutritional benefits as well as to its versatility of use (Alasalvar *et al.*, 2001).

Minimal processing operations damage carrots tissue integrity and triggers deteriorative processes which lead to increases in microbial and non-microbial spoilage during storage (Jacxsens *et al.*, 2003). However, the mechanical and physical stresses imposed to carrots during minimal processing operations are elicitors of wound-induced phenolics and can be used to increase the antioxidant potential of shredded carrot.

Phenolic accumulation is a usual wounding stress response, part of the plants defence mechanism through activation of the phenylpropanoid pathway (Dangl *et al.*, 2000), and is dependent on several factors such as wounding intensity (Heredia & Cisneros-Zevallos, 2009), initial concentration (Reyes *et al.*, 2007) and storage conditions (Jacobo-Vellasquez and Cisneros-Zevallos, 2009). This defence system triggers the activation of phenylalanine ammonia lyase (PAL) and is followed by the synthesis of protective phenolic compounds to reduce water loss or pathogen attack (Rhodes and Wooltorton, 1978).

Plant peripheral tissues provide a primary defence barrier to exogenous stresses (both biotic and abiotic) and are richer in phenolic compounds (Hutzler *et al.*, 1998). It is known that phenolic distribution varies significantly among the different carrot tissues (peel, phloem and xylem) where, according to Zhang and Hamauzu (2004), peels provide about 50% of the total amount of phenolic compounds present in the root. Peel removal is part of the minimal processing operations for shredded carrot production since it provides benefits that include a significant reduction of the initial epiphytic microflora and improves products sensory quality. Although several studies can be found about the effects of wounding intensity over phenolic accumulation in unpeeled shredded carrot, information about the effect of peel removal over the wound-induced stress responses is scarce. For this reason, the aim of this research was to quantify the effect of peeling and shredding on the total phenolic content of *cv*. Navajo carrot during low temperature storage (5 C).

MATERIAL AND METHODS

Plant Material and Processing

Carrots (*Daucus carota* L. *cv.* Navajo) were obtained from a local market (HEB, Grimmway Farms, Bakersfield, CA), sorted and washed with water to remove excess dirt. Carrots were divided into 4 groups: *I)* Whole unpeeled carrots; *II)* Whole peeled carrots; *III)* Unpeeled shredded carrot and; *IV)* Peeled shredded carrot. Carrots were shredded using a West Bend® High Performance Food Processor (The West Bend Co.; West Bend, WI). After preparation, samples were placed separately in 4-L clear glass jars (closed and vented every 8 h to avoid CO_2 accumulation) and stored for 7 days at 5 °C. Total phenolic determination was performed using five replicates for each sample type at days 0, 3 and 7 of storage.

Quantification of total phenolic content

Carrot tissue (5 g) was homogenized with methanol (20 mL) using an Ultra-Turrax homogenizer (IKA Works, Inc., Wilmington, NC) and centrifuged at 29000 g for 15 min at 4 °C. The clear supernatant (methanolic extract) was used for total phenolic content determination using the method described by Swain and Hillis (1959). Methanolic extracts (15 µL) were diluted with nanopure water (240 µL) in a 96-well microplate, followed by the addition of 0.25 N Folin-Ciocalteu reagent (15 µL). The mixture was incubated for 3 min, and then, 1 N Na_2CO_3 (30 µL) was added. The final mixture was incubated for 2 h at room temperature in the dark. Spectrophotometric readings at 725 nm were collected using a plate reader (Synergy HT, Bio-Tek Instruments, Inc., Winooski, VT). Total phenolic content was expressed as mg chlorogenic acid equivalents/100 g of fresh tissue.

Statistical analysis. Data from the trial was subjected to analysis of variance (One-way ANOVA) using the Statistica™v.8 Software from Statsoft (StatSoft Inc., 2007). Statistically significant differences ($P<0.05$) between samples were determined according to Tukey Honestly Significant Difference (HSD) test.

RESULTS AND DISCUSSION

Total phenolic content of whole and shredded carrot, with and without peels, after processing is shown in table 1. According to the higher levels ($p<0.05$) of total phenolics assessed in both unpeeled samples compared to the corresponding peeled ones, it can be concluded that the peel accounts for about 40% of cv. Navajo carrot total phenolic content. Zhang and Hamauzu (2004) also found that even though carrot peel accounted for only 11.0% of carrots fresh weight, it provided about 54% of carrots total phenolic content in Chibagosun and Hitomigosun varieties.

Table 1. Changes in total phenolic content (TPC) after wounding (day 0).

Shredding	Peeling	TPC (mg CAE/100 g)	TPC variation (%)
Whole	With peel	128.6^{b}±17.1	42.81
	Without peel	55.1^{a}±4.5	
Shredded	With peel	111.8^{b}±5.5	44.61
	Without peel	49.9^{a}±3.1	

Results are given as mean ± standard deviation (n=5). In the same column, different letters indicate significant differences (HSD test, at p≤0.05).

Just after processing and despite the peeling effect, when comparing whole and shredded samples it was found that shredding operation itself (table 1) did not introduce any change in TPC levels ($p>0.05$).

Phenolic content of whole samples with peel (raw material) remained relatively unchanged ($p>0.05$) during storage, ranging from 128.6 to 142.6 mg CEA/100 g (Figure 1). The peeling effect in carrot (whole samples without peel – mild wounding), induced phenolic synthesis since a significant increase in TPC of 1.3 times from day 3 to 7 (63.8 to 85.5 mg CEA/100 g, $p<0.05$) was found.

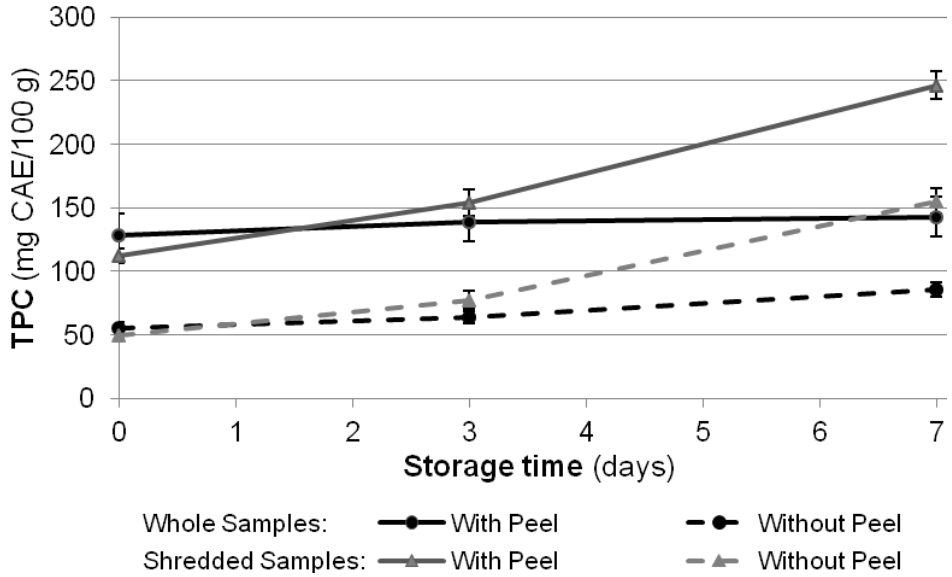

Figure 1. Effects of peeling and shredding on the total phenolic content of carrots during storage (7 days at 5 °C). Results show means of five replicates and their standard deviation.

During storage, both shredded samples had significant increases in TPC levels ($p<0.05$), showing that wound-induced phenolic accumulation is also dependent on storage time in accordance with other works (Reyes *et al.*, 2007; Heredia and Cisneros-Zevallos, 2009). The shredding effect accounted for increases in TPC levels of 2.2 and 3.1 times in unpeeled and peeled samples, respectively. This higher wounding intensity induced higher phenolic synthesis rates than peeling. This points out to the wounding intensity effect over the phenolic synthesis rate and accumulation which is in accordance to the findings of Heredia and Cisneros-Zevallos (2009). The authors found that phenolic synthesis followed a grading order from sliced, pie-cut and shredded carrot tissues while intact tissues (whole and unpeeled) had no significant change in TPC during storage (12 days, 15 °C).

Our results show that peel removal does not compromise wound-induced responses and that phenolic synthesis was independent of the initial TPC level. It is noteworthy from the fresh-cut quality standpoint that, during storage, peeled shredded samples TPC levels surpassed ($p<0.05$) the raw material level (155.3 *vs.* 128.6 mg CAE/100 g).

CONCLUSIONS

Wound-induced responses were dependent on both wounding intensity and storage time but independent on peel presence. Despite initial losses in phenolic content due to peel removal (up to 40%), peeled shredded carrot surpassed the raw material level by 27% during storage. These results are of great importance to the fresh-cut technology since peel elimination prevents accelerated microbial decay while allowing the production of high quality products with expectable longer shelf-lives.

ABSTRACT: Packaging necessary trace food products. Packaging materials with different properties affect the quality and sustainability of the meat and meat products. Consumer's interest has been increasing in natural and quality preserved food products that are not chemically treated. Improvement of the protective effect of applied packaging materials can be achieved by selecting appropriate conditions of packaging (vacuum, modified atmosphere and the latest trend is active packaging). The objective of this study was to review the possibility of application of different materials through examination of their mechanical, barrier and structural characteristics. This paper presents comparative results related to combinations of materials usually used in meat industry, obtained by different methods of production (laminating, extrusion laminating and co-extrusion). The results showed that monomaterials pass their good properties on multilayer materials. Multilayer materials have good characteristics and as such they meet the requirements of specific packaging conditions. These materials provide preservation of the protective atmosphere inside the packaging, thus contributing to the quality and sustainability.
Key words: *packaging materials, packing, characteristics, meat*

INTRODUCTION

The quality of packaged foods is greatly influenced by the properties of packaging materials. These vary depending on factors including the type of material, use of additives and method of manufacture. For instance, the properties of plastic films are mainly dependent on their composition, crystallinity and morphology (Sebranek and Houser, 2006). In meat industry most commonly used material are PA (polyamid) / PE (polyethylene) which could contain barrier layers: etilen-vinil-acetat (EVA), etilen-vinil-alkohol (EVOH), poliviniliden-hlorid (PVDC) and others (Lazić et al., 2002). Traditionally, the plastic films used for vacuum and MAP were developed to improve effectiveness in their gas and moisture barriers, shrinking properties, sealing characteristics, cook-in and retort capability and a variety of print and color options (Sebranek and Houser, 2006).
Modern meat packaging techniques are intended to maintain microbial and sensory quality of the product (Seydim et al., 2006; Fernandez-Lopez et al., 2008). This can be achieved by manipulation of the meat microenvironment (Hotckiss, 1988). Vacuum and modified atmosphere packaging (MAP) conditions are used in the food industry to extend the product shelf-life. MAP can be classified into two main categories, namely, low oxygen modified atmosphere (including vacuum packaging, CO_2 and N_2 gas flushing) and high oxygen modified atmosphere (Robertson, 1993). Modified atmosphere packaging has led the evolution of fresh and minimally processed food preservation, especially in meat and meat products for the past two decades. It was found that the extension of shelf life of meat samples depended on the packaging conditions and augmented in the order: air < vacuum pack < gas mixture 40%CO_2/30%N_2/30%O_2 < gas mixture 80%CO_2/20%air < 100% CO_2 (Skandamis and Nychas, 2002). Modified atmosphere packaging (MAP) using a high carbon dioxide (CO_2) environment is an effective means of prolonging microbial shelf-life of meat during extended storage (Sørheim and Nissen, 1999).

When the packaged meat is exposed to high O_2 concentration, growth of aerobic microorganisms, and oxidation of lipid and myoglobin are accelerated. Therefore, the use of gas barrier film to restrict the entry of O_2 through packaging material has been abundantly reported and widely commercialized in the industry (Kotzekidou and Bloukas, 1996). For instance, it was reported the shelf-life of MA packaged meat increased by 10–15% when using a barrier film with an O_2 permeability below 2 cm^3/m^2/day/atm (Gill and Molin, 1991).
Barrier films with O_2 permeability less than 100 cm^3/m^2/24 h/atm (at 23 ℃ and 0% rh) are generally being used for vacuum packaging or MAP of meat in the industry. The average O_2 permeabilities of polyamide (PA)/polyethylene (PE) films and polyvinylidene (PVDC)/EVA (ethylene vinyl acetate) copolymer films were 48.8 and 14.0 cm^3/m^2/day/atm, respectively. In order to maintain the gas composition inside the MAP over the storage period as constantly as possible, sheet thickness for the MAP tray should be at least 1–2 mm, and CO_2 and water vapor permeabilities should be lower than 65 cm^3/m^2/day/atm and 645 g/m^2/day/atm, respectively (Smith, 2001). In plastic films, CO_2 has 4–5 times and 13 times greater permeability than O_2 and N_2, respectively, because the solubility coefficient of CO_2 is much greater than the other gases (Robertson, 2006). Into commonly used barrier layers (PA, PETP and PVC), EVOH (ethylene vinyl alcohol), PVOH (polyvinyl alcohol) or PVDC are embedded in the multilayered structure by lamination or coextrusion (Lange and Wyser, 2003) of which O_2 permeabilities are normally less than 1 cm^3/m^2/24 h/atm (Stiles, 1990). In order to get an absolute barrier, very thin vacuum metalized aluminum is coated to the PETP layer. These days, consumers and retailers are more likely to demand flexible transparent barrier materials. In this regard, the disadvantages of vacuum metalized aluminum film are its lack of transparency and its inability to be used for microwaving (Lee, 2010).
There are two very popular and widely spread formats of packaging. These are high oxygen/barrier tray/barrier lid and high oxygen/tray/barrier over wrap. High oxygen/barrier tray/barrier lid consists of a clear or colored barrier lined tray (PS, PP, PE) that is paired with a clear or printed barrier film. This style of package normally has a 1:1 headspace ratio and contains an atmosphere of 80% O_2 and 20% CO_2. The 1:1 ratio is needed to give the product a minimum of 55% oxygen throughout the shelf life, which was found to provide optimal color life (Jakobsen and Bertelsen, 2000). The O_2 reacts with the meat to extend the oxymyoglobin state while the CO_2 acts as bacteriostatic agent (Kropf, 2004). The advantages of this type of product is that everything can be done at the packing plant and all that needs to be done by the processor is to place the pre-priced/pre-labeled package into the case. The disadvantage is that by marketing the product in the oxymyoglobin state the quality life of the product is limited to about 10–12 days for ground beef and 12–16 days for whole muscle. Lipid oxidation tends to be a problem with this style of package (Jackson et al., 1992). Also once the product is placed under retail lights the quality life of the product is only 2–4 days (depending on product), which is still about double what the retailer gets now with the traditional PVC wrap (Belcer, 2006). High oxygen/tray/barrier over wrap is similar to the Tray/Lid in that it has the same requirement for head space and uses the same gas mixtures. The difference with this package is that it uses a non-barrier polystyrene tray similar to what is used by retailers today and it is completely over wrapped giving it a more in-store look. The same advantages and disadvantages exist with this option as with the first (Belcer, 2006).
Gas barrier packaging materials available on the market have some drawbacks in terms of their cost, water-sensitivity, opacity and mechanical resistance. For instance, some packaging materials which have polar groups in the chemical structure like –OH (EVOH and PVOH) or –CO (PA) are markedly affected by relative humidity surrounding the packaging material. Therefore, new efficient barrier solutions have been developed in recent years in terms of 1) new barrier polymers, 2) thin and transparent vacuum deposited coatings, 3) blends of barrier and standard polymers, 4) nanocomposites, and 5) organic barrier coatings or adhesives (Lange and Wyser, 2003).
The use of multilayered film including a barrier layer might not be desirable with respect to recycling issues, but a substantial gauge is needed when the PE or PP (polypropylene) film is used alone. Theoretically, approximately 2 cm PE is required to achieve the same O_2

barrier as EVOH at a gauge of 0.4 μm, which prohibits it as an eco-friendly solution (Cerny, 1991).

MATERIALS AND METHODS

In this work, examined materials were: monomaterials (PE, PA and PET), commonly used materials for meat and meat products packaging (PA/PE, PET/PE, PA/EVOH/PE) and highly barrier foils (PVC//PE–EVOH-PE and PET//PE-EVOH-PE).
Physical, mechanical, structural and barrier properties were determined:

- Thickness, determined using micrometer with sensitivity of 0.001 mm. Five thickness measurements were carried out on each film, from which an average was obtained
- Tensile strength (MPa) and elongation at break (%), determined at device on the Instron Universal Testing Instrument Model No 4301, according to ASTM standard method D882-01
- Structure of polymers, using Nicolet iS10 FT-IR spectrometer in Attenuated Total Reflectance (ATR) technique, from 4000 to 500 cm^{-1} with 16 collected scans for each record
- Permeability of gases, using gas chromatography method Lyssy, according to DIN 53380

Descriptive statistical analyses for calculating the means and the standard error of the mean were performed using StatSoft Statistica 10.0. All obtained results were expressed as the mean ± standard deviation (SD). All graphs were performed using MicroSoft Excel software (MicroSoft Office 2003).

RESULTS AND DISCUSSION

The results showed that monomaterials pass their good properties on multilayer materials. **Material thicknesses** are shown in Figure 1.

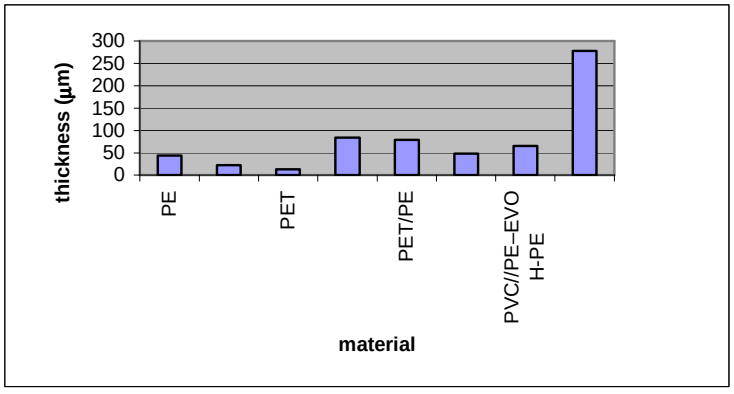

Figure 1. Thickness (μm)

Mechanical characteristics are presented in Table 1 as value of tensile strenght (N/15mm) and elongation at break (%). Results presented in Table 1 show that tensile strenght of sample PET//PE-EVOH-PE has the highest value which is in accordance with highest value of thickness of the PET//PE-EVOH-PE sample.

Table 1. Tensile strength [N/15mm] and elongation at break [%]

Material	Tensile strength [N/15mm]		Elongation at break [%]	
	Longitudinal	Transfersal	Longitudinal	Transfersal
PA	16.3±1.32	16.1±1.77	110.6±8.41	15.5±1.29
PE	13.4±1.61	12.3±1.72	240.7±31.29	710.2±113.63
PET	25.1±1.58	24.9±1.77	37.1±2.22	22.3±1.43
PA / PE	47.0±3.15	36.3±2.82	298.8±22.71	389.2±31.14
PET / PE	40.0±3.6	43.6±4.80	89.4±10.72	50.4±5.55
PA / EVOH / PE	45.7±2.24	48.67±2.68	84.42±4.89	57.72±2.95
PVC//PE–EVOH-PE	65.8±4.2	66.3±3.1	112.84±8.80	115.95±8.57
PET//PE-EVOH-PE	98.4±5.4	102.7±7.9	49.72±7.30	21.47±6.11

Results are given as mean ± standard deviation (n = 5)

Using modern techniques of Attenuated Total Reflection Infrared Spectroscopy with prior chemical layer separation **structural properties,** of individual layers of material which form part of film used for packaging meat and meat products, are presented. Figure 2 presents the following spectra (a) PA, (b) PE, (c) PET, (d) PVC.

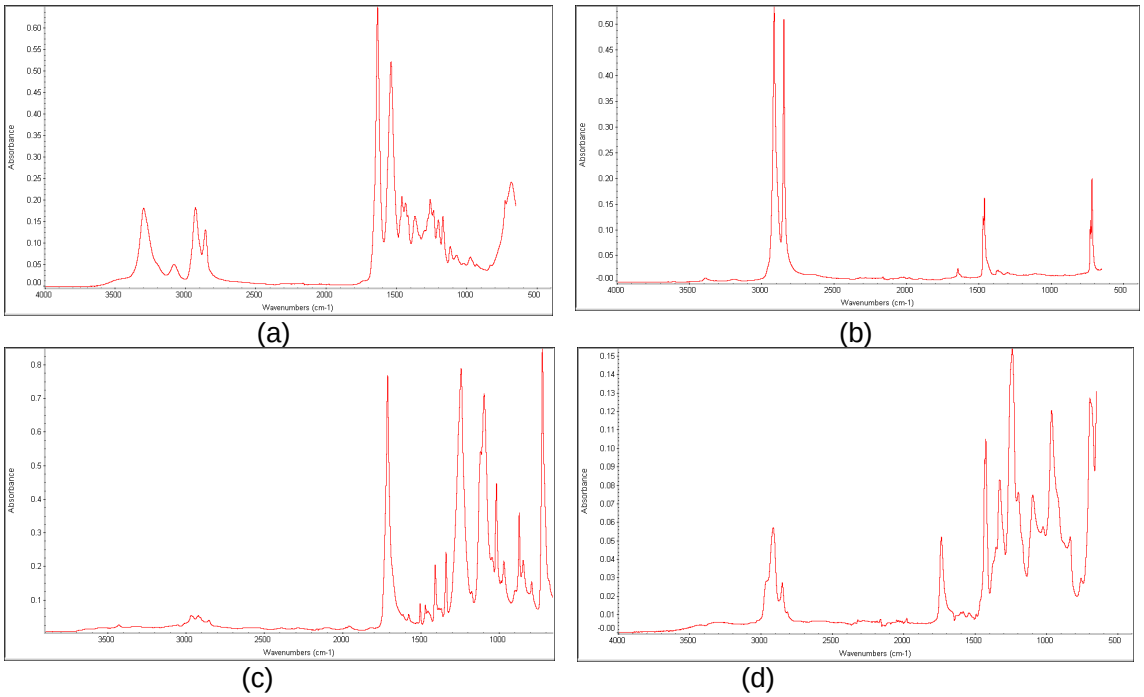

Figure 2. Spectra in different samples

Among the physical properties of packaging materials, the control of gas permeability is very important for maintaining the quality of packaged meat products. Gas permeability can be reduced by combining the base materials with other gas barrier materials through laminating, coating, blending or metalizing. The quantity of gas transmission through a packaging material depends on various factors such as the type, area, thickness and gas permeability of the film, differences in the partial pressure on both sides of the film, and storage temperature and relative humidity (Lee, et al., 2008).

Significant differences in barrier properties were obtained (Table 2). Among monomaterials the highest air permeability showed PE foil.The lowest permeability value was recorded in case of multi-layer foil type PA/EVOH/PE obtained by co-extrusion process, in which the measured value of air permeability was 4.5 ml/m^{2}24h. Obtained results point out that multi-layer materials, that contain barrier materials (PA, EVOH) and are produced by co-extrusion process, show best barrier properties.

Table 2. Gas permeability [ml/m^{2}24h]

Material	Gas permeability [ml/m^{2}24h]			
	CO_2	O_2	N_2	Air
PA	242.7±7.28	53.1±3.24	19.6±0.65	26.7±0.4
PE	7193.8±187.04	3477.2±156.47	1056.9±43.33	1570.2± 25.12
PET	760.12±31.16	248.3±6.95	251.7±4.53	250.8±15.30
PA / PE	196.9±3.74	46.9±3.89	16.7±0.70	23.1±0.62
PET / PE	21.4±0.98	120.3±6.62	115.7±4.05	118.5±2.01
PA / EVOH / PE	56.0±3.47	21.1±4.01	0	4.5±0.14
PVC//PE–EVOH-PE	23.8±1.93	15.5±0.64	0	3.6±0.12
PET//PE-EVOH-PE	23.85±1.4	16±0.57	26.85±1.46	26.65±1.62

Results are given as mean ± standard deviation (n = 3)

CONCLUSION

In the modern food chain system, it is hardly conceivable to distribute foodstuffs without packaging. Traditionally, food packaging has been limited to preservation and protection of food from environmental factors including chemical, physical and biological influences up to the point of consumption. This emphasizes retarding spoilage, extending shelf-life, and preserving the quality of packaged food. Modern packaging, however, should serve not only as an efficient tool for keeping quality of foodstuffs, but also for increasing product values, promoting sales and imparting information. With consumers ageing, factors including price, safety, size of packaging and recyclability are most important, but design, convenience and utility must also be taken into account.

This study confirmed good mechanical properties by analysing tensile strength and elongation at break of tested materials. Results of gas permeability measurements indicate good barrier properties. Examined multilayered packaging materials could be successfully used on meat packaging lines intended for vacuum or modified atmosphere packaging. Improvement of technology of meat products goes towards the development of new products with improved properties for the targeted population, the introduction of new materials and new packaging requirements, with the inevitable quality management in manufacturing.

ACKNOWLEDGEMENTS

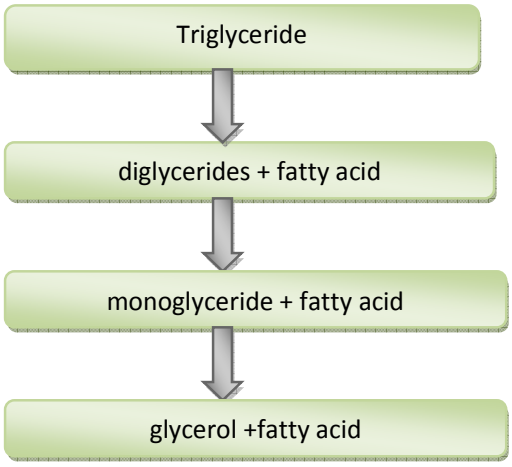
ABSTRACT: Manufacturing of butter in Ukraine has lost its profitability because there are no raw-materials. A combination of butter with oil (spread) is a new product at the Ukrainian market. Studying of the oxidation process of fats is associated with a reduced loss of fat and fat-containing products during their storage. This is important for fat, food, candy, perfume and cosmetic industries. The process of fat oxidation is a chain free radical process with branching chains. Hydrolytic and oxidative processes occur during the manufacturing and storage of fat. The final product of oxidation is malonic dialdehyde. Selection and addition of antioxidants of natural origin of the crude drug is very important. The goal of the studies was to compare the effects of various antioxidants on the stability of spreads to oxidation during storage. Phenolic compounds, natural vitamins A, E and β-carotene materials have been used as antioxidants. Samples were subjected to accelerated oxidation. There are defined organoleptic properties, as well as acid and peroxide numbers and malonic dialdehyde content in the samples. It has been shown that antioxidants exercise an inhibitory effect on the formation of peroxides. The effect of antioxidant action depends on the number of introduced additives. In most cases with increasing concentration of the additive, its stabilizing effect increases. However, there is a negative impact on the organoleptic properties of the spreads. The spreads with antioxidants have high biological and nutritional value.
Key words: *spread, antioxidant, storage, inhibition of oxidative processes.*

INTRODUCTION

Because of a shortage of raw materials in Ukraine, butter manufacture has lost its profitability. Production became not encouraging to the manufacturers (Викторова, 2007). Therefore, a new product - spreads – has appeared in the Ukrainian market. To manufacture the spreads, substitutes of dairy fat on a vegetable basis are used. The fatty acid composition of butter is regulated with the help of substitutes. But in the course of storage of the spreads, oxidative processes can lead to damaging of the product and occurrence of undesirable smacks, such as cardboard, metal, olive, grease, fish and others.

During the storage of fats, especially in adverse conditions, there are changes, which resulted in a number of chemical combinations with an unpleasant taste and odor. Fat damage can occur both under the influence of enzymes, and under the influence of air oxygen. Action of enzymes is accelerated by humidity and temperature increase, light, salts of metals of copper, iron, lead, and zinc. One can distinguish hydrolytic and oxidizing decays of fat. The kind of damage depends on the preservation of fat and conditions of its storage (Горбатова, 2003).

Hydrolysis is a process of disintegration of fat to glycerine and fatty acids. Hydrolysis of triglycerides passes the following three stages:



These stages proceed consistently, but with different speeds.
Fat hydrolysis is caused, mainly, by the enzyme of lipase. Apart from that at high humidity and storage temperature, hydrolysis occurs as a result of the influence of oxygen from air and light on the fat. Fat hydrolysis is characterized by the accumulation of fatty acids. Hydrolytic disintegration of fat results in the accumulation of high-molecular fatty acids which have no taste and smell, so they do not change the organoleptic product indicators. Occurrence of flying low-molecular fatty acids such as butyric, caproic, caprylic which possesses unpleasant smell, sharply worsens organoleptic properties of oil (Горбатова, 2003).
Oxidative damage of dairy fat proceeds at low temperatures in the presence of oxygen from air and light. Thus, there is a deep disintegration of fat which leads to formation of peroxides, aldehydes, ketones, alcoholic acids and other compounds possessing unpleasant smell. Thus, fat oxidation is connected with the formation of extraneous undesirable smacks of the product owing to the fact that the product gets various defects of smell (prorancid, silage, etc.). Polyunsaturated fatty acids are exposed to oxidation first of all.
In the initial stage of oxidation, the essential role is played by free radicals, which appear in fat under the influence of energy (light, thermal), metals, oxygen, etc.
Stability of fats one understands as their ability to remain high quality for a long time. Therefore, stability of fats defines factors that limit their damage of the chemical and biochemical origin. Speed of enzymatic and chemical processes depends on the chemical composition of fat, temperature of storage, moisture content, etc. Oxidation process is influenced by some chemical substances which either accelerate it (prooxidizers), or slow it down (antioxidants).
Antioxidants are a specific group of chemicals of different chemical composition. They possess ability to eliminate free radicals and to slow down oxidation-reduction processes.
The aim of this work was to study the influence of selected antioxidants such as vitamins A, E, carotinoids, phenolic compounds on the oxidative processes during the storage of spreads.
In view of this, the following problems have been defined:
- Selection of a way of the accelerated oxidation of fats;
- Influence of hydrolysis and oxidation processes of a spread with various antioxidants on following indicators: acid number, peroxide value and a malonic dialdehyde formation.

MATERIAL AND METHODS

For carrying out experimental studies, we prepared the spread with a mass fraction of fat 73 ± 0.5 % from cream and a substitute of dairy fat. Reference and experimental samples with antioxidants were tested for organoleptic, physical and chemical indicators. The prepared

spread samples did not differ in their physical and chemical indicators, which corresponded to the requirements of the operating standard documentation of Ukraine for the spreads.
To set up the accelerated oxidation experiment, several ways were considered:
1. At temperature 100 ºC and constant blow of air through the fat during 8–10 hours before achieving 10 mm ½ O_2;
2. At temperature 100 ºC without air purge;
3. At room temperature and absence of direct sun rays within a month;
4. At an irradiation infra-red and ultra-violet beams within 4 hours.
The first and second ways are more suitable for liquid fats, which do not contain moisture, but for the spread they cannot be used. As the spread contains up to 25 % of moisture, treatment at such a high temperature would cause a division of a product into water and fatty fractions, and also moisture evaporation that leads to chemical compound change of the spread. The third and fourth ways are suitable for research of oxidizing processes of spreads, therefore they can be used in the further work.
Spreads with antioxidants were kept at room temperature in standard conditions: thickness of the layer was 4 - 5 mm, area of the contact with air was 2.8 cm^2/g, and duration of storage in a glass case at the North side of the room under the scattered light was 20 days.
Concentration of an antioxidants was chosen not to exceed 40 % of a daily requirement for the person.
The acid number characterizes the presence of free fatty acids in a fat. It is expressed as a mass of KOH in the milligrammes necessary for neutralisation of free fatty acids, in 1 g of a fat. The method is based on titration of free fatty acids by KOH solution (concentration of KOH 0,1 mol/dm^3) with the presence of phenolphthalein as an indicator (Горбатова, 2003).
Peroxide number name is a measurement of the quantity of peroxides in fat. Definition of this indicator is based on interaction of peroxides of fat with sated water solution of KJ and iodine determination with a solution of $Na_2S_2O_3$ (concentration of $Na_2S_2O_3$ 0.1 mol/dm^3) in the presence of starch (Горбатова, 2003). The product with a peroxide number no more than 0.03 % J_2 is considered fresh.
As an end product of lipid peroxidation, malonic dialdehyde is a measurement of the efficiency of an antioxidants. During incubation in a boiling water bath in acidic medium, malonic dialdehyde reacts with 2-thiobarbituric acid, forming a coloured complex with an absorption maximum at 535 nanometers (Андреева, 1988).

RESULTS AND DISCUSSION

Addition of antioxidants in the spread essentially did not influence the organoleptic indicators of the final product. A notable difference was made by the addition of β – carotene at the concentration of 0.8 % and above, which caused a weak taste and aroma of β – carotene to be felt, and the colour became a more intensive orange color, which does not correspond to standard organoleptic indicators of a ready product.
In fresh spread samples the peroxide number was determined to be 0.028 % J_2, which corresponds to norm and indicates the freshness of the product. During the course of storage at room temperature in the presence of light and absence of direct sun rays, an increase of peroxide number values is observed. This showed that the occurrence of free radical chain reactions which are known to happen - at the first stages of formation of peroxides and hydro peroxides. Higher peroxide number of the sample without an antioxidant (control) indicates a faster damage of the product over the storage period of four weeks at room temperature. After a week of storage peroxide number of the control sample increased from 0.028 to 0.058 % J_2 and the spread still remained fresh.

Table 1. Dynamics of peroxide number changes (% J_2) of the control sample and samples of spread with antioxidants during the course of storage

Results are given as mean ± standard deviation (n = 3)

In pre-production models oxidation process was slowed down depending on the quantity of added antioxidant. In spreads which contained a small amount of antioxidants, peroxide value almost did not differ from the control. With increasing of content of biologically active compounds the oxidation process significantly inhibited and in these samples it almost doesn't grow during a week. After two weeks, peroxide value of the control sample increased to 0.1 % J_2. With a such value of the peroxide number, a product has doubtful freshness. Also, organoleptic indicators changed, there was a foreign smell that indicated the beginning of disintegration of peroxides.

The best antioxidant protection was achieved with β - carotene at 1 % level of addition. Throughout the four weeks of storage, peroxide value of this sample fluctuated from 0.028 to 0.07 % J_2. Samples with peroxide value from 0.06 to 0.1 % J_2 are considered as products of doubtful freshness. Despite the best antioxidant activity, addition of 1 % β - carotene significantly changed the colour of the product to brilliant orange, which did not correspond to the natural colour of the product.

Acid number characterizes the process of enzymatic or non enzymatic hydrolysis of fat. Disintegration of fat with formation of fatty acids can promote the process of lipid oxidation as free fatty acids (not connected to triglycerides) are oxidised first of all. For this reason acid number was determined in all pre-production models. Acid number of each of fresh spreads was between 1.01 and 1.3 mg KOH.

Despite the increase in acid number which proved the accumulation of free fatty acids, changes of organoleptic indicators of the products was not observed during the storage.

After three weeks of storage, further increase in acid number to 3.25 mg KOH was observed in all samples including the control. Thus, fat hydrolysis occurred during the storage of samples of the spread at ambient temperature. Process goes almost with identical speed, both in the control sample and in the samples with tested antioxidants. The reason is that the role of antioxidants is that they inhibit the oxidation by breaking free radical chain reactions, but they don't influence the hydrolysis of atsilglitserids.
Malondialdehyde in the control sample and the samples spread with biologically active substances were determined once a week for four weeks. Pink colour didn't appear in the samples, so it can be concluded that the decay of peroxide compounds, even in the control sample did not reach the final products, one of which is malondialdehyde.

CONCLUSIONS

The conducted study has shown that introduction of antioxidants (vitamins A, E, carotinoids, polyphenols) in the spreads brakes the process of the accelerated oxidation at ambient temperature. It was established that over the course of the accelerated oxidation fat hydrolysis occurred, and that acid number of the control and pre-production models changed almost equally. Throughout the four weeks of studies, malonic dialdehyde appeared neither in the control sample nor in the pre-production models with added antioxidants.
It is clear that carotinoids, catechols, tocopherols and other compounds, which are a part of selected antioxidants, actively react with peroxide radicals, eliminating them from the oxidation chain reaction. The offered antioxidants as substances are capable of inhibiting the process of transformation of free-radical chains during oxidation. These antioxidants can be recommended for the manufacturing of the spreads intended for long-term storage, which also possess the high biological and food value.

ABSTRACT: Currently PLA is used in food packaging application only for short shelf-life products, but designing the materials with exact properties provides many opportunities for PLA/nanocomposites for various food packaging applications. Properties of PLA can be improved by incorporation of nanoparticles into polymer matrix. Because of the small particle size and extremely high surface area, the incorporation of nanoparticles into a polymer matrix creates interphases and changes the intermolecular interaction of the matrix. As a result, by incorporation of only small amounts (less than 10 wt %) of nanofillers, a polymer nanocomposite can exhibit markedly improved physical and mechanical properties. The goal of this work was to investigate the potentials of PLA /silica nano composites for food packaging application. Neat PLA and PLA with 0.2, 0.5, 1, 2, 3 and 5 wt% of nanosilica were prepared by solution casting method in chloroform. Several procedures were used to experimentally characterize the PLA/nanocomposite samples. The size of the silica nanoparticles was measured by Zetananosizer. Differential scanning calorimeter (DSC) was used to measure the glass transition temperature (Tg) of the polymer nanocomposite samples. Thermogravimetric analysis was performed for investigation of thermal stability of all samples in inert atmosphere from 25℃ to 600℃ .
Key words: *polylactic acid (PLA), silica , nanoparticles, food packaging*

INTRODUCTION

Polylactic acid (PLA) is recyclable and compostable polymer, with high transparency, good processability and water solubility resistance. The application of pure PLA polymer for food packaging was not possible, because of the poor mechanical properties, barrier and oxidative properties that are not suitable for this kind of application. Biopolymers have increased interest because of their positive environmental impact. They are produced from renewable sources and are biodegradable, so as a result their use have less negative effect compared to conventional petroleum based polymers. Biopolymers are used in variety of applications, like therapeutic aids, medicines, coatings, food products and packaging materials (Petterson and Oksman 2006). Poly (lactic acid) PLA is biodegradable aliphatic polyester derived from 100% renewable resources (corn starch or sugar beet). Popularity of PLA has large increasement because its mechanical strength and easy processability compared to other biopolymers. It has good physical properties for diverse applications including food packaging (Zhang et.al., 2008). It can be processed by injection molding, film extrusion, blow molding, thermoforming, fiber spinning and film forming (Rasal et.al., 2010). Also it requires less energy to produce than petroleum-based polymers (25-55% less) (Rasal et.al., 2010). However PLA in most applications need some modification to enhance thermal stability, mechanical and barrier properties which is possible by filling PLA with nanoparticles (Pluta, 2004). Inorganic fillers as dispersed phases in nanocomposites are nanosized, with at least one dimension in nanometer range (1-100nm). Nanofillers can create very large interfaces with polymer matrix because of their small particle size and extremely high surface area. Incorporation of only small amount of nanofillers (less than10%) can result in improvements of material performances (Wen et.al., 2011). Nanofillers are classified according to their morphology: layered, acicular or spherical (Wen et.al., 2011). Most studies concerning PLA nanocomposites are in PLA/layered nanoparticles. Only a few studies are

published with spherical (silica) nanoparticles. Never the less, spherical (silica) nanoparticles are, because of their great natural abundance, low cost and high thermal resistance and surface functionality very suitable for various applications (Wen et.al., 2011).
Food packaging has the role to protect packaged goods from outside influence and damage, to contain food and to provide that fresh undamaged food gets to consumers (Marsh and Bugusu, 2007). Currently PLA is used in food packaging application only for short shelf-life products, but designing the materials with exact properties provides many opportunities for PLA/nanocomposites for various food packaging applications (Zhang et.al., 2008). The future design of materials gives the opportunity not only to be environmental friendly, but also to satisfy various applications. PLA/nanoreinforced materials are one of the most promising materials for the future times. Scientist and industry stakeholders have already identified potential uses of nanotechnology in virtually every segment of the food industry including food packaging (Duncan, 2011). However, understanding of the stability of PLA under realistic food packaging conditions is essential to match the shelf-life of the foods with the shelf life of the packaging material (Ahmed et.al.2010). The goal of this work was to investigate the potentials of PLA /silica nanocomposites for food packaging application.

MATERIAL AND METHODS

The PLA used in this study was provided from Symbra Technology, Netherlands. The molecular weights of PLA were determined at temperature 25℃ by gel permeation chromatography (GPC) using Agilent 1100 Series system with refractive index, RID 1200, and diode array 1200 detectors. The column ZORBAX PSM 300 was used. The rate flow of the eluent tetrahydrofuran was 1 cm^3min^{-1}. The average molar masses, *Mn*, *Mw* and polydispersity index *Q* were determined using software Agilent ChemStation. Poly(styrene) standards were used for calibration curve. Parameters of the neat PLA from (GPC) are: Mn=60520; weight-average molecular weight Mw=160780, and polydispersity of Q=2.6. The nanosilica (AEROSIL®R812) was supplied by Evonik (Hanau, Germany), and was hydrophobic, with specific area of 260±30m^2g^{-1}, average particle size 7nm. They were used as received without any pre-treatment.

Sample preparation

Neat PLA and PLA films with 0.2, 0.5, 1, 2, 3 and 5 wt % of nanosilica were prepared by solution casting method in chloroform. Silica was measured, added in chloroform and stirred in ultrasonic bath for 10min. PLA was added to solvent and stirred with magnetic bar for four hours on 40℃. After completely dissolved in chloro form samples were poured into glass Petri dishes (10 cm diameter) and vacuum dried. Chloroform was evaporated and the films were peeled of the Petri dishes.

Characterization

Zetananosizer ZS (Malvern instruments) was used to measure the average size of the nanoparticles in chloroform. The measurements were performed in quartz cuvettes.
The dispersion of the silica nanoparticles in the PLA matrix and the silica-matrix interface were studied by scanning electron microscopy (SEM), performed in a JEOL JSM-6460LV microscope operated at 25 kV. Samples were cryogenically fractured and the fracture surface was sputter-coated with very thin gold layer, in a Bal-Tec SCD-005 instrument, before scanning.
Tensile strength was measured on instron dynamometer Toyoseiki AT-L-118A equipment.
Thermal properties of the samples were measured using a DSC model Q20 (TA Instruments, USA). Aluminum pans containing 3-5 mg of polymers were hermetically sealed. The non-isothermal curve of obtained material was scanned from 20 to 200 ℃. The heating rate was 10 ℃ min^{-1}.
Thermogravimetric analysis was performed on the TG analysis device 701 LECO (Leco Corp.,USA). Analyses was performed in defined temperature range from 25 to 600℃,

samples were subjected to thermogravimetric analysis (TGA) in an inert atmosphere of nitrogen with heating rate 10℃/min.

RESULTS AND DISCUSSION

Through sample preparation silica nanoparticles were dispersed using ultrasonic bath, and good dispersion was detected on Zetananosizer (Figure 1). Samples of PLA/silica nanocomposites with 1% silica content were recorded on scanning electron microscope (SEM). Visible nanoparticles on SEM (Figure 2) have size of approximately 50nm which confirms the good dispersion of silica into polymer matrix and confirmation that there was not any agglomeration in PLA/silica samples

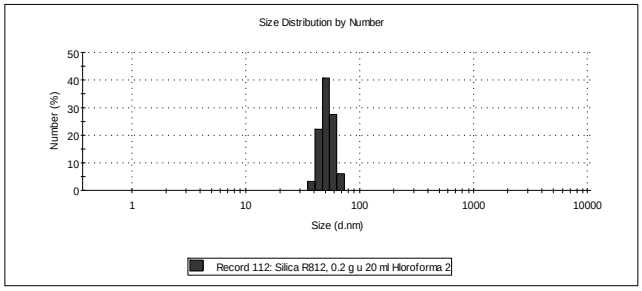

Figure 1. Number size distribution for PLA with 1% silica content

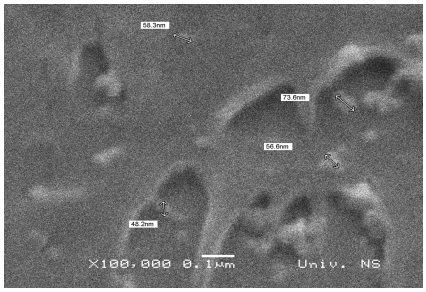

Figure 2. SEM of samples PLA with 1% silica content

Mechanical properties of prepared nanocomposite samples are improved especially for very small concentration of nanosilica particles. The most significant increasing of tensile strength was recorded for the sample with 0.2% silica (Figure 3), as well an improvement for samples with 0.5% and 1%. Decreasing of tensile strength start as the content of silica increased. For 5% content of silica value of tensile strength is below then neat PLA. This behaviour for higher content of nanoslilca is probably because of agglomerate formation, which causes decrease in mechanical properties.

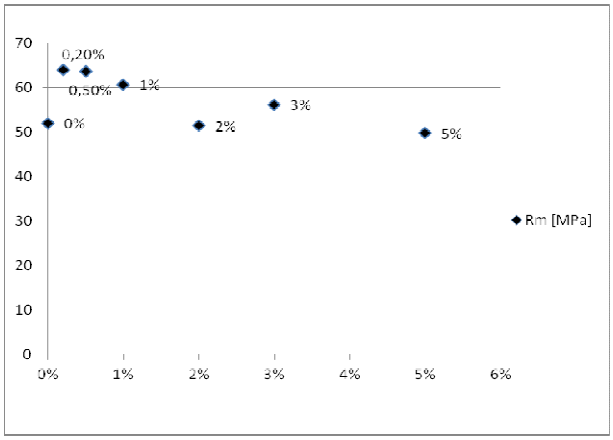

Figure 3. Tensile strength (Rm) dependant of filler content for PLA with different percentage (0,0.2,0.5,1,2,3 and 5%) of silica

The DSC thermograms indicate that the glass transition temperature (Tg) decreased as the filler content in the polymer matrix increased (Figure 4). This result may be attributed to the polymer chains moving due to the presence of the filler between the polymer chains. It has been shown that segmental dynamics of the polymer chains could reduce the Tg (Ristić at.al. 2012). The explanation of this phenomenon can result in improvement of mechanical

behaviour of the hybrid materials which was confirmed in the present study by the composites' measured tensile strength.

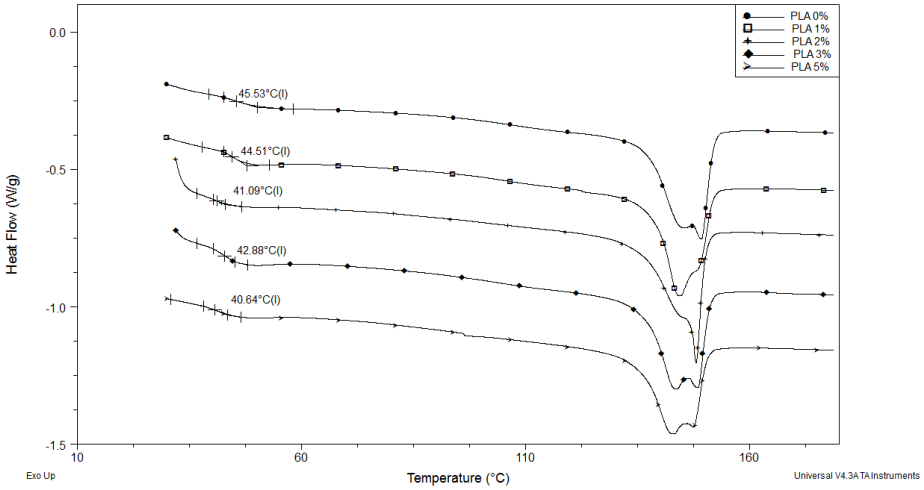

Figure 4. DSC thermogram PLA with different percentage of silica (0,1,2,3 and 5%) nanoparticle defined in figure as PLA (0,1,2,3 and 5%)

Thermogravimetric analysis shows that there are no significant changes in thermal stability (Figure 5). Same figure shows that at the higher temperature there are differences in degradation model due to different percentage of nanosilica.

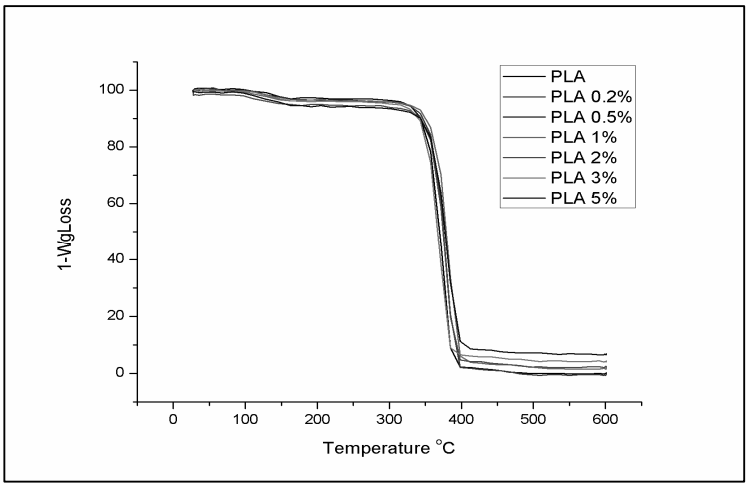

Figure 5. TGA curves for different percentage PLA with different percentage (0,0.2,0.5,1,2,3 and 5%) of silica nanoparticles

CONCLUSIONS

The simple method for PLA/silica sample preparation gave good results concerning distribution of nano particles. Spherical nano particles had very good dispersion in solvent, as well as in prepared films. From the results it can be concluded that the role of spherical nanoparticles is crucial for improvements of mechanical properties of PLA matrix. Incorporation of nanoscale silica particles into PLA matrix shows the improvement in tensile strength for adition of 0.2% concentration of nanosilica. Thermal stability of all samples did

not show any significant improvement. However, glass transition temperature decreased as the percentage of silica increased, due to polymer chain movement..

ACKNOWLEDGEMENTS

This paper is a result of the research within the project III46001 “Development and utilization of novel and traditional technologies in production of competitive food products with added value for national and global market - CREATING WEALTH FROM THE WEALTH OF SERBIA”, financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: Sea buckthorn (*Hippophae rhamnoides L.*) is a unique medicinal and aromatic plant and belongs to the family of *Elaeagnaceae*. Sea buckthorn juice, derived from the sea buckthorn berries, provides a nutritious beverage, high in suspended solids and rich in vitamin C and carotenes. In view of its highly perishable nature, sea buckthorn juice has to be processed in order to extend its shelf-life. The objective of this study was to evaluate the effect of mild heat treatment on microbial behavior and the shelf-life extension of sea buckthorn beverages during storage at temperatures from 5 to 20 ℃. Two different beverages were produced by mixing sea buckthorn juice with concentrated fruit juices from orange or pomegranate. These beverages were evaluated through storage time. Thermal treatments were applied at 60, 70 and 80 ℃ for 1, 3 and 5 min. Total aerobic microflora and yeasts and moulds were enumerated through the whole storage period at appropriate time intervals. Total antioxidant activity was measured for produced samples. Sensory evaluation was performed before microbial analysis of all samples. All thermal treatments delayed the recovery and the growth of all studied microorganisms during storage. All the obtained results were kinetically described. The effect of temperature on the deterioration rates was studied. The shelf-life of all beverages was determined based either on the growth of microorganisms or on the reduction of antioxidant activity, depending on the storage temperature.
The optimum process conditions were chosen based on the shelf-life extension which was estimated according to the higher antioxidant activity and the simultaneous lower microorganisms' growth rates.
Key words: *Sea buckthorn, beverage, extended shelf-life, antioxidant activity*

INTRODUCTION

Nowadays, there is a trend in consumption of fruits, vegetables and other derived plant products due to their beneficial effects on human health mainly attributed to the presence of bioactive molecules such as phenolic compounds (Crozier, Jaganath, & Clifford, 2009). These phenolic compounds including flavonoids, phenolic acids and tannins are a major group of phytochemicals which exhibit strong antioxidant (Pietta, 2000) and antibacterial activities (Mayer et al., 2008; Saleem et al., 2010). *Hippophaë rhamnoides L*., commonly known as sea buckthorn, is an Eurasian nitrogen-fixing actinomycetes plant species, producing yellow-orange berries at the end of summer (Rousi, 1971), from which beverages, jams, candies and cosmetics are manufactured. Sea buckthorn has recently gained in interest for its nutritional and medicinal values (Guliyev et al., 2004). The juice contains an oil phase trapped within the suspended solids. The juice of sea buckthorn is well known for its antioxidant properties, attributed to hydrophilic and lipophilic compounds including ascorbic acid, flavonoids, proanthocyanidins and carotenoids (Fan et al., 2007; Gao et al., 2000; Michel et al., 2011; Rösch et al., 2003). Antimicrobial activities have also been reported for sea buckthorn berries and juice (Puupponen-Pimiä et al., 2001). In the literature there are limited cited papers describing the effect of process conditions and storage time and conditions on the shelf-life of sea buckthorn beverages.

The objective of our work was to refine the formulas for the production of two sea buckthorn beverages, to select the optimum thermal process conditions for pasteurization and to study their shelf-life.

MATERIAL AND METHODS

In our study, two different beverages were produced by mixing the sea buckthorn juice with concentrated fruit juices from Navel var. orange and pomegranate. In general, for both beverages, the 50% was orange and pomegranate reconstituted juice, respectively, 10% was sea buckthorn juice and the rest was water. These beverages were evaluated for their stability through storage time. The quality indices that were measured are described below:

Microbiological analysis
Total aerobic viable count, yeasts and moulds were determined. Two replicates of at least three appropriate dilutions were enumerated. All plates were examined visually for typical colony types.

Color measurement
Quantification of the color change was based on measurement of CIELab values with a CR-200 Minolta Chromatometer (Minolta Co., Chuo-Ku, Osaka, Japan) with an 8 mm measuring area. At predetermined times of isothermal storage, according to the design, measurements were conducted and values of ΔC and ΔE were determined.

Sensory analysis
The sensorial attributes of sea buckthorn beverages were evaluated by a trained sensory panel of 5 people. Panelists were asked to score appearance, color, freshness, odor, taste and overall impression of beverages using a 1 to 9 descriptive hedonic scale.

Antioxidant activity
Antioxidant activity of the samples was expressed through the determination of the effective concentration (EC_{50}). The EC_{50} value expresses the amount of sea buckthorn beverages necessary to decrease the absorbance of DPPH by 50% (Antolovich et al., 2002). The value can be determined graphically by plotting the absorbance against the used extract concentration.

Storage conditions
Sea buckthorn beverages were stored at controlled isothermal conditions of 5 and 15 ℃ and at air temperature (approximately 25 ℃). Sampling was carried out at appropriate time intervals and kinetic analysis of microbial growth, texture analysis, color measurement, pH and sensory analysis were carried out.

Thermal treatment
The effect of temperature treatment on the sea buckthorn beverages stability was examined. The beverages were pasteurized (thermally treated) in thin-walled aluminum spiral placed in water-baths at temperatures in the range of 60-80 °C for 1 to 5 min. The treatment was continuous, using a peristaltic pump to push the liquid into the spiral. After thermal processing, the spiral was immersed into water bath of 15 ℃ for fast cooling. Aseptic packaging of the beverages followed the cooling into glass bottles of 150 ml each. During thermal treatment temperature was monitored in order to assure isothermal conditions.

RESULTS AND DISCUSSION

Thermal treatments were applied at 60, 70 and 80 ºC for 1, 3 and 5 min. Total aerobic microflora and yeasts and moulds were enumerated before and after processing. Total

antioxidant activity was measured for treated and untreated samples. The results indicated that thermal treatment significantly affected the initial microbial load of the beverages and their total antioxidant activity. Higher temperatures combined with longer treatment resulted in decreased colonies forming units and total antioxidant activity (results for sea buckthorn beverage containing pomegranate are shown in Table 1).

Selection of thermal treatment conditions

All thermal treatments resulted in reduced microbial load and reduced total antioxidant activity. The selection of process conditions for the shelf-life experiments was based on the higher antioxidant activity, the not detectable microbial load and the higher score of sensory evaluation. Treatment at 80 ℃ for 1 min resulted in higher antioxidant activity and sensory scoring with decreased number of viable cells (Table 1).

Table 1. Effect of thermal processing temperature and time on the quality indices of sea buckthorn and pomegranate beverage

Treatment temperature (ºC)	Treatment time (min)	Total microflora (logCFU/ml)	Yeasts and moulds (logCFU/ml)	EC_{50} (ml of beverage)	Sensory evaluation
Control	Control	4.75	3.52	0.247	9
60	1	3.54	3.17	0.574	9
	3	2.41	2.28	0.625	9
	5	<2	<2	1.058	8

	3	<2	<2	1.147	8
	5	<2	<2	1.358	8
80	1	<2	<2	0.941	8
	3	<2	<2	1.847	7
	5	<2	<2	2.752	6

Shelf-life experiments

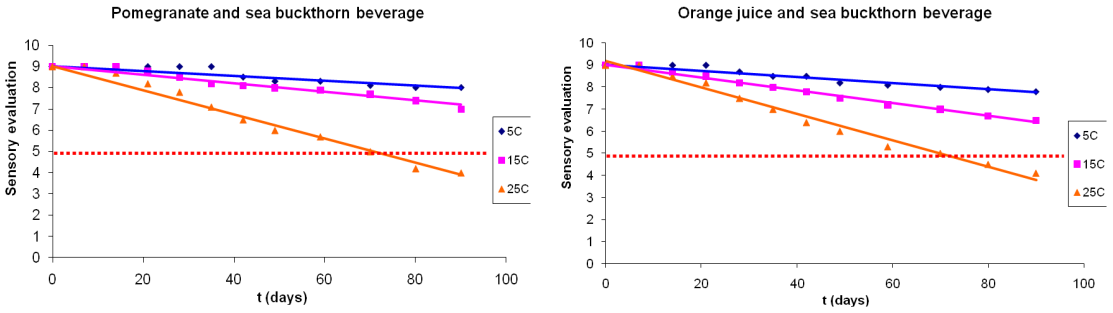
Thermal treatment at 80℃ for 1 min delayed the recovery and the growth of all studied microorganisms during storage for more than 3 months. Microorganisms were under the detection limit for all beverages during the whole storage period.

Color was significantly affected for beverages stored at 25 ℃ (Table 2), while for samples stored at 5 and 15 ℃ the color degradation was slower (Table 2). The same trend was observed for sensory evaluation of the beverages. For those stored at 5 ℃ the sensory degradation was significantly low, while for those stored at 25℃ a bitter taste was observed after approximately 60 days of storage (Figure 1).

Table 2. Effect of storage time on the ΔE color parameter of sea buckthorn beverages

Storage time (days)	Pomegranate and sea buckthorn beverage			Orange juice and sea buckthorn beverage		
	5 ℃	15 ℃	25 ℃	5 ℃	15 ℃	25 ℃
0	30.6	30.6	30.6	47.1	47.1	47.1
7	31.8	32.7	35.7	47.7	48.5	51.7
14	32.2	34.3	39.3	44.1	49.2	52.7
21	33.5	35.9	42.9	45.7	49.9	57.9
28	38.4	40.2	46.2	47.2	50.7	54.8
35	37.4	41.2	48.8	48.4	51.7	57.7
42	39.6	44.8	51.7	50.2	52.4	58.1
49	42.1	46.1	54.2	51.5	57.5	59.4
59	43.5	48.7	57.1	52.7	54.8	71.7
70	44.7	49.8	60.2	55.4	57.7	77.4
80	48.5	52.4	62.3	57.7	58.7	75.7
90	49.7	55.1	64.8	59.8	71.2	77.4

The organoleptic deterioration rate constants for each storage temperature for both beverages were estimated (Table 3). Increase of storage temperature resulted in significantly higher deterioration rates as expected.



(a) **(b)**

Figure 1. Effect of storage time on the sensory evaluation of (a) pomegranate and sea buckthorn beverages and (b) orange juice and sea buckthorn beverage. The red dot line represents the acceptance/non-acceptance limit for the products

Table 3. Organoleptic deterioration rate constants of sea buckthorn beverages at different storage temperature

Storage temperature (℃)	Sea buckthorn + orange juice beverage organoleptic deterioration rate constant ($days^{-1}$)	Sea buckthorn + pomegranate juice beverage organoleptic deterioration rate constant ($days^{-1}$)
5	0.0111	0.0136
15	0.0201	0.0286
25	0.0565	0.0597

Shelf-life determination

The quality degradation and the shelf-life estimation of the developed beverages can be correlated to the development of off-odour in the products and by the color alteration. Taking into consideration all the received results from our study, the shelf-life can be determined based on color alteration (ΔE-value equal to 60) or the sensory evaluation (scoring equal to 5). The shelf-life of the sea buckthorn beverage with pomegranate is estimated as 325, 180 and 70 days (Table 4), after storage at 5, 15 and 25 ºC, respectively. For the orange juice and sea buckthorn beverage, the corresponding shelf-life is estimated as 285, 130 and 70 days (Table 4), respectively for the same storage temperatures. Comparing the received results with corresponding results for untreated samples stored at 5 ºC (shelf-life estimated as 7 and 5 days, respectively), a 40-fold increase is achieved when pasteurizing at 80 ℃ for 1 min.

Table 4. Shelf-life (days) determination of sea buckthorn beverages at different storage temperatures

Storage temperature (℃)	Sea buckthorn + orange juice beverage	Sea buckthorn + pomegranate juice beverage
5	285	325
15	130	180
25	70	70

CONCLUSIONS

The development of two commercially viable sea buckthorn beverages with fresh-like characteristics and extended shelf-life was achieved. Optimum time and temperature conditions (80 ℃ for 1 min) for pasteurization wer e selected, based on microorganisms and enzymes inactivation while maintaining the nutrients and sensorial quality. The quality degradation and the shelf-life estimation of the developed beverages can be correlated to the the color and sensory degradation. In general, the shelf-life is estimated as 180 and 130 days for storage at 15 ºC, for sea buckthorn beverage with pomegranate and orange juice, respectively.

ABSTRACT: Metal cans as an economic and useful packaging usually have a polymeric coating, and it is possible that different compounds can transfer from this coating to foodstuff. If this transferring includes known and unknown compounds, it will be known as Overall migration. In this study overall migration caused by metal can polymeric coatings in food stimulants, is investigated. Investigated metal can lacquer coatings, were from golden phenolic epoxy kind, beige phenolic epoxy kind, and white Andric epoxy kind, and 10% ethanol and 3% acetic acid was used as stimulant for overall migration testing. The Overall migration was calculated by determination the lose weight of lacquers after storage at mentioned conditions. Result showed that overall migration ranges obtained from golden phenolic epoxy, beige phenolic epoxy, and white Andric epoxy liquors are around 2-4.2 mg/dm^2, 1.65-4.9 mg/dm^2, 2-4.2 mg/dm^2 , respectively. Results show that the amounts of overall are adopted with (European Union) EU legislation that identifies as overall migration limit (OML).
Keywords: *Can, Lacquers, Overall migration*

INTRODUCTION

Polymeric coatings or lacquers prevent reaction between metal and food. Epoxy phenolic lacquers with gold and beige appearance and epoxy anhydride lacquers with white appearance are more useful coatings in metal cans (Forrest, 2005; Nehring, 2007; CFR/175300, 2007). Migration in food from packaging is transferring parts or compounds from packaging to foodstuff and it caused by contact or reaction between packaging and foodstuffs (Schaefer, 2004; Ruyon et al., 2002; Lund et al., 2000). Specific migration from packaging to foodstuff follows mass transferring so it is necessary to know about mass lows and diffusion phenomenon. Migration is in accordance to Fick's low (i.e. migration has direct relation with concentration of present compounds in packaging and temperature) (Piringer 1994; Schaefer, 2004). Migration in food packaging science is studied from two point of view: overall migration and specific migration (Piringer,1994 ; Uematsu et al., 2004). Overall migration includes monomers and oligomers and intermediate compounds with molecular weight below 1000 Dalton and can be determined by gravimetric method (Commission Directive, 2002; CEN/ EN 1186-1,2002; CEN/TS 14235, 2002).Overall migration test in foodstuffs in order to its heterogeneous nature and possible interfere, is impossible. Therefore simulants are used to determination real value of overall migration (Piringer et al., 2000; Piringer et al., 2008). In order to determine overall migration importance allowed limits of overall migration have been determined in different countries by internal and international authorized organizations. This values in accordance with EU standard must be 10 mg/dm^2 of surface or 60 mg/kg in weight (Commission Directive, 2002; CEN/ EN 1186-1, 2002; CEN/TS 14235, 2002). In This study overall migration from polymeric coatings of metal can coatings which they are used in packaging industrial in Iran has been investigated. Then the results have been compared with standards.

MATERIALS AND METHODS

Materials

Metal cans were coated with golden epoxy phenolic, beige epoxy phenolic, and white epoxy anhydride lacquers, obtained from four main metal can producer factories; they were coded as A, B, C, D, Also the used chemical (Ethanol 96%, Acetic acid, Distilled water) were purchased from Merck Co., Germany.

Equipment

Analytical balance with 0.1 mg accuracy, Oven capable to 110^0C, Quartz or stainless steel containers, containers

Method

Simulant preparing

Acetic acid 3%

Weight 30ml acetic acid and then pure it into a 1000ml ground neck flask and poured with distilled water.

Ethylic ethanol 10%

Pure 104ml ethylic ethanol (96%) was poured into 1000ml ground neck flask with distilled water.

Preparing samples

Empty cans with golden epoxy phenolic, beige epoxy phenolic, and white epoxy anhydride coatings were placed in 110ºC oven, maintain for 30 min until they reached stable weight and then, placed in a desiccator. Then samples had been transferred to desiccators, and after they had been cooled, they were weighted by an analytical balance. Then cans were filled with acetic acid (3%) and ethanol (10%), and then they were sealed.

Applying thermal and time conditions

Filled cans had conditioned similar to food production process. For foods that are sterilized during production, filled cans with simulant were placed in 121^0C (sterilization temperature) for 1h. Then cans had placed in 40^0C oven for 10days (The recommended overall migration testing).So the real condition of heating that they were being used by industry can be obtained.

Determination of overall migration

After exposure can samples to thermal and time treatment, simulants had completely discharged from cans and purred in special quartz, stainless still containers that had previously reached constant weight, and evaporated on hot plate. After evaporating simulant, special containers had placed in 110^0C oven for 30 min and after cooling in desiccators, had weighted again. Obtained residues from evaporating represent overall migration and the results were expressed in mg/dm^2 of surface of metal can in contact with foodstuff.

In the same time migration value were determined in blank simulants to determine the residue of simulant after evaporation (Commission Directive, 2002; CEN/ EN 1186-1, 2002; CEN/TS 14235, 2002).

Calculations

Overall migration had calculated by this formula:

$$M = \frac{[(m_a - m_b) - m_d] * 1000}{S}$$

M; the overall migration to acetic acid 3% and ethanol 10% in mg/dm^2 in surface

m_a; initial weight of sample before exposing to simulant in gram

m_b; sample weight after exposure to simulant in gram

m_d; blank weight in gram

S; surface of sample, which had exposed to simulant in dm^2

Statistical analysis

Experiments on each of samples were performed at four replicates. Two analyses were taken from the test samples at each specific time interval. Statistical analysis (Mean values and standard division were calculated at each time interval, so were analyzed by SPSS ver. 11.5 (SPSS Inc. Michigan Avenue., Chicago, USA) and Minitab ver 11.12 (Minitab Inc., State College , USA)

RESULT AND DISCUSSION

1- Overall migration average value results for white epoxy anhydride and golden epoxy phenolic in A, B factories in acetic acid 3% and ethanol 10% simulants

Results obtained from determination overall migration value in white epoxy anhydride and golden epoxy phenolic in A, B factories in acetic acid 3% and ethanol 10% simulants are in table 1.

Table1. Result of overall migration for epoxy anhydride and golden epoxy phenolic lacquers

Food Simulant+ Factory / Lacquer	Overall migration (Mg/dm^2)			
	Ethanol 10%		Acetic 3%	
	B Factory	A Factory	B Factory	A Factory
Golden Epoxy Phenolic	3.8882	2.738	4.254	2
White Epoxy Anhydride	0.65	3.2606	2.7042	1.4462

Overall migration results for golden epoxy phenolic lacquer in A factory in ethanol 10% was higher than in acetic acid 3% and the results of overall migration for same compounds in B factory in acetic acid 3% was higher than in ethanol 10% simulant. Also the results of overall migration for white epoxy anhydride lacquer in A factory in ethanol 10% was higher than amount in acetic acid 3% and the results of same migrated compounds in B factory in acetic acid 3% was higher than in ethanol 10%. Moreover amount of migrated white epoxy anhydride lacquer in A factory in ethanol 10% was higher than in acetic acid 3% simulant but in contrast the mentioned amount of migrated compounds in B factory in acetic acid 3% was higher than in ethanol 10%.

Results shows that particle migration value from white epoxy anhydride lacquer in ethanol 10% and in acetic acid 3% have a significant difference($P<0.05$), whereas migration value in both ethanol 10% simulant and acetic acid 3% simulants have not a significant difference. Studying on overall migration in golden epoxy phenolic lacquer and white epoxy anhydride lacquer in acetic acid 3% simulant and ethanol 10% simulant that reported as mg/dm^2 in two factories A and B showed that there is a significant difference ($P<0.01$). Statistically analysing of A and B, also relation between lacquers and factories showed that there is a significant difference in amount of migration ($P<0.05$). Finally, considering both three parameter; factory, lacquer kind, and simulant we can report that there are significant differences in overall migration.

According to overall migration analyse, lacquer kind had highest effect on the amount of overall migration while factory and simulant kind had second and third grade, respectively.

2- Overall migration average value results for white epoxy anhydride in A - B- C- D factories in acetic acid 3% and ethanol 10% simulant

Overall migration value results for white epoxy anhydride in A - B- C- D factories in acetic acid 3% and ethanol 10% simulant are in table 2.

Table 2. Result of overall migration for epoxy anhydride lacquer in different factories

Lacquer + Factory Food Simulant	Overall migration (Mg/dm^2)			
	White Epoxy Anhydride			
	A	B	C	D
Acetic 3%	1.4462	2.7042	4.9196	1.541
Ethanol 10%	3.2606	0.65	2.266	0.873

Amount of Overall migration for white epoxy anhydride lacquer in A, B, C and D factories in acetic acid 3% and ethanol 10% simulant, showed this amount in acetic acid 3% simulant in C factory was the highest, and in A factory was the lowest. Also in ethanol 10% simulant in a factory was highest and in B factory was lowest. This fact is depended on some factors such as Tinplate sheets kind, lacquer formulation kind, quality of lacquer fill it expire date, lacquer storage condition, etc. Significant differences.($P<0.01$) were observed in overall migration values between acetic acid 3% and ethanol 10% simulants.

3- Overall migration average value results for white epoxy anhydride and beige epoxy phenolic in C factories in acetic acid 3% and ethanol 10% simulants

Overall migration value results for white epoxy anhydride and beige epoxy phenolic in C factories in acetic acid 3% and ethanol 10% simulants are included in table 3.

Table 3. Result of overall migration for epoxy anhydride and beige epoxy phenolic lacquers

Lacquer + Factory Food Simulant	Overall migration (Mg/dm^2)	
	Beige Epoxy Phenolic	White Epoxy Anhydride
Acetic 3%	1.6526	4.9196
Ethanol 10%	3.3454	2.266

Overall migration value in white lacquer in 3% simulant and ethanol 10% simulant in C factory was different to overall migration value in beige lacquer. This may caused by difference in stability or instability of these coatings to each one of two simulants and reaction of lacquers in contact with acid and ethanol. In addition, present difference between lacquers, can be related to formulation of each one of lacquers (in a view of resin base, and ingredients, etc,) and sheet kind and lacquer coating thickness on sheet surface etc. In addition, adhesion ability and plasticity of coating film and quality of consistence coating can also be effective on difference in migration value.

Overall migration in different coatings and acid and ethanol simulants in different factories

Summary, overall migration results were obtained in studying different metal container internal coatings in contact with food simulants (acetic acid 3% and ethanol 10%) has shown in table 4.

Table 4. Result of overall migration in different lacquers with simulants in different factories

Factory	Lacquer	Simulants	migration (Mg/dm^2)
A	White Epoxy Anhydride	Acetic 3%	1.4462
A	White Epoxy Anhydride	Ethanol 10%	3.2606
A	Golden Epoxy Phenolic	Acetic 3%	2.00
A	Golden Epoxy Phenolic	Ethanol 10%	2.738
B	White Epoxy Anhydride	Acetic 3%	2.2704
B	White Epoxy Anhydride	Ethanol 10%	0.6278
B	Golden Epoxy Phenolic	Acetic 3%	4.425
B	Golden Epoxy Phenolic	Ethanol 10%	3.8882
C	White Epoxy Anhydride	Acetic 3%	4.9196
C	White Epoxy Anhydride	Ethanol 10%	2.266
C	Beige Epoxy Phenolic	Acetic 3%	1.6526
C	Beige Epoxy Phenolic	Ethanol 10%	3.3454
D	White Epoxy Anhydride	Acetic 3%	1.541
D	White Epoxy Anhydride	Ethanol 10%	0.8732

CONCLUSION

Results obtained in this study can give some useful and practicable data about contaminants migration situation in internal produced metal cans. According to EU committee (EC) legislations, coatings must do not transfer their ingredients to foodstuff in values higher than 10 mg/dm^2. Studies showed that all examined samples have overall migration were adopted by specific migration limit, in accordance to EN14235. This showed that produced lacquers have desirable properties, and metal can producers followed safety and technical principals and legislations considering sheet kind and can applications in accordance to package foodstuffs and responsible person's controls was effective.

ACKNOWLEDGEMENTS

ABSTRACT: Packaging has an active role in processing, preservation and retaining the quality of the food. The growing consumers demands for the food that are ready to eat, fresh-tasting, nutrient and vitamin rich and minimally-processed and preserved are a major challenges for the current food industry. In order to realize these demands more significant role is gained to the packaging techniques and materials. Development in packaging is focused primarily towards the better protection of packaged food products, greater reliability, increased functionality, better environmental attributes of packaging, as well as in the development of new materials and packaging technology. In this paper the method of modified (protective) atmosphere packaging, biodegradable packaging as well as active and intelligent packaging are discussed. In addition the advantages of nanoscale materials for application in food packaging is also reviewed.
Key words*: MAP, biodegradable packaging, active and intelligent packaging, nanoscale materials*

TRENDS IN FOOD PACKAGING

Due to increasing consumers demands for the food that are mildly preserved, fresh, tasty with a prolonged shelf-life, the food packaging industry has rapidly developed to meet and satisfied these expectations. The global trends such as increased industrial processing of food, greater importation and exportation of food products, and less time for preparation of fresh foods are the driving force for the food and beverage packaging industry to investigate advanced packaging solutions (Lazić et al. 2008).

Modified Atmosphere Packaging (MAP) is a technique used for prolonging the shelf-life of fresh or minimally processed foods (Church, 1994). Protective atmosphere enables that packaged food products maintain their visual, textural and nutritional properties. Modifying of the gas atmosphere in food packaging could be achieved by removing gas (vacuum packaging) or by replacement the air in the packaging by introducing the desired gas composition. For achieving the desired atmosphere in the packaging air could be mechanically replaced by the desired gas or gas mixture, the desired atmosphere in the package could be achieved passively, by metabolism (respiration) of packaged product and the desired gas atmosphere can be implemented actively, by adding absorbers or emitters of certain gases in the packaging. Today, MAP has become the dominant packaging method for some products, like fresh pasta, chilled meats, snacks and dried food, cooked meats and seafood, bakery goods like bread, muffins, croissants, pizza etc. In addition, fresh fruits and vegetables, particularly prepared salads have also been packed in MAP. Figure 2. shows binding of oxygen and releasing of carbon dioxide and water vapor in packaged fruit, and their transport through packaging. The composition of the gas which will be used for the MAP depends on the packaged product (Lazić et al, 2007). In order to assess and calculate the gases and water vapor permeability of polymer films, depending on the speed of "breathing" of packaged products and the desired concentrations of gases, corresponding software has been developed (Jovanović and Džunuzović, 2011).
In order to improve the mechanical, thermal and gas barrier properties of polymer films used in MAP, the introduction of nanocomposite material could be of great importance (Brody,

2003). Nanocomposite materials might dramatically increased the barrier properties comparing with conventional ones, such as lower levels of transmission of oxygen. For example, the transmission of oxygen in Nylon-6 nanocomposite was 4 times lower than in the conventional nylon-6 (Brody, 2003).

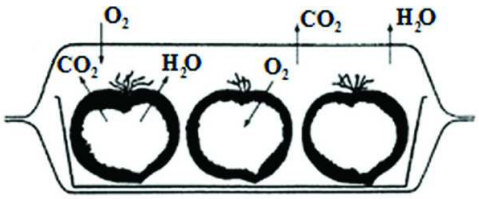

Figure 1. Formation, bonding and diffusion of O2, CO2 and
Water vapor during packaging of fresh fruits and vegetables in a partially permeable atmosphere
(Jovanović and Džunuzović, 2011)

BIODEGRADABLE MATERIAL FOR PACKAGING

There is an increasing demand for identifying biodegradable packaging materials and finding innovative methods to make plastic degradable (Lazić and Gvozdenović, 2007). Biomaterials are polymers produced from renewable resources (polysaccharides, lipids, proteins etc). Biodegradation is the process by which carbon-containing chemical compounds are decomposed in the presence of enzymes secreted by living organisms (Lazić et al., 2008). In addition, edible packaging refers to the use of edible films, coatings, pouches, bags and other containers as a means of ensuring the safe delivery of food product to the consumer in a sound condition (Mc Hugh et al., 1994). These films can also act as carrier of antioxidant, flavor and antimicrobials and can improve mechanical integrity of food products (Seydim and Sarikus, 2006).

ACTIVE AND INTELLIGENT FOOD PACKAGING

Traditionally, food packages have been defined as passive barriers to delay the adverse effect of the environment on the packed product. However, the modern trends include the development of packaging materials that interact with the environment and food, playing an active role in their preservation.
Active packaging changes the conditions of the packaged food in order to extend shelf life or to improve the safety or sensory properties, while maintaining the quality of packaged food (Brody et al., 2001; Lopez-Rubio et al., 2004). For example, oxygen scavengers remove oxygen from food packages, thereby prevents the growth of aerobe microbes and preserving the desired flavor and odor of foods. Carbon dioxide emitters suppress the growth of anaerobes in products such as meat, poultry, and cheese (Lopez-Rubio et al., 2004). Moisture-control agents suppress water activity, serving to remove fluids from products, prevent condensation from fresh produce, and prevent lipid oxidation (Kerry et al, 2006). Also, maintaining humidity in packages is accomplished by humidity controllers. Other tools used as active packaging components include antimicrobials and ethylene absorbers, emitters of preservatives such as ethanol, sorbate or benzoate, absorbers of light of specific wavelength, which adversely affects the packaged product as well as flavor releasing/absorbing systems (Tab.1.)

Table 1. Examples of active packaging applications for use within the food industry (Kerry et al. 2006)

Absorbing/scavenging properties	Oxygen, carbon dioxide, moisture, ethylene, flavours, taints, UV light
Releasing/emitting properties	Ethanol, carbon dioxide, antioxidants, preservatives, sulphur dioxide, flavours, pesticides
Removing properties	Catalysing food component removal: lactose, cholesterol
Temperature control	Insulating materials, self-heating and self-cooling packaging, microwave susceptors and modifiers, temperature-sensitive packaging
Microbial and quality control	UV and surface-treated packaging materials

Quality and safety are two of the key requirements in the food manufacturing supply chain - from packaging, distribution and food retailing through to the consumer. The intelligent packaging is designed to monitor the quality of packed food (Brody et al., 2001; Kerry et al., 2006). Time temperature indicators (TTIs), ripeness indicators, biosensors, and radio frequency identification devices (RFID) are examples of intelligent packaging components. TTIs indicator provides an affordable and widely used solution for the monitoring of products that are sensitive to time/temperature abuse, offering an easy-to-read irreversible signal that estimates the time the threshold temperature has been exceeded.

RFID provides wireless monitoring of food packages through tags, readers, and computer systems (Wanga et al., 2006). Its use in the food industry are numerous and range from facilitating the traceability of food to improve supply chain efficiency. With an appropriate sensors in the chip the relevant information about the quality of the products, such as temperature, moisture, gas composition etc. might be permanently collected. If the predicted values entered with the program are exceeded for some reasons the alarm is activated. All collected data from the chip can be transferred to the computer and the “life path of the product” from the day of production until consumption could be reproduced.

Cheap, thin and flexible electronics, which can be applied to flexible polyester substrate, can be easily integrated in packaging and in particular packaging of polymeric materials.

It is expected that this technology will soon completely replace the traditional use of bar codes (Jovanović and Džuzunović, 2011).

NANOTECHNOLOGY IN FOOD PACKAGING

Food nanotechnology is an area of emerging interest and opens up a whole universe of new possibilities for the food industry. The science about very small materials is ready to have a major impact in food packaging materials (Sanguansri and Augustin, 2006). Promising results and applications are already being developed in the areas of food packaging and food safety.

Nanotechnology may be used to produce packages with stronger mechanical, thermal and barrier properties. These properties may be developed by using *nanocomposites* (Henriette and de Azeredo, 2009).

Nanocomposites are materials that are made up of nanoparticle components. In food packaging, montmorillonite clay is being explored as the nano-component in a variety of polymers: polyethylene, polyester, nylon, and starch. Nanocomposite plastic films block oxygen, carbon dioxide, and moisture from reaching food, so when used as packaging, the material extends the shelf life of food (Henriette and de Azeredo, 2009). Nanocomposite food packages are also light, strong, and heat resistant. In addition, research into the development of biodegradable nanocomposite packages is in progress. The use of bionanocomposites for food packaging not only protects the food and increases its shelf life but also help to manage the world’s waste problem (Henriette and de Azeredo, 2009). Edible nanomaterials could find applications in fresh fruits and vegetables, bakery products and

confectionery, where they might protect the food from moisture, lipids, gases, off-flavors and odors.
In addition, the nanomaterials that might have a great potential for use in the field of food packaging is *nanotubes*. A nanotube is a nanometer-scale wire-like structure and most frequently composed of carbon (Sozer and Kokini, 2008). It has been discovered that carbon nanotubes possess antimicrobial effects (Kang et al., 2007). Direct contact with aggregates of carbon nanotubes proves to be fatal for the cells of Escherichia coli. The hypothesis is that the cellular demages occurs when long, thin nanotubes puncture the cells of E. coli, (Kang et al., 2007).
Also, carbon nanotubes can be incorporated into polymer structures (liquids, solutions, melts, gels, amorphous and crystalline matrices) to increase their mechanical properties in terms of tensile strength and elasticity (Ruoff and Lorents, 1995). In addition, particulary important to the food sector is the possibility to obtain nanotubes by partial hydrolysis of milk protein α-lactalbumin (Figure 2). The resulting α-lactalbumin nanotubes are able to increase viscosity (due to their large surface area) and stiffness, (Graveland-Bikker and de Kruif, 2006). Moreover, α-lactalbumin nanotubes have cavities of 8 nm in diameter, which might enable the binding of food components, such as vitamins or enzymes. These cavities could also be used to encapsulate and protect nutraceuticals or to mask undesirable flavor or aroma compounds (Graveland-Bikker and de Kruif, 2006).

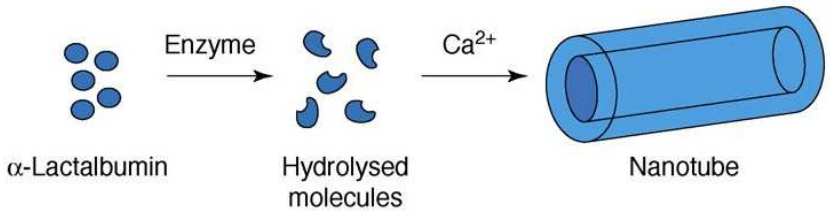

Figure 2. Partially hydrolised α-lactalbumine into nanotubes in the presence of Ca^{2+} (Sozer, N. and Kokini, 2009)

The following example of nano-sized solution with positive effect for the future of food packaging is *nanosensors*, that might be integrated with food packaging. These nanosensors can detect pathogens, toxins and chemicals in the food product. In fact, an array of thousands of nanoparticles could be designed to fluoresce in different colors in contact with food pathogens. For example, nanosensors have been developed to detect *Staphylococcus* enterotoxin B, *E. coli*, *Salmonella* spp. and *Listeria moncytogenes* (Liu et al., 2007). Nanosensors can also detect allergen proteins to prevent adverse reactions to foods such as peanuts, walnuts and gluten. Nevertheless, progression in the field of application of nanotechnology moves cautiously because the effects of nano-sized materials on humans' health are still under investigation.

CONCLUSION

Food products follow the progress in the food packaging processes and implementation of new developments in the food packaging technology. It is obvious that in the future it could be expected the greater use of MAP and CAP technology, the application of active and intelligent packaging, development and increasing application of new types of biopolymers, development and use of nanotechnology, tendency for the formation of brand and greater concern about the environmental aspects of packaging. However, regarding the implementation of nanomaterials in the food sector, there are social and ethical issues that must be well considered. Governments should consider appropriate labeling of these products and should also impose the packaging regulations that will help to increase consumer acceptability to these new materials.

ABSTRACT: Reliable information on the cold chain conditions, the main shelf life determining post-processing parameter, is an essential prerequisite for effective shelf life management of food products. Application of an optimized quality and safety assurance system for the distribution of chilled and frozen products requires continuous monitoring and control of storage conditions. FRISBEE is a Food Refrigeration Innovation for Cold Chain European project. Within FRISBEE a user friendly web-based cold chain database (http://frisbee-wp2.chemeng.ntua.gr/coldchaindb/) is being built. At all stages of the cold chain, the needs of consumer and European industry were considered, gaining a greater insight into deviations between real cold chain data and targeted specifications. Systematic data collection and processing allowed identification and evaluation of the weak links of the cold chain of chilled and frozen products. Data from all stages (production to consumption) of the cold chain were collected from researchers, industry, distributors, retailers and consumers. The developed FRISBEE cold chain database web based platform linked to appropriate shelf-life predicting tools offers the potential to effectively manage and improve cold chain weak links using appropriate shelf-life decision systems leading to an optimized handling.
Using the response of Time-Temperature Integrators (TTI), inexpensive, smart labels that show an easily measurable, time-temperature dependent change reflecting the temperature history of the food product, the integral effect of temperature can be monitored, and quantitatively translated to food safety and quality, from production to the point of consumption. SLDS (Shelf Life Decision System) and SMAS (Safety Monitoring and Assurance System) are TTI chill chain management systems that lead to an optimized handling of products in terms of quality and safety risk.
Key words: *cold chain, management, TTIs, FRISBEE*

INTRODUCTION

The main shelf life determining post-processing parameter in the chill chain of chilled and frozen food products is temperature. Practice and industrial studies have shown that temperature conditions in the distribution, handling, transport and storage of products often deviate from the recommended ones. Thus, monitoring, recording and controlling them becomes crucial for product's safety and quality as well as for shelf life predictions and expiration date labeling. Application of an optimized quality and safety assurance system for the chilled distribution of a food product requires good knowledge of the conditions of the particular cold chain. A comprehensive European data base for identification and evaluation of the weak links of the cold chain for different types of chilled and frozen products is necessary. Additionally continuous monitoring and control of storage conditions, from production to consumption would be required. Cost effective monitoring of temperature conditions of food products in the chill chain can be realized by Time Temperature integrators (TTI), inexpensive, active "smart labels" based on physicochemical, chemical or biological principles of operation and exhibiting an easily measurable response that integrates the temperature history of the product (Taoukis and Labuza, 2003). TTIs can serve as temperature monitors and tools for the optimization of stock rotation policies and chill chain management in general. Prerequisite for application of TTI is a correlation system to translate TTI response to the quality status of the food at any point of the chain. Basic structural elements of this system are validated kinetic models of TTI response and kinetics of the degradation indices of the food, such as predictive models of microbial growth. Based

on reliable models of the shelf life and the kinetics both of the product and the TTI response, the effect of temperature can be quantitatively translated to food quality, from production to the point of consumption (Taoukis, 2001; Taoukis, 2011). SLDS (Shelf Life Decision System) (Giannakourou et al., 2001) and SMAS (Safety Monitoring and Assurance System), based on the real quality and risk profile of products, use the information from the TTI response at designated points of the chill chain, ensuring that the temperature-burdened products reach consumption at acceptable quality level. SMAS system was evaluated by running a large number of chill chain scenarios using a Monte Carlo simulation approach. Experiments at chill chain conditions also demonstrated and quantified the improvement at the time of consumption in comparison to the conventional First In First Out (FIFO) approach (Koutsoumanis et al., 2005; Tsironi et al., 2008; Vaikousi et al., 2009).

MATERIAL AND METHODS

A systematic data collection for identification and evaluation of the weak links of the cold chain for different types of chilled and frozen products is necessary in order to gain quantitative insight into deviations between real cold chain data and targeted specifications. Within European FRISBEE project ("Food Refrigeration Innovations for Safety, consumers Benefit, Environmental impact and Energy optimisation along the cold chain in Europe", www.frisbee-project.eu), a web-based platform has been built for time-temperature (t-T) data collection, maximizing information retrieval with user friendliness (http://frisbee-wp2.chemeng.ntua.gr/coldchaindb/). In this platform, all t-T files were correlated to their meta-data and organized according to: Stage of the Cold Chain -Food Storage temperature range- Characterization of food-Type of food- Food product-Packaging- Country of origin. A software tool linked to the web data base was developed that allows the building of a most likely t-T distribution for selected stages of the cold chain for a specific food product, through Monte Carlo simulations on the numerous relevant t-T profiles drawn from the database, and calculates the shelf life loss of the product from stage to stage, based on shelf life kinetics.
For developing and demonstrating the TTI based management systems two TTI technologies were used. An enzymatic and a solid state photoactivatable TTI. The enzymatic TTI are based on a color change caused by a pH decrease which is the result of a controlled enzymatic hydrolysis of a lipid substrate. The Check Point® TTI type M (VITSAB, Malmo, Sweden) starts from initial green colour, becomes progressively green-yellow and reaches a final yellow color. By controlling type of enzyme substrate and concentration of the lipase the length and the temperature sensitivity of the TTI can be set. The OnVuTM TTI (BASF, Germany), is based on the inherent reproducibility of reactions in crystal phase (Patent EP 1049930 B1). Photosensitive compounds such as benzylpyridines and spyropyrans are excited and coloured by exposure to low wavelength light. This coloured state (dark blue) reverses to the initial colourless at a temperature depended rate. By controlling the type of the photochromic compound and the length of UV light exposure during activation the length and the temperature sensitivity of the TTI can be set. Kinetic modelling of response was based on measurements, at appropriate time intervals, of the response of a number of both TTI tags, isothermally stored at constant temperatures (from 0 to 15ºC). TTI color change was measured instrumentally using the Eye-one Pro (X-Rite, Michigan, USA) at D50 illumination and 2° observation angle conditions. Kinetic modelling of TTI response was based on measurements, at appropriate time intervals, of the response of 5 TTI tags, isothermally stored in high-precision low-temperature incubators at constant temperatures. The response of the TTI was modelled by defining a mathematical function that better describes the response vs time at all temperature and initial charging conditions. Model coefficients were calculated by non linear regression using SYSTAT 10.2® Software.
As example case studies, kinetic models for growth of spoilage bacteria in modified atmosphere packed (MAP) minced beef and fish fillets were used to select appropriate TTI, based on their modelled response. The aim was to evaluate the potential of applying TTI in an optimized distribution management system.

RESULTS AND DISCUSSION

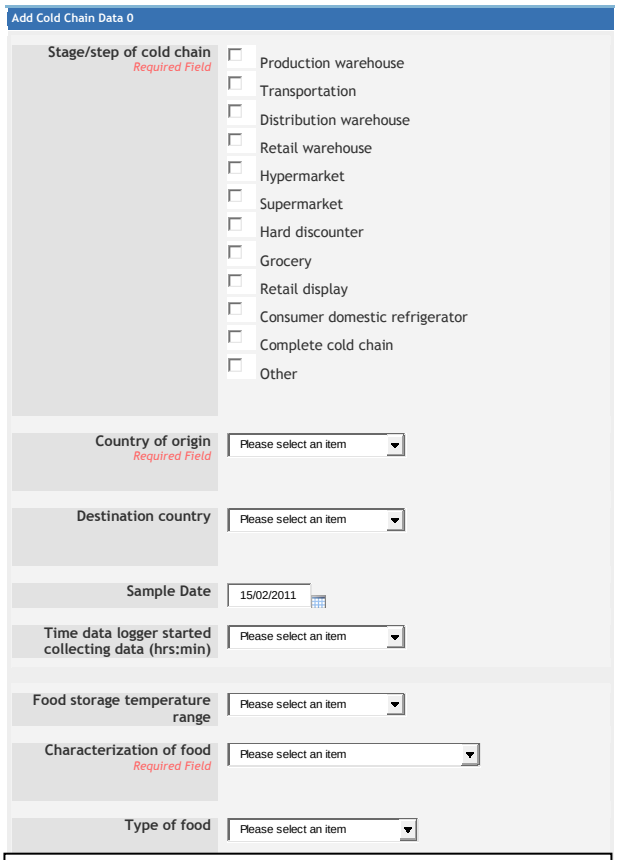

Figure 1. FRISBEE Cold Chain Data Collection

In the Data Collection platform (Figure 1), data from industry, cold chain parties (distributors, retailers) and consumer surveys, including all stages of the cold chain (from production to consumption) are continuously collected. All contributors have privileged access to this database (by login and password) and the access to the database is secured. This platform consists of a menu driven web-based software retrieving information to accompany the contributed food product time-Temperature data. The inputs are building a comprehensive and extensive database which will serve as a valuable tool to people that are involved in the Cold Chain as researchers or industrial players. All received data are further processed in such a way that the output of the web-based database includes (Figure 2):

- Actual Time-temperature profiles
- Mean, min and max value of temperature for the whole time-Temperature profile
- Effective temperature of the time-Temperature profile: To demonstrate the integrated effect of the temperature variability on product quality, the term of the effective temperature T_{eff} is introduced. T_{eff}, which is defined as the constant temperature that results in the same quality value as the variable temperature distribution over the same time period, is based on the Arrhenius model and integrates, in a single value, the effect of the variable temperature profile T(t):

$$T_{eff} = \int_0^t - \frac{E_a \cdot T_{ref}}{R \cdot T_{ref} \cdot \ln \frac{k(T(t))}{k_{T\,ref}} - E_a} \cdot dt$$

where E_a the activation energy of the quality index, T_{ref} the reference temperature, k(T(t)) the rate costant of the quality index change (e.g. growth of a microorganism) at temperature T which in turn is a function of time, k_{Tref} the rate of the quality index alteration at the reference temperature, t the time of the variable profile and R the universal gas constant.

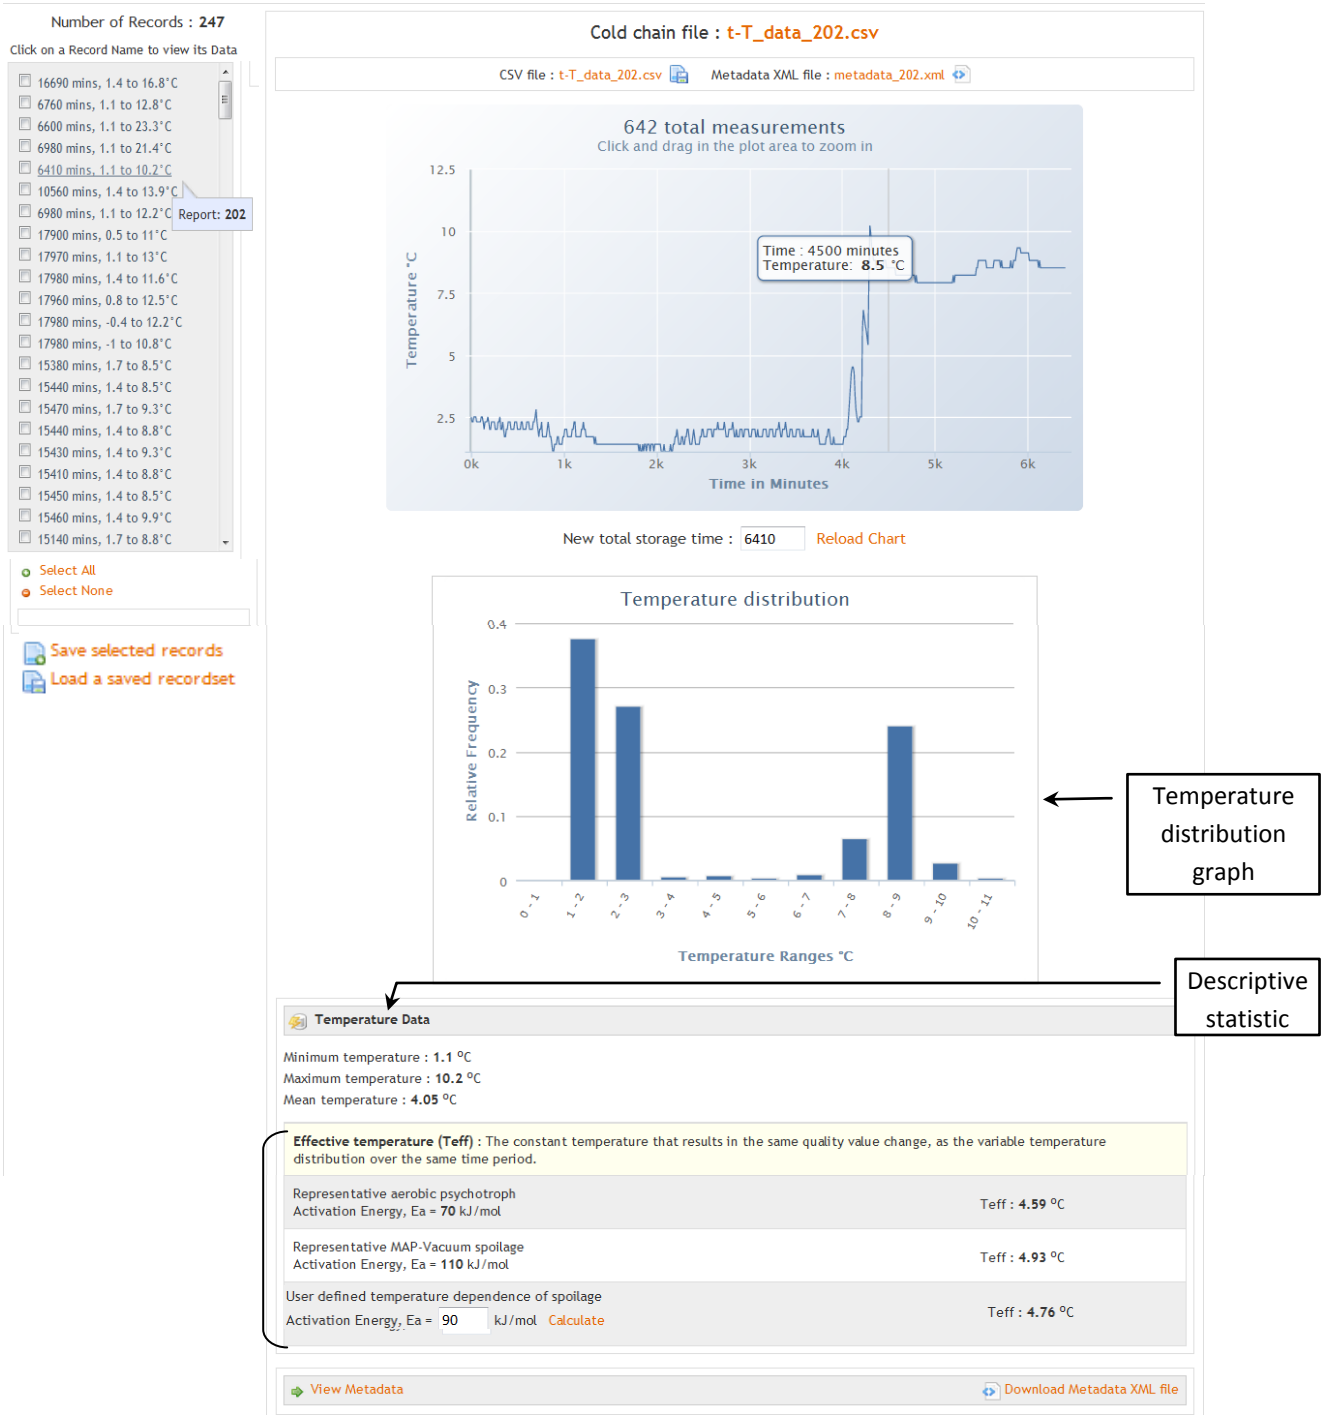

Figure 2. Example of the Cold Chain Database output

In this database, the user can build a specific sequence of cold chain stages for specific food product. The FRISBEE Cold Chain Predictor (FRISBEE_CCP), , allows the user to calculate the remaining shelf life of a specific food product at different stages of the cold chain corresponding to a specific time-temperature profile, if deterioration factor kinetic data are known (Figure 3).

Using this tool, one can efficiently manage the food cold chain and do corrective actions to predetermined stages of the cold chain for certain food products. This could result in significant increase of the remaining shelf-life at the end of each stage.

Additionally actual monitoring of storage conditions can be realized by TTIs. TTIs allow such control down to product unit level.

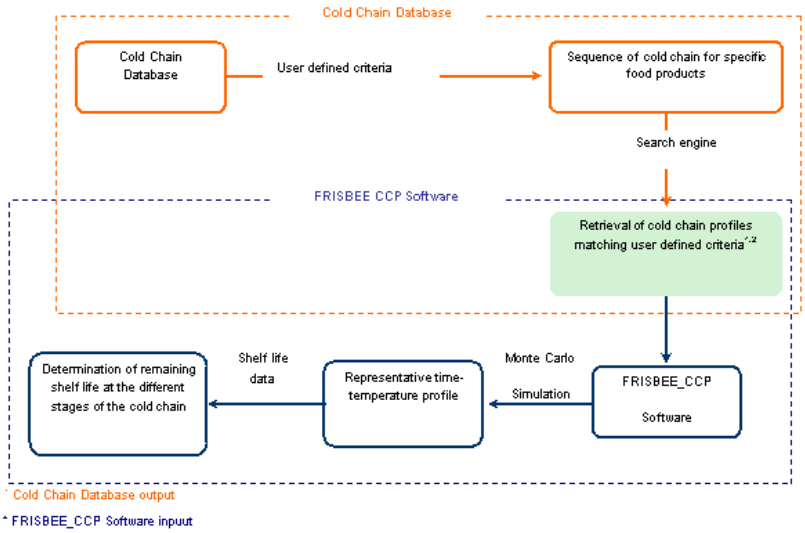

Figure 3. Architecture of the Cod Chain Database and FRISBEE_Cold Chain Predictor Software

Based on the results of the testing of the TTI, composite models that allow the calculation of their response rate, k, at any selected enzyme concentration or charging times were developed. These models allow the selection of the suitable TTI design to much the shelf life kinetics of the targeted food. For example it was calculated that charging time of 2 s for the OnVu TTI and 50U for the M-type Check Point TTI could lead to suitable TTIs for monitoring the quality of MAP minced beef during refrigerated storage (Taoukis et al., 2010). The effectiveness of several TTI based systems was evaluated by simulated chill chain experiments based on the level of dominant deterioration factor of food products at the end of their storage. For example, for the case of MAP gilthead sea bream fillets, the FIFO approach resulted in 6 out of 40 samples to have reached the spoilage level at the end of storage period. When the TTI based management was applied, only 2 of the 40 samples reached the spoilage level, significantly reducing the number of rejected products before the "time of consumption" (Figure 4) (Tsironi et al., 2011).

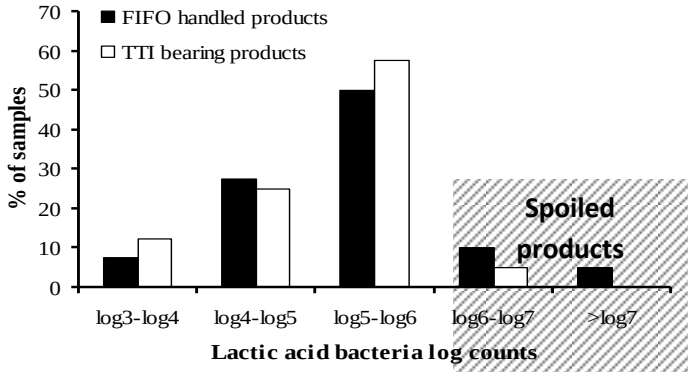

Figure 4. Distribution of the calculated lactic acid bacteria log counts in MAP (50% air-50% CO_2) gilthead seabream fillets based on FIFO and TTI based management system (Tsironi et al., 2011)

Overall, taking into consideration several respective studies for different food products conducted in our laboratory, it is concluded that the TTI based system may result in reducing the number of spoiled products. The use of TTIs at appropriate points of the chill chain (e.g. at a central distribution centre) could significantly help making decisions for the further management of products based on their temperature history and hence quality and safety status.

CONCLUSIONS

Two different approaches are proposed for the management of the cold chain of food products. In the first approach, the use of appropriate developed tools developed within FRISBEE project is proposed. The aim is the estimation of the remaining shelf-life of food products after each stage of the cold chain, based on t-T profiles inputted in a cold chain database. The contributed data of the cold chain will allow one to run simulations and distribution scenarios based on real cold chain data. Corrective actions could be applied for maximizing remaining shelf-life. The other approach is the application of TTIs which allow such control down to product unit level. The selection and use of the optimum TTIs for a particular product, with regard its visual response characteristics and temperature sensitivity, could lead to realistic control of the cold chain, reduction of waste and efficient shelf life management. If the temperature conditions of the products could be continuously monitored by TTIs, reliable estimation of the quality status and the remaining shelf life could be performed, allowing better management and optimization of the cold chain from production to the point of consumption.

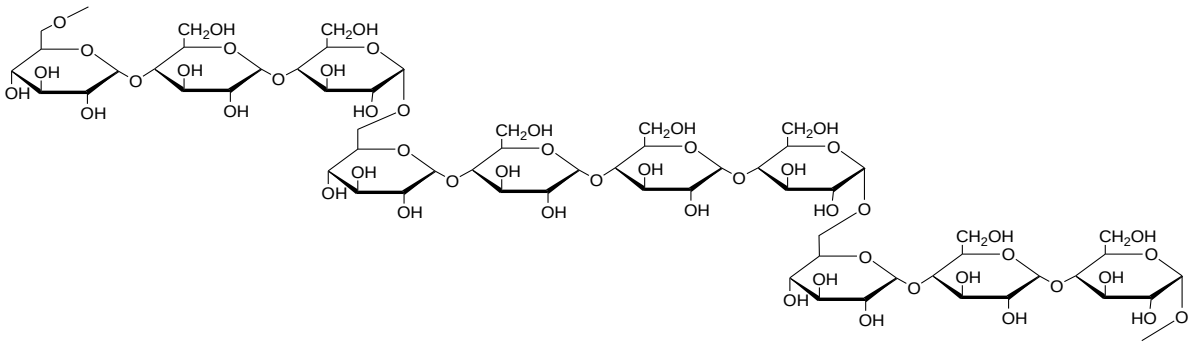
ABSTRACT: Microbial exopolysaccharides (MPSs) such as xanthan, dextran, gellan or pullulan have been commercially used, in their natural or modified state, for many years.
A large number of these natural polymer applications is a consequence of their excellent physical and chemical properties, based on their capacity to alter the basic properties of water (e.g. thickening or gelling). In addition, these polymers have related secondary functions, such as emulsification, suspension, stabilization, encapsulation, flocculation, film forming, binding and coating.
MPSs, and particularly exopolysaccharides have many other novel properties to offer, and discovery of immune modulation and bifidogenic effect of some of them should provide other applications.
This work focuses on the more recent developments in the extent of application of microbial polysaccharides in the various fields what makes these polymers promising and versatile materials in future, and also on our investigations within these natural products.
Key words*: microbial polysaccharides (MPSs), properties, material, application, industry*

BASIC KNOWLEDGE AND APPLIED ASPECTS

The ability to produce polysaccharides is widely found among different species, but despite many sources of these biopolymers, those from algae and higher plants are dominant on the world market. Polysaccharides derived from microorganisms, including bacteria, yeasts and moulds, are still not exploited enough. The main reasons for that are linked to the costs of production, because of specific substrate requirements in certain cases, bioreactors demands or obtaining aseptic conditions. Nevertheless, polysaccharide production from microorganisms has many advantages: it takes much less time compared to plants; in the case of some algae species it is more energy efficient because of use of solar energy for production; and a lot of industrial wastes and raw materials can be used as carbon sources, which is probably the greatest advantage of all (Donot et al., 2012).
MPSs are synthesized and accumulated mostly after the growth phase, and, in regard to their location in the cell, they can be divided into three main groups. Inside the cell, as carbon and energy sources are cytosolic endopolysaccharides. The second group is made of those that make up the cell wall. Polysaccharides exuded into the extracellular environment are known as exopolysaccharides (EPSs), and they appear in the form of capsules or slime. They are also involved in biofilm formation, where they have many significant roles: participation in attachment to a surface, formation and stabilization of biofilm structure, enhancement of resistance to environmental biotic and abiotic stresses and antimicrobial agents, preventing of desiccation and assumption of nutrients (Shia and Zhua, 2009).
MPSs are divided into two groups: homopolysaccharides, made up of a single type of monosaccharide (e.g. pullulan,dextran.or levan) and heteropolysaccharides, made up of several types of monosaccharide, with complex structures (e.g. xanthan or gellan). Structures of some MPSs are shown in Figure 1. In any case, they are mainly composed of



1.1.

Figure 1. Structure of some widespread MPSs.
Homopolysaccharides: 1.1. Pullulan; 1.2. Dextran and 1.3. β-glucan (frequently component of cell wall-endopolysaccharide). Heteropolysaccharides: 1.4. Xantan and 1.5. Gellan.

glucose, galactose and mannose, but many other neutral, amino sugars and uronic acids are often present, too. Also they can contain some organic ester – linked substituents and pyruvate ketals, which give them anionic character and increase their lipophilicity (Freitas et al., 2011). Despite of differences in monosaccharide composition, they differ in charge, type and configuration of glycosidic linkages (which affects the rigidity of molecule), molecular weight, length and frequency of branches (from which rheological properties depends) (Duboc and Mollet, 2001).

EPSs have many various functions for microbial cells. Their role is mainly protective, against competition or extreme environmental conditions. On the other hand, their specific functional physicochemical properties are also the main reason for great interest for their application in various fields of industry – food, cosmetics, pharmaceutical, as well as in biomedicine and ecology. Despite that, only several have been industrially used since today (Freitas et al., 2011). Since they are involved in biofilm formation, they can make some serious problems (e.g. in food, process and paper industry, cooling water systems), because of causing food and water reservoirs spoiling, toxin production, pipes blockage, corrosion of the process equipment, etc. (Shia and Zhua, 2009).

One of the most important applications of microbial polysaccharides in industry is in drilling fluids for oil recovery, sequestration of toxic compounds, activating of sludge settling, suppressing of gasoline vaporization and chemical absorption of carbon dioxide. They are also used as depollution agents, and in processes of biofloculation, settling and dewatering of activated sludge (Neyens et al., 2004). Due to their texturing properties, microbial polysaccharides (such as xanthan, galactomannans and native or modified starch), independent or in combination with some other polymers, are widely applied in controlling the rheological properties and stabilizing oil-in-water emulsions (Desplanques et al., 2012).

The special rheological properties of xanthan, polysaccharide isolated from *Xanthomonas campestris* makes this polysaccharide very suitable for application in many industries, but especially in oil industry, for 'enhanced oil recovery' applications. In petroleum industry, it is used for oil drilling, fracturing, pipeline cleaning, and also in micellar – polymer flooding as a tertiary recovery operation (Palaniraj and Jayaraman, 2011). Emulsan, a lipopolysaccharide from *Acinetobacter calcoaceticus* is also able to stabilize oil-in-water emulsions, just like some other complexes made of polysaccharides, proteins and lipids (Lang, 2002).

Cyanobacterial EPSs, which are complex heteropolysaccharides, have a strong anionic character due to high content of uronic acids. Because of large number of negative charges, these polymers can effectively remove heavy metal ions from water solutions, and therefore can be used in remediation of polluted aqueous environments (De Philippis et al., 2011).

In food industry, microbial polysaccharides are mostly used as thickening, stabilizing, emulsifying, binding, structure creating and gelling agents, because of their high viscosity in aqueous media (Freitas et al., 2011). They need to have physicochemical properties that can satisfy some food processing conditions – variations in pH, temperature, ionic strength, influence of other food components etc. Many of EPSs have such properties, however, only two are allowed for use as additives in the food industry in Europe and United States: xantan and gellan (Donot et al., 2012).

Certain strains of lactic acid bacteria synthesize EPSs, which participate in production of fermented milk products: yoghurt, cheese, fermented cream, kefir, etc. They are very important for final texture (as biothickening agents they improve the reology of product – viscosity which makes them slimy and fluid, and elasticity which gives them firmness and gum-like properties), taste and stability of products (they bind water and limit syneresis). EPSs from lactic acid bacteria don't have only technological utility, but also have some health benefits on consumers. Their viscosity increases time that fermented product spends in gastrointestinal tract, which helps its colonization with probiotic bacteria. Also they can be metabolized by the colon microorganisms to short-chain fatty acids (acetate, propionate, butyrate), and those can not only provide energy to epithelial cells, but also play role in the prevention of colon cancer (Duboc and Mollet, 2001). Because of this property, some microbial polysaccharides are defined as prebiotics – "non-digestible food ingredients that beneficially affect the host by selectively stimulating the growth and/or activity of one or a

limited number of bacteria in the colon, and thus improve host health" (Scantlebury Manning and Gibson, 2004).
Microbial exopolysaccharides can be shaped into micro/nanoparticles, scaffolds and hidrogels, which can be applied in biomedicine for drug delivery, encapsulation of bioactive compounds, imaging, tissue engineering and wound dressing. Some of those EPSs (xanthan, sulfated dextran, sulfated curdlan) posses some biological activity too, so their use is very important for design of such pharmaceuticals. Also, some formulations that contain fucose and oligosaccharides obtained by its hydrolysis are known as anti-cancerogenic, anti-inflammatory and anti-aging agents (Freitas et al., 2011). After adequate chemical modifications, they may serve as covalent carrier for drugs, e.g. antibiotics, facilitating their solubility in water while decreasing citotoxicity and retaining drug activity. The main advantages for use of such polymers in this kind of formulations are their biocompatibility, nontoxicity and biodegradability (Zhanga et al., 2011).
β-Glucans are structural polysaccharides of the cell wall of fungi, yeast, some bacteria and cereals. Those polysaccharides are non-digestible and can be, in some degree, fermented by intestinal microbial flora. They have the ability to stimulate immune system in the defense against some viruses, bacteria, protozoa and fungi, but also have anti-tumor activity even thou they have no direct cytotoxic effects. Therefore they are known as immunomodulators and anti-cancer agents. They participate in activation of macrofages, neutrophils, natural killer cells and lymphocytes. The main advantage of these supplements over conventional immune therapies is in possibility of oral administration, less costs and fewer side effects, but their independent use as therapeutics is still not enough (Chan et al., 2009; Murphy et al., 2010).
Bacterial cellulose, which has identical chemical composition as those from plants, has unique fibrillar nanostructure. It is used as component of high quality audio membranes, electronic paper, membranes of fuel cells and biomedical material (Weia et al., 2011). One of the most interesting uses is in treatment of chronic wounds, such as venous leg and diabetic ulcers, bedsores and burns, where this polysaccharide, in the form of film, provides necessary moist environment. It also helps in eliminating pain symptoms by isolating the nerve ending, provides good barrier against infection, and decreases healing time (Czaja et al., 2006). However, cellulose does not have antibacterial properties, but those can be obtained by impregnation with silver nanoparticles (Maneerung et al., 2008) or benzalkonium chloride (Weia et al., 2011).
To date, polysaccharides isolated from microorganisms are of great interest in the overall hydrocolloid market, even thou they are not represented enough. Research interest in its production is exponentially growing, especially because of possibilities of using low-cost substrates in their production and improving downstream processing, as well as possibility of metabolic engineering which allows controlled production of polymers with exact, fine-tuned properties. By altering conditions of some biotechnological process for obtaining microbial polysaccharides, such as nutrient media for growth of polysaccharide producing microorganism, carbon and nitrogen content, temperature, pH, aeration, stress conditions etc., polymers with various chemical composition, structure and consequently properties, can be obtained. In the next few years, significant increase in number of different products and technologies based on microbial polysaccharides can be expected.

REVIEW OF THE SOME OUR ESSENTIAL RESULTS IN THE MPSs RESEARCH

Our research group, Group of microbial chemistry, from Faculty of Chemistry, University of Belgrade and Department of Chemistry, Institute of Chemistry, Technology, and Metallurgy (IChTM), University of Belgrade, for several years is engaged in studying the microbial polysaccharides: dextran (in collaboration with the Faculty of Technology in Leskovac), pullulan (in collaboration with the Faculty of Technology in Leskovac) and β-glucan from the cell wall of baker's yeast (in cooperation with the fermentation industry Fermin, now Alltech-Serbia from Senta). These microbial polysaccharides are well known and have been commercial products.

Dextran is a glycan which can be characterized by its main structural feature, a backbone chain of α-(1→6)-glycosidic linked D-glucose units and *branch* points at *position 2*, 3 or 4. Strains of Leuconostoc *mesenteroides* are involved in *the production of this glucan*. Fractions of dextrans have application in medicine, biochemistry and biotechnology. One of the objects of our interest, in respect of this polysaccharide, was influence of process conditions on effects in biotechnological production of dextran by *Leuconostoc mesenteroides* (Lazic et al., 1993).

Pullulan is extracellular microbial polysaccharide which is produced by the yeast-like fungus *Aureobasidium pullulans*, strain CH-1 (IChTM, Collection of Microorganisms). This polysaccharide can be described as a linear α-D-glucan that consits of α-1,6-linked a regular repeating maltotriosyl units having about 7% of maltotetraosyl units randomly distributed in the polysaccharide chain (Jakovljevic et al., 2001.). *A. pullulans* CH-1 exhibited two beneficial effects, i.e., a biosorption of metal pollution and the production of pullulan (Radulovic et al., 2008). The choice of pullulan for object of our interest is based on the its properties such as non-toxicity, plasticity, lower permatibility of oxygen gas, and so on make it widely used in food packing, pharmacy, environmental protection and other industries.

In the last years β-glucans from cell wall many microorganisms attracted much attention due to their antitumor activity. Particular interest is devoted to β-glucans that isolated from cell wall of *Saccharomyces cerevisiae*. In addition to antitumor activity, these polysaccharides posses anti-inflammatory properties and manifest as nonspecific immunomodulators, as well as other, less significant and examined characteristics associated with their biological activity. Biological activity of the yeast cell wall glucan is the main reason for interest of our group for this polysaccharide (Zekovic et al., 2005). In this sense we perfected methods for isolation and purification of cell wall glucan from commercially available active dry yeast (Zlatkovic et al., 2003). By mild Pfitzner-Moffat oxidation of this glucan keto-aldehydo polymer was obtained (Zekovic et al., 2006). Bifidogenic properties of samples of β-glucans with different degrees of purity was investigated recently (Laugier et al., 2012).

The obtained results, as a result of interesting of our group for chemistry and applications of microbial polysaccharides should be a guideline for further work towards the study of biochemical properties of microbial polysaccharides, which are the subject of great interest in the world and in our laboratories.

ABSTRACT: Olive leaves and grape skin with seeds produced as by-products in olive oil and wine production constitute a cheap source of plant material with certain amount of bio-active substances. Antioxidant, antimicrobial, anti-inflammatory and anticancer properties of the phenolic extracts were reported. The efficiency of extracts depends also on the ability to preserve their biological activity. Encapsulation of the extracts can improve stability, biological availability, hydrophobic/hydrophilic character and unpleasant taste for potential use in food preservation. Antimicrobial activity was first screened by broth microdilution method for minimal inhibitory concentrations (MICs) of phenolic extracts from olive leaves (*Olea europaea,* cv. "Leccino") and grape skins and seeds (*Vitis vinifera* L., cv. "Zelen") against 14 strains of *Candida, Pichia* and *Ogataea* sp., which were isolated from spoiled olive oil, and *Dekkera bruxellensis* from spoiled grape must. The kinetics of antifungal activity was followed by the yeast inhibition curves in YPD medium with phenolic extracts added in MICs. Finally, the impact of extract encapsulation into ß-cyclodextrin and liposomes on antifungal activity was tested. Phenolic extracts from olive leaves and grape skins with seeds expressed high efficiency against most isolates of spoilage yeasts. Encapsulated olive leaves extracts showed the same or better efficiency than non-encapsulated extracts in broth microdilution screening test and during yeast growth inhibition in liquid medium. The encapsulation into ß-cyclodextrin was more efficient than encapsulation into liposomes. Grape skins and seeds and olive leaves as plant waste materials have been proven to be a rich source of phenolic compounds with antimicrobial activity against spoilage yeasts.
Key words: *Minimal inhibitory concentration, plant phenolic extract, spoilage yeast, encapsulation*

INTRODUCTION

Grape skin and seeds are known to be a rich source of flavonoid and non-flavonoid phenolic secondary metabolites. They are only partly extracted during maceration and/or fermentation. Remaining seeds and skins present winery by-product which gives us an available and cheap material to work with. Bioactive compounds such as phenols are compounds that plants produce for their own protection, we can add them to increase the value of different products (e.g. food or cosmetic preparations). Recent investigations have been carried out on the content of specific secondary metabolites of certain indigenous and local Slovenian *V. vinifera* grape varieties, such as the 'Zelen'. These grape varieties are a rich source of caftaric acid, flavonoids, including quercetin derivatives, proanthocyanidins and various catechins, which are known to have a positive impact on human organism (Trošt et al. 2011).
Olive leaf extract (OLE) is a dark brown, bitter-tasting liquid derived from the leaves, an agricultural waste, of the olive tree (*Olea europaea* L., Oleaceae). OLE is marketed as a natural medicine with wide-ranging health benefits. In addition to its antioxidant properties, phenolic compounds within olive leaf extract have shown antimicrobial activities against several microorganisms. Although the individual phenolic compounds in olive leaf extract may show strong *in vitro* activities, the antioxidant and antimicrobial activities of combined phenolics showed similar or better effects than the individual phenolics. It had also been

previously supported that extracts may be more beneficial than isolated constituents, since a bioactive component can change its properties in the presence of other compounds present in the extract (Aytul, 2010).
The effectiveness of biophenols depends on preserving the stability, bioactivity and bioavailability of the active ingredients. This is a big challenge, as only a small proportion of the molecules remain available following oral administration, due to insufficient gastric residence time, low permeability and/or solubility within the gut, as well as their instability under conditions encountered in food processing and storage (temperature, oxygen, light), or in the gastrointestinal tract (pH, enzymes, presence of other nutrients), all of which limit the activity and potential health benefits of the nutraceutical components, including polyphenols. The unpleasant taste of most phenolic compounds also limits their application. The utilization of encapsulated polyphenols, instead of free compounds, can effectively alleviate these deficiencies. Microencapsulation is defined as a technology of packaging materials in miniature, sealed capsules that can release their contents at controlled rates under specific conditions (Fang and Bhandari, 2010).
Cyclodextrins (CDs) are non-branched cycloamyloses composed of α-(1→4)D-glucopiranoside units. Typical cyclodextrins, α-, β- and γ-cyclodextrin, contain six, seven or eight glucose monomer units. They have the ability to form inclusion complexes with a wide variety of organic compounds, which enter partly or entirely into the relatively hydrophobic cavity of CDs, therefore the CDs act as molecular encapsulants. Encapsulation with CDs leads to enhanced dissolution rate, membrane permeability and bioavailability of nutraceuticals of low solubility. They protect against oxidation, light-induced decompositions and heat-induced changes. CDs improve shelf life of food products and mask or reduce undesired taste (Szente and Szejtli, 2004). Possibly the most important property of encapsulation is that CDs increase the aqueous solubility of various sparingly soluble compounds (Kalogeropoulos et al., 2010; Karathanos et al., 2007). ß-cyclodextrin has been approved as GRAS to be used as a food additive.
Liposomes are constructed of polar lipids that form self-organized colloidal particles when placed in the aqueous medium. The hydrophilic interaction of the lipid head groups with water results in the formation of multilamellar and unilamellar systems (vesicles). They consists of simple lipid bilayers that resemble biological membranes, in the form of a spherical shell. Because of their entrapping ability, biocompatibility and non-toxicity, liposomes are considered as vesicles, being utilized in the entrapment, delivery, and release of water soluble, lipid-soluble, and amphiphilic materials (Vemuri and Rhodes, 1995; Keller, 2001).

MATERIALS AND METHODS

Preparation and characterization of phenolic extracts

White grape variety ‘Zelen’ (*Vitis vinifera* L.) from the Vipava Valley wine-producing region (Slovenia) was selected on the basis of previous antimicrobial testing (Smole Možina et al., 2011). The grapes were harvested at technological maturity and processed by typical vinification procedure, with only 2h of maceration. Grape seeds and skins as winery wastes after pressing were collected from a large scale press (approx. 2 kg), stored at -20 °C overnight and freeze dried. Freeze dried samples were kept frozen at -20 °C until the extraction. Prior extraction, the samples were powdered in a mortar with the liquid nitrogen and mixed with the extraction solvent (0.5g/10mL), which was in this case water:ethanol (1:1). The extraction was performed overnight including 40 min of ultrasonication in Sonorex bath (Bandelin, Germany) and prepared for further analysis as described previously (Trošt et al., 2011). The total phenolic concentration (TP) was determined by the Folin-Ciolcalteau method, calibrated against gallic acid standard and expressed in mg GAE/g of dry extract, for the sample ‘Zelen’ it was 80 mg GAE/g of extract (Trošt et al., 2011).
The olive leaf samples were taken from the cultivar ‘Leccino, harvested in 2010 from the same tree, freeze dried and pulverized. The extraction was done with ethanol:water (7:3) extraction solvent, followed by dewaxing step with the hexane and dried in rotary evaporator

at 40 °C. The extraction yield was determined gravimetrically and total phenolic content was calculated on the basis of HPLC UV-DAD response for biophenolic determination of hydroxytyrosol, tyrosol, luteolin-7-O-glucoside, oleuropein, and apigenin-7-O-glucoside. Some other non-assigned biophenols were quantified using detector response for oleuropein, as reported previously (Butinar et al., 2011). The amount of total phenolic compounds in 'Leccino' extract was 76 mg GAE/g of dry extract (Butinar et al., in press).

Encapsulation of the plant phenolic extracts

The inclusion complexes of plant extract in β-cyclodextrin (β-CD) were prepared by dispersing ethanol solution of extract in aqueous solution of β-CD in 1:2 molar ratio of total phenols to β-CD and mixed in a laboratory stirrer for 24 h at room temperature. In order to remove any insoluble monoterpenes, the suspensions were filtered through a 0.45-μm membrane filter. The filtrates were frozen at –40°C for 24 h and lyophilized. Dry β-CD-extract complex was dissolved in distilled water and filtered through 0.2-μm membrane filter in order to remove microorganisms (Mourtzinos et al., 2008).

The multilamelar liposomes (MLV) were prepared using L-α-phosphatidylcholine (Egg, Chicken; Avanti Polar Lipids, Inc. U.S.A.) and cholesterol (Sigma Aldrich, St. Louis, USA) in 5 to 1 molar ratio. Appropriate weights of lipids, dissolved in chloroform and OLE which was dissolved in etanol were transferred into 50 mL glass round-bottomed flask where solvent was evaporated under reduced pressure (17 mbar). The film was then hydrated with 2 ml of a phosphate buffersaline solution (PBS) (pH 7.4) and vigorously vortexed for 15 min. This suspension was allowed to hydrate for 2 h in the dark at room temperature in order to anneal any structural defects. The compound-incorporated MLV were separated from the unincorporated compounds by ultracentrifugation. 21% of phenolic compund was incorporated. Vesicular dispersions were spun in an ultracentrifuge at 4°C and 30,000 rpm for 60 min (Liolios et al., 2009). Since the encapsulation in β-cyclodextrin (β-CD) gave better results than MLV for olive leaves extracts, we used for grape skin extracts only β-CD encapsulation.

Antimicrobial susceptibility testing

In this study spoilage yeasts were used as target organisms. We tested 14 strains belonging to genera *Candida, Pichia*, *Ogataea* and *Dekkera bruxellensis,* which were isolated either from spoiled olive oil or grape must, respectively. They were identified on the basis of their physiological characteristics and by sequencing of LSU rRNA gene (Cadez *et al.,* in press). They were deposited in Collection of Industrial Microorganisms (ZIM, Slovenia). Yeast cultures were incubated for 24-48 h in YPD broth (Sigma), and properly diluted for further testing.

Broth microdilution method was used to determine minimal inhibitory concentrations (MICs) of all the extracts tested against selected target yeasts. The tests were performed in sterile 96-well microtitre plates already containing 50 μL of two-fold serially diluted extracts. The concentrations of total phenols ranged from 10 - 0.06 mg GAE/mL YPD. The final volume in each well was 100 μL, the contents were mixed on a microplate shaker (Eppendorf, Hamburg, Germany) at 900 rpm for 1 min prior to incubation for 24 h at 37 °C. The MIC was defined as the lowest concentration where no viability was observed after 24 h. The presence of the purple colour, as indicator of the respiratory activity, was determined visually after adding 10 μL $well^{-1}$ of yeast growth indicator p-iodo-nitro tetrazolium violet (INT, Sigma) and incubated at 37 °C for 30 min in dark. MICs were tested in triplicate and given in the concentration where no metabolic activity was most often observed. The kinetics of microbial inhibition was evaluated using the broth macrodilution method where the extracts were added to the growth medium (5 mL) in concentrations equal to MICs determined in broth microdilution test as described earlier (Klančnik et al. 2010). Microbial growth inhibition was followed by sampling during 5 days of incubation in two replicates. The samples were taken, diluted and cultured on YPD agar in order to determine the cell concentration. The mean log CFU mL^{-1} were presented.

RESULTS AND DISCUSSION

Antimicrobial activity of the phenolic extracts obtained from the grape seeds and skins after vinification process as well as from the olive leave extracts was first screened by broth microdilution test and expressed in minimal inhibitory concentrations (in gallic acid equivalents (GAE) of total phenolic compounds in these extracts. They differed significantly in qualitative and quantitative composition of phenolics and reached for olive leaves extracts the MIC values from 0.19-3.0 mg GAE/ml for different spoilage yeasts isolated from olive oil and wine. For the extracts from grape skins and seeds (GSSE) the MIC values were from 0.008-3.0 mg GAE/ml. In Table 1 the activity is expressed for comparative analysis of the non-capsulated extracts as well as for the capsulated extracts in β-cyclodextrin (β-CD) and also MLV (only in case of OLE), where the encapsulation resulted in improved antimicrobial efficiency (Table 1).

Table 1. Antimicrobial activity of the phenolic extracts from olive leaves (OLE) and grape skins and seeds (GSSE), expressed as MICs (in mg of GAE of total phenols/ml of the medium. MICs of the encapsulated extracts (in CD and liposomes) are presented as well.

	Candida tenuis **ZIM 2324**	***Candida molendinolei*** **ZIM 2329**	***Dekkera bruxellensis*** **ZIM 701**	***Ogatea dorogensis*** **ZIM 2322**
OLE	0.38	0.75	0.19	0.75
OLE – β-CD	0.064	0.25	0.13	n.d.
OLE - MLV	0.085	0.34	0.17	0.17
	Candida molendinolei ZIM 2280	*Candida adriatica* ZIM 2334		
GSSE	0.12	0.12	1.5	0.004
GSSE – β-CD	0.07	0.14	2.2	0.009

Phenolic extracts from olive leaves and grape skins and seeds in general expressed high efficiency in growth inhibition of most of the spoilage yeasts tested. MICs values were comparable to the results collected in a similar way on bacterial pathogens as target organisms (Katalinić et al., 2010; Trošt et al., 2011).

Encapsulated GSSE and OLE in ß-cyclodextrin and in liposomes (only in case of OLE), have shown similar or better efficiency than non-capsulated in broth microdilution screening test (Table 1). OLE and GSSE which are normally hydrophobic after encapsulation become soluble in water. Lipid bilayer of liposomes and hydrophobic cavity of β-CD in which hydrophobic phenol compounds are placed make this phenomenon possible. Due to encapsulation, contact of active compounds and cells was better and therefore bioavailability increased.

According to the most efficient antimicrobial activity expressed in low MICs in broth microdilution test we selected combinations of yeast and extract preparations for further testing of kinetics of growth inhibition in broth macrodilution test with prolonged incubation time. In case of olive leaves extract we compared the activity of control culture with antimicrobial additives as well as non-capsulated extract (OLE), and the extract prepared in liposomes (OLE-LP) and in ß-cyclodextrin (OLE-CD) (Figure 1), but in case of grape seed extracts we selected *Candida adriatica* ZIM 2334 (Figure 2a) and *Candida molendinolei* ZIM 2280 (Figure 2b) to test non-capsulated extract (GSSE) and encapsulated in ß-cyclodextrin (GSSE-CD).

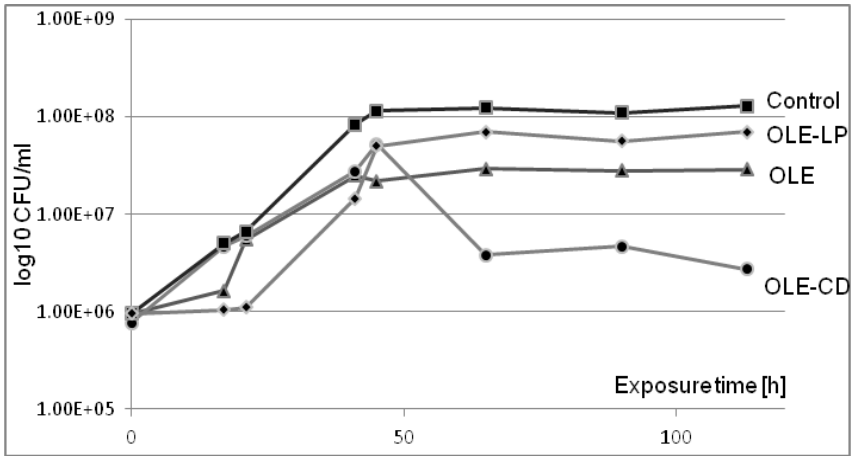

Figure 1. Growth inhibition curves of the yeast *Dekkera bruxelensis* after exposure to olive leaves phenolic extracts at concentrations found as MICs in broth microdilution test (0.13-0.19 mg GAE/mL).

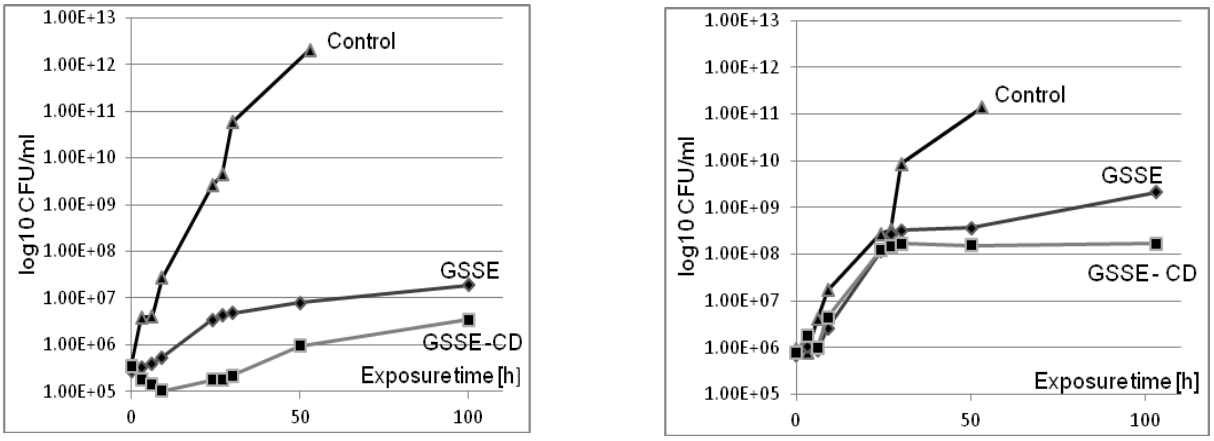

a) **b)**

Figure 2. Growth inhibition curves of the yeast *Candida adriatica* (a) *Candida molendinolei* (b) after addition of grape seeds and skins extracts (GSSE) in YPD at concentrations found as MICs in broth microdilution test (0.12-0.14 and 0.07-0.12 mg GAE/mL, for non-capsulated (GSSE) and encapsulated (GSSE-CD) extracts, respectively).

During prolonged cultivation encapsulated extracts showed better inhibition properties (Fig. 1,2). This may be due to the protective ability of liposomes and β-CD, which protected sensitive phenolic compounds from degradation caused by oxygen, light, temperature, etc. We showed that the encapsulation into β-CD is more efficient than into the liposomes. Better stability of capsules of β-CD than liposomes may be the reason why the extracts encapsulated in β-CD have shown better results in both microdilution test and kinetics of antifungal activity.

CONCLUSIONS

Grape skins and seeds and olive leaves as plant waste materials have been proven as a rich source of phenolic compounds with antimicrobial activity against spoilage yeasts. In addition, a positive impact of encapsulation was confirmed with preserved or enhanced antimicrobial activity of tested phenol extracts against spoilage yeasts. Considering demands of consumers to use natural preservatives in food products, these results provide a solid basis for further research in order to use plant extracts as food preservative.

ABSTRACT: The aim of this study was to investigate characteristics of fermented milk products, obtained from milk with 2.8% milk fat, by using two starter cultures at 37, 40 and 43°C. One starter culture was kombucha fermentative liquid, obtained from peppermint extract sweetened with sucrose (7%), and the other was a mixture of kombucha fermentative liquid on peppermint and probiotic yoghurt culture. The quality of the products was followed by monitoring of chemical composition, physico-chemical characteristics, syneresis, water holding capacity and sensory characteristics of the products after fermentation and after 10 days of storage. Fermentation performed using a mixture of fermentative liquid of kombucha on peppermint and probiotic yoghurt culture was significantly shorter in comparison to the other starter culture, at all temperatures. It was the only major difference because the quality of the obtained products was very similar regardless of the fermentation temperature, applied starter culture and storage.
Key words: *kombucha, fermented milk products, peppermint*

INTRODUCTION

Kombucha is a symbiotic association between yeasts and acetic acid bacteria. It is capable to convert the simple substrate, usually black or green tea sweetened by sucrose, into a pleasant, refreshing and slightly carbonated beverage. On this substrate, fermentation lasts about 7 days, on temperature 20-30^{o}C. It was found the possibility of obtaining of fermented milk beverages by means of kombucha (Malbaša et al., 2009).
Using an appropriate technological process, it is possible to produce fermented milk products from milk with 1.5% milk fat, with the addition of 10% kombucha inoculum cultivated on herbal extracts (winter savory, peppermint, wild thyme and stinging nettle) at 42^{o}C. The characteristic pH value for this type of products is 4.5. The fermentations with inoculums containing wild thyme and stinging nettle lasted for approximately the same time (10.5 and 11 h, respectively), whilst for fermentations with inoculums containing winter savory and peppermint this time was 13 and 17 h, respectively. Chemical composition and physico-chemical characteristics of the obtained products corresponded to the current Regulation on quality of yoghurt and kefir. The highest value of water holding capacity, the lowest value of syneresis and the best textural characteristics showed sample produced with inoculum containing peppermint. This indicated on better quality of this product compared to others (Vitas et al., 2011).
However, the best characteristic of the products containing peppermint in previous investigations (Vitas et al., 2011), inspired the further investigations with kombucha inoculum with peppermint. The intention was the shortening of the fermentation time. Some of the process conditions like fermentation temperature, milk fat in substrate, kombucha inoculum containing peppermint were changed.
The aim of this study was to investigate characteristics of fermented milk products, obtained from milk with 2.8% milk fat, by using two starter cultures at 37, 40 and 43°C. One starter culture was kombucha fermentative liquid, obtained from peppermint extract sweetened with sucrose (7%), and the other was a mixture of kombucha fermentative liquid on peppermint and probiotic yoghurt culture. The products quality was monitored using typical chemical,

physico-chemical and sensory analyses after fermentation and after 10 days of storage, as well as comparison with commercial probiotic yoghurt (Y) and kefir (K).

MATERIAL AND METHODS

Inoculums

Two types of inoculums were used for production of fermented milk products.
The first inoculum was fermentation liquid obtained by cultivation of kombucha on cooled tea, which was prepared as follows: in 1 L of boiling tap water was added 70 g sucrose and 2.25 g of peppermint tea. Prepared tea has cooled to room temperature, strained and then added 100 mL of inoculum from a previous fermentation. A glass jar was covered with fabric bandwidth. Kombucha incubation was performed at room temperature for 7 days.
The other inoculum was a combination of starters: 10% kombucha inoculum on peppermint and 0.01% probiotic ABT-7 culture (Probiotic culture-Probio-Tec®Contains BB-12®, CHR Hansen, Denmark).

Production of fermented milk products

A pasteurized, homogenized milk with 2.8% milk fat, from the manufacturer ››AD IMLEK‹‹ Beograd, branch „Novosadska mlekara“, Novi Sad, was used for the production of fermented milk products in the laboratory.
Amount of 10% (v/v) of kombucha inoculum on peppermint (P) and a combination of starters (PP) was added to milk with 2.8% milk fat. Fermentation was performed at 37, 40 and 43°C until pH value of 4.5 was reached. Gel was then cooled to the temperature of 8°C and homogenized by mixer. The obtained samples were labeled with P37, P40, P43, PP37, PP40 and PP43. The labels indicate used inoculum as well as fermentation temperature.

Methods of analysis

The milk, which was used for the production of fermented milk products, the obtained fermented milk products, commercial probiotic yoghurt (manufacturer Somboled, Sombor), and kefir (manufacturer ››AD IMLEK‹‹ Beograd, branch „Novosadska mlekara“, Novi Sad) were analyzed by measuring the pH, acidity, dry matter, ash, milk fat, total protein and lactose, according to standard methods (Carić et al., 2000).
Syneresis of whey (Atamer et al., 1996) and water holding capacity (WHC) (Guzman-Gonzalez et al., 1999) of laboratory-obtained fermented milk products, commercial probiotic yoghurt and kefir were determined, and given their sensory evaluation.
All fermented milk products were analyzed after production and after 10 days of storage.

RESULTS AND DISCUSSION

Analysis of milk

The results of the quality of milk used in the production of kombucha fermented milk products are given in Table 1.
Based on the results given in Table 1 it was found that the characteristics of milk correspond to the current Regulation on quality of milk products and starter cultures.

Table 1. Chemical composition and physico-chemical characteristics of milk

characteristic	milk
pH	6.61
dry matter (%)	11.50
ash (%)	0.72
acidity (˚SH)	6.40
milk fat (%)	2.80
total proteins (%)	3.17
lactose (%)	4.60

Relative standard deviation (RSD) for all measurements was up to 5%.

Changes of pH during fermentation of milk

Course of fermentation of milk with 2.8% milk fat in the production process of kombucha fermented milk products is shown in Figure 1.

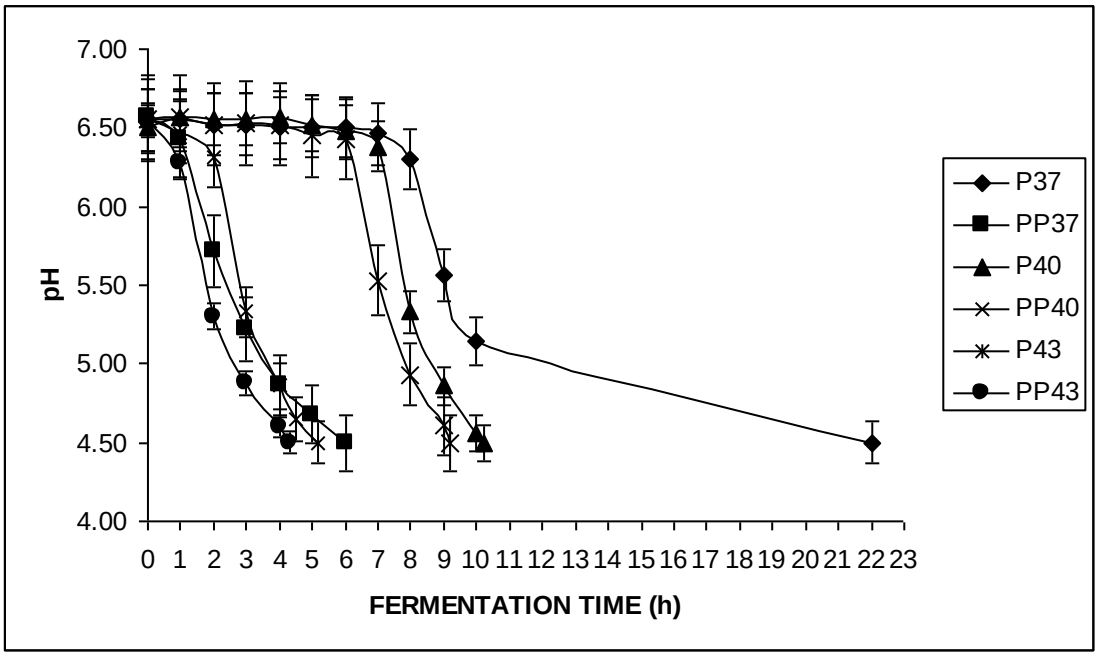

Figure 1. Fermentation process of kombucha fermented milk products

Fermentation was stopped after reaching the pH value of 4.5. With temperature increase, time of fermentation process was shorter, with all applied inoculums. Combination of starters (PP) shortened the fermentation process significantly, compared to P inoculum, at all applied temperatures.

Significant changes in pH values for sample P37 was recorded after 10h of fermentation, whilst for samples P40 and P43 these changes occurred after 8h of fermentation. For samples PP37 and PP40 significant changes in pH values occurred after 3h of fermentation, and for sample PP43 these changes occurred after 2h of fermentation.

The patterns of decrease in pH value during fermentation of P37, P40 and P43 were typical for kombucha fermentation on milk, i.e. the curves were sigmoidal. The fermentation curves for PP37, PP40 and PP43 were almost linear which is usual for yoghurt (Malbaša et al., 2009). It indicates that the probiotic bacteria took major role during the fermentation of combination of starters on milk.

Fermentation was the longest for sample P37 (22h), and shortest for sample PP43 (4.30h).

Analysis of kombucha fermented milk products

The chemical composition and physico-chemical characteristics of kombucha fermented milk products after production is shown in Table 2.

Table 2. Chemical composition and physico-chemical characteristics of kombucha fermented milk products after production, yoghurt and kefir

characteristic	P37	PP37	P40	PP40	P43	PP43	Y	K
pH	4.10	4.05	4.10	4.33	4.17	4.11	3.96	4.22
acidity (^{o}SH)	40.20	42.20	38.00	40.00	36.00	35.80	39.20	37.80
dry matter (%)	10.95	10.62	11.18	11.04	11.29	10.97	11.12	11.24
ash (%)	0.65	0.64	0.65	0.63	0.66	0.63	0.69	0.71
lactose (%)	3.91	3.93	3.98	3.88	3.62	3.95	4.29	3.86
total proteins (%)	3.18	2.97	3.00	2.99	3.03	2.98	3.41	3.15
milk fat (%)	2.64	2.64	2.64	2.64	2.64	2.64	2.75	2.53
syneresis (mL)	24.50	20.00	29.00	31.00	32.00	30.00	26.00	25.00
WHC (%)	66.05	49.50	32.84	42.79	41.00	39.50	52.24	71.50

Relative standard deviation (RSD) for all measurements was in a range from 3 to 12%.

The laboratory-produced samples with the addition of P showed higher dry matter content compared to the ones produced with the addition of PP, at all applied temperatures. The highest value of dry matter and ash content of samples obtained in the laboratory showed P43, 11.29% and 0.66%, respectively. Sample P43 showed higher dry matter content compared to Y and K. Ash content of all laboratory-produced samples was lower compared to Y and K.

In all laboratory-produced samples was determined the same percentage of milk fat, which was 2.64%. Y and K showed milk fat content which was in accordance to the value stated on the declaration of the product packaging. The content of total proteins for all laboratory-produced samples was in narrow interval and ranged from 2.97 (PP37) to 3.18% (P37). Protein content for Y and K was in accordance to values given on product declaration. The lowest value of lactose content showed sample P43. This value for other laboratory produced samples ranged from 3.88 (PP40) to 3.98% (P40).

Acidity of all samples was characteristic for this type of products and ranged from 35.80 (PP43) to 42.20^{o}SH (PP37).

pH value of all samples was in accordance with current Regulation for yoghurt and kefir.

Compared to K all laboratory-produced samples showed lower WHC. The highest water holding capacity of laboratory-produced samples showed sample P37 (66.05%) and this indicates the better quality of this product comparing to the other laboratory-produced samples, and including Y. This value is also higher than value obtained for set yoghurt made from goat milk (Vučić et al., 2010).

The values of syneresis of whey of laboratory-produced samples were in narrow interval and ranged from 20.00 mL for PP37 to 32.00 mL for P43. These values are in accordance with experimentally determined limits, for fermented milk beverages obtained by applying kombucha cultivated on black tea (Malbaša et al., 2009), kombucha cultivated on stinging nettle and combination of kombucha on stinging nettle and probiotic starter culture (Lončar et al., 2011). Samples P37 and PP37 showed lower value of syneresis comparing to Y and K.

Table 3. shows the chemical composition and physico-chemical characteristics of kombucha fermented milk products after 10 days of storage.

P40 and P43 showed higher dry matter content compared to P37, PP37, PP40 and PP43. The highest value of dry matter content of samples obtained in the laboratory showed P40 (11.35%). Laboratory-produced samples, except P37, showed higher dry matter content compared to Y. Sample K showed the highest dry matter content. Ash content of all laboratory-produced samples was lower compared to Y and K.

Table 3. Chemical composition and physico-chemical characteristics of kombucha fermented milk products, yoghurt and kefir after 10 days of storage

characteristic	P37	PP37	P40	PP40	P43	PP43	Y	K
pH	4.09	4.00	4.10	4.11	4.15	4.15	4.08	4.33
acidity (^{o}SH)	40.20	47.60	41.40	46.00	40.60	37.20	39.80	41.80
dry matter (%)	10.96	11.10	11.35	11.18	11.34	11.19	11.07	11.38
ash (%)	0.62	0.64	0.65	0.63	0.65	0.63	0.67	0.71
lactose (%)	2.50	3.27	2.98	3.34	3.34	3.34	3.64	3.32
total proteins (%)	2.95	2.89	3.11	3.04	3.06	3.05	3.39	3.17
milk fat (%)	2.64	2.64	2.64	2.64	2.64	2.64	2.86	2.53
syneresis (mL)	30.00	28.00	29.00	30.00	32.00	30.00	26.00	25.00
WHC (%)	55.22	48.00	38.50	44.28	37.00	38.69	57.71	55.50

Relative standard deviation (RSD) for all measurements was in a range from 2.5 to 10.5%.

In laboratory-produced samples the percentage of milk fat did not changed during the storage period. Y and K showed milk fat content which was in accordance to the value stated on the product declaration. The content of total proteins for all laboratory-produced samples was in narrow interval and ranged from 2.89 (PP37) to 3.11% (P40). Values of protein content of Y and K were in accordance to product declaration. The lowest value of lactose content (2.50%) showed sample P37. This value for other laboratory-produced samples ranged from 2.98 (P40) to 3.34% (PP40, P43 and PP43). The lactose content of all samples decreased during storage period of 10 days.

Acidity of samples increased during storage. For sample P37 this value did not changed.

pH value of all samples was in accordance with current Regulation for yoghurt and kefir.

After storage, all laboratory-produced samples showed lower WHC compared to Y and K. The highest water holding capacity of laboratory-produced samples showed P37 (55.22%). WHC of P40, PP40 and Y increased during storage.

The values of syneresis of whey of laboratory-produced samples were in narrow interval and ranged from 28.00 mL for PP37 to 32.00 mL for P43. The values of syneresis for samples P37 and PP37 increased during storage, and decreased for sample PP40. This value did not change for samples P40, P43, PP43, Y and K.

Sensory analysis of kombucha fermented milk products

Sensory evaluation of produced fermented milk products and commercial yoghurt and kefir was obtained by qualified assessors.

After production, assessment noted that all laboratory-produced samples did not have separated whey on the surface; their color and consistency were typical for that type of product. Samples P37, PP37 and P40 had bitter taste, whilst samples PP40, P43 and PP43 showed mild and pleasant taste, which is typical for fermented milk beverages obtained by applying kombucha cultivated on peppermint extract. In addition, samples produced with PP addition were more sourly comparing to samples produced with P addition. Y and K showed sensory characteristics that were in accordance to the current Regulation.

After 10 days of storage, assessment established that all laboratory-produced samples did not have separated whey on the surface; their color and consistency were typical for that type of product. All of these samples showed bitter taste which was slightly less pronounced in the case of P40, PP40, P43 and PP43. Characteristic odor on peppermint extract was not determined in the case of P37, PP37 and P40, and in the case of PP40, P43 and PP43 it was slightly pronounced. Bitter taste after storage (Table 3.) could be the consequence of higher acidity. Y showed sensory characteristics that were in accordance to the current Regulation, whilst K had bitter taste.

CONCLUSIONS

Using an appropriate technological process, fermented milk products were produced from milk with 2.8% milk fat, with the addition of 10% kombucha inoculum cultivated on peppermint extract and with the addition of combination of starters.
Combination of kombucha and probiotic starters significantly shortened the fermentation.
All products were in accordance to actual Regulation.
After 10 day storage the taste was less or more bitter as a consequence of higher acidity.

ABSTRACT: In addition to raw materials, wort, fermentation conditions, methods of stabilization, and technological equipment, brewing yeasts have also a significant impact on the flavor profile of beer. Brewing yeasts with good reproductive capacity, fermentation activity, metabolism and stable properties are crucial for producing competitive beers with high quality. Therefore, an important step in the development of a new technology or the improvement of an existing one is the selection of yeast strains.
In the present study three dry brewing yeasts strains – two lager strains and an ale one were investigated. Fermentation processes were carried out with free and immobilized cells at different initial wort extracts. Yeast immobilization was carried out in the capsules of chitosan-alginate with an internal liquid core. Some basic parameters of produced beers were investigated and an initial organoleptic evaluation of the beverages was made. All analyses were performed according to the standard methods of brewing technology and microbiology. As a result of the study, yeast strains suitable for beer production with immobilized cells were selected.
Key words: *brewing yeast, immobilization, beer quality*

INTRODUCTION

The conventional brewing process consists of four stages: malting, wort production, fermentation, and beer stabilization together with filtration. The purpose of malting is to produce enzymes in the barley kernel, which will cause defined changes in its substances.The purpose of wort production is to transform and dissolute the insoluble components of the malt into soluble and particularly fermentable sugars. During fermentation wort transforms into beer under the action of active yeast cells inoculated into the cooled and aerated wort. The filtration and stabilization of the beer is carried out in order to achieve microbial, colloidal, and flavour stability so that beer quality remains unchanged for a long time (Branyik et al., 2005).
During fermentation and maturation yeasts not only produce alcohol and CO_2 but also significantly affect the taste and character of beer with their metabolism. Brewing yeasts are classified as: ale strains (Saccharomyces cerevisiae) and lager strains (Saccharomyces pastorianus) according to their behaviour during fermentation. Ale strains rise to the surface during fermentation, while lager strains settle to the bottom at the end of fermentation (Kunze, 2004). Lager strains are capable of utilizing disaccharide melibiose and exhibit a greater affinity for galactose and maltotriose than ale strains. Lager strains are better 'equipped' to grow at lower temperatures, and perform fermentation at lower temperatures than ale strains (Boulton and Quain, 2001). The products of yeast metabolism, which affect beer quality, are: vicinal diketones, aldehydes, esters and higher alcohols. Their production is different for ale and lager strains. Ale strains produce more fusel alcohols and esters than lager ones. The proportion of these fermentation by-products is up to 50 % more than in the case of bottom fermentation (Kunze, 2004). The ales flavor is usually described as "robusty, hearty and fruity". Lagers are characteristically "smooth, elegant, crisp, fruity, and clean".
Fermentation is the most time-consuming step in overall beer production. In such a competitive market, the potential time savings offered by immobilized cell technology (ICT) has to be taken into account. The immobilization of microbial cells includes any technique

that limits their free migration (Masschelein et al., 1994). Cell immobilization methods can be classified into four main categories: (i) attachment to the surface of solid carriers; (ii) entrapment within a porous matrix; (iii) self-aggregation naturally or artificially induced; (iv) containment behind barrier (Nedovic et al., 2005). Microencapsulation is an interesting variation of standard containment behind barrier method. Cells are usually entrapped in gel, coated with a polymer such as chitosan, and then, after the gel is dissolved, the cells are contained behind polymer barrier (Masschelein et al., 1994). The main challenge for fermentation with immobilized cells is to reproduce the traditional beer flavor. The differences between beers produced conventionally and beers produced using ICT were discussed in many papers (Willaert and Nedovic, 2006; Branyik et al., 2008).
In this study we compared the effect of immobilization on the fermentation activities of three brewing yeast strains and on the quality of the final product. The choice of yeast strain, suitable for beer fermentation was based on the comparison of some basic parameters such as: extract, alcohol content, and degree of attenuation. On the other hand, the initial organoleptic evaluations of the produced beers, made by experienced tasters were also crucial for the yeast choice.

MATERIAL AND METHODS

Yeast strain

Three dry brewing yeast strains were used – two lager strains: Saflager S-23 and Saflager W/34-70 and one ale strain: Safbrew S-33. They were re-hydrated in sterile water (10 times their own weights) at temperature 23±3°C for lager strains and 27±3°C for the ale one before the immobilization.

Cell immobilization

The cells were immobilized in 3 % calcium alginate gel. Sodium alginate (Algogel 6021) was purchased from “Degussa” (France). After having autoclaved the alginate solution for 20 min at 120°C, the latter was mixed with the cell suspension to obtain a cell concentration of 10^7 cells/mL of gel. This suspension was forced through a syringe needle by means of peristaltic pump and dropped into 2% (w/v) $CaCl_2$ solution. The resulting beads were approximately 2 mm in diameter. The beads were left for 30 min in calcium chloride solution and then were placed into 0.38% (w/v) chitosan solution in 1% acetic acid (v/v). Alginate beads stayed in chitosan solution for 60 min. Afterwards, chitosan-alginate beads were washed with sterile water in order to remove the excess of chitosan. Beads stayed in 0.05 M sodium citrate solution for 30 min to construct microcapsules with liquid core. Alginate gel is sensitive towards chelating agents like citrate, so its property is of key importance for dissolving alginate and producing capsules with liquid core. Chitosan-alginate microcapsules were stored in physiological solution (saline) before use.

Wort

Wort supplied by a local brewery with extract of 12% and 17% was used. It was autoclaved at 120°C for 20 min.

Fermentation

7 g microcapsules were added to 200 ml sterile wort. Free cell fermentation process was used as a control probe for fermentation rate. The free cells suspension, containing 10^7 cells/mL was added to 200 ml sterile wort. The fermentation was carried out in fermentation bottles, equipped with airlock system. The fermentation processes were monitored via the amount of released CO_2 which was measured from the weight loss. The fermentation was carried out in temperature controlled room at 15 °C.

Analytical methods

Extract, alcohol content, and degree of attenuation of produced beers were analyzed according to the EBC methods of analysis (Analytica - EBC, 2004). The biomass

concentration was measured at OD 600. Microcapsules were dissolved in 1 M magnesium citrate solution. The solution was centrifuged at 3000 rpm for 10 min. The biomass was washed with saline twice and OD 600 was measured by „Shimatzu UV-VIS 1800". The results were converted to the corresponding g dry weight/l using a standard curve according to Zhou et. al., 1998.

RESULTS AND DISCUSSIONS

The results for fermentation activities of free and immobilized cells of yeast strain Saflager S-23 are presented in Figure 1. The fermentation proceeded normally, regardless of the original gravity of wort. The fermentation activities of free and immobilized yeast cells reached their maximum between 2nd and 3rd day. Afterwards, they began to fluently decrease. When immobilized cells were used, shifted maximum of fermentation activity was observed. The main reason for the latter is that microencapsulation makes CO_2 release more difficult. The increase of original gravity of wort led to an increase in the observed shift. However, the fermentation proceeded without significant modifications. The amount of non-fermented extract was higher for free cells, which led to lower real degree of attenuation of produced beer.

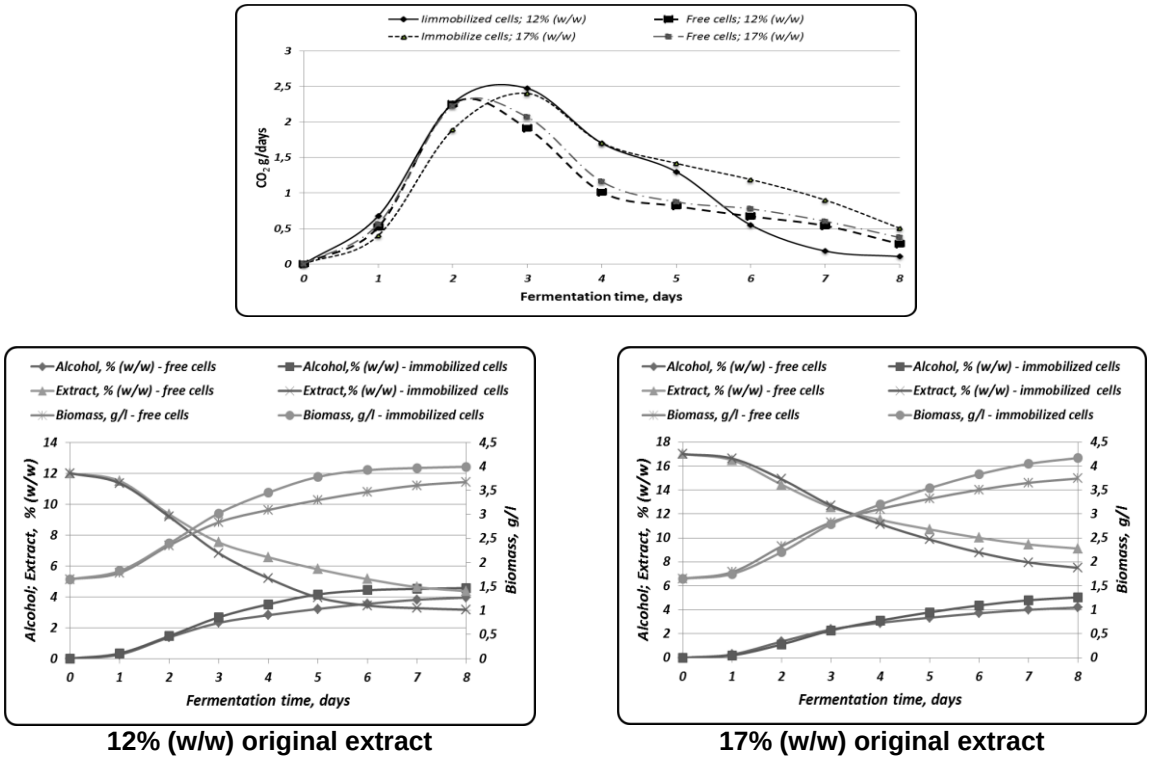

Figure 1. Fermentation activity of yeast strain Saflager S-23

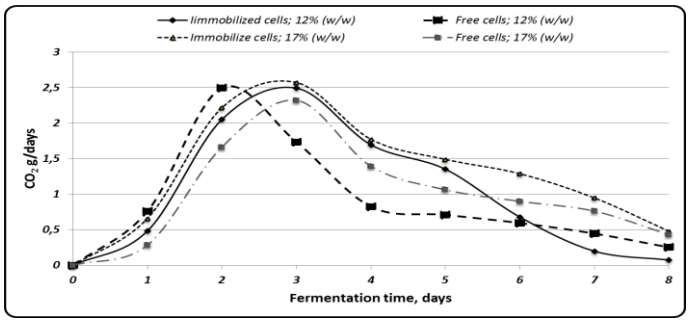
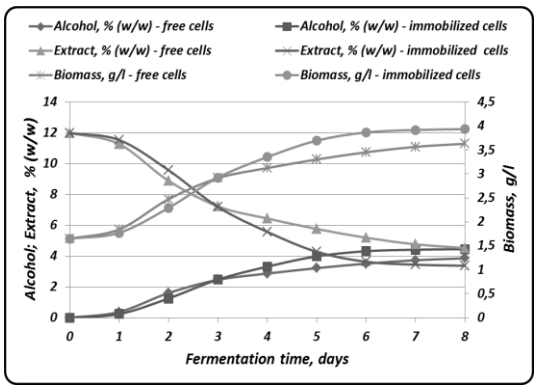
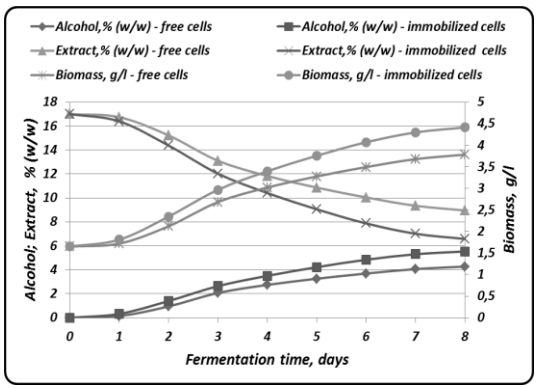
Fermentation activity of yeast strain Saflager W/34-70 is shown on figure 2. The fermentation activity of both immobilized and free cells was almost the same for wort with original extract of 12%. When the original gravity of wort increased, the difference between the fermentation activities of corresponding cells also increased. Comparison of fermentation activity indicated shifted maximum in the case of immobilized yeast. Immobilized yeast showed higher real degree of attenuation compared to free cells.

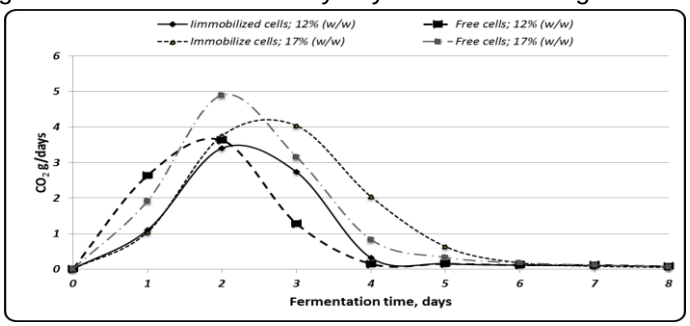


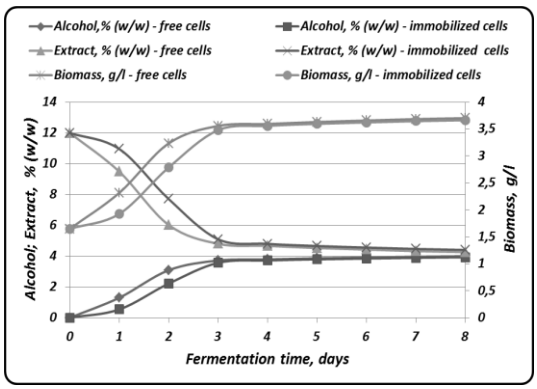


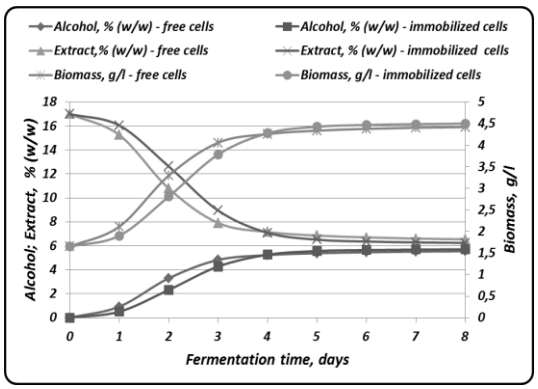


12% (w/w) original extract **17% (w/w) original extract**

Figure 2. Fermentation activity of yeast strain Saflager W34/70







12% (w/w) original extract **17% (w/w) original extract**

Figure 3. Fermentation activity of yeast strain Safbrew S-33

Fermentation activity of yeast strain Safbrew S-33 is shown on figure 3. The differences between free and immobilized yeasts were more significant for that yeast strain. The maximums of fermentation activity for all investigated variants were in different periods of time. The strain is potentially interesting for study because significant differences in fermentation processes with free and immobilized cells were observed. The main reason is that yeast immobilization affects the yeast growth and consequently the fermentation process. Furthermore, few studies on the immobilization of ale strains are represented in the literature.

Table 1 shows results for extract, alcohol, and real degree of attenuation of beers at 8th day of fermentation. Analyses of all beers showed higher degree of attenuation for beers produced by immobilized cells. The highest degree of attenuation was achieved with yeast strain Saflager S-23 when the original gravity of wort was 12 %. The increase of the original gravity of wort led to the decrease of the degree of attenuation.

Table 1. Effect of original gravity of wort and type of yeast on primary fermentation parameters of different yeast strains

Original gravity of wort	Yeast strains	Type of yeast	Apparent Extract % w/w	Real Extract % w/w	Alcohol % w/w	Real degree of attenuation %
12%	S-23	immobilized	2.23	4.24	4.36	**68.00**
		free	3.06	4.93	4.06	62.99
	W-34/70	immobilized	2.31	4.31	4.35	**67.59**
		free	3.15	5	4	62.31
	S-33	immobilized	3.03	4.79	3.82	**62.24**
		free	3.24	5.05	3.93	61.66
17%	S-23	immobilized	5.16	7.45	5.1	**58.59**
		free	6.42	8.46	4.5	52.36
	W-34/70	immobilized	3.99	6.49	5.58	**63.99**
		free	6.16	8.26	4.64	53.72
	S-33	immobilized	4.53	7	5.53	**62.01**
		free	4.63	7.08	5.5	61.62

In addition to fermentation activity, the flavor profile of beer is crucial for the choice of yeast strain for beer fermentation. Experienced tasters carried out descriptive sensorial tests in order to determine the taste and aroma profile of beers produced by ICT and conventional technology. The results are shown in Table 2. Beers produced by yeast strain Safbrew S-33 received the highest sensory evaluations. The sensory profiles of beers produced by free and immobilized yeast Safbrew S-33 revealed minor differences when wort with original gravity of 17% was used. The differences in flavor profiles of beers became more significant when the original gravity of wort decreased. The lowest sensory evaluations received all beers produced by yeast strain Saflager W 34/70.

Table 2. Descriptive sensorial tests of beers produced by immobilized and free yeast strains

Original gravity of wort	Yeast strains	Type of yeast	Description of aroma and flavor of produced beers
12%	S-23	immobilized	fruity, phenolic
		free	fruity, sweet, honey
	W-34/70	immobilized	phenolic
		free	malty, musty
	S-33	immobilized	cooked-vegetable
		free	oxidized, butterscotch, full and harmonic body
17%	S-23	immobilized	malty flavor and aroma
		free	sour-acidic odor
	W-34/70	immobilized	swampy odor, malty taste
		free	sour, unpleasant aroma
	S-33	immobilized	fruity, malty
		free	fruity – banana, apple, pear, sweet

CONCLUSION

Two lager yeast strains and an ale one were compared for beer production with immobilized cells. The beers were produced with wort of different original gravity. The ale strain showed the highest fermentation activity and initial sensory evaluation, but also the lowest degree of attenuation. The lager strains revealed minor differences in fermentation activities, but significant differences in sensorial evaluations. The beers produced by yeast strain Saflager W 34/70 were found unacceptable in flavor and aroma by experienced tasters. Acceptable and balanced beer flavor is an important prerequisite for producing competitive beers. Therefore, yeast strain Saflager W 34/70 seems not suitable for production of high quality beers.
Yeast strains Safbrew S-33 and Saflager S-23 were chosen for further studies on beer production with immobilized cells. The effect of temperature and original gravity of wort on the yeast metabolism and beer quality will be investigated in more detail and one of the yeast strains will be chosen for batch and continuous fermentation with immobilized yeast.

ACKNOWLEDGEMENTS

We would like to thank to the Bulgarian brewery “Kamenitza” Plc for generously supplying us with the wort, needed for our experiments.

ABSTRACT: Food products containing beneficial microorganisms, mostly lactic acid bacteria which effectively affect human digestive and immune systems, represent one of the largest market of functional foods, with dairy products as the most accessible ones. However, for some, non-negligible percentage of the global consumer's population, usage of dairy products is limited due to diet (vegetarian), traditional reasons, or because of lactose intolerance, cholesterol content and allergenic milk proteins. These major drawbacks related to the intake of dairy products promote the idea of replacement of milk with alternative delivery formats for probiotics, which makes the development of new nondairy probiotic foods, that can appeal to a wider range of consumers, essential. In this context, our idea was related to the incorporation of probiotic microorganisms into one of the most popular foods - chocolate, which significantly contributes to the favorable impact of this product on human health. Therefore, in this study addition of probiotic strain *Lactobacillus acidophilus* NCFM® in dark chocolates with 44 % cocoa solids, was carried out in industrial conditions. In order to determine the shelf-life of these chocolates their sensory properties (appearance, texture, aroma) were evaluated, along with the determination of viability of added probiotic bacteria during storage at different temperatures (4ºC and 22ºC), immediately after production and after 90 and 180 days. Results indicated that the enrichment of dark chocolates with *Lactobacillus acidophilus* NCFM® caused no modification of the their sensory properties, and the number of incorporated live probiotic bacteria maintained at a high level of 8 log cfu/g during storage of 180 days. Based on the above it can be concluded that dark chocolates with 44 % cocoa solids have a protective effect on *Lactobacillus acidophilus* NCFM® cells and make a good matrix for the preparation of functional probiotic products.
Keywords: *dark chocolate, Lactobacillus acidophilus, probiotics, sensory properties*

INTRODUCTION

According to the definition given by FAO/WHO (2001) probiotics are „live microorganisms which, when administered in adequate amounts, confer a health benefit on the host". Most commonly this refers to certain strains of lactic acid bacteria (LAB), particularly from the genera *Lactobacillus* and *Bifidobacterium.* Their impacts are primarily associated with maintaining or improving the balance of intestinal microflora (Fuller, 1989) which may provide protection against gastrointestinal disorders including gastrointestinal infections, inflammatory bowel diseases and even cancer (Saarela et al., 2000). Additional health benefits atributed to probiotics are the stimulation of immune system, blood cholesterol reduction, enhancement of the digestibility of protein and vitamin synthesis, anti-bacterical activities, treatment of lactose intolerance and food-related allergies (Ouwehand et al., 2009; De Smet et al., 1998; Lee and Salminen, 2009; Lomer et al., 2008; Prescott and Bjorksten, 2007). Although the whole idea of probiotics is not new and their usage in treating body ailments is even mentioned in the Biblical scriptures, it was only in the early 20th century that the Russian scientist Elie Metchnikoff gave the first scientific explanation for the beneficial effects of lactic acid bacteria and proposed the concept of probiotics as it is known today (Ranadheera et al., 2010).
Originally, probiotic delivery was consistently associated with foods, particularly dairy foods, such as yoghurts and fermented milks. However, lactose intolerance, cholesterol content and allergenic milk proteins are the major drawbacks related to the intake of dairy products. Also, dietary habits, traditional and economic reasons limit the use of dairy products in some

countries (Granato et al., 2010). Furthermore, milk-based products must be maintained at refrigerated temperatures and are characterized by relatively short shelf-life. In this context, the development of new non-dairy probiotic foods is of great importance. An alternative strategy to increase the efficacy of a probiotic treatment would be to use a food matrix which naturally contains a higher content of ingredients with protective properties. Chocolate is one such product that meets many of these demands. Nowadays chocolate is not just an indulgent snack, it is also increasingly recognised as possessing many qualities that are beneficial to health. This is particulary true of dark chocolate made with more cocoa solids due to its content of the polyphenol components, acting as natural antioxidants. In view of the growing market deman for products that combine delight with health, chocolate represent a good opportunity to add further health benefits via the use of probiotic cultures. In addition, according to a recent study conducted at the University of Ghent (Belgium), supported by Barry Callebaut, one of the leading manufacturers of cocoa and chocolate products, over 80 % of probiotics in chocolate as a "carrier" safely pass through the stomach, compared to only 20 % when the "carriers" are milk/yogurt drinks. This also means that a smaller amount of food is needed to achieve therapeutic effects. Cocoa-butter provides protection for probiotic bacteria, so it is not necessary to store chocolates in a refrigerator, and shelf-life of the product by far exceeds that of dairy based foods (www.maramor.com).

However, incorporation of probiotic in food is linked to some serious obstacles arising from the definition of probiotics itself: they need to reach digestive tract, a place of their action, alive and in sufficient number. For probiotic functionality, the numbers of live cells of these bacteria in foods should not be lower than 10^6 cfu/g at the time of consumption (Patel et al., 2008).Their survival is linked to several factors: first the endogenous properties of the chosen bacteria strain, their environment (other ingredients properties, humidity, temperature, oxygen…), the digestive process (gastric acidity, biliary salts), as well as various mechanical stresses linked to food processing (Maillard and Landuyt, 2009). To overcome these limitations, it is necessary to apply new or adapt existing technological process to allow, not only the survival of conditions during production, but also sufficient viability of probiotic bacteria during extended storage. This represents a great challenge for technologists and manufacturers of non-dairy products, which are usually kept at room temperature.

Combination of enrichment of dark chocolate with viable cells of probiotic bacteria, together with other favorable components in its composition (poliphenols), would represent a new funtional product whose influence on the health of entire population is inasmuch greater given that chocolate is preferably eaten by children and teenagers. Because the unique taste of chocolate is particularly valuable for consumers, its sensory attributes should remain unaltered despite the addition of preparation of probiotic bacteria. Sensory properties of chocolate are among the most important parameters in defining its overall quality (Torres-Moreno et al., 2011). General sensory acceptability and appealing by consumers is the key factor for successfully placing chocolate on the market. A melted chocolate is a complex suspension of at least two dispersed phases (Beckett, 2009), but with addition of probiotic culture, a new solid phase is introduced. This can affect the crystallisation of cocoa butter in chocolate and lead to appearance of fat bloom, and/or changes in structural properties and occurrence of difficulty in chewing. Also, textural changes can cause differences in release of volatile aroma compounds in the mouth headspace, thus influencing the perception of both odor and taste of chocolate (Afoakwa et al., 2009). For these reasons, the significance of sensory analysis in the process of development of new products with funtional properties is crucial.

Sensory attributes of dark chocolates supplemented with probiotic strain *Lactobacillus acidophilus* NCFM® and survival of these bacteria during storage of 180 days at different temperatures were examined within the scope of presented work. Production of this sort of chocolate is a novel approach in the area of successful applications of lactic acid bacteria, including their probiotic strains, for manufacturing of non-dairy products.

MATERIAL AND METHODS

Probiotic preparation

Dark chocolate mass, that is dark chocolates supplemented with live cells of a *Lactobacillus* strain with probiotic properties were the examined material.

Concentrated probiotic preparation in lyophilized form, which contained probiotic strain *Lactobacillus acidophilus* NCFM® , was used. This strain was obtained from Danisco (Denmark), and is commercially known as HOWARU DOPHILUS. Declared starting cell count in the preparation was ≥ 10^{11} DCU.

Chocolate production

Dark chocolates composition was as follows: sugar (sucrose), cocoa mass, cocoa butter, emulsifier (soy lecithin), flavour (ethylvanillin), and they contained 44 % of cocoa solids. Chocolate production was carried out in industrial conditions in the joint-stock company „Štark“ (Belgrade, Serbia). To obtain chocolate mass, production was done folowing the standard technological operations, with one alteration upon completion of tempering. Namely, cocoa mass, part of cocoa butter, sucrose and 1/3 of emulsifier were mixed in a mixer for 2 hours. Obtained mass was subjected to coarse, and then fine grinding (refining) on the five – rollers machine, until an average size of solid particles reached approximately 25 μm. Subsequently, after adding the remaining cocoa butter and 2/3 of lecithin (in two portions), the conching operation was performed at 75°C during 9 hours. Tempering was carried out in multistage heat exchanger with strict control of temperature in order to gain appropriate form of cocoa fat crystals (β V) (cooling to ~ 28°C and rise up to 32°C). After tempering, dark chocolate mass was separeted from the production line with purpose of dispersion of probiotic preparation in the amount of 3.5g/kg. This was done for optimizing stability of live probiotic cells by introducing them at lower temperatures. Next, chocolate mass containing probiotic bacteria was poured to forms, and then returned to production line for cooling, and removing from the forms. Finished chocolates were packed in lacquered aluminium foil, and cardboard checks on the packing machine.

Microbiological analysis

Lactobacillus acidophilus NCFM® was determined on agar MR-IM medium supplemented with 20 % maltose solution, incubated at 37˚C for 48 hours in the facultative anaerobic conditions in a Gas-Pak system (BBL, Germany). All measurements were performed in triplicate. Live cells were enumerated as colony forming units (cfu). Survival of probiotic bacteria cells was determined immediately after production and after 90 and 180 days of storage. In order to appoint the recommended storage temperature suitable for this kind of products, samples designed for microbiological analysis were keept at 4°C and 20°C and analyzed at the indicated periods.

Sensory analysis

The overall sensory quality of dark chocolate samples with probiotic bacteria during storage was determined using modified scoring method of sensory evaluation of chocolate (Popov-Raljić, Laličić-Petronijević, 2009).

Sensory evaluations included the selected, representative, or dominant attributes of chocolate quality, i.e.: appearance (color, gloss, form and surface); texture (structure, snap, hardness, chewiness); aroma (odor, taste). During evaluating the scoring range from 1.00 to 5.00, with the possibility of assigning half and quarter points, was applied. Nonetheless, Planck (Joksimović, 1977) as far back as 1947, introduced and scientifically explained the so-called “weight coefficient”. With application of the weight coefficients, a quantitative expression of the total product quality is obtained as the “weighted” mean value of the scores for each evaluated parameter. Because of that, prior to performing the evaluation, it is important to determine weight coefficient for each property, and balance them in such a way, that their sum equals to 20. Summarizing the individual scores, a complex indicator representing overall sensory quality of chocolates, is obtained. This indicator is expressed as

"% of the maximum possible quality". Dividing this value by the sum of weight coefficient, a weighted average value of ratings is gained, which also represents the overall sensory quality of chocolate. Quality category was determined in dependence of scores spans; samples which were evaluated with less than 2.5 points were considered as unsatisfactory, i.e. as inacceptable; scores within limits 2.5 – 3.5 characterized good quality products, 3.5 – 4.5 very good quality and 4.5 – 5 – excelent products.
Sensory evaluation of dark chocolates with probiotic bacteria was performed by five experienced assessors. Panelists all met the criteria specified by the ISO standards for selection, training and monitoring of assessors (ISO 8586-1, 1993; ISO 8586-2, 1994).

Statistical analysis
Basic parameters of the descriptive statistics included calculations of the arithmetic mean values (X_m), and variability parameters of the investigated sensory properties of dark chocolate samples supplemented with probiotic bactera, included determinations of standard deviations (S_d) and variation coefficients (C_v) expressed in percents (Hadživuković, 1991).

RESULTS AND DISCUSSION

The results of survival of incorporated probiotic strain *Lactobacillus acidophilus* NCFM® in dark chocolate are shown in Figure 1.

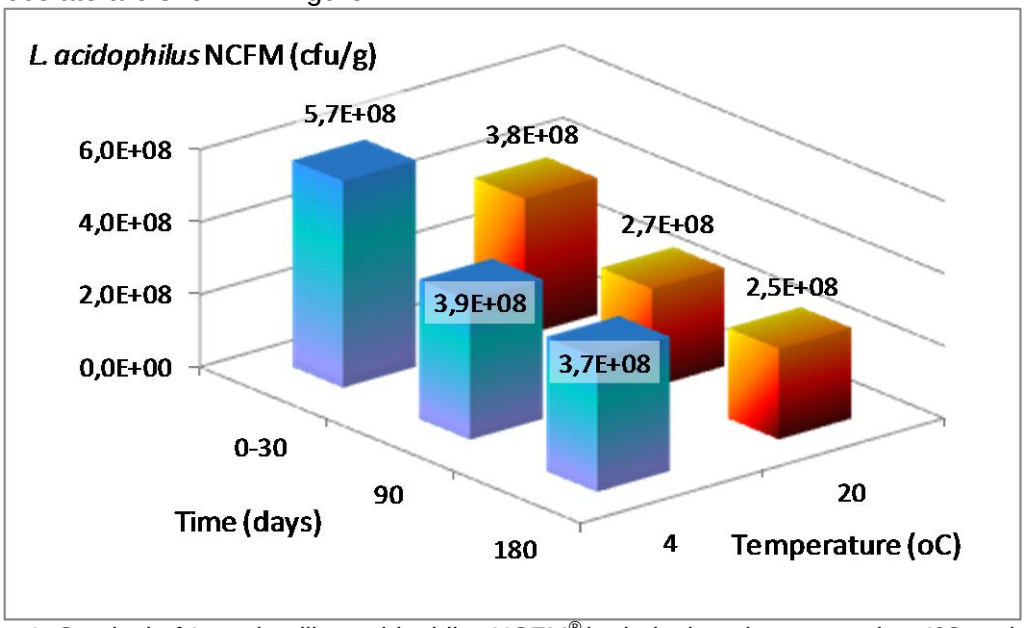

Figure 1. Survival of *Lactobacillus acidophilus* NCFM® in dark chocolates stored at 4ºC and 20ºC during period of 180 days.

As it can be seen from the results, probiotic strain *Lactobacillus acidophilus* NCFM® exibited a very good viability in dark chocolates with 44 % of cocoa solids. Although a slightly higher number of cells survived at a lower tempareture, it can be concluded that during the entire storage period of 180 days the number of viable cells remained at the same level of 8 log cfu/g at the refrigerator temperature (4ºC) as well as room temperature (20ºC). Despite a gradual decrease in a number of live probiotic cells with time, their count was maintained at the functional level. Among many factors affecting the survival of probiotic bacteria in confectionery, water activity, osmotic tension, oxygen and temperature could be considered as critical (Mattila-Sandholm et al., 2002).In this respect, a first step to protect the viability of probiotic bacteria represented their incorporation in dark chocolate mass at fairly low temperature during the manufacturing process (at ~ 30ºC). Furthermore, inside the chocolate bars the penetration of oxygen is very limited, so its harmful impact on probiotic bacteria is minimized due to the virtually anaerobic environment. Besides, chocolate is a product with very low water activity and with high concentration of fats, all of which favorably

affect the survival of probiotic bacteria. Package of chocolates in a double packaging material additionaly protect LAB during storage. All of the above contributed to a satisfactory survival of *Lactobacillus acidophilus* NCFM® in the dark chocolates during storage at 4ºC and 20ºC for up to 180 days. Obtained results are in agreement with findings of other authors (Nebesny et al., 2007; Zyzelewicz et al., 2010).
Addition of lyophilized preparation of *Lactobacillus acidophilus* NCFM® did not change the sensory properties of dark chocolates, as follows from the results of sensory analysis shown in Table 1.
Evaluated samples has high scores for almost every sensory attribute which were retained throughout the experiment. Distinguished gloss of tested samples indicated that there was no appearance of fat bloom, despite adding of new solid phase to the dark chocolate system. Samples were characterized by an appropriate structure and hardness, shell-like snap and good chewiness. Most importantly, the addition of probiotic bacteria did not disrupt the odor and taste of dark chocolate samples and these attributes were given excellent marks by the members of the panel. Based on weighted average value dark chocolate samples enriched with *Lactobacillus acidophilus* NCFM® belonged to the category of excellent sensory quality in all testing periods during storage of 180 days.

Table 1. The results of sensory analysis of dark chocolates supplemented with probiotic cells during storage of 180 days

Time of storage (days)	Calculated indicators	Evaluated sensory properties					Percent of the maximum possible quality	Weighted average value
		APPEARANCE	TEXTURE		AROMA

	C_v	2.51	5.45	3.72	2.26	2.82		

CONCLUSIONS

Probiotics can be applied to dark chocolates with good efficiency. As the lipids in chocolate provide a nice barrier to the environmental conditions, the stability of probiotics in chocolate can be kept quite high compared to other applications. Also, dark chocolates containing probiotic bacteria have extended shelf-life in relation to dairy products. Although, when stored at 4ºC slightly higher number of viable probiotic cells is achieved, the results of our study show that the chocolates with probiotic bacteria may be stored at room temperature as well, without a significant decrease in cell viability. Enrichment with probiotic strain *Lactobacillus acidophilus* NCFM® did not change the sensory attributes of dark chocolates. Therefore, dark chocolate represent a good matrix for probiotic delivery, and at the same time, because of added value, contributes to expanding assortment of both confectionery products and functional foods.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project 046010 “The development of new encapsulation and enzymatic technologies for production of biological active substances and other food components in order to increase competitiveness, quality and safety of the products”, financed by the Ministry of Science and Technological Development, Republic of Serbia.The authors want to thank the joint-stock company „Štark“ (Belgrade, Serbia) for providing raw materials, facilities and personnel to perform this experiment.

ABSTRACT: This study evaluated the impact of the different fermentation temperatures on the fatty acids profile of fermented milk beverages produced by kombucha cultivated on black tea.
Milk with 2 g/100g was inoculated with 10 mL/100mL kombucha inoculum. Fermentations were performed at 37°C and 42°C until pH 4.60 was reached. Content of fatty acids was determinated during fermentation on pH 6.07; 5.10 and 4.60. Analyses of fatty acids composition were carried out by gas chromatography – mass spectrometry.
The results of this investigation indicate that fatty acids profile were similar in milk and fermented milk beverages produced by kombucha. The level of palmitic acid was the highest of all fatty acids among investigated samples.
Key words: *fermented milk beverages, kombucha, fatty acids*

INTRODUCTION

During the yoghurt production the microorganisms of the starter cultures play an important role in development of physicochemical, textural and sensory characteristics of the product. Nowdays, traditional process has been improved, and the basic changes depend on the following: the purity of commercially manufactured starter cultures; direct-to-vat inoculation (DVI) of starter cultures is widely used; incubation temperature can be accuratelly controlled so the rate of acid development and processing time is known in advance; cooling of the product can be carried out quickly at the desirable level of acidity resulting in uniform yoghurt quality; measuring the rate of acid development in milk during fermentation enables even a semi-skilled operator to control the process adequately.
Fat content of yoghurt differs from one country to another according to the existing or proposed standards, or alternatively in relation to the types of products. Although much quantity of fermented dairy products sold worldwide is manufactured from skimmed milk, traditional yoghurts have always contained around 3-4 g/100g milk fat, thus concentrated yoghurt (labneh) or Greek-style yoghurt contain 9-10 g/100g (Tamime and Robinson, 2004). The influence of milk fat content on yoghurt properties, especially the consistency and flavour, is of great importance as well as the fact that lipids are an integral part of a balanced diet (Lori et al., 2000).
In the milk fat, triacylglycerols are the major lipid class accounting for 97-98 g/100g of the total lipids and the remaining fraction consists of phospholipids, sterols, fat soluble vitamins (A,D, E and K), fatty acids, waxes and squalene (Fox, 1994). It is important to stress that milk fat contains an extremely wide range of fatty acids. Most of these are present in the form of various glycerides, but over 400 individual fatty acids have been identified in cow's milk. The milk fats are characterized by the presence of relatively high concentrations of short-chain fatty acids, especially butiric and hexanoic acids. Appreciable amounts of medium-chain-length fatty acids are also present, but relatively low proportion of polyunsaturated fatty acids i.e. essential linoleic fatty acid (Fox, 1994).

The triacylglycerol lipase enzymes that can cause the enzymatic hydrolysis of milk fat in yoghurt may originate from starter culture or from microbial contaminants that survived the heat treatment of milk. Lipases which occur naturally in milk, are inactivated at ordinary pasteurization temperatures. Therefore, any reduction in the percentage of fat, or increase in the level of fatty acids (free or esterified) or volatile fatty acids content in yoghurt can be attributed to lipid metabolism by microorganisms of the applied starter cultures.
Hydrolysis of milk fat by starter cultures occures only to a limited degree. Formisiano et al. (1974) estimated decrease of 3.4 g/100g of milk fat in yoghurt stored for 21 days at 40°C. Fermentation of full fat milk with *S. thermophilus*, *L. delbrueckii* subsp. *bulgaricus* or *L. acidophilus* resulted in different effects on lipids: significant increase in saturated fatty acids and oleic acid and a concomitant decrease in linoleic and linolenic acids in the glyceride fraction (Rao and Reddy, 1984). The total level of volatile fatty acids (VFA) increase during the manufacture and storage of yoghurt. The increase in the level of VFA is dependent of the starter bacteria strains, type of milk, duration and temperature of incubation, temperature of milk heat treatment and/or yoghurt shelf life (Tamime and Robinson, 2004).
During fermentation of milk, some strains of bacteria, as the result of their growth and metabolism, are able to change the fatty acid profile of milk and produce functional fatty acids (Yadav et al., 2007; Ekinci et al., 2008). Coskun and Ondul (2004) reported that the addition of mesophilic lactic acid bacteria to milk may contribute to the production of free fatty acids by spontaneous lipolysis during cold storage.
The aim of this research was to evaluated the impact of the different fermentation temperatures on the fatty acids profile of fermented milk beverages produced by kombucha cultivated on black tea.

MATERIAL AND METHODS

Milk

Homogenized and pasteurized milk from AD Imlek, Division Novi Sad Dairy, was used for the production of kombucha fermented milk beverage. The composition of milk was as follows: fat content – 2.00 g/100g, total solids – 10.59 g/100g, total proteins – 3.30 g/100g, lactose – 4.60 g/100g and ash – 0.69 g/100g.

Kombucha inoculum

Kombucha inoculum was prepared according to procedure published by Malbaša et al., (2009). Kombucha is cultivated on black tea (*Camellia sinensis* – oxidized, 1.5 g/L) with saccharose concentration of 70 g/L. The tea was cooled to room temperature, after which inoculum from a previous fermentation was added in concentration of 10%. Incubation was performed at 25°C for 7 days. Inoculum in concentration of 10 mL/100mL was used for milk inoculation.

Samples production

Samples were produced by addition of 30 mL of kombucha inoculum in 300 mL of milk at two different temperatures: 37°C and 42°C simultaneously. Fermentation was continued until pH= 4.6 was reached. Samples were taken at pH values: 6.07, 5.10 and 4.60 and cooled to 4°C.

Determination of fatty acids in samples

Fat was extracted from samples (4 cm^3) by adding methanol (4 cm^3) and chloroform (4 cm^3). The mixture was shaken vigorously for 1 min. and then centrifuged at 3000 rpm for 10 min. under room temperature. The lower phase containing the lipid fraction was isolated and evaporated to dryness under nitrogen (Havemose et al., 2004).
Previosly extracted fats were dissolved in hexane (2.4 cm^3). An aliquot (0.6) of 2 mol/dm methanolic KOH solution was added. The tube was capped and vigorously shaked for 20 s and allowed to boil 1min. in water bath at 70°C. After 20 s of shaking 1.2 cm^3 of 1 mol/dm HCl was

added and gently stirred. After phase separation the upper phase containing the fatty acid methyl esters was decanted and 1µL was used for further analysis (Kravić et al., 2011).
The analysis of fatty acid methyl esters were performed on a Hewlett–Packard (HP) 5890 gas chromatograph coupled with a HP 5971A mass spectrometer detector. Supelco fused silica capillary column SP–2560 (100 m x 0.25 mm i.d., 0.20 µm) was used. The inlet temperature was 230°C with a split ratio 1:40, and the carrier gas was helium with constant flow rate of 0.58 cm^3/min. The initial temperature of 100°C was held for 5 min. and increased by 6°C/min to an end temperature of 240°C. The mass spectrometer was operated in the electron ionization mode with quadruple temperature of 180°C. Data acquisition was carried out in the scan mode (range 50–400 m/z).

RESULTS AND DISCUSSIONS

The fatty acids content in milk and samples during fermentation on 37°C and 42°C are shown in Table 1. The level of palmitic acid (C16:0) in milk and samples was the highest of all fatty acids. In milk that was 27.31 g/100g of total fatty acids, in fermented milk beverages on 37°C and 42°C (pH=4.60) 24.69 g/100g and 25.07 g/100g, respectively. Beside the palmitic acid three fatty acids (C18:1, C14:0 and C18:0) were found to be predominant acids in milk and all samples. They accounted 45.27 g/100g (milk), 46.61 g/100g (fermented milk beverages on 37°C and pH=4.60) and 49.52 g/100g (fermented milk beverages on 42°C and pH=4.60) of total fatty acids.
There is no significant difference between samples in fatty acids content during fermentation on 37°C and 42°C. The content of myristic acid (C14:0) in samples produced on 37°C was 12.02 g/100g (pH=6.07), 12.68 g/100g (pH=5.10) and 12.37 g/100g (pH=4.60) while in samples produced on 42°C was 11.52 g/100g (pH=6.07), 11.41 g/100g (pH=5.10) and 11.57 g/100g (pH=4.60).
Milk fat typically contains a high proportion of saturated fatty acids (SFA; 70–75 g/100g) and monounsaturated fatty acids (MUFA; 20–25 g/100g) and small amounts of polyunsaturated fatty acids (PUFA; 5 g/100g) (Lock and Shingfield, 2004). Obtained results are in accordance with that. The medium–chain SFA (*i.e.*, C12:0, C14:0 and C16:0) which account for the majority of SFA in milk fat have been implicated in increasing total and low density lipoprotein (LDL) cholesterol concentrations (Williams, 2000). Stearic acid (C18:0) is considered to be neutral in this regard. Generally, PUFA and MUFA are regarded as beneficial to human health. In this research milk showed the highest content of SFA. However, fermented milk beverages produced on 37°C and 42°C (pH=4.60) had higher content of MUFA, as well as PUFA compared with milk.

Table 1. Fatty acids content (g/100g of total fatty acids; means±SD (n=3)) in milk and samples during fermentation on 37°C and 42°C

SFA – saturated fatty acids; MUFA – monounsaturated fatty acids; PUFA – polyunsaturated fatty acids

CONCLUSION

The present study examined the changes in fatty acids content during fermentation on two different temperatures (37°C and 42°C) of fermented milk beverages produced by kombucha cultivated on black tea. Result showed that there is no significant difference between samples in fatty acids content during fermentation. Also, fermented milk beverages produced on 37°C and 42°C (pH=4.60) had higher content of MUFA, as well as PUFA compared with milk. That increases must be attributed to the kombucha. It is therefore possible to obtain fermented milk beverages by kombucha with potential health benefit.

ABSTRACT: The survival of the encapsulated potential probiotic strain *Lactobacillus paracasei* 08 and commercial probiotic bacteria *Lactobacillus acidophilus* LA-5 and their effect on the soft goat cheese production were investigate**.** Three batches of soft goat cheeses were produced using mesophilic lactococci starter culture CHN 11 (*Lactococcus lactis* and *Lactococcus cremoris,* Chr. Hansen): 1. control cheese (starter); 2. starter + spray-dried potential probiotic *Lb. paracasei* 08 (Culture Collection of the Department for Food Microbiology, University of Belgrade); 3. starter + freeze-dried commercial probiotic *Lb. acidophilus* LA-5 (Chr. Hansen).
Cheese samples were assessed for viability of encapsulated probiotic bacteria, starter bacteria counts, chemical composition, pH values and sensory evaluation during 5 weeks of storage. *Lb. paracasei* 08 and *Lb. acidophilus* LA-5 counts maintained at the level of 10^7-10^8 cfug^{-1}. Starter bacteria counts were >10^6 cfug^{-1} in all cheeses samples. The chemical composition and pH values of probiotic cheeses haven't been significantly different from the control cheese. Sensory evaluation has shown that cheese produced with *Lb. acidophilus* LA-5 had an acceptable sensory quality, while control cheese and cheese produced with *Lb. paracasei* 08 had a high sensory quality.
The data demonstrate that the spray-dried potential probiotic strain *Lb. paracasei* 08 could be successfully used in the soft goat cheeses production, without significant effect on the cheese quality during storage.
Key words: *encapsulated probiotic, soft goat cheese, chemical composition, sensory properties*

INTRODUCTION

Food that contains probiotic bacteria belongs to the functional food category that claimed to have positive effect on human health beyond their contribution to basic nutrition (Roberfroid, 1998). Studies have shown that functional foods with probiotic bacteria have a beneficial influence on human health by improving the balance of intestinal microbiota and mucosal defenses against pathogens (Cínthia and Susana, 2009).
The survival of probiotic bacteria could be preserved with microencapsulation method spray-drying, which is most commonly used method in the food industry. The process of spray drying involves the dispersion of the core material into a polymer solution, forming an emulsion or dispersion, followed by homogenization of the liquid, then atomization of the mixture into the drying chamber (Jackson and Lee, 1991). Spray drying is desirable for commercial application, enabling convenient transport and storage of cultures and their application in functional food (Gardiner et al., 2002). It is economical, easily scaled up and uses equipment readily available in the food industry (Gibbs et al., 1999). However, cell injury emerges during heat stress and spray drying, which can potentially destroy some of the characteristics of the probiotic bacteria strains (Teixeira et al., 1997; Gardiner et al., 2000).
The nutritional and health benefits of goat milk are related to a number of medical problems of people foremost being food allergies with cow's milk proteins (Walker, 1964). Fermented dairy products, such as yogurts, fermented milk and cheeses are good delivery system for

probiotic bacteria. Nevertheless, cheese have higher pH, higher fat content, buffering capacity and solid matrix, so they protect probiotic bacteria more efficiently during the storage of the food and its passage thought the gastrointestinal tract (Kailasapathy and Chin, 2000; Vinderola et al., 2002). For these and many other reasons, there are numerous studies on various types of cheeses with probiotic bacteria, such as Cheddar cheese (Phillips et al., 2006), Turkish white cheese (Kasimoğlu et al., 2004), Cottage cheese (Heller, 2001), Caprine cheese (Gomes et al., 1998).
There is limited knowledge about soft cheese made from goat's milk with spray-dried probiotic bacterial strains. Therefore, the objective of this study was to determine viability of survival of potential spray-dried probiotic bacteria and commercial probiotic bacteria in soft cheeses made from goat milk during 56 days of storage, and their effect on chemical properties and sensory quality of cheeses.

MATERIAL AND METHODS

Probiotic bacteria strains

Potential probiotic strain used in this study *Lb. paracasei* 08, was isolated from traditionally made white brined cheese (Radulović, 2007). *Lb. paracasei* 08 was selected taking into account its technological and probiotic potential properties which are tested by Radulović et al. (2010, 2011). Commercial probiotic strains used in study is lyophilized *Lb. acidophilus* LA-5 (Chr Hansen, Denmark).

Spray-drying conditions

Spray-drying test were performed using the method of Petrović (2011). Overnight culture of *Lb. paracasei* 08 (300ml) was centrifuged (4500 x g, 15min, 15˚C). The pellet was washed twice in 50mM K_2HPO_4 (pH 6.5) and resuspended in 300ml of the sterile reconstituted skim milk (20% w/v). Inoculated sterile reconstituted skim milk was spray-dried with a laboratoryscale spray-dryer (model B-290 Buchi mini spray dryer, Switzerland), using a constant inlet air temperature of 170˚C and outlet temperature 80˚C.

Cheese production

Milk was pasteurized at 85°C for 10 min. After the milk was cooled to 30°C, it was divided into three equal parts. Control batch (C1) was produced using commercial starter culture mix CHN 11 *Lactococcus lactis* and *Lactococcus cremoris* (Chr. Hansen, Denmark). Test batches C2 contained starter culture CHN 11 + spray-dried potential probiotic strain *Lb. paracasei* 08, while test batch C3 contained starter culture CHN 11 + commercial probiotic strain *Lb. acidophilus* LA-5. Each batch was inoculated with starter cultures (1mL/100mL), after which potential and commercial probiotic strains were added in order to reach 7 log $cfug^{-1}$. After the cultures addition, solution of rennet (Sacco Clarifici, Italia) was added in concentration of 0.5g/100 L^{-1} to each batch. Fermentation lasted for 15 hours. After fermentation, cheeses were cut into small cubes, placed in sterilized cotton cheese cloth, and allowed to drain for 10 hours at 15°C. After draining, the cheeses were salted with 1% of NaCl and packed in individual plastic cups. Cheeses were stored under refrigeration temperature at 4°C for 56 days. Sampling was carried out on storage days 1, 7, 21, 35 and 56 day for microbiology analysis and on 7 and 21 day for chemical and sensory analysis.

Microbiological analysis

From each cheese variant, 10 g of cheese were weighed aseptically and transferred into an sterile Stomacher bag under aseptic conditions and homogenized in 90 ml of sterile sodium citrate 2% (w/v) for 5 minutes using Lab Blender 400 stomacher (Seward, London, UK). Appropriate decimal dilutions of the samples were prepared using the same diluents and plated on different growth media. Starter bacteria counts were determined on M17 agar (Oxoid, CM 785) aerobically at 30°C for 48 h. Potential probiotic strain *Lb. paracasei* 08 was enumerated on MRS agar (Oxoid, CM 361) and incubated anaerobically (Gas Pak, BBL,

Germany) for 48 h on 37°C. Colonies of this strain was different from NSLAB as specific mucoid colonies which were EPS positive. This characteristic was determined in previously studies (unpublished data). Commercial probiotic strain *Lb. acidophilus* was enumerated on MRSiM agar with addition of maltose dilution (200g/l) and incubated anaerobically (Gas Pak, BBL, Germany) on 37°C for 48 h. Microbiological data were transformed into logarithms of the number of colony-forming units ($cfug^{-1}$).

Chemical analysis

Cheese samples were analyzed for the determination of total solid content according to the IDF standard method (1982), fat content according to Van Gulik butyrometers methods (IDF, 1986) and determination of nitrogen content were analyzed according to the IDF standard method (2002). The pH value of cheese slurry was measured by a pH meter (Consort, Belgium).

Sensory analysis

Sensory analysis of all variants of chesses, were conducted after 7 and 21 days of storage. Five panel members, selected and trained for sensory analysis on Faculty of Agriculture, University of Belgrade, evaluated cheese for exterior and interior appearance, body and texture, and flavour (odour and taste) using 5-point scale, with 1 being the worst and 5 the best quality. Depending on the importance of attributes, they were multiplied by 3, 7 and 10, respectively. The total sensory quality (100) was expressed as a percentage of the maximum quality.

RESULTS AND DISCUSSION

The viability of potential probiotic *Lb. paracasei* 08 and commercial probiotic *Lb. acidophilus* LA-5 are shown in Figure 1.

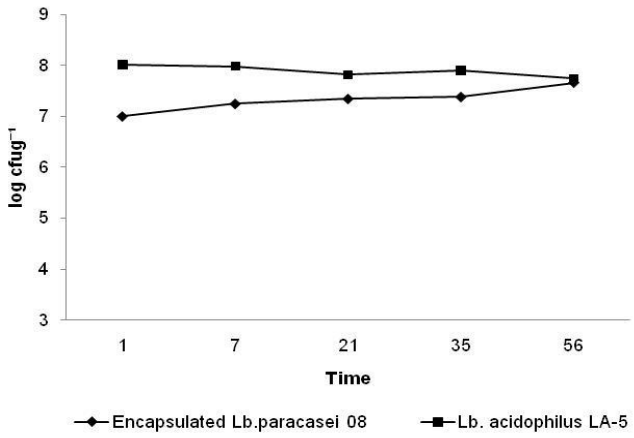

Figure 1. Survival of potential spray-dried and commercial probiotic bacteria during storage

At the first day of storage, potential spray-dried probiotic strain *Lb. paracasei* 08 count was 7 log cfu g^{-1} and after 56 days it was 7.69 log cfu g^{-1}. *Lb. acidophilus* LA-5 count was 8.01 log cfu g^{-1} in the first day of storage, and 7.04 log cfu g^{-1} after 56 days of storage. It is recommended that the minimal concentration of probiotic in food should be 10^7 cfu/g at the moment of intake to assure a favorable impact on a consumer's helath (De Vuyst, 2000). Furthermore, these results are in accordance with studies by Gardiner et al. (2002), who added spray-dried *Lactobacillus paracasei* NFBC 338 in Cheddar cheese.

The number of starter lactococci in cheeses during storage is shown in Figure 2. There is no significant difference between C1, C2 and C3 cheeses for starter lactococci count during storage period.

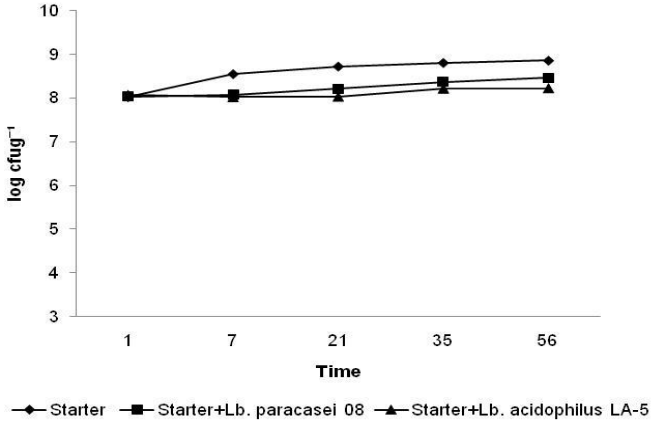

Figure 2. Starter bacteria count in cheeses during storage

Changes in chemical composition of cheeses are shown in Table 1.

Table 1. Chemical composition of cheeses during storage

Parameters	Dry matter (%)	Fat (%)	Protein (%)
Day 7			
Cheese C1	25.37	10.50	7.76
Cheese C2	24.25	9.00	7.50
Cheese C3	24.89	9.50	7.75
Day 21			
Cheese C1	25.24	12.00	7.03
Cheese C2	24.24	12.00	7.80
Cheese C3	24.89	12.00	7.65

After 7 day of storage, all variants of cheeses had similar dry mater content (24-25%). At the beginning of storage, there were some differences in fat content, but after 21 day of storage, all variants of cheeses had the same fat content (12%). Protein content in all variants of chesses was similar after 7 day of storage, but after 21 day of storage cheese C1 had some lower (7.03%), while cheeses C2 and C3 had higher protein content (7.80% and 7.65%).

Changes in pH values are shown in figure 3.

Initially pH ranged from 4.08 and 4.09 for cheeses C1 and C2, and 4.16 for cheese C3. At the end of storage, cheese variants reached their minimum pH values of 3.75-3.81. There is no significance difference in chemical composition between control cheese with starter culture (C1) and cheeses with added probiotic strains (C2 and C3).

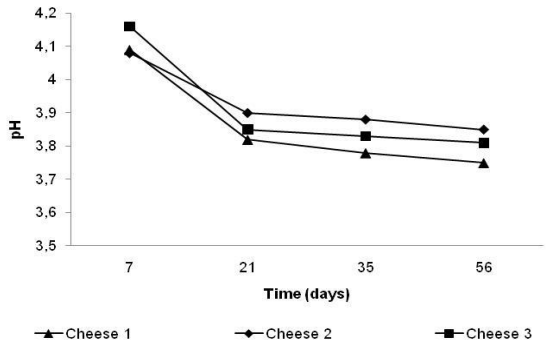

Figure 3. Changes in pH values of cheese during storage

Table 2. The sensory evaluation of cheeses

Sensory attributes*		Exterior and Interior Appearance		Body and texture		Flavor and odour		% Maximum quality
Cheeses	Time (days)	R*	W*	R*	W*	R*	W*	
Cheese 1	7	4.9	14.70	4.9	34.30	4.5	45.00	94.00
	21	5.0	15.00	5.0	35.00	4.2	42.00	92.00
Cheese 2	7	4.88	14,63	5,00	35,00	5,00	50,00	99,63
	21	5.00	15.00	4,80	33,60	4,10	41,00	89,60
Cheese 3	7	4.88	14.64	4.88	34.16	3.75	37.50	86.30
	21	5.0	15.00	4.80	33.60	2.8	28.00	76.60

**R-rating (mean value); W-weighted (mean value multiplied with coefficient): Appearance 3; Body and texture 7; Flavour and odour 10*

The results of sensory analysis are shown in table 2. Cheese samples were evaluated after 7 and 21 day of storage.
After 7 day of storage, all cheese samples were grated high for every parameter of sensor quality. However, cheese C3 with commercial probiotic *Lb. acidophilus* LA-5, received lower grades for flavour. After 21 day of storage, all variants of cheeses were similar grated for exterior and interior appearance and for body and texture, but there were some difference in flavour grades. Cheese C2 with potential spray-dried probiotic *Lb. paracasei* 08 was similar graded as control variant, while cheese with commercial probiotic *Lb. acidophilus* LA-5 had the lowest grade for flavour (2.8). All variants were grated as acceptable.

CONCLUSIONS

The current study showed that spray-dried potential probiotic *Lb. paracasei* 08 and commercial probiotic *Lb. acidophilus* LA-5 can be successfully used as adjunct cultures in production of probiotic soft cheeses made from goat's milk. Probiotic strains maintained viability of > 7 log cfu g^{-1} during storage period. There were no significante differences in starter bacteria count. Chemical composition and pH values were similar between control cheese and probiotic cheeses. In sensory analysis both probiotic cheeses received high scores, but better aroma, taste and texture were detected in cheese with spray-dried potential probiotic bacteria *Lb. paracasei* 08. These results indicate that autochthonous potential spray-dried probiotic strain *Lb. paracasei* 08 is suitable for development of an acceptable probiotic soft goat cheeses as new functional product.

ABSTRACT: During espresso coffee preparation large amounts of spent coffee residues are produced and discarded daily as a part of the communal waste. However, there is a great potential in recycling this type of waste for extraction of natural antioxidants and manufacture of dietary supplements. The aim of this study was to investigate the effect of fermentation on the antioxidant properties of spent coffee extracts. Six series of spent espresso-type coffee samples were inoculated with selected natural strains of Streptomyces sp. The solid state-fermentation was carried out at 30°C five days. Aqueous extracts have been prepared and evaporated in the spray-dryer. The total polyphenol content was determined by Folin-Ciocalteu method and the antioxidant activity by two methods: inhibition DPPH (2,2-diphenyil-1-picrylhidrazyl) radicals and FRAP (Ferric Reducing Antioxidant Power). Inhibition of DPPH radicals was expressed as IC_{50} value. Results were compared to those of nonfermented control sample. Fermentation of spent coffee with these cultures have resulted in increased contents of polyphenols. Also, both methods have confirmed increased antioxidative activity in certain samples depending on the selected strains. It was therefore concluded that fermentation of spent coffee with *Streptomyces* sp. cultures have improved its antioxidative properties which presents a potential for its application in pharmaceutical and food industry.
Key words: *spent coffee, fermentation, Streptomyces sp., antioxidant activity, polyphenols*

INTRODUCTION

The coffee tree belongs to the family *Rubiaceae*. There are about 70 different coffee species, but only two of these are commercially explored worldwide: *Coffea arabica* (Arabica) and *Coffea canephora* (Robusta) (Mussatto et al., 2011).
Coffee is one of the most popular beverages consumed by millions of people every day. Some studies have shown that consuming coffee has certain benefits on human health, so it manifests strong antioxidant and anti-tumor activity and limited anti-inflammatory and anti-allergic (Ramalakshmi et al., 2009). These properties are determined directly by the composition of coffee. Roasted coffee is composed by carbohydrates (38–42% dry basis), melanoidins (23%), lipids (11–17%), proteins (10%), minerals (4.5–4.7%), chlorogenic acid (2.7–3.1%), aliphatic acids (2.4–2.5%), caffeine (1.3–2.4%) (Esquivel and Jiménez, 2011). The beverage is very well known for the antioxidant properties of its components - polyphenols and phenolic acids, particularly chlorogenic acid, which is about 56 ±11% total polyphenols (Naidu et al., 2008).
During the production of consumer coffee a large amounts of waste are obtained. Due to the presence of organic material, spent coffee residues are highly pollutant residues, and represent a pollution hazard if discharged into the environment. Despite this negative characteristic, there are few studies focusing on their use in different and profitable applications. Many attempts have been made to use coffee waste as fertilizer, animal feed or as fuel (Saenger et al., 2001; Silva et al., 1998; Pandey et al., 2000).
Waste coffee, prepared from espresso coffee, is very appropriate for exploitation as raw material in the production of biologically valuable ingredients under solid-state fermentation (SSF) conditions. The most commonly used microorganisms for fermentation of coffee residue are filamentous fungi (Machado et al., 2012; Nava et al., 2006; Arellano-González et

al., 2011) but it is also reported the use of *Streptomyces* sp. (Orozco et al., 2008). *Streptomyces* are Gram-positive soil bacteria that are able to degrade many macromolecules such as proteins, cellulose, starch, lipids, and chitin. For the degradation of cellulose, hemicellulose, and lignin that are abundant in coffee, different strains of *Streptomyces* sp. have been studied and found to be good producers of cellulases (Jang and Chen, 2003).
The aim of this study was to investigate the effect of fermentation of selected natural strains of *Streptomyces* sp. on the antioxidant properties of spent coffee extracts for its possible application in pharmaceutical and food industry.

MATERIAL AND METHODS

Bacterial strains

Five isolates of *Streptomyces* sp. obtained from the forest (coniferous) land sample were selected for this investigation. All isolates showed a cellulolitic activity, as determinated by the method of staining iodine on CMC agar (Kasana et al., 2008) and morphological properties characteristic for the species *Streptomyces* (Kampfer,2006). By addition, three isolates (CKS 5, CKS 8 and CKS 18) produce extracellular, dark brown pigment, melanin. The strains were routinely grown on ISP1 broth medium (pancreatic digest of casein 5.0g/l; yeast extract 3.0 g/l) at 30 °C until sporulation occurred (5-7 days).

Substrate for fermentation

Spent coffee residues produced after espresso coffee ("Cream coffee" Italia) preparation were used as a substrate for fermentation. Spent coffee was dried in a thermostat at 44 ºC, 48 hours, until the moisture content of about 10%. 50 ml of distilled water was added into 300 ml Erlenmeyer flasks with 30 g (dry matter) prepared spent coffee and samples were sterilized in an autoclave, under standard conditions. After sterilization, prepared samples were cooled to room temperature and inoculated with 10 ml *Streptomyces* pellet suspension (previously grown 5 days at 30 ºC, with stirring, 150 rpm/min). All samples plus the control (without *Streptomyces*) were incubated at 30 ºC for 3 days.

Preparation of coffee extracts

After completing the period of fermentation, 100 ml of distilled water were added to samples and extraction was performed on a magnetic stirrer, at room temperature for 2 hours. After extraction, centrifugation was performed (10 minutes, 4500 rpm/min). Supernatant was separated and the residue was subjected to re-extraction, under the same conditions. The obtained supernatant was added to the above and a total volume of liquid extract was adjusted to 300 ml, to determine the total dry matter. Thus prepared extracts were stored in a refrigerator (4ºC).
Drying of prepared liquid extract was performed on the spray-dryer (Büchi). Spray drying conditions were: inlet (the default) temperature of 170 ºC and the outlet (the temperature of the sample) of about 80 ºC. The obtained powder samples were used for further analysis.

Determination of total polyphenols content

Total polyphenol content of powdered coffee extracts was determined using the Folin–Ciocalteu method (Djordjevic et al., 2009; Lee et al., 1998), with slight modifications. Powdered extracts were dissolved in distilled water at a concentration of 10 mg dry matter/ml. 500 μl of Folin – Ciocalteu´s reagent and 6 ml of distilled water were added in 100 μl appropriately dissolved extracts. After that, 2 ml of 15 % sodium carbonate solution was added and the whole solution was adjusted to 10 ml with distilled water. Absorbance was measured after 2 h at 750 nm in a spectrophotometer UV/VIS ultrospec 3300 pro (Amersham Bioscience). As a standard curve was used a solution of gallic acid and the results were expressed as mg of gallic acid (GA) per gram of dry matter extract.

DPPH radical scavenging activity

Free radical scavenging activity was measured by 1,1- diphenyl-2-picrylhydrazyl (DPPH) by method of Lee et al. (1998). Powdered coffee extracts were dissolved in distilled water at certain concentrations. 50 µl of extracts at different concentrations were taken in different test tubes. The volume was adjusted to 4 ml by adding MeOH and so the concentrations of extracts obtained from 1 µg/ml, 2 µg/ml, 5 µg/ml, 10 µg/ml, 20 µg/ml and 50 µg/ml. One milliliter of 0.1 mM methanolic solution of DPPH was added to these tubes and shaken vigorously. The tubes were allowed to stand at room temperature for 30 min in the dark. Absorbance was measured at 517 nm. Pure methanol was used for the baseline correction and distilled water (50 µl) as a control sample. Results were expressed as the inhibition percentage and were calculated using the following formula:

$$Inhibition = \frac{Ac - As}{Ac} \cdot 100\%$$

Ac = Control absorbance, *As* = Sample absorbance.

IC_{50} values (concentration of sample requires to inhibit 50 % of the initial amount of DPPH radicals) were calculated by using Origin Pro 7.

Reducing power assay (FRAP)

FRAP method is based on the ability of water soluble phenolic substances to reduce Fe^{3+} to Fe^{2+}. The resulting Fe^{2+} with TPTZ reagent (2,4,6-tri(2-pyridyl)-s-triazine) creates complex with maximum absorption at 593 nm. The reaction occurs in acidic conditions (pH 3,6). The method was performed according to standard procedure described by Benzie and Strain (1996) with slight modifications. Dry extracts were diluted with water to a concentration of 1 mg/ml. 150 µl of dissolved sample was added in 4,5 ml FRAP solution consisting of 25 ml of acetate buffer (pH 3,6), 2,5 ml of TPTZ solution (10 mmol) in HCl solution (40 mmol) and 2,5 ml of $FeCl_3*6H_2O$ solution (20 mmol). Absorbance was measured after 5 min at 593 nm and results were expressed as mmol Fe^{2+} per liter of the extract solution. Freshly prepared solution of $FeSO_4*7H_2O$ of different concentrations (200, 400, 600, 800 i 1000 µmol/l) was used for the standard curve constructing.

Statistical analysis

Statistical analyses were performed in Origin pro 8. All the analyses were carried out in triplicate, and the results are shown as mean value and standard deviation. The data were analyzed by analysis of variance (one-way ANOVA), and were compared by Tukey's difference test; the 1% level being used to determine the significance.

RESULTS AND DISCUSSION

In the recent years there is an increased interest in obtaining polyphenolic antioxidants from spent coffee residues (Mussatto et al., 2011; Murthy and Naidu, 2012). However, the number of available information on the application of fermentation to enhance biological activity of spent coffee extracts is still limited.

Orozco et al. (2008) examined the influence of fermentation by different strains of *Streptomyces* sp. on the polyphenol content in the waste coffee pulp. They concluded that some strains of *Streptomyces* reduce polyphenol content up to 30,5 %, which improves the properties of waste pulp for use as animal feed.

The coffee pulp fermentation by strains of fungi *Aspergillus tamarii* was reported by Arellano-Gonzalez et al. (2011). A solid-state fermentation was applied and extraction was performed by aqueous methanol. It was found that the total polyphenol content does not differ significantly between fermented and nonfermented samples. However, fermentation increased the concentration of free polyphenols in relation to the covalently linked polyphenols, especially free hydroxicinamic acid which led to increased antioxidant activity of fermented samples. Machado et al. (2012) investigated the possibility of coffee waste solid-state fermentation by different strains of fungi (*Aspergillus*, *Mucor*, *Penicillium*, and *Neurospora*) and their influence on the concentration of released polyphenols. It was found

that this type of fermentation could be promising method for obtaining polyphenols without using of chemical solvents.
In our work, spent coffee extracts fermented by different strains of *Streptomyces* sp. was used to determine their effect on yield, content of polyphenols and antioxidant activity of obtained extracts. Extraction yield is expressed as a percentage (g dry matter of obtained extract per 100 g dry matter of spent espresso coffee) and total polyphenol content is expressed as mg GA per g dry matter of the extract. DPPH radical scavenging activity was expressed by IC_{50} values (μg / ml), while the FRAP values are expressed in mmol / l of extract solution (concentration 1 mg / ml). The results of these determinations are summarized in Table 1.

Table 1 Total polyphenol content and IC_{50} values in coffee extracts samples

Sample	Yield (%)	Total polyphenol content (mg GAE*/g d.m.)	IC_{50} (μg/ml)	FRAP values (mmol Fe^{2+}/l) **
Control	3.657	89,35±0,19 [a]	24.81±0.22 [a]	1.31±0.03
CKS1	5.150	86,01±0,14 [b]	32.82±0.17 [b]	1.22±0.03
CKS5	4.187	94,27±0,11 [c]	24.57±0.08 [a]	1.42±0.11
CKS7	5.006	89,72±0,14 [a]	27.73±0.12 [c]	1.41±0.21
CKS8	4.208	88,67±0,15 [d]	25.09±0.13 [a]	1.25±0.08
CKS18	4.780	99,93±0,14 [e]	23.54±0.09 [d]	1.50±0.11

*GAE – gallic acid equivalents
** Sample concentration is 1 mg/ml
Results are expressed as the mean value±standard deviation on dry matter basis;
[a, b, c] the same letter indicates no significant difference ($p<0.01$)

According to the obtained results, fermentation increases the total yield of extraction in all samples. However, total polyphenol content and antioxidant activity are strain depended. Fermentation by *Streptomyces* strains CKS 5, CKS 7 and CKS 18 increase the polyphenol content, compared to the nonfermented control sample. On the other hand, coffee samples fermented by strains CKS 1 and CKS 8 showed a decrease in polyphenol content, compared to the nonfermented control sample. It should be noted that the higher content of polyphenols was detected in samples obtained by strains which produce dark brown pigment (probably melanin) in growth medium. It is known that some strains of *Streptomyces* produce melanins, which show different biological properties including antioxidant (Diraviyam et al., 2011). Thus, the presence of melanin could be the reason of increasing of polyphenols in extracts of fermented spent coffee.

CONCLUSIONS

Spent coffee produced during espresso coffee preparation contain significant amounts of biologically valuable ingredients which may be a good source of natural antioxidants. Our results indicate that fermentation of spent coffee by *Streptomyces* strains could be useful for modulating its biological properties. Some strains increase the content of total polyphenols in the extracts and their antioxidant properties respectively. These strains could be applied to obtain dietary supplements with antioxidant activity. On the other hand, some strains affect the reduction of total polyphenol content in spent coffee extracts, which can be used for their utilization as feed components. In any case, the spent coffee fermentation by selected strains of *Streptomyces* can help to improve the properties of final products and its potential application in the food and pharmaceutical industries.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR31035 “Application of biotechnological methods for sustainable exploitation of by-products of agro-industry” financed by the Ministry of Science and Technological Development, Republic of Serbia.

ABSTRACT: The purpose of this study was to encapsulate caffeine in alginate-chitosan cross-linked microparticles enriched with ascorbic acid by applying electrostatic extrusion technique. Three different forms of caffeine were encapsulated: liquid extract of caffeine from the plant guarana (*Paullinia cupana*), food-grade solid caffeine and analytical-grade caffeine. High performance liquid chromatography (HPLC-PDA) was used to evaluate the release kinetics of caffeine from microbeads in water, while the corresponding antioxidant capacity was evaluated by applying the ABTS radical scavenging assay. Scanning electron microscopy and laser diffraction particle size determination were used to provide information about the physical properties of microparticles. The microbeads encapsulating caffeine were uniformly sized spheres of about 600-800 μm. The encapsulation efficiency of all microparticles ranged between 70-80%. Caffeine was mainly released within 10-15 min, depending on the used caffeine form, while the ascorbic acid was relatively rapidly released from microbeads according to antioxidant capacity exhibited in water. The obtained results suggest that electrostatic extrusion can be applied for the entrapment of caffeine in alginate-chitosan microbeads, while the addition of ascorbic acid further enhances the antioxidant activity of such obtained microcapsules.
Key words: *alginate, antioxidant capacity, ascorbic acid, caffeine, chitosan, encapsulation*

INTRODUCTION

In the past decade, increased progress has been achieved towards the production of microencapsulated therapeutic products and formulations, and their commercialization. Micro- and nanoparticles have the potential to revolutionize food production and nutrition, and modify modern drugs and phytochemicals by increasing their efficacy, stability, and solubility, decreasing their toxicity and sustaining their release, thus enabling advanced pharmacological effects.

Food-based materials that are usually used as carriers for controlled drug-release include whey protein, gum arabic, gelatin, alginate, pectin and chitosan (Deyao et al., 1993; Wang et al., 2004; Gunasekaran et al., 2007; Joseph and Venkataram, 1995; Ramakrishnan et al., 2007). Alginate is a water-soluble linear polysaccharide, which forms gels in aqueous solutions in the presence of divalent ions, such as $Ca^{2+,}$ due to the creation of intermolecular cross-links with the carboxyl groups. However, the effectiveness of Ca^{2+} alginate microspheres as drug carriers is mainly limited by the hydrogel high porosity, responsible for possible burst effect or too fast release of the entrapped drug, as well as for low drug loading ability due to drug leakage through the pores during their preparation (Matricardi et al., 2008). Combination of Ca^{2+} alginate with chitosan, by interaction between the free carboxyl groups of the first and the amino groups of the second one, has proven to be a successful strategy not only to overcome these drawbacks, increasing the gel mechanical properties and reducing its permeability, but also to combine the favourable properties of both polymers, improving their ability as carriers for achieving a specific drug delivery (Matricardi et al., 2008; Wittaya-Areekul et al., 2006; Mladenovska et al., 2007).

Hydrogel beads are usually produced by a so called dropping method which consists of droplet formation by pumping of a solution through a needle and further solidification of the falling droplets in a hardening solution via counter ion exchange or thermic gelling. Most studies have been conducted with large alginate beads (2-3 mm) produced by droplet formation from a syringe under gravity or under coaxial air flow (Klein et al., 1983). The application of electrostatic extrusion for production of microparticles and entrapment of biologically active compounds has been investigated more extensively in recent years. This encapsulation technique introduces high electrostatic potentials between the needle and the hardening solution and thus greatly improves droplet formation and production of small beads (0.1-1 mm). Moreover, among different encapsulation techniques, electrostatic extrusion provides uniformly sized gel microbeads (Bugarski et al., 1993; Bugarski et al., 1994a; Bugarski et al., 1994b), with the advantage of forming small particles (≥ 50 μm)
In recent years, caffeine has received increasing attention in food and pharmaceutical industries, due to its pharmacological properties which comprise stimulation of the central nervous system, peripheral vasoconstriction, relaxation of the smooth muscle and myocardial stimulation (McLellan et al., 2005). The intake of caffeine by consumption of coffee, tea, cola and energy drinks is widely spread by consumers with the aim of overcoming sleep deprivation and enhancing sport performance. As caffeine absorption from the gastrointestinal tract is rapid and reaches 99% in humans about 45 min after ingestion (Blanchard and Sawers, 1983), efforts to control the release of caffeine after ingestion may be beneficial for food and nutraceutical applications. So far, attempts to entrap caffeine by microencapsulation have been conducted using combined cross-linking treatments of bovine serum albumin gel beadlets (Gan et al., 2009), hydrogenated and fluorinated gel emulsions and cubic phases (Fa et al., 2004) and concentrated W/O emulsions (Clément et al., 2000), while alginate-chitosan hydrogel has not been used yet as a carrier for encapsulation of caffeine performed. Therefore, in this study the electrostatic extrusion technique was applied to immobilize caffeine in alginate-chitosan cross-linked gel microbeads and, duration of release and the quantity of the drug released was examined.

MATERIALS AND METHODS

Preparation and characterization of alginate-chitosan microcapsules

Three different forms of caffeine were evaluated for immobilization in alginate-chitosan microbeads; liquid extract of caffeine obtained from the plant guarana (*Paullinia cupana*), solid caffeine isolated from a natural source for food purposes (Döhler, Darmstadt, Germany) and analytical standard of caffeine for drug analysis (Sigma Aldrich, USA). Alginate solution (1,5% w/v) was prepared by dissolving a low viscosity sodium alginate Protanal LF 20/40 (purchased from FMC Biopolymer) in previously prepared caffeine solutions in water (2% (v/v) of liquid guarana extract, 2% (w/v) of solid caffeine for food purposes and 3% (w/v) of analytical standard of caffeine. Each mixture was well homogenized and drawn into a 5 ml syringe attached to 23-gauge metal needle with a blunt tip. The syringe was placed in a syringe pump (Razel, Scientific Instruments, Stamford, CT) and a high voltage dc unit (Model 30R, Bertan Associates, Inc., New York) was applied to control the potential difference. The solution was extruded at a voltage of 6.3 kV and flow rate of 25.2 cm^3/h to a receiving beaker containing cross-linking solution which was constituted of 50 ml 2% (w/v) calcium chloride solution, 0.5% (w/v) chitosan (molecular weight: 100 000-300 000) and 2% (w/v) of ascorbic acid dissolved in the previously prepared caffeine solutions (the final pH of receiving solutions was 2.65). The microparticles were left in the solution for 24h and then washed several times with the respective caffeine solution.
Shape and surface morphology of microspheres were examined using a FEI Quanta200™ environmental scanning electron microscope (ESEM), with a spatial resolution at 30 kV of 3 nm (FEI Company, Oregon, USA). Particle size of the obtained microparticles was determined using Mastersizer 2000 (Malvern Instruments, Worcestershire, UK) equipped with the Hydro 2000S dispersion unit.

Encapsulation efficiency
The amount of caffeine entrapped in the microparticles was estimated by dissolving a known amount of capsules in sodium citrate (2% w/v) during 60 min by vigorous shaking on a Vortex mixer (Tehnica, Železniki, Slovenia) at room temperature. The content of caffeine loaded in the beads was determined by a HPLC method described by Belščak-Cvitanović et al. (2011). The percentage of encapsulation efficiency was calculated according to the following equation:

$$\text{Encapsulation efficiency (\%)} = \frac{A}{A_0} \times 100$$

where A is the caffeine content determined after destabilization of the microparticles with the sodium citrate solution and A_0 is the caffeine content of the initial extract.

Release kinetics in water
The release of caffeine from the alginate-chitosan microbeads in water was followed in terms of quantifying the caffeine content by HPLC analysis and determination of antioxidant capacity by using the ABTS assay (described in the following section). For the analysis a known amount of particles (~ 3g) was suspended in 50 mL of distilled water. The samples were submitted to continuous agitation on an orbital shaker (New Brunswick Scientific Co., Inc., Edison, NJ) operating at 100 rpm. At certain time intervals, an aliquot of the supernatant was taken for analysis and replaced by the same amount of fresh distilled water. The experiments were performed in triplicate.

Determination of antioxidant capacity
The Trolox equivalent antioxidant capacity (TEAC) was estimated by the ABTS radical cation decolorization assay (Re et al., 1999). The results, obtained from triplicate analyses, were expressed as Trolox equivalents, and derived from a calibration curve determined for this standard (100-1000 µM).

RESULTS AND DISCUSSION

Table 1 shows the encapsulation efficiency of caffeine in alginate-chitosan microbeads. The highest encapsulation efficiency was obtained by using liquid extract of caffeine derived from guarana (81.50%), while the lowest was observed for 3% solution of standard of caffeine (71.61%).

Table 1. Encapsulation efficiencies and particle size of alginate-chitosan microbeads encapsulating three different caffeine forms.

	2% guarana caffeine	**2% food caffeine**	**3% standard caffeine**
Encapsulation efficiency (%)	81.50 ± 2.48	76.45 ± 3.25	71.61 ± 4.52
Particle size range (µm)	620 – 750	670 - 750	700-850

Results are given as mean ± standard deviation (n = 3)

As it can be seen, the encapsulation efficiency is on average 79% when 2% caffeine is encapsulated in microbeads, and ~76% in case of caffeine standard which is added in 3%. Particle size of the microbeads was inversely related to the encapsulation efficiency: the microbeads encapsulating 2% of guarana caffeine exhibited the lowest particle size, while the microbeads encapsulating 3% of standard of caffeine were the largest. Namely, caffeine exhibits moderate solubility in water (about 2g/100ml at room temperature), and when 3% solution of caffeine was used for the preparation of microbeads, saturation was achieved, followed by crystallization of caffeine. The outcome of this process was the presence of caffeine crystals which may have resulted with larger particles and lower encapsulation

performance. This can also be observed on SEM micrographs of the produced microbeads shown in figure 1. The microbeads encapsulating 2% guarana caffeine were round, while the microbeads obtained from the dissolved caffeine were irregular in shape (2% of food caffeine) or aggregated (3% of standard of caffeine).

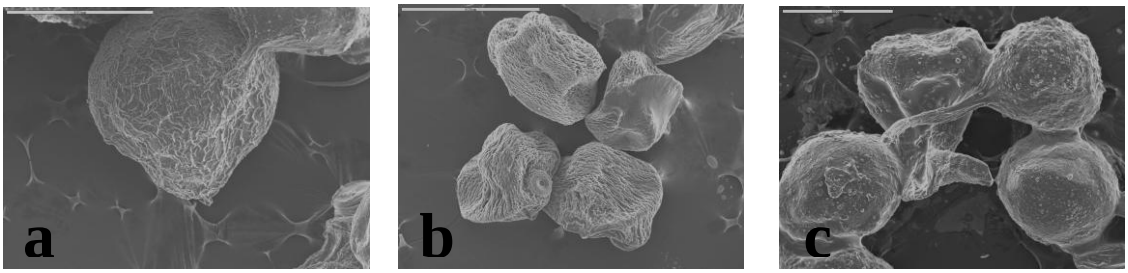

Figure 1. SEM micrographs of alginate-chitosan microbeads encapsulating a) 2% guarana caffeine, b) 2% food purposes caffeine and c) 3% of caffeine standard.

Release of the entrapped caffeine from alginate-chitosan microbeads also depended on the caffeine form and concentration. As it can be seen, the major content of caffeine contained in the microbeads was released within the first 10-15 minutes from microbeads encapsulating 2% of guarana caffeine and 3% of caffeine standard, followed by prolonged release of the rest, up to 24h (figure 2). Surprisingly, the microbeads encapsulating 2% of caffeine for food purposes exhibited a very rapid release of caffeine in water and after 2 min, the concentration of caffeine reached a steady state.
However, despite the rapid release of caffeine, it was observed that the amount of caffeine released from the microbeads was notably lower compared to the other two encapsulated caffeine forms. Poor diffusion of food-grade caffeine indicates the potential of using alginate-chitosan for the encapsulation of caffeine for food purposes, since it enables better retention of caffeine.

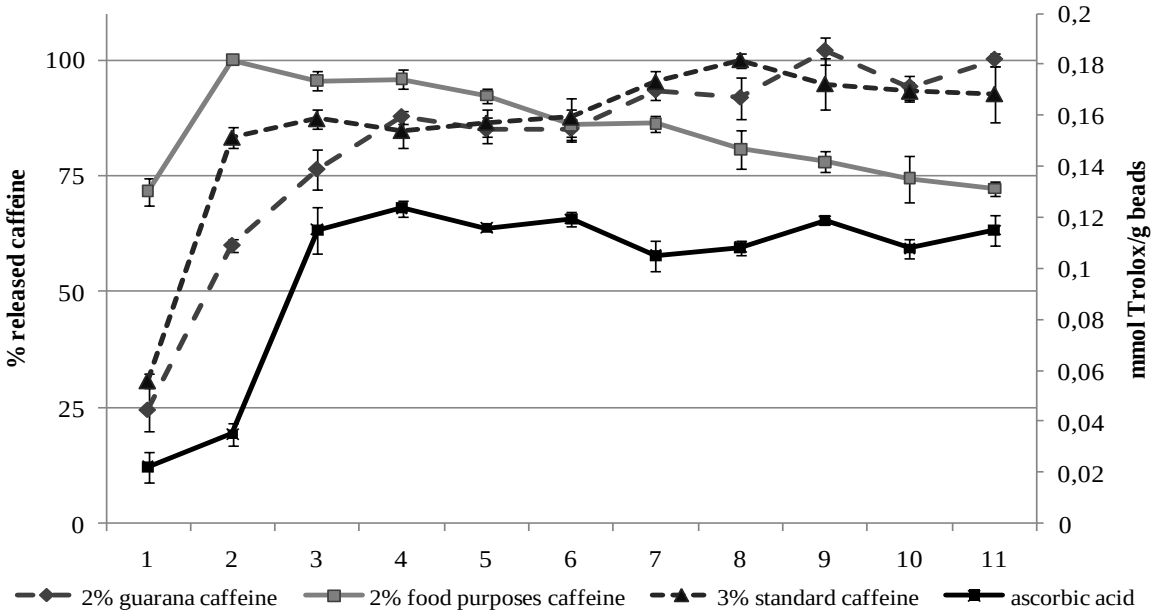

Figure 2. Release profile of caffeine and antioxidant capacity of ascorbic acid from the alginate-chitosan microparticles.

Kinetics of ascorbic acid release was followed in terms of antioxidant capacity detected in water as a function of time (figure 2). Ascorbic acid was used in order to ensure low pH necessary for the dissolution of chitosan, which additionally enhanced the bioactivity and antioxidant capacity of obtained microparticles. Alginate-chitosan cross-linked microbeads

enhanced with ascorbic acid are already approved as suitable for encapsulation of polyphenols derived from different medicinal plants (Belščak-Cvitanović et al., 2011). According to the results, the microbeads obtained in this study exhibited significant antioxidant capacity, and release of caffeine occurred simultaneously with the release of ascorbic acid which ended within 5 min.

CONCLUSIONS

Alginate-chitosan crosslinked microparticles obtained by electrostatic extrusion can be used for the encapsulation of caffeine regardless of the caffeine origin and concentration. High encapsulation efficiency of caffeine was obtained for all caffeine forms, while caffeine for food purposes was retained in the highest amount in the particles when subjected to release in water. The evaluated combination of encapsulating agents provides a potentially effective way to entrap caffeine and exhibit antioxidant capacity due to applied ascorbic acid.

ABSTRACT: Liposomes have been shown to be suitable systems for encapsulation and preserving the health–beneficial properties of a wide range of biological active ingredients such as resveratrol (RSV). The aim of this study was to encapsulate RSV in liposomes, with a goal to achieve the extended release and improved stability of RSV. Multilameral liposomes were prepared by means of two different methods: thin film method (TF) and proliposome method (PRO). In both methods, the ratio between added RSV and phospolipon 90G (P90G) was 1:20 w/w. Extrusion and sonication were applied in order to obtain unilameral liposomes. Both methods were efficient in capturing RSV within the microparticles, thus encapsulation efficiency had high values (92,9% in case of TF and 97,4% in case of PRO). The size reduction of liposomes resulted with particles of the average diameter ranged between 120 and 270 nm. Antioxidative activity was retained at a high level (approximately 95%). Franz diffusion cell was used for release studies and diffusion of RSV was monitored for 6h. According to the results, liposomes appeared to be suitable vehicles for encapsulation of resveratrol where PRO is particularly useful for encapsulation of antioxidants.
Key words: *encapsulation, liposome, resveratrol, release study*

INTRODUCTION

Antioxidants have been widely used as food additives to provide protection against oxidative degradation of foods. They can scavenge free radicals and slow down the process of lipid peroxidation. Antioxidants can also protect human body from free radicals and block the progress of many different chronic diseases (Aruoma et al., 1998). RSV has been shown to possess a remarkably strong antioxidant activity, even stronger than vitamins E and C in some assay systems (Stojanović et al., 2001). It exists in two structural isomeric forms, *cis* and *trans*, but the *trans*-resveratrol is more active than the *cis* isomer (King et al., 2006).

At least 72 plant species contain RSV and it is known that plants produce RSV in response to different kinds of stress factors (Jang et al., 1997). The primary dietary sources of RSV in human diet are peanuts, berries, grapes and wine but it is also reported that coco and chocolate contain RSV too (Counet et al., 2006). It is considered that increased consumption of food which contains RSV may improve health. Some authors have presented that RSV displays wide pharmacological activities such as antioxidant, anti-inflammatory, analgesic, cardioprotective, neuroprotective, chemo-preventive and antiaging activities (Baur and Sinclair, 2006).

Though, this positive effect of RSV is very restricted because RSV is easily oxidizable and photosensitive compound (Pineiro et al., 2006). Furthermore, RSV is highly lipophilic, poor soluble in water and has rapid metabolism, thus it is very hard to use RSV in native form as a food additive or food supplement (Walle et al., 2004; Lopez-Nicolas et al., 2006). All this drawbacks of RSV can be overcome to some extent by microencapsulation.

Liposomes approved to be suitable vehicles for encapsulation and delivery of wide variety of substances (Peschka et al., 1998; Gibbis et al., 1999). Liposomes are spherical particles, consisting of a membrane. The membrane is made up of phospholipid bilayer which is

similar to the lipid fraction of cell membranes. If liposomes have just one bilayer they are called small (<30 nm) or large (30–100 nm) unilamellar vesicles (SUV and LUV). Those which contain more than single bilayer membrane are called multilamellar vesicles (MLV)
The aim of this study was to encapsulate RSV in liposomes, with a goal to achieve the extended release and improved bioavailability of RSV. Furthermore, *in vitro* releasing properties of RSV was investigated to show potential of loaded liposomes to be used as an additive to functional food.

MATERILAS AND METHODS

Preparation of liposomes

P90G (phosphatidylcholine 92–98% pure, supplied by Natterman Phospholipids, Germany,) was used for liposome preparation. It provides liposomes which are highly bioavailable (Pjanović et al., 2010). Both, empty liposomes and liposomes loaded with RSV were prepared by two different methods.
The first method was thin film method (TF) and liposomes were prepared as follows: 1,4g of P90G, 0,6g of cholesterol (Cholesterol, Sigma–Aldrich, Sigma Grade, ≥99%) and 0,07g of RSV (Resveratrol, ChromaDex, California) were dissolved in ethanol in a round-bottomed flask (Lasch et al., 2003). The solvent was completely removed on a rotary vacuum evaporator (BUCHI Rotavapor R-114), at 45^{o}C and pressure of 175 mbar. The resulting film was further dried for 15 min and then hydrated by adding an aqueous phase (100 ml of distilled water). The dispersion was hand-shaken for 20 minutes. In the same way was prepared liposomal dispersion without RSV, used for computation.
The second method of liposomes preparation, PRO method, was derived according to literature data (Perrett et al., 1991) with slight modifications. A mixture of 2g P90G, 0,1g of RSV and ethanol was stirred and after adding a small quantity of distilled water, heated to 60 ^{O}C for a few minutes. After cooling to room temperature, aqueous phase (100 ml distilled water) was added in small parts. The suspension was stirred for one more hour at 800 rpm. In this case liposome dispersion without RSV was also prepared using the same procedure
All samples prepared as described above were MLV dispersions. In order to get LUV and liposomes with smaller diameter, two different techniques were applied: extrusion and sonication.
The extrusion technique is based on forced passes of dispersed phase containing MLV through a membrane with a uniform pore size distribution. These passages generate a homogeneous population of smaller vesicles (Gregoriadis, 2006). In this study 1ml of each sample was extruded 11 times through polycarbonate membranes with decreasing pore sizes (800 nm, 400 nm, 200 nm and at the end 100 nm) using the LiposoFast Basic extrusion device (Avestin, Ottawa, Canada).
Application of high-intensity ultrasound to liposome dispersions can result in formation of unilamellar vesicles (Gregoriadis, 2006). For this purpose a probe was directly immersed in 10 ml of each sample. Sonication was achieved with Ultrasonic Processor VCX 500 W (Cole Parmer, Vernon Hills, IL); amplitude was 40 % and duration 360s. During whole process samples were constantly cooled with ice (Lasch et al., 2003).

Size measurements and stability of liposome dispersions

The size of the liposomes (average diameter), polydispersity indexes (PDI) and zeta potential were determined by photon correlation spectroscopy using a Zetasizer Nano ZS (Malvern Instruments, Malvern, UK). Each sample was measured three times at room temperature and the average values were taken as results. The measurements were repeated on the 1st, 3rd, 7th, 14th and 21st day after preparation of dispersions in order to examine stability of the liposomes. The dispersions of liposomes were storage in the refrigerator at about 4°C.

Encapsulation efficiency
In order to determined encapsulation efficiency (EE%) samples were centrifuged at 45000 rpm for 45 minutes at 10°C in a Thermo Scientific Sorval WX Ultra series ultracentrifuge (Thermo Scientific, Waltham, MA). The amount of RSV in supernatant was defined spectrophotometrically at 306 nm. EE% was calculated as the amount of RSV encapsulated in liposomes divided by the amount of RSV used for their preparation as shown in Equation 1:

$$EE\% = [(m_i - m_{sup})/m_i] \times 100 \quad (1)$$

where m_i is amount of RSV used for the preparation of liposomes and m_{sup} is amount of RSV determined in supernatant.

Determination of free radical-scavenging activity (ABTS)
This method was used for measuring the relative ability of RSV to scavenge the free 2,2-azinobis-(3-ethylbenzthiazoline-6-sulfonic acid) radical cation (ABTS•). This radical was formed by mixing 5 mL of ABTS water stock solution and 88 µL of potassium persulfate. Before use, the mixture was incubated at room temperature in the dark for 12 to 16 h. On the day of analysis, the ABTS• solution was diluted with ethanol to achieve absorbance of 0.70 (±0.02) at 734 nm. A 4 µL aliquot of a sample was added to 4,5 mL of the prepared ABTS• solution and the absorbance was measured after 4 min. The inhibition of ABTS• was estimated based on the method of Re et al., 1999 with a slight modification and calculated by the following equation:

$$\% \text{ inhibition} = [A_0 - (A_1 - A_s)/A_0] \times 100 \quad (2)$$

where A_0 is the absorbance of the control solution (containing only ABTS), A_1 the absorbance of the sample and A_s is the decrease of the absorbance of ABTS• caused by blank sample.

Release study
Jacketed Franz diffusion cell (donation of PermeGear, Inc., USA) was used for release experiments. The cell contains the donor and the receptor section which were separated with an acetate-cellulose membrane (pore size 0,45 µm). Receptor section has a fixed volume (20 ml) and contains a magnetic stirrer. Before the start of the experiment, the cell was thermostated with receptor fluid (ethanol 50%) for 30 minutes. As a donor phase was used 1ml of liposome dispersions with RSV which were prepared as described above. During the experiment 0,5 mL of a sample was taken from the receptor section and the same volume of fresh fluid was added back. Each experiment lasted 6 hours and concentration of RSV was determined spectrophotometrically, measuring the absorbance at 306 nm.

RESULTS AND DISCUSSION

For easier discussion in the table 1 is given an overview of the abbreviations which are going to be used further in the text for sample names.

Table 1. Overview of the abbreviations

Method for liposome preparation	Technique applied for size reduction (LUV)	Empty samples	Samples with RSV
Thin film	/	TF-MLV	RSV-TF-MLV
	Extrusion	TF-100	RSV-TF-100
	Sonication	TF-SON	RSV-TF-SON
Proliposome	/	PRO-MLV	RSV-PRO-MLV
	Extrusion	PRO-100	RSV-PRO-100
	Sonication	PRO-SON	RSV-PRO-SON

Stability of the liposomes was monitored during 21 days and the size of the liposomes, polydispersity index and zeta potential were measured on the 1st, 3rd, 7th, 14th and 21st day after preparation. The results showed that liposomes were uniform and an average diameter depended on the technique used for liposome size reduction. PRO-MLV were almost five times smaller than TF-MLV (Figure 1). Liposomes which were reduced by sonication had average diameter between 120 and 290 nm (results are not shown). TF-100, RSV-TF-100, PRO-100 and RSV-PRO-100 had average diameter between 150 and 270 nm, but the one with RSV have shown slightly smaller average diameters then empty liposomes (Fig. 2). If one compares liposomes with and without RSV, obtained by the same method, it is apparent that RSV reduced the size of liposomes. PDI values of all samples were smaller than 0,7 which means that liposomes had fine size distribution, therefore a good quality (Caddeo et al., 2008). We notice that the extrusion technique enabled to get more homogeneous distribution of particles which was also confirmed by Budai et al., 2004. The zeta potential was negative for all samples and RSV did not have any influence on this parameter. The results show that liposomes were physically stable during 21 days of storage (significance was tested at the 0,05 levels of probability).

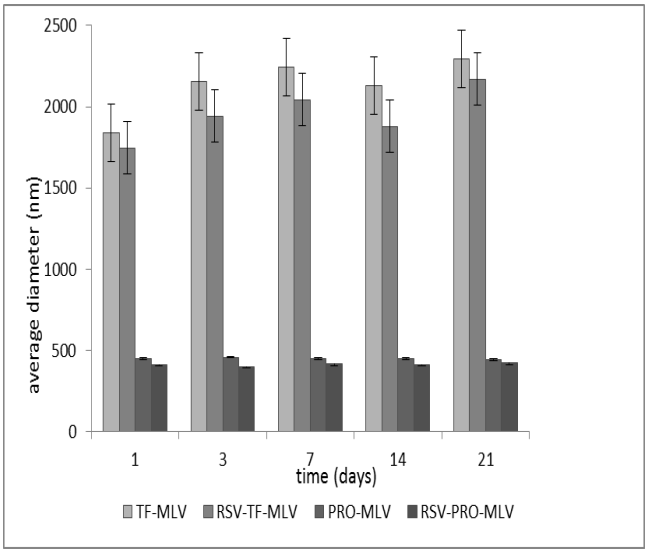

Figure 1. Average diameters of multilamelar liposomes during 21 days of storage, (error bars denote S.D., *n*=3)

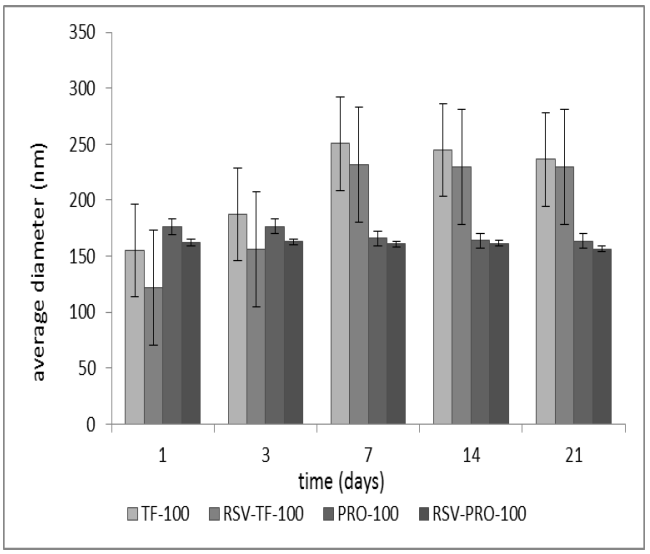

Figure 2. Average diameters of LUV liposomes obtained by extrusion technique during 21 days (error bars denote S.D., *n*=3)

The results of encapsulation efficiency of RSV in liposomes are shown in Table 2. As it can be seen, PRO method provided better EE% for MLV then TF method. The same result was noticeable for RSV-PRO-SON and RSV-PRO-100. The results suggest that during sonication there was significant loss of RSV, probably because of high shear forces on MLV, which caused disruption of the MLV structures and leakage of RSV from liposomes. The encapsulation efficiency of RSV in liposomes treated by extrusion through membranes was the same as for MLV (prior to extrusion). The results of encapsulation efficiency show great advantage of extrusion technique over the sonication

Table 2. Encapsulation efficiency (EE %) of RSV in liposomes and relative antioxidative capacity (RAC%) of RSV loaded liposomes to scavenge ABTS• free radical

Sample	Thin film method		Proliposome method	
	EE%	RAC%	EE%	RAC%
RSV-MLV	92,88±0,27	88,38±5,22	97,36±2,00	90,35±1,74
RSV-SON	44,22±1,26	38,86±1,46	55,88±2,81	40,07±4,27
RSV-100	92,27±0,82	96,55±1,17	96,08±0,62	94,66±0,57

Results are given as mean ± standard deviation (n = 3)

The relative antioxidative capacity of RSV is also given in Table 2. Dilution of RSV in ethanol was prepared in the same concentration as it was in liposomes samples and this solution (control sample) was also tested by the ABTS assay. Compared to control sample antioxidant activity of RSV was preserved at a high level. Only in case of LUV obtained by sonication technique relative antioxidative capacity of RSV was low. The reason for this result could be local overheating during sonication and loss of antioxidant activity of RSV at high temperatures.

The diffusion of RSV from liposomes was monitored during 6 hours using Franz diffusion cell. Solution of RSV in ethanol in appropriate concentration (control solution) was used for comparison. Four samples were chosen to be monitored (RSV-TF-MLV, RSV-PRO-MLV, RSV TF-100 and RSV-PRO-100) as they exhibited high EE% and consistent antioxidant activity. According to our results (Fig. 3) diffusion of RSV (from control solution) occurred rapidly and concentration of RSV in acceptor compartment reached maximum approximately after 100 minutes. RSV diffusion from liposomes was slower than diffusion of free RSV and RSV reached final concentration in acceptor compartment after more than 200 minutes. The results show that liposomes could be used for prolonged release of RSV which is important concern in real food applications. MLV liposomes were able to better retain RSV than LUV: in comparison after 100 min, ~50% of RSV was released from PRO-MLV and ~80 % from TF-100. This is directly related with size of the liposomes. Namely, MLV are of the one order larger than LUV (Fig. 1 and 2) and thus provide longer path for diffusion.

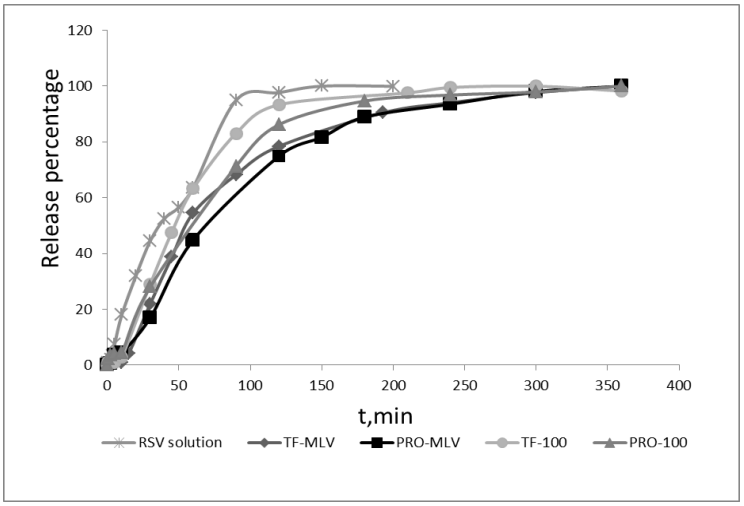

Figure 3. The diffusion of RSV from the solution and liposome dispersions

CONCLUSIONS

Two methods were used for preparation of RSV loaded liposomes: proliposome and thin film method. High encapsulation efficiency was achieved using both methods and the obtained liposomes were physically stabile during 21 days. According to the results, extrusion technique was shown as more suitable then sonication technique for size reduction of MLV. It also enabled more homogeneous distribution of liposomes. Antioxidative activity of RSV loaded in liposomes was retained at a high level. The diffusion experiments of RSV from liposomes indicated that liposomes could be used for prolonged release of RSV. Formulations based on proliposomes were easy for preparation and have shown good results, thus they are suggested as useful for encapsulation and controlled delivery of functional food ingredients.

ABSTRACT: The aim of this study was to investigate encapsulation processes of *Thymus serpyllum L.* aqueous extract in chitosan and alginate-chitosan microbeads and its consecutive release. Chitosan microbeads were prepared in water-in-oil (W/O) microemulsion, while alginate-chitosan microbeads were prepared by electrostatic extrusion. The outer surface of microbeads was observed by optical microscopy. The interaction between chitosan or alginate-chitosan microbeads and extract compounds were analyzed by FT-IR. Release profiles of polyphenolic compounds from the microbeads in water was monitored. Experimental results show that the applied methods gave chitosan and alginate-chitosan microbeads with an average diameter of 390 μm and 890 μm, respectively. FT-IR analyses confirmed the presence of polyphenolic extract within the synthetized microbeads. The encapsulation efficiency was determined with respect to total polyphenolic content. Chitosan microbeads showed lower encapsulation efficiency of ~10%, but prolonged release, compared to alginate–chitosan microbeads where encapsulation efficiency was ~70%. The uniformity of the obtained microbeads was confirmed by optical microscopy. This study showed that, by some synthesis modification of both, chitosan and alginate-chitosan microbeads have the potential to be used for encapsulation of aqueous phenolic extracts.
Key words: *encapsulation, alginate, chitosan, polyphenols, release study*

INTRODUCTION

One of the current focuses of the life science community is naturally derived antioxidants, especially plant polyphenols, which exhibit high antioxidant properties (Stojanovic et al., 2011). One of the popular herbs rich in polyphenols is thyme (*Thymus serpyllum L.*). A wide array of positive health effects has been described to plant polyphenols, such as antimicrobial properties and the ability to protect against cancer and cardiovascular diseases. Plant polyphenols are usually consumed by preparing a tea or herbal infusion through an aqueous extraction process. However, in this way active compounds can be easily affected by detrimental effects of oxygen, moisture or incompatible compounds during storage or consumption (Fang&Bhandari, 2010). This problem can be solved by applying the microencapsulation technology in order to improve the stability of extracted compounds during transport, storage or processing. Moreover, the goal is to achieve superior handling of the active compounds by conversion of liquid active compounds into solid forms, which in addition can be used as food additives or food supplements.
Among numerous entrapping materials used for the encapsulation of a targeted substance, sodium alginate and chitosan have received much attention in drug delivery system for their excellent biocompatibility (Xu et al., 2007). Among polyanionic polymers, alginate has been widely studied and applied for its possibility to modulate the release, according to the properties of its carboxyl groups as well as its biodegradability and absence of toxicity. Chitosan also has wide applications in pharmaceutical technology as tablet disintegrant, for

the production of controlled release solid dosages (Illum, 1998; Kas, 1997; Sezer&Akbuga, 1999) or for improving of drug dissolution (Gupta&RaviKumar, 2000). Much attention has been given to the use of chitosan-alginate polyelectrolyte complex in controlled drug delivery (Lee&Park, 1996). The use of chitosan has been reported in the literature for coating alginate beads in order to control the diffusion rate of the encapsulated substances and also as an additive for the bulk modification of the bead structure (Anal&Stevens, 2005).
In this study, alginate-chitosan and chitosan microbeads were used for encapsulation of polyphenolic extract of *Thymus serpyllum L.* The release profile of encapsulated polyphenols from both types of microbeads was monitored and compared. The microbeads size, as well as the morphology and the interactions between chitosan or alginate-chitosan microbeads and extract compounds were analyzed.

MATERIALS AND METHODS

Preparation of thyme aqueous extract

Thyme (The Institute for Medicinal Plant Research "Dr Josif Pancic", Belgrade, Serbia) extract was prepared by conventional water extraction, by pouring 200 mL distilled water over 10 g of ground plant at room temperature. The extraction was carried out for 30 min with stirring, and after that the obtained extract was filtered through medical gauze.

Preparation of alginate-chitosan microbeads

Medium viscosity alginate (Sigma-Aldrich, St. Louis, MO, USA) was used to obtained alginate-chitosan microbeads by electrostatic extrusion technique according to Belscak-Cvitanovic et al. (2011).

Preparation of chitosan microbeads

Firstly, 2% (w/v) chitosan solution was prepared by dissolving chitosan (*Fluka*, Japan) powder in acetic acid (HAc). Then, *n*-hexane as continuous phase, *n*-hexanol as aided surfactant, and HAc solution containing chitosan were mixed in a flask at the volume ratio of 11:6:4. The microemulsion was formed by adding Tween 80 into the mixture, drop by drop while stirring, until the mixed emulsion became semi-transparent. Chitosan microbeads were prepared by emulsion cross-linking method, slightly modified, according to Denkbas&Odabasi (2000). Briefly, chitosan aqueous solution was emulsified by mechanical stirring (1000 rpm) in oil phases containing surfactant. After 30 min of stirring, the obtained microbeads were solidified by cross-linking with 5% (w/v) glutaraldehyde (related to the chitosan solution volume), and the mixture was stirred for 1 hour more. Then the microbeads were filtered and washed three times with ethanol and distilled water and, at the end, with 0.1 M potassium phosphate buffer of pH 8. Then, microbeads were left to dry under vacuum, after which they were kept in desiccators. Dried chitosan microbeads (about 0.5 g) were placed in a flask containing 30 mL of freshly prepared thyme extract containing 2% (w/v) ascorbic acid for about 24h. During that time polyphenols from thyme extract were absorbed by chitosan microbeads.

Determination of total phenol content (TPC) of thyme extract

Total phenol content was determined spectrophotometrically using the Folin-Ciocalteau reagent (Kemika, Zagreb, Croatia), according to the method of Lachman et al. (1998). All measurements were performed in duplicate.

Encapsulation efficiency

Encapsulation efficiency (EE%) was calculated as the amount of TPC encapsulated in beads ($m_{TPC,e}$) divided by the TPC of the polymer-extract solution used for the preparation of beads (m_{TPC}), as shown in Equation 1:

$$EE\% = \frac{m_{\mathrm{TPC,e}}}{m_{\mathrm{TPC}}} \quad (1)$$

Alginate-chitosan microbeads: Quantification of polyphenolic compounds ($m_{\mathrm{TPC,e}}$) in microbeads was performed after dissolving beads in a sodium citrate solution (2 g/mL) (HiMedia Laboratories, Mumbai, India). Briefly, the fresh alginate-chitosan beads were homogenized with sodium citrate (in a weight ratio of 1:5) for 15 min under vigorous mixing using a vortex mixer to chemically dissolve them. The polymer-extract solution and polyphenolic-citrate solution were analyzed for TPC using the Folin–Ciocalteu method according to the procedure described in the section above.

Chitosan microbeads: Quantification of polyphenolic compounds ($m_{\mathrm{TPC,e}}$) in beads was calculated as difference between polyphenolic content in thyme extract (containing 2% of ascorbic acid) used for microbeads preparation and polyphenolic content in thyme extract after 24 h of absorption of polyphenols by chitosan microbeads. TPC was determined using the same procedure described in the section above.

Release studies

Release studies of polyphenols from freshly prepared hydrogel beads were performed at room temperature. About three grams of beads were placed in a flask containing 50 mL of water. The samples were submitted to continuous agitation on an orbital shaker. Successive aliquots of the surrounding aqueous medium (2 mL) were drawn from a water solution at proper time intervals. The content of polyphenols in aliquots was determined as previously described.

Fourier transform infrared spectroscopy

Powdered xerogel/KBr pastilles were submitted to FT-IR analysis and the spectra were obtained using a Bomem MB 100 FT-IR Spectrophotometer. The proper ratio (sample: KBr = 1:50) was mixed and grounded and then compressed into a pellet under a pressure of 11 t, for about a minute, using Graseby Specac Model: 15.011. Spectra were obtained in the 4000-400 cm^{-1} wave number range, at 25 ºC and at 4 cm^{-1} spectral resolution.

Morphology of the alginate-chitosan and chitosan microbeads

The alginate-chitosan and chitosan microbeads were characterized by optical microscopy (Olympus UC 30, USA). The volume mean diameters of the prepared microbeads, measured in triplicate for each batch, were determined in water (Pham at al., 2002). Particle size is expressed as volume mean diameter (μm) ± standard deviation (SD).

RESULTS AND DISCUSION

Table 1 shows the effect of matrix on TPC encapsulated or absorbed by 1g of microbeads. Chitosan microbeads exhibited higher TPC compared to alginate-chitosan, due to high sorption capacity of chitosan hydrogel. In our study, encapsulation efficiency (also presented in Table 1) is mainly influenced by preparation procedure (*in situ* encapsulation by electrostatic extrusion *versus* absorption method). In case of chitosan microbeads it is possible to increase encapsulation efficiency by reducing the expenditure of aqueous extract solution which is used for encapsulation. Future studies should be oriented toward optimization of microbeads-to-extract ratio which is applied during encapsulation by absorption method.

Table 1. Total phenol content (TPC) and encapsulation efficiency (EE) for alginate-chitosan and chitosan microbeads encapsulating *Thymus serpyllum L.* aqueous extract.

Type of matrix	TPC [mgGAE/g_{beads}]	EE [%]
Alginate-chitosan microbeads	11.89	68.02
Chitosan microbeads	23.83	9.65

Release studies

The release profiles for alginate-chitosan microbeads and chitosan microbeads encapsulating thyme extract are shown on Fig. 1. Most of the polyphenolic compounds were released relatively rapidly from alginate-chitosan beads and the curve plateau was reached after about 15 min. On the other hand, chitosan microbeads although smaller, showed somewhat better retainment of polyphenolic compounds, up to 50 min. Prolonged release of compounds from chitosan microbeads can be explained by less porous structure of chitosan matrix compared to alginate-chitosan structure (George&Abraham, 2006). The release-retarding property of chitosan may also be attributed to chemical interactions between polyphenolic compounds and hydroxyl and amino groups of chitosan matrix, as confirmed by FT-IR analysis described below. In case of both types of microbeads, decrease in size of microbeads occurred after release of extract compounds (Table 2), i.e. shrinkage of ~23 and ~35 vol% for alginate-chitosan and chitosan microbeads, respectively.

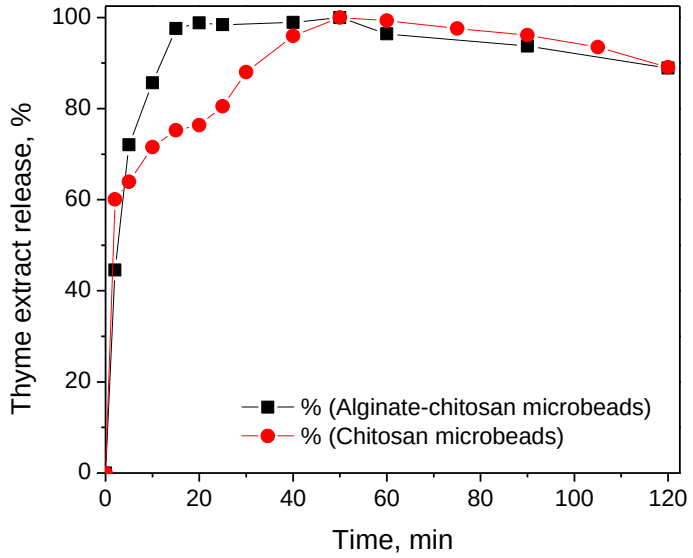

Figure 1. The release profiles for alginate-chitosan and chitosan microbeads encapsulating thyme extract.

FT-IR analysis

The FT-IR spectra of pure chitosan and alginate-chitosan microbeads, after encapsulation and release, were recorded and shown in Fig. 2. Those spectra are similar with several relevant peaks: between 3500 and 3000 cm^{-1}, corresponding to stretching vibration of free hydroxyl and N–H bonds in amino group, respectively, which are stronger in pure microbeads when compared to those with tea extract; the peaks at 2930.0 and 2880.1 cm^{-1} assigned to the asymmetric and symmetric mode of CH_2, respectively; the peaks at 1654 and 1595.4 cm^{-1} corresponding to the amide I and amide II band, respectively. As it is expected, extract encapsulation causes some changes in the peak position and intensity. The peak at 1092.0 cm^{-1} in the spectrum of pure alginate-chitosan is shifted to the lower wave length, 1073.0 cm^{-1}, while three peaks, at 1595.4, 1460.9 and 1319.0 cm^{-1} (Fig. 2) disappear after encapsulation indicating some modification and/or interaction between the extract and microgel carrier. (Knaul et al.,1999).

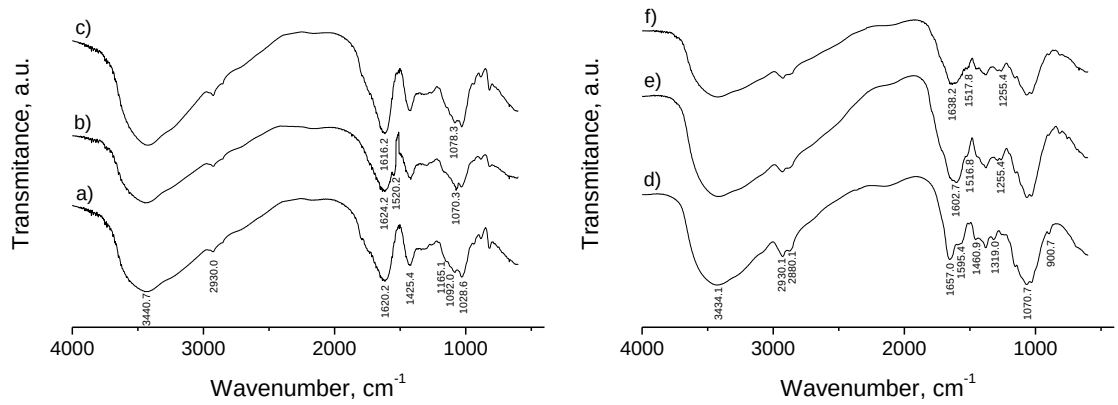

Figure 2. FT-IR spectra of a) pure alginate-chitosan microbeads, b) alginate-chitosan microbeads after extract encapsulation, c) alginate-chitosan microbeads after extract release; d) pure chitosan microbeads, e) chitosan microbeads after extract encapsulation, f) chitosan microbeads after extract release.

The observed results showed that there could be a particular arrangement within the microbeads due to the interactions of the tea polyphenolic compounds with hydroxyl and amino groups in chitosan matrix. Therefore, it is evident that addition of *Thymus serpyllum L*. extract, polyphenols could form some bonding and thus occupy the functional group of chitosan matrix.

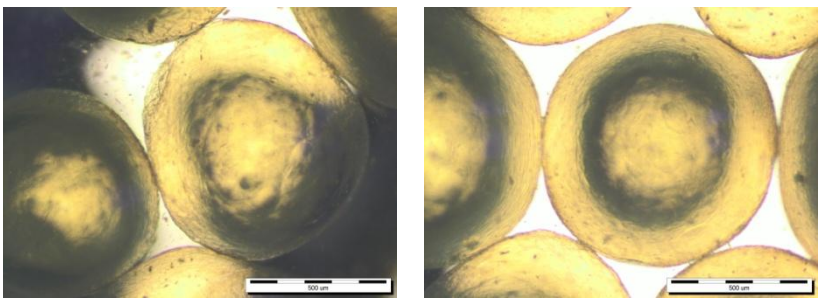
Morphology of the alginate-chitosan and chitosan microbeads

The morphologies of prepared alginate-chitosan and chitosan microbeads, dry and dispersed in distilled water, were assessed via optical microscopy.

As presented in Fig. 3, alginate-chitosan microbeads encapsulating thyme extract (Fig. 3a), as well as after extract release (Fig. 3b), were found to be spherical and discrete with the average diameter between 818 and 892 μm (Table 3), having smoother surfaces when compared to related chitosan microbeads. On the other hand, dry chitosan microbeads were smaller and had irregular shape (Fig. 2c), while after reemersion into water the sphericity was improved (Fig. 3d and 3e) and the volume increased by a factor of 3.

Table 3. Microbeads size (mean ± SD, n=3)

Formulation	Mean diameter, μm
Alginate-chitosan microbeads encapsulating thyme extract	891.5 ± 14.5
Alginate-chitosan microbeads after extract release	817.8 ± 32.1
Chitosan microbeads encapsulating thyme extract	392.2 ± 27.7
Chitosan microbeads after extract release	339.5 ± 27.4



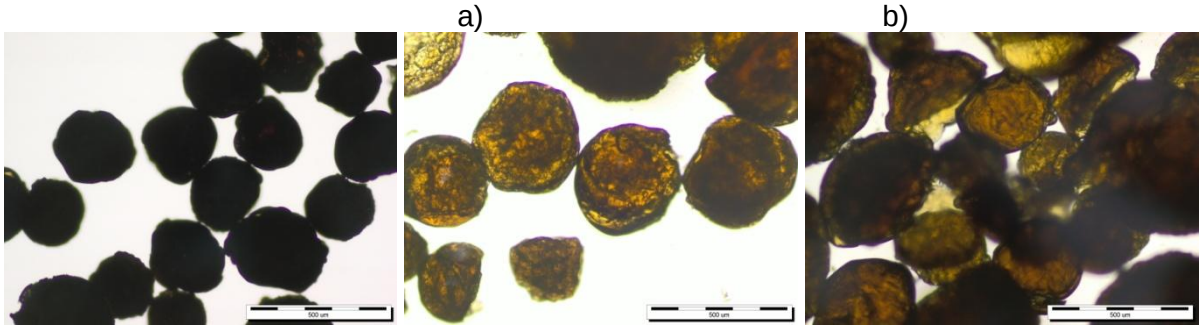


Figure 3. Optical microscopy photographs of the a) alginate-chitosan microbeads after extract encapsulation; b) alginate-chitosan microbeads after extract release; c) dry chitosan microbeads; d) chitosan microbeads after extract encapsulation and e) chitosan microbeads after extract release.

Both techniques are effective for producing microbeads of desired diameter. By increasing the applied electric potential in case of electrostatic extrusion or speed of stirring in case of emulsification (with adjustment of other operating parameters) it is possible to reduce particle size. However, a compromise regarding size of the beads has to be achieved concerning two opposite demands. Namely, larger-sized beads are necessary for a prolonged release of the encapsulated compounds while smaller-sized beads are desirable from the aspect of textural and sensorial properties of food products.

CONCLUSION

As shown in the results, both alginate-chitosan and chitosan microbeads can be used for encapsulation of polyphenolic compounds. Stability tests regarding preservation of antioxidant activity of encapsulated compounds are necessary if dosage forms developed here are going to be used in real food systems. In order to achieve desirable properties, future investigations are planned based on the matrix optimization and determination of microbeads size as well as concentration of polyphenols.

ABSTRACT: The objective of this study was to investigate the effect of different starter cultures and transglutaminase on chemical characteristics and textural properties of fermented dairy beverages produced from milk of 0.9 $g100g^{-1}$ fat content. Samples were produced by application of a probiotic starter culture or a microfiltrated kombucha inoculum. The quality of fermented dairy beverages was analyzed after production. It was found that, two times faster fermentation was achieved in the probiotic yoghurt compared to samples of fermented milk with microfiltrated kombuha inoculum. Chemical analyses of the obtained beverages has shown that the fermented dairy beverages produced with the microfiltrated kombucha inoculum contained higher concentration of a lactose and lower level of a galactose and L-lactic acid than the probiotic yoghurt**.** Probiotic yoghurt had better textural properties than a sample with the microfiltrated kombuha inoculum. Application of a transglutaminase in a production of fermented dairy beverages improved physicochemical properties.
Key words: *fermented dairy beverages, probiotic starter culture, kombucha, transglutaminase*

INTRODUCTION

Yoghurt is a protein network formed by casein micelles entrapping serum and fat globules. Metabolic activities of the starter culture during a gelation process of milk are of specific importance. Type and ratio of microorganisms in starter culture contribute to different physicochemical and sensory characteristics of fermented dairy products. Nowadays, application of probiotics is very popular in yoghurt thanks to their prophylactic and therapeutic properties to human health (Tamime and Robinson, 2004; Tamime, 2006). Symbiotic association of yeasts and acetic acid bacteria in kombucha is well known. Metabolic activities of kombucha on a sweetened tea produce a pleasant sour beverage containing, in addition to ethanol and acetic acid, a number of useful compound. Their positive influence on a human health has been investigated and confirmed by a number of authors (Allen, 1998, Malbaša et al., 2008). Activity of kombucha on sucrose has been investigated and main pathways of a conversion of sucrose into numerous products have been determined (Malbaša et al., 2008). In addition to sucrose, application of any other sugar (lactose, glucose or fructose) is a possibility. For example, it was proved that the fermentation on lactose gave insignificant quantities of ethanol in a comparison to the fermentation on sucrose. There is a lack of research of kombucha's metabolic activity on milk (Malbaša et al., 2009; Milanović et al.; 2008, Iličić, 2010).
Improvement of rheological properties of low fat fermented milk products can be achieved by applying several techniques: ultrafiltration, addition of skim milk powder, by usage of stabilizers or by an addition of enzyme transglutaminase (TG) (Patocka et al., 2004; Sandoval-Castilla, 2004; Rodriguez-Nogales, 2006). Transglutaminase forms both inter- and intramolecular isopeptide bonds in and between food proteins. The casein in milk represents favorable substrate for cross-linking by TG application, due to non-globular easily accessible structure. Cross-linking of food proteins by TG can modify their solubility, hydration and heat stability, as well as their gelation, rheological, emulsifying or renneting properties. Rate of TG cross-linking depends on the macromolecular structure of each protein substrate (Lorenzen

et al., 2002; Carić et al., 2006; Bönish et al. 2007; Duraković et al., 2008; Milanović et al., 2009; Iličić, 2010).
The aim of this research was to examine physicochemical characteristics and textural properties of fermented milk beverages produced by application of probiotic starter cultures and the microfiltrated kombucha inoculum with or without addition of TG.

MATERIAL AND METHODS

Milk (0.9 g100g^{-1}fat, 3.1 g100g^{-1} proteins, and 4.54 g100g^{-1} lactose), obtained from AD IMLEK division Novi Sad Dairy (Novi Sad, Serbia), was used for the production of fermented dairy beverages (Table 1).
The probiotic lyophilised starter culture DIRECT-SET DELVO-YOG® MY-721 (*Streptococcus thermophilus, Lactobacillus acidophilus* LAFTI® L10 and *Bifidobacterium* sp. LAFTI® B94)**,** (DSM Food Specialties, Netherlands) and the microfiltrated kombucha inoculum were used for milk inoculation. This microfiltration of a kombucha inoculum was performed using apparatus that contains a tubular ceramic membrane module (200 nm), under process parameters: temperature 25°C, pressure difference at modules input and output 40 kPa and flow of 5 Lmin^{-1}. The concentration factor was 2.3.
Microbiological transglutaminase was isolated from *Streptoverticillium* strains (Ajinomoto Co. Inc., Hamburg, Germany). Transglutaminase Activa MP was activated in milk at 40°C for 2 hours, and then inactivated at 80°C for 1 minute prior to the fermentation. After cooling to an optimal temperature (42°C), chosen starter culture was added in milk. In all cases fermentation stopped when the pH 4.5 was reached. The gels were cooled to 8°C, homogenized by mixing and packed in plastic containers.

Table 1. Plan of experiments

No.	Description of fermented milk beverages	Sample
1.	Sample produced by probiotic application - probiotic yoghurt	PY
2.	Sample produced by probiotic application and by addition of 0.02 g100ml^{-1} TG	PY+TG
3.	Sample produced with 10% [v/v] of microfiltrated kombucha inoculum	MFI
4.	Sample produced with 10% [v/v] of microfiltrated kombucha inoculum and by addition of 0.02 g100ml^{-1} TG	MFI + TG

Physicochemical analysis

pH value of samples was measured by pH meter (Vario pH SET, Germany). The following physicochemical characteristics were analysed: total solids (TS) by oven drying, protein (TP) by Kjeldahl method, fat by Gerber method (Carić et al., 2000). Content of lactose, galactose and acetic acid was analysed by using an assay kit, test K-LACGAR 12/05, Megasyme, Ireland (Bergmeyer, 1988). Textural characteristics: firmness, consistency, cohesiveness and index of viscosity of fermented dairy beverages were measured by Texture Analyser TA.HDplus (Stable Micro System, Godalming, England) through a single compression test, using a back extrusion cell (A/BE) disc and an extension bar, using 5 kg load cell at 5°C.

RESULTS AND DISCUSSION

The fermentation process lasted two times longer in fermented dairy beverages with microfiltrated kombucha inoculum compared to the fermentation in the probiotic yoghurt (Figure 1). Fermentation time for the probiotic yoghurt sample with TG activation lasted 5 hours, while fermentation time for fermented milk beverages produced by addition of TG and the microfiltrated kombucha inoculum varied from 10 to 11 hours. These results are in concordance with the literature data (Lorenzen et al., 2002; Iličič et al., 2009; Milanović et al., 2009) showing increased fermentation time for yoghurt milk treated with the activated TG.

Færgemand et al. (1999) attributed this effect to a reduced availability of peptides' low molecular mass for the growth of lactic acid bacteria.

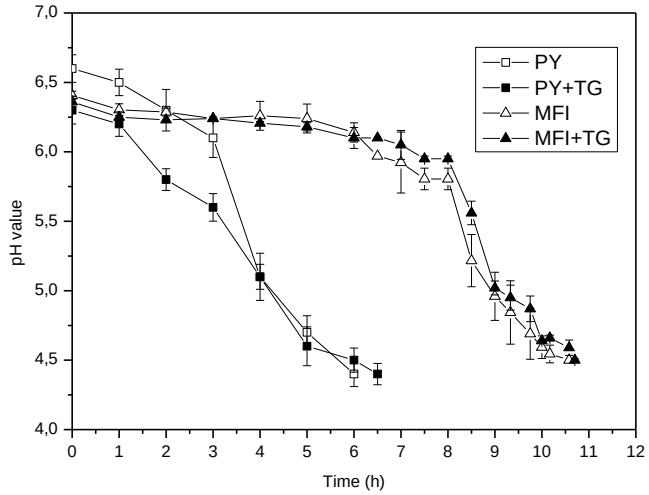

Figure 2. pH changes during milk fermentation

Table 2. Chemical composition of milk and fermented milk beverages produced by probiotic starter culture and the microfiltrated kombucha inoculum (with and without TG addition)

Samples	Characteristics ($g100g^{-1}$)				
	Total solids (TS)	**Total proteins (TP)**	**Lactose**	**Galactose**	**L-lactic acid**
Milk (M)	9.85±0.33	3.15±0.04	4.74	0.0115	0,0015
PY	9.89±0.01	3.19±0.02	3.33	0.640	0.81
PY+TG	9.72±0.08	3.30±0.06	3.26	0.640	0.869
MFI	9.63±0.26	2.78±0.05	3.89	0.557	0.535
MFI+TG	9.86±0.29	2.73±0.22	3.74	0.601	0.565

Total solids and total protein in probiotic yoghurt were higher than in kombucha fermented milk beverages. During fermentation of milk with usage of probiotic starter culture, lactose content decreased around 44%.

Lactose content of the probiotic yoghurt was approximately 16% lower compared to samples produced with the microfiltrated kombucha inoculum (Table 1). All samples had higher content of lactose compared with literature data (Belloso-Moralles and Hernandez-Sanchez, 2003). Belloso-Moralles and Hernandez-Sanchez (2003) found that samples produced from whey contained about 1 $g100g^{-1}$ of lactose after fermentation. Content of galactose and L-lactic acid in all samples was higher than in milk used for the fermentation (Table 2).

Differences in chemical composition between probiotic yoghurt and kombucha fermented milk beverages were result of different metabolic and microbiological characteristics of probiotic starter culture and microfiltrated kombucha inoculums.

Table 3. Textural properties of fermented milk beverages produced by probiotic starter culture and the microfiltrated kombucha inoculums (with and without TG addition)

Samples	Characteristics			
	Firmness (g)	Consistency (gs)	Cohesiveness (g)	Index of viscosity (gs)
PY	15.05±1.08	443±14.82	-7.637±1.6	-4.361±1.371
PY+TG	22.8±1.13	588.73±23.1	-18.79±1.23	-29.78±4.6
MFI	13.86±1.09	394.70±40.43	-5.02±0.8	-1.205±0.663
MFI+TG	21.32±7.4	555.981±187.4	-16.591±7.6	-23.962±2.4

Textural characteristics of fermented dairy beverages are presented in Table 2. Probiotic yoghurt with TG had the highest textural characteristics (firmness 22.8 g, consistency 588.73 gs, cohesivness -18.79 g, index of viscosity -29.78 gs), while the sample MFI had lowest textural characteristics (firmness 13.86 g, consistency 394.70 gs, cohesivness -5.02 g, index of viscosity -1.205 gs). This is in accordance with Iličić et al. (2009) where fermented dairy beverages containing 1.5% of the kombucha concentrated inoculum and 0.02% of activated TG had the highest textural characteristics (firmness 34 g, consistency 900 gs, cohesivness -33 g, index of viscosity -80 gs). Samples with 3% of concentrated inoculum (without TG) had the lowest textural characteristics (firmness 14 g, consistency 400 gs, cohesivness -7 g, index of viscosity -5 g) (Iličić et al., 2009).

CONCLUSIONS

The probiotic starter culture and the microfiltrated kombucha inoculum had significant influence on differences in physicochemical and textural properties of fermented dairy beverages. Fermentation process was faster in the the probiotic yoghurt compared to all fermented dairy beverages produced with the microfiltrated kombucha inoculum. Addition of TG at level of 0.02% contributed significantly to the formation of stirred fermented milk beverages with improved physical characteristics and textural properties.

ACKNOWLEDGEMENTS

Authors would like to thank the Ministry of Education and Science of the Republic of Serbia for a financial support for this study, which is a part of project III 46009. Also, authors are grateful to Ajinomoto Company for the sample of enzyme transglutaminase, as well as to NS Trading, Novi Sad for gratis sample of the probiotic starter culture.

ABSTRACT: Non-commercial milk and water kefir grains (from a household in Belgrade, Serbia) were used for isolation of lactic acid bacteria on TSA, MRS and M17 agar.
Preliminary identification has been performed according to morphological traits (Gram staining, cells shape and colony characteristics on agar plate). Isolates suspected to lactic acid bacteria were tested for selected physiological and biochemical characteristics. Investigations of potential probiotic properties included antimicrobial activity against three different pathogens, sensitivity to simulated gastrointestinal tract conditions and autoaggregation ability. In total, ten cultures were selected for further analysis, five from each milk and water kefir grains.
The morphological and physiological profiles showed that isolated strains belong to genera *Lactobacillus* and *Leuconostoc*. There were some differences in their sugar fermentation pattern as well as in their antimicrobial activities, with milk kefir cultures being more potent pathogen inhibitors. In simulated gastrointestinal tract conditions all strains showed high sensitivity towards bile acids, while their growth in low pH and pepsin was good. Two cultures only (one from water kefir grains and one from milk kefir grains) showed good autoaggregation ability.
Overall, most isolates exposed good probiotic potential. There are no significant differences between lactic acid bacteria isolated from milk and water kefir grains.
Key words: *lactic acid bacteria, probiotic, milk and water kefir*

INTRODUCTION

Functional foods remain the hottest topic in the food industry and nutrition. The term functional foods means products with a potential positive effect on health. This food beside basic food nutrients (fats, proteins, carbohydrates) contain specific biologically active substances that have a proven positive effect on human health and that may be useful in the treatment of many chronic diseases (different types of cancer, high cholesterol, etc.), (Annuk et al., 2001).
Food products containing probiotic microorganisms are especially highlights of numerous researches (Vaughan and Mollet, 1999). There are numerous studies about the positive physiological and health effects after regular intake of probiotics on human health, the prevention of acute and chronic diseases, work capacity, etc (Fuller, 1989).
Kefir is fermented beverage produced by the action of lactic acid bacteria, yeasts and acetic acid bacteria on milk. The microbiological population is firmly embedded in kefir grains. The grains have been described as resembling elastic small florets similar to cauliflower in shape, yellow or white in color, and 20-30 mm in size (Farnworth, 2008). However, there is another beverage, made from sugar and water with figs and lemon added, whose fermentation is induced by grains of a different type which are transparent, mucilaginous, but less resilient. The grains of the water kefir are described to consist of dextran, an α 1-6 linked glucose polymer in contrast to milk kefir grains,which are made of more complex heteropolysaccharides, namely kefiran. Microbiota of water kefir grains also consists of LAB and yeasts (Pidoux, 1989).

Beneficial effects of milk and water kefir on human health are anticipated by consumers but have not yet been scientifically substantiated. Nevertheless, probiotic properties are widely spread among lactic acid bacteria (LAB).
Probiotic properties of LAB are proven in numerous clinical and laboratory studies. It is primarily reflected in the good antimicrobial activity and ability to survive adverse conditions in the gastro-intestinal tract (GIT) (Macfarlane and Cummings, 2002, Kaur et al., 2002).
The aim of this work is to characterize lactic acid bacteria isolated from non-commercial milk and water kefir according to the requirements for probiotics in order to consider their further application in the development of new functional products.

MATERIALS AND METHODS

Isolation and phenotypical characterization of non-commercial milk and water kefir isolates

Non-commercial milk and water kefir grains (from a household in Belgrade, Serbia) were used for isolation of lactic acid bacteria. The grains were mechanically homogenized and appropriate dilutions were inoculated into sterile Petri dishes with 3 different media: TSA (Tryptic Soy Agar), MRS and M17 agar. After 2 days incubation at 30°C, five to ten colonies from each sample were inoculated in MRS broth and then stored at -20 °C in MRS broth containing 20% glycerol. Strains were routinely propagated in MRS broth at 30°C in microaerofilic condition.
The first tentative identification as LAB was performed according to morphological characteristics (cells shape, Gram staining) and physiological characteristics (catalase test, growth at different temperatures, growth in milk and litmus milk, growth in media with different concentration of NaCl and sugar fermentation).

Antimicrobial activity

Selected isolates were screened for their ability to inhibit strains: *S. aureus* ATCC 25923, *C. albicans* ATCC 10259 and *E. coli* ATCC 25922. This was performed by using the spot method where 2 µl of active (overnight) MRS culture of isolates were spotted on TSA. Plates were dried for 30 min at room temperature and incubated semi anaerobically at 30°C for 18 h; overlaid with 6ml of TSB containing 0.6% agar at 45°C, seeded with 1% (v/v) of an active overnight culture of the target strain and incubated aerobically at 30°C for 18 h.
Sensitivity to simulated gastrointestinal conditions (gastric test and bile salts test)

Gastric test

0.5 % NaCl and 0.3% pepsin solution is simulating gastrointestinal conditions. pH of this solution is set to 3.2 with 1M HCl and solution is filtered sterile. 9 ml of this solution was inoculated with 1 ml overnight culture of selected strains and was incubated at 30°C aerobically. After 2h cell count was determined on agar plates (TSA). The plates were incubated aerobically at 30°C for 24h. The percentage of survived cells was determined by comparing the number of colonies from gastric juice and that from saline which has been used as a control. Each strain was tested twice.

Bile salts test

MRS broth with 0.05% and 0.1% bile salts (Oxgall) were simulating duodenal conditions. 3 ml of this solution was inoculated with 50 µl overnight cell culture and incubated on 30^{o}C. After 24h cell concentration was determined by optical density (620 nm). The percentage of survived cells was determined by comparing the cell concentration in MRS broth with bile salts and MRS broth without bile salts which has been used as a control. Each strain was tested twice.

Autoaggregation ability

The cell cultures were grown 18 hours at 30ºC and centrifuged at 7000 rpm for 15 minutes. Supernatant was drained; the cells were washed twice and resuspended in saline. 4 ml of suspension was than mixed in a vortex at maximum speed and the degree of autoaggregation was determined during the next 5 hours at room temperature. For every hour 0.1 ml of suspension was taken from the top, poured in 3.9 ml saline, and mixed. Optical density was measured on colorimeter using a yellow filter (570 nm). Autoaggregation percentage is calculated by the following equation:

% autoaggregation = 1- (At / Ao)* 100

Ao – absorbance measured at t = 0h

At – absorbance measured every hour

RESULTS AND DISCUSSION

In the present study, 10 bacteria were isolated from milk and water kefir grains. Strains isolated from milk kefir are signed as K1 to K5, and those from water kefir are signed as T1 to T5. Isolated bacteria were able to grow on MRS, M17 and TSA plates at 30°C. All strains tested were catalase-negative and Gram-positive with various shapes ranging from long rods to coccoid rods. Testing the growth at different temperatures showed that optimal temperature is 30°C for all strains, all can grow at 37°C and only one (T1) cannot grow at 15°C. Nine strains were tolerant to NaCl at concentrations of 4% and 6.5%, but not at 9.6%; only T1 did not grow in the presence of NaCl at all. The absence of gas production from glucose was used to differentiate homo- and heterofermentative group. Sugar fermentation was used for determination of fermentation pattern of isolates. The results of physiological characteristics are shown in Table 1 and sugar fermentation patterns are presented in Table 2. According to these results 4 of isolated species belong to genus *Lactobacillus* and 6 to genus *Leuconostoc*.

Glu – glucose, Gln - gluconate

Many LAB strains are known by exopolysaccharides (EPS) production (Ruas-Madiedo & de los Reyes-Gavilán, 2005). This property was used for characterization of isolates. They formed mucous colonies on modified MRS agar (with sucrose instead of glucose) which is indication of EPS production (Table 1).

The antimicrobial activities of the LAB strains tested were variable (Table 3).
According to the presented results it can be seen that all strains showed a certain antimicrobial activity under the given conditions of the experiment. Isolates from milk kefir are more potent pathogen inhibitors.

Table 3. Antagonistic activity of kefir isolates against the pathogen indicators

ND - not determined

Acid tolerance is a property that any strain expected to have effects in the GIT should possess (Salminen et al., 1996, Marteau et al., 1997). Resistance at pH 3.2 for 2h (Arihara et al., 1998) is one of the standards for low pH tolerance of probiotic bacteria. All strains showed high survival (100%) at low pH, with two strains from milk kefir had a slightly lower percentage with about 60 - 70%, (Table 4).

Table 4.
Sensitivity to simulated GIT conditions

Table 5.
Autoaggregation ability

Isolate	Percent of survived cells

T4	0.00	0.00	0.00	0.00	0.00
T5	0.00	16.67	16.67	33.33	33.33

The results indicate that the strains could survive in the acidic stomach environment and reach the areas of beneficial activity (small intestine and colon) when ingested.
After passage through acidic stomach conditions it is important that, for application of LAB strains as probiotics, they are able to survive the bile salt in the intestine. Most researchers assess bile resistance within the range of 0.1-0.5% (Lankaputhra and Shah, 1995). At concentration of 0.1% viability was very low for all strains. Better results were observed at bile concentration of 0.05%, although the percentage of survival is low. Strains isolated from water kefir showed better tolerance to the conditions in the intestine (Table 4). The probably reason for poor surviving is that the isolated strains are not of intestinal origin.
Autoaggregation ability points to the possibility of cell attachment to one another as well as the ability to form biofilms on the walls of the intestinal epithelium. It can affect the ability to retain in their communities as well as resistance to the effects of adverse conditions (Vandevoorde et al., 1992, Boris et al., 1997). Two cultures only (K4 from water kefir grains and T1 from milk kefir grains) showed good autoaggregation ability (Table 5).

CONCLUSIONS

There are lots of problems in reliable characterization of probiotic strains using *in vitro* methods, but the initial screening of strains in this manner remains useful for detection of probiotic candidates.
Determination of fermentation pattern of lactic acid bacteria is the first step in the identification of strains, but molecular methods are needed for accurate determination.
More research is needed on other potential probiotic properties of the strains such as antibiotic resistance, antimicrobial activity against increased number of pathogen strains and ability to adhere and colonize human intestinal cells.

ABSTRACT: In the present study, we investigated the use of spray drying as a way to prepare dairy-based powders with high number of viable cells of the potential probiotic strain *L. plantarum* JS7A. Microencapsulation was done using reconstituted skim milk (RSM), inulin and maltodextrin as carriers. When RSM was used as a spray drying carrier a microbial survival rate of 73 % was achieved, although the partial substitution of skim milk with inulin also resulted in high level of survival of 70 %. The poorest survival of 41 % was obtained with maltodextrin as a carrier. The moisture contents in powders were ranging from 4.1 % to 4.4 %. Spray drying process stressed the cells which was shown by increased sensitivity to NaCl. However, it was obtained that reconstituted skim milk showed the significantly lower inhibition of cells of 49 % comparing with inulin and maltodextrin with 55 and 75 % of inhibition, respectively.
Key words*: microencapsulation, potential probiotics, Lactobacillus plantarum, spray drying*

INTRODUCTION

Probiotics are live microorganisms which when administered in adequate amounts, confer a health benefit on the host (FAO, 2006). However, many studies have demonstrated their poor viability and stability in the fermented products. The different techniques of encapsulation, which include formation of a protective layer around the bacterial cells, can be applied for their better survival under adverse environment (Zuidam and Nedović, 2010).
There are a several techniques available for the production of encapsulated probiotics as follows: extrusion, emulsion, drying (fluidized bed, freeze, spray) and spray-coating technique (Petrović et al., 2007; Manojlović et al., 2010). Spray drying is an economical process of preservation of probiotic cultures, which provides high productivity and relatively low operating costs. Spray drying is a methods when an active material is dissolved or suspended in a melt or polymer solution and became trapped in the dried particles.The main advantages of spray drying is the ability to handle heat sensitive materials such as protein, enzymes, flavors, living cells etc., because of the short contact time in the dryer.
Reconstituted skim milk is the most common used carrier for spray drying of probiotics, because it is widely used in the dairy industry (Desmond et al., 2002; Corcoran et al., 2004; Ananta et al., 2005). Furthermore, milk proteins can form a protective layer around the bacterial cells, while calcium enhances cell survival after dehydration. The prebiotics like inulin could be also used as a carrier, for enhance the viability of probiotic cultures in the gastrointestinal tract (Corcoran et al., 2004).
In this study the possibility of using spray drying technique for microencapsulation of potential probiotic *Lactobacillus plantarum* JS7A, with different carriers, reconstituted skim milk, prebiotics inulin and carbohydrate maltodextrin was investigated (Petrović, 2011). Also, the degree of cell damage as a result of high temperature of drying was determined.

MATERIAL AND METHODS

Bacterial strain and culture condition

Potential probiotic strain JS7A which was isolated previously from the fermented carrot and was identified as member of *Lactobacillus plantarum,* by PCR based methods (Petrović, 2011) was obtained from the strains collection of the Department of Industrial Microbiology, Faculty of Agriculture, Belgrade.

Fresh 24 hours culture (1% v/v) was inoculated in MRS broth and incubated for 20 h at 37 °C in order to achieve stationary phase of growth. For spray-drying purposes strain was cultured as follows. Cells were harvested by centrifugation (4 500 x g, 15 min) from the incubated broth and rinsed in saline solution. The resulting culture was then used to inoculate the feed media.

Spray-dried feed media

Spray-dried feed media was consist of either reconstituted skim milk - RSM (20 % w/v), RSM (10 % w/v) and maltodextrins (10 % w/v) or RSM (10 % w/v) and inulin (10 % w/v). Feed media were prepared by dissolving the carrier in distilled water and their sterilization by autoclaving at 105 ° C, 5 min. For the adaptation of LAB to the drying temperature, inoculated media were incubated at 37 °C, for 30 min.

Spray drying of potential probiotic strain

A laboratory scale spray dryer (model B290 Büchi mini spray dryer, Switzerland) was used to process samples at a constant air inlet temperature of 170 ºC. The feed solution was atomized in drying chamber using a two-fluid nozzle. The outlet air temperature was maintained at 80 - 85 ºC, in order to obtain powders with around 4% (w/w) moisture (Master, 1991).

Per cent of survived bacteria were calculated as follows:

$$\% \text{ survivors} = N/N_0 x100,$$

where N_0 - represented the number of bacteria in medium before drying and N - was the number of bacteria in spray-dried powder. Both N and N_o were expressed per gram of dry matter.

Salt tolerance test

The sensitivity of tested cultures to NaCl before and after drying was determined as described by Gardiner *et al.* 2000. Fresh overnight MRS broth culture and culture-containing spray-dried powders were pour plated onto MRS agar supplemented with 5% NaCl. The plates were examined after 72 h of anaerobic incubation at 37 °C, and the colony sizes and numbers were compared with the colony sizes and numbers on MRS plates without NaCl.

The percent of inhibition of bacterial cells in medium supplemented with 5 % of NaCl, was calculated as followed:

$\% I = N_0 - N / N_0$, where:

N_0 - represented the colony numbers from the fresh overnight culture inoculated in MRS with 5 % of NaCl;

N – represented the colony numbers of spray-dried bacteria inoculated in MRS with 5 % of NaCl.

Moisture content in spray-dried powders

The moisture content in the spray-dried powder was determined by drying 3 - 5 g of powder in the oven at 102 ± 2 °C. On the basis of differences in the sample weight before and after drying it was calculated the moisture content (%).

RESULTS AND DISCUSSION

In order to obtained spray-dried powders with high numbers of potential probiotic strain *L. plantarum* JS7A, it must withstand the high temperatures encountered during spray-drying, which has been shown to vary among strains of probiotic lactobacilli (Gardiner et al. 2000). Also, the viability of lactobacilli during spray drying depends on the growth phase of bacteria prior to drying. Teixeira et al. (1994) have previously shown that exponential - phase cells of *L. bulgaricus* are more susceptible to spray drying than cells in the stationary phase of growth. From this reason the tested culture was grown to stacionar phase prior to spray drying, which may have increased their survival to the process.
Regarding the total solids content of spray-drying medium (RSM, and combination of RSM with inulin and maltodextrin) it was held constant at 20 % (w/v), because the solid content of 20 % has been consider as optimum for assuring high residual viability of different strains of lactic acid bacteria (Desmond *et al.* 2001; Gardiner *et al.* 2000; Mauriello *et al.*1999; Johnson i Etzel, 1993).
In addition, the outlet air temperature of 80 to 85°C was held constant during drying as it was necessary in order to obtain powders with moisture contents that did not exceed the level required for prolonged powder storage life (Master, 1991). In this work the moisture content in powders were ranging from 4.1 % to 4.4 % which was regarded as a good-quality parameter of dried-dairy products.
The figure 1 shows a very good survival of *L. plantarum* JS7A in powder with 20 % RSM of 73 % (with $2.77x10^{10}$ CFU g^{-1} of viable cells) while in combination of RSM with inulin it was 70 % of survived bacteria. In the combination of RSM with maltodextrin the significantly lower survival of *L. plantarum* JS7A of 41 % was obtained.. On the other hand, in the work of Ananta et al., (2004) it was obtained the good survival of probiotics using a combination of carriers as maltodextrin, gelatin, glycerol, and lactose.

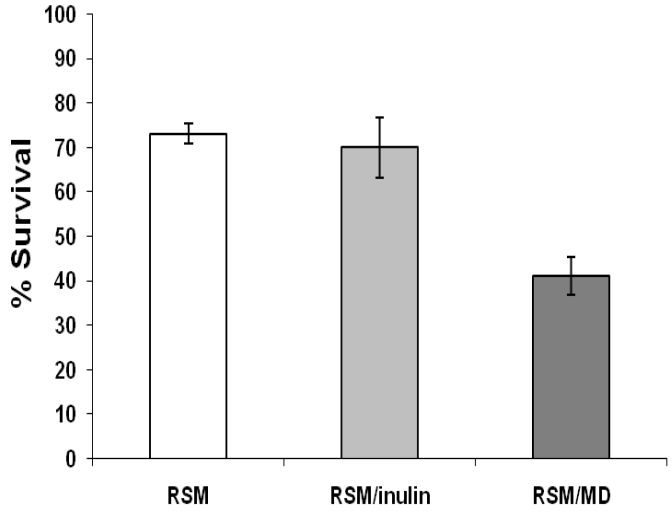

Figure 1. Average (± standard deviation) survival of *L. plantarum* JS7A spray-dried in the presence of reconstituted skim milk (RSM) (20 % w/v), RSM (10 % w/v) and inulin (10 % w/v) and RSM (10 % w/v) and maltodextrin (10 % w/v).

In addition, after spray drying at outlet temperature of 70 - 75 °C, it was obtained high survival rate of 97 % for *L. paracasei* NFBC 338 in 20 % RSM, while significantly lower survival of only 11 % was performed for *L. salivarius* UCC 18 at lower outlet temperature of 60 - 65 °C (Gardiner et al., 2000).
A potential disadvantage of spray-drying process as a way to preserve microbial cultures is the damage on bacterial cells caused by high temperature. In order to study potential cellular damage resulting from the spray-drying process the sensitivity of tested cultures to NaCl before and after drying as described by Gardiner *et al.* 2000 was determined. Increased

sensitivity of sublethally injured bacteria to NaCl has been associated with cytoplasmic mambrane damage (Brennan et al. 1987; Teixeira *et al.* 1995a).
Spray dried *L. plantarum* JS7A exibited the highest damages with approx. 75 % of inhibition in the presence of NaCl in the RSM/MD mixture while it was 55% and 49% in RSM/inulin and RSM feed respectively (Figure 2). When spray-dried powder was plated in the presence of 5% NaCl, colony size was found to be considerably reduced compared to the colony size prior to spray drying (data not shown). This morphological change, in the presence of NaCl, indicates that the spray drying process stressed the cells.

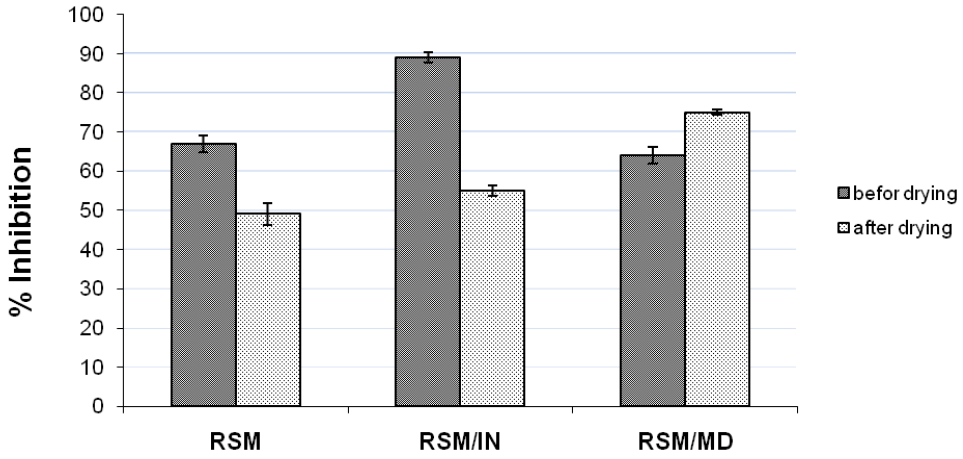

Figure 2. Average (± standard deviation) percent of inhibition of spray-dried *L. plantarum* JS7A cells with high concentration of NaCl

The high inhibition by NaCl was obtained for *L. salivari*us UUC 500 with 90 % susceptibility to NaCl, after drying (Corcoran *et al*. 2004). In addition, Gardiner *et al.* (2000) has been reported the total inhibition (100 % of damaged cells) with 5 % NaCl for *L. salivarius* UUC118 in RSM feed.
It can be generally concluded that probiotic survival is dependent on the spray-drying carrier applied, as differences in thermal conductivity and diffusivity can affect survival of spray-dried probiotic (Lian et al. 2002). However, the partial substitution of RSM with carbohydrate maltodextrin in the feed solution during drying demonstrated the poorest survival and protection of tested culture compared with RSM as a whole carrier.

CONCLUSION

Our data demonstrate that spray drying may be a cost-effective way to produce large quantities of some probiotic culture. Also, powder obtained with skim milk or inulin as a carrier could be a useful ingredients in functional food applications.

ABSTRACT: The bioactivity of natural antioxidants from plant extracts is well known. Still, the effectiveness of these natural antioxidants, namely polyphenols, depends on preserving their stability, which can be increased by microencapsulation. The aim of this study was to protect natural antioxidants from the aqueous extract of Portuguese wild herb *Pterospartum tridentatum* by encapsulation in alginate hydrogel microbeads. Microbeads were prepared by electrostatic extrusion technique: plain Ca-alginate microbeads and Ca-alginate microbeads with 10 and 20 mass% of inulin as a filler substance. Total polyphenol content (TPC) and the radical scavenging activity using ABTS and DPPH cations were determined. The release studies of polyphenols from microbeads were performed. The microbeads were analysed by Fourier transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM) and optical microscopy (OM). Encapsulation efficiency (EE) was in the range from 49 to 73%. Antioxidant assays and release studies showed that alginate-inulin microbeads appeared to be suitable dosage forms. The inclusion of inulin contributes to improved microbeads structure, as well as to nutritional values of food. Thereby, potential applications of these microbeads could be functional food products, an increasingly valued market.
Key words: *encapsulation, electrostatic extrusion, antioxidants, Pterospartum tridentatum, alginate*

INTRODUCTION

From the ancient times, herbs and spices were being added to different food and beverages to improve flavour. It has been also shown that bioactive compounds commonly found in herbs contain health benefits because of their significant antimicrobial and antioxidant capacities and anticarcinogeni activities (Cao et al., 1999). Various bioactive compounds, such as alkaloids and flavonoids, have been identified in aqueous extracts of *Pterospartum tridentatum* which is wild herb widely used in traditional medicine and cuisine (Vitor et al., 2004). *Pterospartum tridentatum* L. is a European endemic species belonging to the subfamily *Papilionoideae* (Talavera, 1999) and known as *carqueija* or *carqueja* in Portugal. Some authors refer the use of this herb in popular medicine for colds, stomach aches, intestinal problems, kidney disease, liver and bladder problem. However, most of bioactive compounds are very sensitive to many factors. The effectiveness of these natural antioxidants, namely polyphenols, depends on preserving their stability, which can be increased by microencapsulation.

Microencapsulation is an effective method to protect bioactive components, preserve their stability during processing and storage and prevent undesirable interactions with food matrix (Wandrey et al., 2009, Nedović et al., 2011). Electrostatic extrusion is technique used for encapsulation of the compounds by production of spherical, small and uniform microparticles which are desirable in food applications (Manojlović et al., 2008, Kostić et al., 2012).

The goal of the present study was to develop *P. tridentatum* extract formulations aimed at delivery of bioactive compounds in functional food products. The extract was encapsulated

in alginate and alginate-inulin microbeads by electrostatic extrusion and the obtained microbeads were characterized from the aspect of TPC and antioxidant activity. Besides hydrogel microbeads, freeze-dried forms of microbeads were also assessed, as they are convenient for long-term applications.

MATERIAL AND METHODS

Na-alginate (medium viscosity) was purchased from Sigma. Folin-Ciocalteu, Na-carbonate, Ca-chloride and Na-citrate were of analytical grade and supplied by Sigma-Aldrich (St. Louis, MO, USA). 2,2′-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)diammonium salt (ABTS), 2,2-diphenyl-1-picrylhydrazyl (DPPH), sodium chloride, potassium persulfate were obtained from Sigma -Aldrich (Germany). Inulin was generously gifted from a local milk factory.

Preparation of microbeads

The appropriate amount of *P. tridentatum* aqueous extract (2 mg mL^{-1}) was added to Na-alginate water solution (1,5% w/v) to prepare extract-alginate solution. In addition, extract-alginate solution was mixed with 10 and 20 mass% of inulin to prepare extract-alginate-inulin solutions. Both types of solutions were submerged to electrostatic droplet generation in order to produce alginate and alginate-inulin microbeads entrapping extract compounds as described in the next paragraph.

The obtained solutions were extruded through a blunt stainless steel needle (23 G) at a constant flow rate of 25,2 mL h^{-1}, by a syringe pump (Razel Scientific Instruments, Stamford, CT, USA). The extrusion was performed under an applied electric field between the positively charged needle and grounded collecting solution. The potential difference was controlled by a high voltage unit (Model 30R; Bertan Associates, Inc., New York, USA) and kept at a constant voltage of 7,0 kV. Collecting solution was mixture of *P.tridentatum* extract and Ca-chloride 1,5% (w/v). After ions exchange, alginate droplets formed insoluble hydrogel microbeads with the extract entrapped in. The microbeads were left in the cross-linking solution for 30 min and then used for further analysis (Bugarski et al., 2004). Hydrogel microbeads were observed under optical microscope (Olympus CX41RF, Tokyo, Japan) and average diameter was measured with the image analysis program Cell^{A} (Olympus, Tokyo, Japan).

In order to produce freeze-dried beads, hydrogel microbeads were frozen at −80°C for 1 h before freeze drying, which was carried out at −50°C at a pressure of 30 Pa for 10 min and 10 Pa for 24 h. The surface morphology of carefully freeze-dried microbeads was determined by scanning electron microscopy (SEM, model RESCAN MIRA3XMU, Czech Republic).

Fourier transform infrared spectroscopy (FTIR)

The interactions between the different components of the alginate-inulin systems were analysed by Fourier transform infrared (FTIR) using a FTIR spectrophotometer (BOMEM, Hartmann & Braun). Microbeads samples were dried in a vacuum desiccator, triturated with micronized KBr powder and compressed into discs by pressing the powders. Discs and scanned from 4000 to 450 cm^{-1} at a resolution of 4 cm^{-1} at room temperature.

Determination of total phenol content (TPC)

TPC was determined using the Folin-Ciocalteau reagent, according to a modified method of Lachman et al (1998). In brief, 70 µL of the sample was pipetted into a 15 mL volumetric flask containing 350 µL of Folin–Ciocalteu reagent, 4,2 mL of distilled water and 1,05 mL of 20% (w/v) Na-carbonate, and the volume was made up with distilled water. After 2h, the absorbance of was measured at 765 nm against a blank sample. Gallic acid was used as the standard and the results expressed as mg L^{-1} of gallic acid equivalents (GAE).

Encapsulation efficiency

Encapsulation efficiency (EE%) was calculated as the amount of TPC encapsulated in microbeads (m_b) divided by the TPC of the solution used for the preparation of microbeads (m_s), as shown in equation 1:

$$EE\% = m_b/m_s \times 100 \quad (1)$$

Quantification of TPC in microbeads (m_b) was performed after dissolving microbeads in 2% (w/v) Na-citrate solution (in a weight ratio of 1:5), using a Vortex mixer to chemically dissolve them at room temperature. TPC was determined using the Folin–Ciocalteu method according to the procedure described in the upper section.

Determination of free radical-scavenging ability

The radical scavenging activity of the extract was determined according to Dudonne et al. (2009). The DPPH• solution in ethanol ($6x10^{-5}$M) was mixed with 100 µL sample and after 30 min the decrease in absorbance at 515 nm was measured (A_E). A blank sample contained 100 µL of ethanol (A_B). Percentage of cation inhibition was calculated using equation 2:

$$\% \text{ inhibition} = [(A_B - A_E)/A_B] \times 100 \quad (2)$$

where (A_B) is absorbance of the blank sample and (A_E) is absorbance of the sample.

The free radical scavenging capacity of the extracts was also studied using the ABTS radical assay. ABTS• was produced according to Re et al. (1999). An appropriate solvent blank reading was taken (A_B). Extract solutions (30 µL) was mixed with 3 mL of ABTS• solution and absorbance reading was taken after 6 min (A_E). The percentage of inhibition of ABTS• was calculated using equation 2.

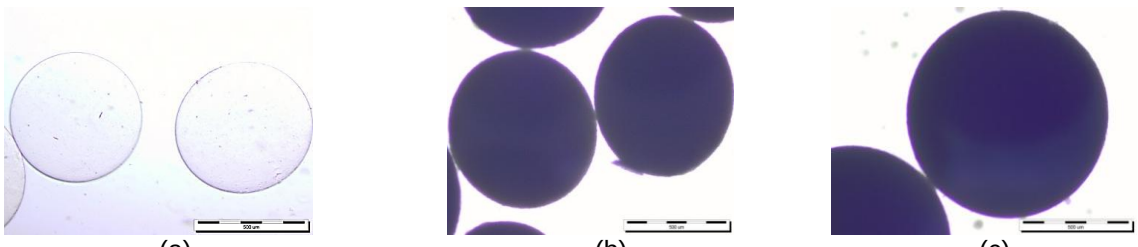
In order to test radical scavenging activity of the extract after microencapsulation, certain amount of hydrogel microbeads with encapsulated extract was suspended in 3 mL of distilled water. The samples were left on an orbital shaker operating at 100 rpm and when the extract was completely released the samples were analysed on TPC, DPPH and ABTS.

Release studies

The release studies of polyphenols from freshly prepared hydrogel microbeads were performed at laboratory conditions. About 5 g of microbeads was suspended in 12,5 mL of distilled water. The samples were submitted to continuous agitation on an orbital shaker operating at 100 rpm (New Brunswick Scientific Co., Inc., Edison, NJ). At defined time intervals (2, 5, 10, 20, 30, 45, 60 min), an aliquot (70 µL) was taken for analysis of TPC.

RESULTS AND DISCUSSION

The obtained hydrogel alginate and alginate-inulin microbeads were analysed by optical microscope. Alginate microbeads encapsulating *P. tridentatum* extract appeared spherical with a quite smooth surface and average diameter of ~500 µm (Fig. 1a). Alginate microbeads with 10 mass% of inulin were slightly distorted from a perfect sphere and they are larger compared to alginate microbeads, ~700 µm (Fig. 1b). Alginate microbeads with 20 mass% of inulin had spherical appearance with the average diameter of ~800 µm (Fig. 1c).



(a) (b) (c)

Figure 1. Photos of alginate microbeads encapsulating *P. tridentatum* extract: (a) alginate microbeads; (b) alginate microbeads with 10 mass% of inulin; (c) alginate microbeads with 20 mass% of inulin.

After the freeze-drying, removed water accounts for 93,9, 86,0 and 78,6% of the initial weight for alginate, alginate with 10 mass% and 20 mass% of inulin, respectively. Microbeads treated by freeze-drying process were analysed by SEM. SEM was used to give information about features of the surface and the influence of inulin on surface morphology. Freeze-drying damaged the walls of alginate microbeads so they got irregular shape, with the surface of a spongy texture (Fig. 2 Ia, Ib, Ic). The problem of the gel collapse during freeze-drying process was significantly reduced by addition of inulin. The microbeads with 10 mass% (Fig. 2 IIa, IIb, IIc) and 20 mass% (Fig. 2 IIIa, IIIb, IIIc) of inulin have a rather smooth surface with a preserved round structure. SEM micrographs were also analysed using ImageJ application. The outcomes showed that the average diameter of alginate freeze-dried microbeads was 212,5±32,6 μm. Microbeads with 10 mass% of inulin, had average diameter 553,9±72,3μm and the one with 20 mass% of inulin, 578,8±83,5μm. The average diameters were determinate on a sample of 100 microbeads.

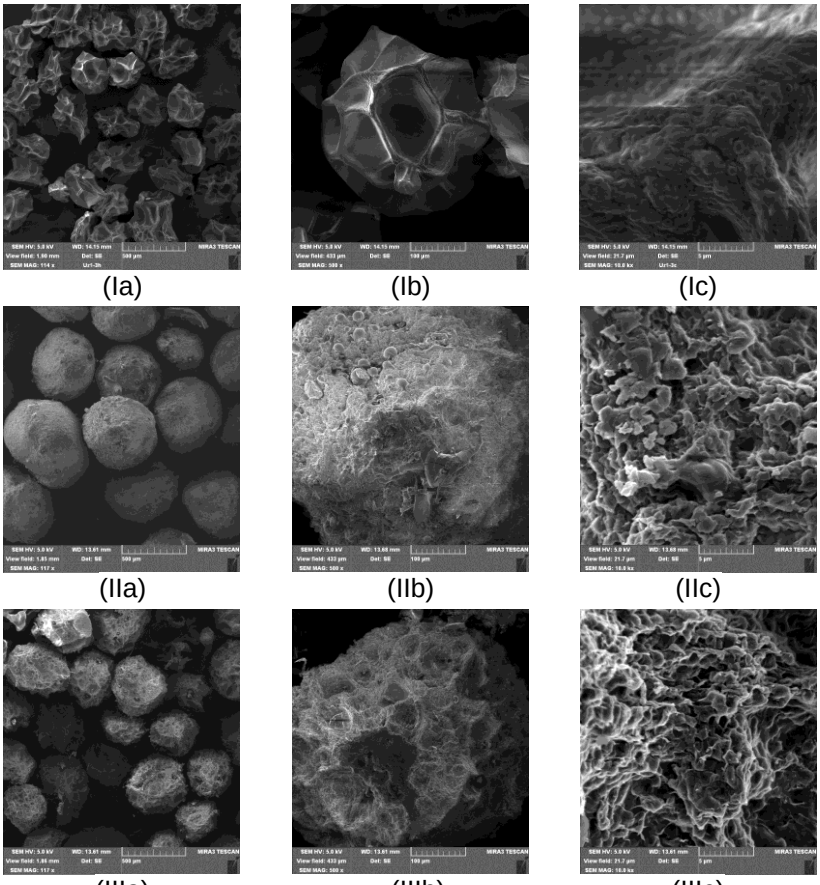


Figure 2. SEM micrographs of the freeze-dried microbeads: (I) alginate microbeads, (II) alginate microbeads with 10 mass% of inulin, (III) alginate microbeads with 20 mass% of inulin, (a) low magnitude, (b) medium magnitude, (c) high magnitude

The results of TPC and EE% for all microbeads are given in table 1. Depending on the addition on inulin, TPC in microbeads ranged from 0,24 to 0,33 mg GAE g_{beads}^{-1} and the highest amount of TPC was detected in alginate microbeads with 20 mass% of inulin. The results indicate that this type of microbeads has the highest encapsulation capacity. This can be explained by reduction of pore size of alginate in the presence of fillers (Rassis et al., 2002). In that way prevention of leakage of the encapsulated compounds was achieved.

Table 1. TPC, DPPH and ABTS of *P. tridentatum* extract and TPC, EE%, DPPH and ABTS of *P. tridentatum* extract encapsulated in hydrogel microbeads

SAMPLE	TPC (mg GAE g_{beads}^{-1})	EE(%)	DPPH(%)	ABTS(%)
Fresh extract	0,35[a]	/	57,5	47,7
Alginate microbeads	0,24	49,0	33,6	30,3
Alginate microbeads with 10 mass% of inulin	0,30	63,8	39,5	31,5
Alginate microbeads with 20 mass% of inulin	0,33	73,8	40,7	34,6

[a]*The unit is mg GAE mL^{-1}*

In this study, the antioxidant capacity of microbeads was determined by two analytical assays: (a) by ABTS radical cation ($ABTS^{*+}$) decolourization assay and (b) by DPPH radical photometric assay. The results are expressed as the percentage of radical inhibition and compared to antioxidant activity of the fresh extract (Tab. 1). The inhibition of the DPPH• radical with fresh extract (2 mg ml^{-1}) was around 57% and the inhibition of ABTS• was 47%. Upon encapsulation, antioxidative activity of extract compounds was preserved at a high level, as confirmed by both assays and alginate microbeads with 20 mass% of inulin showed the highest antioxidative potential.

FTIR was used to identify functional groups and characterise the relationship between the matrix and the extract components. In spectra of alginate freeze-dried microbeads (Fig.3) the strong and broad absorption band has been observed at 3430 cm^{-1} due to –OH stretching. This peak is slightly wider and moved to 3427 and 3417 cm^{-1} for samples with 10 and 20 mass% of inulin, respectively, due to overlap with the corresponding band in the case of inulin, located at 3380 cm^{-1} (pure inulin spectrum is not shown). The strong asymmetric stretching absorption band at 1625 cm^{-1} and weaker symmetric stretching band near 1440 cm^{-1} appeared due to the presence of carboxylate anions COO^- (Singh et al., 2009; Vijaya et al., 2008). The weak peak at 2920 cm^{-1} becomes stronger with increase in the amount of inulin, because this peak is related to the $–CH_2$ groups present in both, alginate and inulin. Similarly, the band at 1030 cm^{-1} becomes stronger and sharp, due to the C-O-C stretching of inulin (Fares et al, 2011). There are some changes in the peak intensity in the range of 900-1500 cm^{-1} between FTIR spectra of the native (not shown) and extract-encapsulating microbeads. The results of FTIR analyses indicate the absence of chemical interactions between extract compounds and alginate, thus it can be deduced that alginate hydrogel is a compatible material for encapsulating biochemical active compounds extracted from plants.

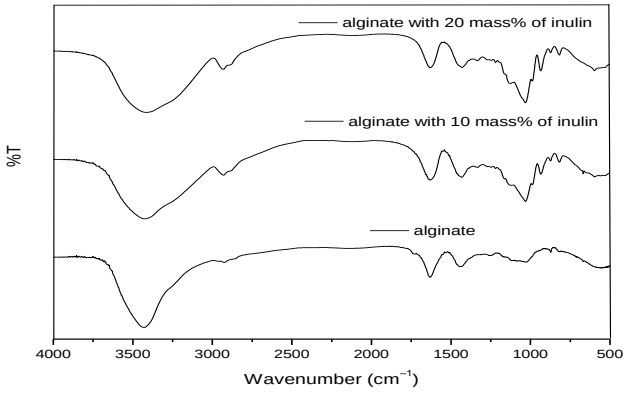

Figure 3. FTIR spectra of microbeads with encapsulated *P. tridentatum* extract

The release profiles for all three types of microbeads encapsulating *P. tridentatum* extract are shown on Fig. 4. The polyphenolic compounds were released after 30-40 min and the presence of inulin enabled better retention of polyphenols, especially in the first few minutes. For sake of comparison, two minutes after sinking microbeads in water, almost 90% of polyphenols was already released from alginate microbeads, while at the same time, about 30% was still captured within the alginate matrix containing 20 mass% of inulin.

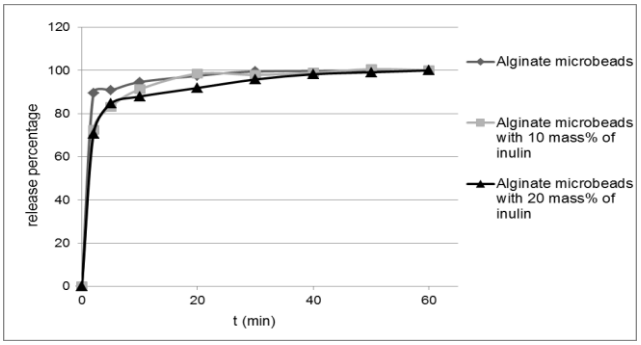

Figure 4. Release profiles of polyphenols from freshly prepared microbeads encapsulating *P. tridentatum* extract.

CONCLUSIONS

Encapsulation of aqueous *P. tridentatum* extract within alginate and alginate-inulin microbeads has been assessed. The obtained microbeads displayed significant polyphenol content. The best results were achieved with alginate-inulin microbeads, as they were treatable by freeze-drying. They were also richer in polyphenols and they protected the extract from release better than plain alginate forms. The antioxidant activity of the extract was preserved after microencapsulation at a high level, especially in case of alginate microbeads with 20 mass% of inulin.

ABSTRACT: Probiotic are "living microorganisms, which upon ingestion in certain numbers, exert health benefits beyond inherent basic nutrition", and it is recommended that probiotic products contain at least 10^7 live microorganisms per g or per ml. Spray-drying is one of the possibilities to improve the survival of probiotic bacteria against negative environmental effects. The aim of this study was to compare survival of two spray-dried *Lactobacillus plantarum* TA and *Lactobacillus plantarum* 7A strains isolated from plant and breast-fed baby's feces. In addition, beside the plate-count technique, the aim was to examine the possibility of using propidium monoazide (PMA) in combination with real-time polymerase chain reaction (real-time PCR) for determination of spray-dried *Lb. plantarum* strains after two years of storage at 4°C. Both tested strains showed very good ability to survive spray-drying. After two years of storage at 4°C, the number of intact cells, *Lb. plantarum* TA and *Lb. plantarum* 7A, was determined by real-time PCR with PMA, and it was similar to the number of investigated strains obtained by plate count method. The spray-drying was effective in maintaining the viability of *Lb. plantarum* TA and 7A strains after two years of storage at 4°C. The PMA real-time PCR determination of the viability tested strains could complement the plate count method.
Key words: *real-time PCR, propidium monoazide, probiotic bacteria*

INTRODUCTION

During the last few decades, a wide variety of novel products containing probiotics have been developed. A number of definitions of the term "probiotic" have been used over the years, but the one derived by the Food and Agriculture Organization (FAO/WHO, 2002) best exemplifies the breadth and scope of probiotics as they are known today: "Live microorganisms, which when administered in adequate amounts, confer a health benefit on the host" (Reid, 2006). They are able to survive the low pH of the stomach, which is normally destructive for most microbes (Holzapfel et al., 1998) and to contribute positively in the activity of intestinal microflora. The most probiotic bacteria belong to the *Lactobacillus* genera and *Bifidobacterium* strains (Prasad et al., 1998).

In the recent past, there has been an explosion of probiotic health-based products. Many reports indicated that there is poor survival of probiotic bacteria in these products (Shah, 2000; Lourens-Hattingh and Viljoen, 2001). Several approaches have been adopted in endeavoring to improve probiotic survival in traditional probiotic foods. Freeze-drying and spray-drying are most commonly used microencapsulation methods. The process of spray-drying is economical, can be operated on a continuous basis, it is easily scaled up and uses equipment readily available in the food industry (Gibbs et al., 1999). The disadvantage is that the high temperature used in the process of spray-drying, may not be suitable for encapsulating probiotic bacterial cultures. However, proper adjustment of the processing conditions, such as the inlet temperature, can achieve viable encapsulated cultures.

Viability is generally considered a prerequisite for optimal probiotic functionality (Maukonen et al., 2006). Many studies have shown that the viability of bacteria is not a simple question of cells being dead or alive (Nystrom, 2001; Bogovic Matijasic and Rogelj, 2006). Plate counting is one of the classic and most widespread techniques for determining the viability of

spray-dried bacteria, though there are obvious disadvantages, such as limiting microbial recovery and sensitivity and relatively long times needed for the growth of colonies. Therefore, during the recent years there has been increasing interest in the development of culture-independent molecular methods for identification and quantification of probiotic bacteria. Quantitative real time polymerase chain reaction (real-time PCR) is the most widely applied technique for direct quantification of bacteria in mixed samples (Juste` et al., 2008). However, at the moment, there are still some limitations to overcome before the introduction of such methods in routine analysis. Real-time does not enable the distinction between DNA arising from dead or alive cells; therefore, the DNA from dead cells contributes to the results. A possible way to distinguish between alive and dead cells is the integrity of membrane. Viable cells with intact membranes are impermeable to the passage of certain intercalating DNA agents, which, however, selectively penetrate dead cells. Propidium monoazide (PMA) has been shown to be useful for differentiating between some live-dead Gram-positive and Gram-negative bacteria (Nocker et al., 2006). PMA is a DNA-intercalating dye with the azide group, which enables covalent binding to DNA under bright visible light and, consequently, strongly inhibits PCR amplification.
The aim of this study was to compare survival of two spray-dried *Lactobacillus plantarum* TA and *Lactobacillus plantarum* 7A strains isolated from plant and breast-fed baby's feces. Furthermore, beside the plate-count technique, aim was to examine the possibility of using PMA in combination with real-time PCR with SYBR Green I chemistry for selective quantification of live spray-dried tested strains after two years of storage at 4°C.

MATERIAL AND METHODS

Strains and culture conditions

Strains *Lb. plantarum* TA and *Lb. plantarum* 7A isolated from plant and breast-fed baby's feces, belong to the strain collection of the Department for Industrial Microbiology, Faculty of Agriculture, University of Belgrade, Serbia. The strains were cultured in MRS broth (Merck, Darmstadt, Germany) at 37ºC. For both strains, cell enumerations were carried out on MRS agar (Merck, Darmstadt, Germany) 48 h at 37˚C under anaerobic conditions (Gas Pak, BBL, Germany).

Spray-drying

Spray-drying tests were performed using the method of Petrovic (2011). Overnight cultures (300 ml) were centrifuged (4500 x g, 15 min, 15˚C). The pellet was washed twice in 50mM K2HPO4 (pH 6.5) and resuspended in 300 ml of sterile RSM (20% w/v). Both tested strains were spray-dried with a laboratory scale spray-dryer (model B-290 Buchi mini spray dryer, Switzerland) by using the constant inlet air temperature of 170˚C and the outlet temperature of 80˚C.

Determination of viability of tested strains in spray-dried powders

Plate count method

The colony forming units (CFU) of cultures were assessed by the plate count using MRS agar. 9 ml of Na-citrate (2% w/v) was added to 1 g spray-dried powder and the preparation allowed to rehydrate before further dilutions were performed and appropriate dilutions plated (1ml) onto MRS agar. The plates were placed in anaerobic conditions and incubated at 37˚C for 48 h (Gas Pak, BBL, Germany). The number of bacteria before drying was determined and compared with the number of bacteria per spray-dried powders, CFU/g dry weight was determined from CFU/ml after drying a known volume of the original sample used for plating.

Real-time PCR for selective quantification

Sample preparation

Both spray-dried tested strains were well resuspended in Na-citrate (2%) solution to prepare 1% (w/w) solution. One milliliter of 1% spray-dried suspension was centrifuged (5000 x g, 10

min), and DNA was extracted from pellet by the method described below. Samples were tenfold serially diluted prior to PCR analysis.

PMA treatment

Spray-dried tested lactobacilli were treated with PMA, as described by Nocker et al. (2006). PMA (Biotium, Inc, CA, USA) was dissolved in dH2O to create 20 mM PMA stock solution and stored at -20˚C in the dark. Powders of each tested strain were resuspended in Na-citrate solution to prepare 1% (w/v) solution. An adequate volume of PMA stock solution was added to 500 µl of aliquots of spray-dried cultures to make the final concentration of 50 µM. This was followed by an incubation period of 5 min of 5 min in the dark with occasional mixing to allow the PMA to penetrate the dead cells and to bind to the DNA.

Samples were light-exposed to a halogen light source (650W, 150V) for 5 min and samples were laid horizontally on ice to avoid excessive heating and placed about 20 cm from the light source. After photo-induced cross-linking, the cells were pelleted at 5000 x g for 10 min prior to DNA isolation by the bellow described protocol.

DNA isolation

Total genomic DNA from the samples was extracted using MaxwellTM 16 cell tissue DNA purification kit applied with MaxwellTM 16 instrument (Kramer et al., 2009). 400 µl of TE buffer and 100 µl of lyzozyme (25 mg/ml) with mutanolysine (10 U/ml) were added to the pellet, which was further resuspended and incubated for 2 h at 37˚C for bacterial cell lyses, before isolation by the Maxwell system. The whole volume of prepared samples was transferred into the first well of the cartridge and further treated according to the manufacturer`s instructions. Finally, DNA was resuspended in 300 µl of elution buffer with added 1.5 µl RNAse (4mg/ml).

Real-time PCR

PCR amplifications were performed with an MX3000P (Strategene, LA Jolla, CA, USA) instrument (Kramer et al., 2009). The reaction mixture (25 µl) containing Platinum SYBR Green qPCR Super Mix UDG (11733; Invitrogene, Carlsbad, CA, USA), 0.2 µM of each primer and 5 µl of genomic DNA diluted -10 fold. The following primers were used LactoR`F (5`-CACAATGGACG(A/C)AAGTCTGATG-3`) and LBFR (5`-CGCCACTGGTGTTCTTCCAT-3`) (Songjinda et al., 2007). The amplification programme was 50˚C for 2 min and 95˚C for 2 min, 35 cycles of 95˚C for 30 s, 60˚C for 15 s, 72˚C for 20 s, and then 95˚C for 1 min and 55˚ for 30 s.

Statistical analysis

The Ct values were automatically generated by the Invitrogene software. Experiments were replicated at least three times. Means and standard deviations were calculated using one-way analysis of variance (ANOVA).

RESULTS AND DISCUSSION

Viability of tested strains in spray-dried powders determined by plate counting

The main factor that governs microbial survival during spray-drying is the ability of the strain to survive high temperatures. The heat resistance experiments demonstrated that stationary-phase cultures are more resistant to heat stress than cells in exponential growth phase (Texeira et al., 1994). In relation to that it should be mentioned that both tested strains were in stationary phase.

The viability of strains, *Lb. plantarum* TA isolated from plant and *Lb. plantarum* 7A isolated from breast-fed baby's feces, in spray-dried powders are shown in Table 1. The survival rates of tested *Lb. plantarum* TA and *Lb. plantarum* 7A strains after spray-drying, determined by plate counting, were very high, 91.00% and 85.20%, respectively. *Lb. plantarum* TA decreased slightly more than 1.0 log, while *Lb. plantarum* 7A decreased less than 2.0 log after spray-drying.

Table 1. Viability of tested strains in spray-dried powders

Strains	Before spray-drying log (CFU/g)[a]	After spray-drying log (CFU/g)[a]	Percent of survival (%)
Lb. plantarum TA	11.23 ± 0.07	10.20 ± 0.12	91.00%
Lb. plantarum 7A	12.61 ± 0.04	10.75 ± 0.03	85.20%

[a] *Mean values (log CFU/g) and standard deviation were calculated from three parallel plate count analyses*

Viability of tested strains in spray dried powders after two years of storage at 4ºC

Different methods were used for the enumeration of probiotics in the products containing dried probiotic bacteria. As an alternative for the most common plate count methods, real-time PCR methods have been used for the quantification of probiotic bacteria in several studies, however, most often in different foods, such as fermented milk products, while studies reporting the application in probiotic food supplements are few (Grattepanche et al., 2005). In some studies, the real-time PCR method was successfully used for the enumeration of LAB in lyophilized dairy starter cultures (Friedrich and Lenke, 2006).

One of the aims of this study was to evaluate the possibility of using PMA in combination with real-time PCR using SYBR Green I chemistry for the selection of viable lactobacilli in spray-dried powders. Optimal conditions of PMA treatment for enumeration of viable cells of tested strains were 50µM PMA, 5 min incubation, 5 min photoactivation (Fujimoto et al., 2010; Noecker et al., 2007). Bacterial counts derived from real-time PCR determination of PMA-treated and non-treated samples of spray-dried tested strains were compared to the plate count method (Table 2).

Table 2. The number of cells of spray-dried tested strains performed by the plate count method, real-time polymerase chain reaction (PCR), and propidium monoazide (PMA) real-time PCR after two years of storage at 4°C

Strains	Plate count[a]	Real-time PCR without PMA[b]	Real-time PCR with PMA[b]
Lb. plantarum TA	9.80 ± 0.04	9.68 ± 0.41	9.34 ± 0.42
Lb. plantarum 7A	9.49 ± 0.14	9.75 ± 0.08	9.13 ± 0.42

[a] *Mean values (log CFU/g) and standard deviation were calculated from three parallel plate count analyses*

[b] *Mean values (log CFU/g) and standard deviation calculated from Ct values; based on two parallel DNA extracts from which two real-time cycles were run*

Spray-dried *Lb.plantarum* TA strain showed reduction in cell counts less than 2 log, while spray-dried *Lb. plantarum* 7A strain showed reduction in cell counts higher than 3 log, after two years of storage at 4°C, determined by plate count method. The concentrations log (CFU/g) of tested strains obtained by plate count method were not significantly ($p < 0.05$) different from the values obtained by real-time PCR analysis. The comparison of plate count real-time PCR for enumeration of LAB commercial milk products showed that the loss of cultivability during storage was train dependent (Furet et al., 2004). For instance, when it comes to the *Lactobacillus casei* group, the results of real-time PCR quantification did not differ from the results of the plate count, while for most of the strains of *Lb. delbrueckii*, ten to 100 lower values were detected by plate counting (Kramer et al., 2010). The treatment of samples with PMA, followed by real-time PCR analysis, as presented in this study, appears a promising approach for a routine method of enumeration of probiotic bacteria in spray-dried powders.

CONCLUSION

Both tested strains have shown very good ability to survive process of spray-drying. Further, the results of this study indicated that the spray-drying process of microencapsulation offered protection to the tested strains during storage for two years at 4°C. Because of the

complexity of the bacterial population, including physiological states of bacteria, the combination of different methods would represent a significant improvement of the analysis of bacteria. The real-time PCR approach will be further improved in the way that will be enable to distinguish between DNA derived from intact or damaged cells.

ABSTRACT: Basil (*Ocimum basilicum*) is an aromatic plant widely used as a culinary herb, commonly added as fresh. There are many scientific studies that have confirmed health benefits of the basil oil. Bioactive compounds of the essential oils found in basil have antioxidant and antimicrobial properties. However, effectiveness of these compounds depends on preserving their stability, which can be increased by encapsulation.
The aim of this study was to encapsulate the basil essential oil (EO) in alginate microbeads in order to protect and stabilize bioactive compounds in it. Calcium alginate microbeads entrapping the EO were produced by electrostatic extrusion technique. The obtained microbeads were characterized from the aspect of total phenol content, encapsulation efficiency and antioxidant capacity. Total polyphenol content (TPC) of microbeads was analyzed by the Folin-Ciocalteu reagent. Encapsulation efficiency was calculated as the ratio between the TPC in the citrate solution of dissolved microbeads and the TPC of the initial EO. The radical scavenging activity was determined as Trolox equivalent antioxidant capacity (TEAC) and by using stable free radical 1,1-diphenyl-2-picrylhydrazyl (DPPH). The rehydration properties of air dried calcium alginate gel microbeads were investigated in water and phosphate buffer solution. Also, samples were analyzed by optical microscopy (OM).
Encapsulation efficiency was obtained to be approximately 60 %. The results of TEAC and DPPH tests indicate that antioxidant activity was preserved at a satisfactory level. The average diameters of fresh and dried microbeads were 860.8±44.9 and 416.0±37.2 μm, respectively. The particles, with and without EO, rehydrated in buffer were highly swollen, from 5000 to 10000 %w/w.
The results suggest that alginate microbeads encapsulating EO appeared to be suitable dosage forms. Thus, possible applications of these microbeads could be in the production of functional foods.
Key words: *basil, essential oil, encapsulation, alginate microbeads, rehydration*

INTRODUCTION

Basil (*Ocimum basilicum*) is a popular culinary herb in many traditional cuisines and diets. Also, this plant is a source of valuable essential oil and extracts used in cosmetic industry and pharmacy. Basil is well known as a source of antioxidant, antimicrobial and antitumor active compounds. The activity of basil essential oil and extracts is mainly connected to a presence of phenolic and aromatic compounds (Mäkinen & Pääkkönen, 1999; Holm, 1999; Taie et al., 2010). During production and storage, some of the active compounds can be permanently damaged, since most of these compounds are too sensitive to many factors. The effectiveness of these valuable active compounds can be protected using encapsulation processes. Encapsulation is defined as a process of entrapping active compounds within another substance (Zuidam & Shimoni, 2010). Thus, encapsulation is an effective method to protect bioactive compounds, preserve their stability, and prevent some interactions with food matrix which are undesirable (Nedović et al., 2011).
Electrostatic extrusion is a promising encapsulation technique for production of spherical beads loading active compound. This technique has been intensively used for encapsulation of cells, plant extracts as well as food additives in calcium alginate matrix (Nedovic et al.,

2001; Manojlović et al., 2008; Stojanović et al., 2011; Belščak-Cvitanović et al., 2011). The objective of this study was to investigate the encapsulation of basil EO in calcium alginate matrix using electrostatic extrusion. The efficiency of encapsulation procedure was evaluated by comparison of both, total polyphenols content and antioxidant activity of free and encapsulated basil EO. Also, the dehydration and rehydration properties of the samples were analyzed and microbeads were observed under optical microscope.

MATERIALS AND METHODS

In this study, sodium-alginate (medium viscosity) purchased from Sigma was used for a matrix preparation. Calcium chloride dihydrate was purchased from Analytika (Czech Republic). Folin-Ciocalteu, Na-carbonate, and Na-citrate were of analytical grade and supplied by Sigma-Aldrich (St. Louis, MO, USA). 2,2′-azino-bis(3- ethylbenzthiazoline-6-sulphonic acid)diammonium salt (ABTS), 2,2-diphenyl-1-picrylhydrazyl (DPPH), sodium chloride, potassium persulfate, monosodium phosphate monohydrate and disodium phosphate heptahydrate were obtained from Sigma-Aldrich (Germany).

Plant material and cultivation conditions

The seeds of *O. basilicum* subs. *basilicum* var. *glabratum* cultivar Cinnamon were planted in the greenhouse in March of 2009, and stuffed with commercial substrate (Beatović et al., 2006). Seedling production lasted 48 days. During May of 2009, nursery plants were transplanted into the experimental field in a randomized complete block design with four replicates. The harvest of plants was performed at the full flowering stage in June of 2010. Plants were air dried in the shade, and then packed and stored. Seeds of *O. basilicum* subs. *basilicum* var. *glabratum* cultivar Cinnamon were obtained from the Institute for Crop Sciences of the Faculty of Agriculture in Belgrade and the Plant Gene Bank of Serbia where plants were designated and deposited under DB codes.

Extraction of basil essential oil

The extraction of the EO was carried out in order to extract and quantify the amount of EO present in dried basil herbs. A weight of 20 g of dried herbs was mixed with 400 mL of distilled water and subjected to hydro-distillation for 2,5 hours using a Clevenger apparatus. The volume of the extracted EO was determined and recorded. The extracted oil was dehydrated over anhydrous sodium sulfate and stored in a glass vials at 4°C.

Determination of total phenol content (TPC)

Total phenolic content was determined spectrophotometrically using the Folin-Ciocalteau reagent, according to the method of Singleton et al (1998). In brief, 125 µL of the sample was pipetted into a volumetric flask containing 125 µL of Folin–Ciocalteu reagent, 0,5 mL of distilled water and after 6 minutes 1,25 mL of 7% (w/v) Na-carbonate was added, and the volume was made up with 3 mL of distilled water. After 90 minutes, the absorbance of the blue colouration was measured at 760 nm against a blank sample. Gallic acid was used as the standard and the results expressed as mg L^{-1} of gallic acid equivalents (GAE).

Determination of free radical-scavenging ability (DPPH)

The DPPH radical scavenging activity of the basil EO was determined according to Molyneux (2004). The DPPH• solution in ethanol ($5x10^{-5}$M) was mixed with 100 µL sample, incubated for 30 minutes in dark and then the decrease in absorbance at 517 nm was measured (A_s). A blank sample contained 100 µL of ethanol in the 3mL of DPPH• solution (A_B). Radical scavenging activity was calculated using the following formula:

$$\% \text{ Inhibition} = ((A_B - A_s)/A_B) \times 100$$

where (A_B) is absorbance of the blank sample and (A_s) is absorbance of the sample.

Trolox equivalent antioxidant capacity (TEAC)
The free radical scavenging capacity of the EO was also studied using the ABTS radical assay (Re et al. 1999). ABTS• was produced by mixing 5 mL of ABTS water stock solution (7 mM) with 88 µL of potassium persulfate (140 mM) and allowing the mixture to stand in the dark at room temperature for 12-16 h before use. The ABTS• solution was diluted with ethanol to an absorbance of 0.7 (±0.02) at 734 nm. An appropriate solvent blank reading was taken (A_B). After the addition 30 µL of the EO solutions to 3 mL of ABTS• solution, the absorbance reading was taken 6 minutes after initial mixing (A_s).

Encapsulation of basil essential oil
Encapsulation of basil essential oil in calcium alginate matrix using electrostatic extrusion was realized according to procedure described by Nedović et al. (2001), with some modifications. The first step in encapsulation process was a preparation of a shell solution by dissolving sodium alginate powder in distilled water (0.02g/mL). Alginate/EO emulsion (2.5% w/w of EO) was prepared using Ultra-Turrax T25 (T25 digital ULTRA-TURRAX®, IKA, Germany) at a speed of 10000 rpm for 5 minutes. Emulsion was extruded through blunt stainless still needle (22 gauge) using a syringe pump (Razel, Scientific Instruments, Stamford, CT) under constant flow rate of 70mL/h. Electrostatic potential (6.0kV) was formed by high voltage dc unit (Model 30R, Bertan Associates, Inc., New York). The collecting solution was calcium chloride (0.015 g/mL). The distance between the needle tip and the collecting solution was 2.5 cm. After extrusion, the beads were left in the collecting solution for 45 minutes. After gelling period, microbeads were rinsed with distilled water. In order to produce dried encapsulated samples loading essential oil, wet beads were air-dried at room temperature to a constant mass.

Encapsulation efficiency (EE)
Encapsulation efficiency (EE) was calculated as the amount of TPC encapsulated in microbeads (m_b) divided by the TPC of the solution used for the preparation of microbeads (m_s), according to the formula:

$$EE\% = m_b / m_s \times 100$$

Quantification of TPC in microbeads (m_b) was performed using dissolved microbeads in 2% (w/v) sodium citrate solution, in a weight ratio of 1:4, using a Vortex mixer (Tehnica zeleznik EV-102) to chemically dissolve them at room temperature. TPC was determinated using the Folin–Ciocalteu method.

Bead size measuring
The diameter of beads was determined microscopically using binocular microscope DMLS Leica (Leica, Germany) equipped with a camera DC 300 (Leica, Germany) and a software for measuring IM 1000 (Leica, Germany). At least 50 microbeads were measured and the average diameter and standard deviation were calculated.

Drying kinetics
Drying kinetics study was carried out by measuring weight loss of alginate microbeads during the time. The wet microbeads were air-dried at room temperature and weight loss of the samples was measured at defined intervals of time on an analytical balance until the constant mass was achieved.

Rehydration of dried microbeads
The same amounts of air dried microbeads with and without basil EO were placed in a (1) 20 mL of distilled water and in a (2) 20 mL of phosphate buffer (pH=7.4), and then shaken at a speed of 100 rpm. Samples were measured during 420 minutes at definite intervals of time.

RESULTS AND DISCUSSION

Extraction of basil essential oil

Essential oil extracted from basil dried herbs was light yellow coloured with the specific aroma. The total content of essential oil in dried herbs was 1.0%. Generally, oil yield for basil is in the range 0.2-1.0%, which depends on plant physiology and source. According to the results, basil plantation for production of essential oil can be effective in ecological conditions of Serbia.

Encapsulation efficiency

The results of TPC, DPPH, TEAC of basil EO and TPC, EE%, DPPH, TEAC of alginate microbeads loaded with basil EO are given in Table 1.

Table 1. TPC, DPPH and TEAC of basil EO and TPC, EE%, DPPH and TEAC of alginate microbeads loaded with basil EO

test / sample	Basil EO	Alginate microbeads loaded with basil EO
TPC(mgGAE/gDW)	7.54	4.53
TEAC(%)	67.40	39.30
DPPH(%)	74.50	48.50
EE(%)	-	60.13

According to the results, the content of polyphenols as well as antioxidant capacity (expressed in both terms, DPPH and TEAC) of encapsulated basil EO were proportional to the encapsulation efficiency.

Bead size measuring

The average diameter of freshly-prepared beads encapsulating basil essential oil was 860.8±44.9 μm (Fig 1-a). After drying, the contraction of beads occurred, probably as a result of water evaporation (Fig 1-b). The mean diameter of dried beads (416.0±37.2 μm) decreased for about 50% compared to freshly-prepared beads. Also, the changes in beads shape during drying process were noticed, such as distortion of sphericity. According to the literature, the distortion of sphericity and gel collapse during drying could be prevented by addition of filler substances (Zohar-Perez et al., 2004).

Figure 1. Photos of beads loading basil essential oil: (a) wet calcium alginate beads with encapsulated EO; (b) dried calcium alginate beads with encapsulated EO

Drying kinetics

Drying is a way of food preserving frequently used in the food industry. However, drying and subsequent rehydration often results in a decline of food quality. Therefore, in this study we examined the rates of drying and rehydration of alginate microbeads encapsulating basil essential oil and compared to those of plain alginate microbeads. Fig 2. shows weight loss of alginate microbeads with and without basil essential oil during 30 hours of drying. Constant weights were achieved after 8 hours.

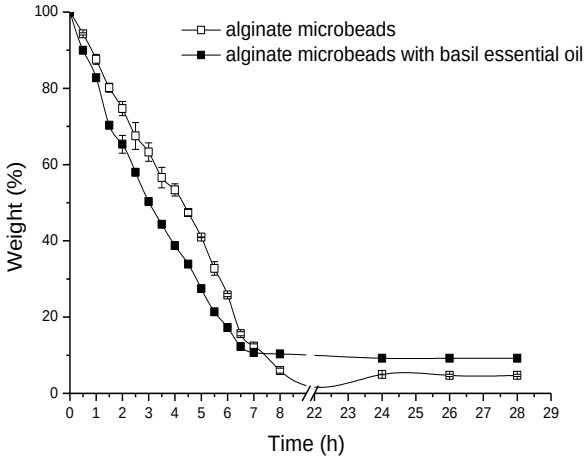

Figure 2. Weight loss of alginate microbeads and alginate microbeads with basil EO during drying process.

Rehydration of dried microbeads

As shown in Fig.3-A equilibrium was reached after 3 - 4 hours and the particles rehydrated in phosphate buffer were highly swollen. For example, after 90 minutes particles swelled about 60 times. However, after approximately 4 hours unfilled particles continued to swell more than 10000 %w/w, while particles with EO after same period started to decompose. In general, rehydration of calcium alginate beads is dependent on the ionic strength of the rehydration medium as well as on alginate source (i.e. mannuronic to guluronic acid ratio). At the high salt concentration such as one of the phosphate buffer used in this study (100 mM and pH=7.4) disintegration of alginate beads occurs after several hours of hydration; this happened faster in case of alginate microbeads encapsulating basil oil. According to our results (Fig.3-B) and literature data (Vreeker et al, 2008), calcium alginate beads do not rehydrate to a significant extent in pure water (i.e. in the absence of salt).

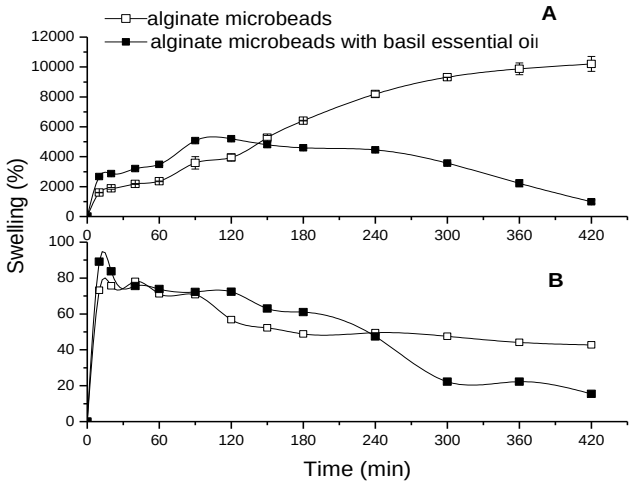

Figure 3. Swelling of alginate microbeads and alginate microbeads with basil EO (A) in phosphate buffer and (B) in water

CONCLUSIONS

Basil is widely used in the culinary and the food processes as an aroma to improve the taste, odor, and digestability of food products. The results show that basil EO has a signficant antioxidative potential and total polyphenol content. According to the results, the antioxidant activity of the basil EO was preserved after encapsulation at a high level. As shown,

encapsulation of the basil EO in alginate microbeads is suitable for protection and controlled delivery of functional compounds.

ABSTRACT: Stillage as a by-product of bioethanol production on starch substrates is rich in proteins and minerals essential for lactic acid bacteria (LAB) growth. Parallel production of lactic acid and biomass for animal feed on the stillage could bring additional value to the bioethanol production process and resolve environmental problem of the stillage disposal. Fermentations were preformed on liquid and whole stillage from bioethanol production on wasted bread with a strain *Lactobacillus rhamnosus* ATCC 7469. The stillage was obtained from ethanol factory Reahem, Srbobran and sterilized (121°C/103kPa/15 min). After adjustment of reducing sugar concentration with sterile 70% (w/w) glucose solution, the media was inoculated with 5% (v/v) of the overnight *L. rhamnosus* ATCC 7469 culture. Effect of different initial sugar concentrations was studied in batch fermentations at 41 ^{o}C, under microaerophilic conditions, with shaking (90 rpm). Lactic acid concentration (enzymatic method), reducing sugar concentration (spectrophotometric method according to Miller) and a number of viable cells (pour plate technique) were determined during the fermentation. Under selected conditions the highest yield of lactic acid of 92.7% was achieved on whole stillage with initial sugar concentration of 55 g/l. The number of viable cells at the end of fermentation was above 10^9 CFU/ml. Whole stillage from bioethanol production could be used without nitrogen or mineral supplementation as a substrate for parallel production of lactic acid and biomass. Spent fermentation media enriched with LAB biomass may be used as a valuable animal feed.
Keywords: *lactic acid, fermentation, Lactobacillus rhamnosus ATCC 7469, stillage, probiotic biomass, animal feed*

INTRODUCTION

Fermentative production of chemicals for food industry on cheap substrates is important for sustainable food manufacturing. Lactic acid is used in food industry as an acidifying agent, flavour and preservative due to its antimicrobial activity. Polymers of lactic acid (PLA) are extensively utilized for biomedical purposes (implants, suture materials, bone fixations, tissue engineering) (Bastiol, 1997) and as a biodegradable packaging materials (Data and Henry, 2006). Today, fermentation by lactic acid bacteria is a main production route in industrial facilities. Starch feedstocks are extensively studied as substrates for lactic acid fermentations (Anuradha et al., 1999; Rojan et al., 2005); however, establishment of efficient processes on wastes and by-products is desirable, although challenging approach.
Stillage from bioethanol production is a complex waste product which has been previously used in fermentative processes for single cell protein, biogas and fertilizers production (Wilkie et al., 2000). In Serbia, bioethanol production is mainly based on starch substrates and molasses. Main by-product of bioethanol production is distillery stillage which had a significant negative environmental impact. Because of high BOD_5 values of 15-340 g L^{-1}, depending on a feedstock, and pour odour of stillage, it cannot be disposed without previous treatment (Pejin et al., 2009). Costs of its treatment significantly influence financial aspects of bioethanol production and stillage utilization could be a possible solution. Nutritional requirements of lactic acid bacteria employed in lactic acid production are fastidious, especially for nitrogen sources. Almost 38 % of total costs of lactic acid production are taken by costs of yeast extract, as a nitrogen source (Teleyadi and Cheryan, 1995). Stillage

remained after bioethanol production contains residuals of yeast cells from alcoholic fermentation rich in B vitamins and nitrogen and they have a proven positive effect on growth and productivity of lactic acid bacteria (Altaf et al., 2007). Lactic acid bacteria are also well-known as species with potentially probiotic characteristics (Naidu et al., 1999). The strain *Lactobacillus rhamnosus* ATCC 7469 was used for lactic acid fermentation of stillage in our study. This strain had shown *in vitro* adherence capability (Tuomola and Salminen, 1998) and it is recommended as safe for use in animal nutrition (EFSA, 2007). Intended use of spent fermentation media rich in *L. rhamnosus* biomass could bring significant additional value to the process.
In this study, the possibility of parallel lactic acid and animal feed production was investigated. Initial sugar concentrations were varied in order to obtain efficient lactic acid production and high concentration of viable *Lactobacillus rhamnosus* ATCC 7269 cells. The spent fermentation media with *L. rhamnosus* biomass media was subjected to low pH in order to evaluate the survival of this potentially probiotic biomass.

MATERIAL AND METHODS

Microorganism

Lactobacillus rhamnosus ATCC 7469 used in this experiment was obtained from American Type Culture Collection (ATCC, Rockville, USA). Stock cultures of lactic acid bacteria (LAB) were stored at -20 °C in 3 ml vials containing Man Rogosa Sharpe medium (MRS) (Fluka, USA) and 50 % (v/v) of glycerol as a cryoprotective agent. The culture was propagated under anaerobic conditions using Anaerocult ® C bags (Merck KGaA, Darmstadt, Germany) at 37 °C for 18 h in MRS broth before inoculation to fermentation medium. The fermentation was initiated by addition of 5 % (v/v) of the inoculum.

Lactic acid fermentation

A whole stillage (without separation of solid fraction) remained after bioethanol production on wasted bread was obtained from Reahem Ethanol Plant (Reahem, Srbobran, Serbia). The pH of the stillage was adjusted to 6.5 with 30 % solution of NaOH (Sigma-Aldrich, USA), and then sterilized (120 °C/15 min). Sugar concentration in the stillage was relatively low (12.6 g L^{-1}) and initial sugar concentrations were set at 55 g L^{-1}, 75 g L^{-1} and 85 g L^{-1} by addition of sterile 70 % glucose solution. The effect of different initial sugar concentrations on lactic acid and biomass production in batch fermentations was studied. All lactic acid fermentations were performed with shaking (150 rpm, KS 4000i control, IKA®, Werke GmbH & Co. KG, Staufen, Germany) at temperature of 41 °C. During the fermentation, pH was adjusted to 6.5 in all samples, and maintained at 6.5 by addition of 30 % solution of NaOH in four hour intervals. The fermentations were preformed in 500 ml flasks with 250 ml of the fermentation media under anaerobic conditions in the gas pack system. During the fermentation: pH, sugar consumption, lactic acid concentration and a number of living cells were analyzed.

Survival of *Lactobacillus rhamnosus* ATCC 7469 under the low pH

Survival of *L. rhamnosus* under the pH of 2.5 during three hours was studied in 100 ml flasks. Volume of 50 ml spent fermentation media with *L. rhamnosus* cells was transferred in the flask and pH was adjusted to 2.5 by addition of 1 M HCl. In a control sample (50 ml) pH was adjusted to 6.5 by addition of 30 % NaOH. Samples were taken in an hour long intervals and the number of viable cells was counted using pour plate technique on MRS agar after incubation for 48 h at 37 °C.

Analytical methods

The dry matter percent was determined by a standard drying method in an oven at 105 °C to constant mass (A.O.A.C., 2000). The protein content was estimated by Kjeldahl method as the total nitrogen and multiplied by factor 6.25 (A.O.A.C., 2000). The lipid content was determined by Soxhlet method and ash content was determined by slow combustion method

at 650 °C for 2 h (A.O.A.C., 2000). The concentration of reducing sugars, calculated as glucose, was estimated by 3, 5-dinitrosalicylic acid method using spectrophotometer, Ultraspec 3300 pro, Biochrom LTD, UK (Miller, 1959). Lactic acid concentration was determined by enzymatic method (L-/ D-Lactic acid assay, Megazyme®, Wicklow, Ireland) according to procedure prescribed in assay. Number of viable *L. rhamnosus* ATCC 7469 cells was estimated using pour plate technique. The chemicals used in experiments were analytical grade.

All experiments were done in triplicates. The values are expressed as means ± standard deviation. Mean values of treatments were compared by the analysis of variance (One-Way ANOVA) followed by Tukey test. Differences were considered significant at $p < 0.05$.

RESULTS AND DISCUSSION

The chemical composition of the stillage used in our study is presented in Table 1. Low concentration of sugars in the stillage is a result of previous complete alcoholic fermentation. The stillage was supplemented with glucose as a carbon source and initial glucose concentration was found as an important parameter for lactic acid and biomass production kinetics in following experiments. Relatively high amount of proteins (more than 50 % of dry matter) indicated that the stillage could be suitable as a substrate for growth of nutritionally fastidious microorganisms like lactic acid bacteria (LAB).

Table 1. Chemical composition of the stillage

Chemical composition of stillage	Content
Total reducing sugar (% of dry matter)	9.74 ± 0.04
Lipid (% of dry matter)	8.49 ± 0.12
Protein (% of dry matter)	58.50 ± 0.12
Ash (% of dry matter)	21.47 ± 0.20
Dry weight (% of total stillage)	11.55 ± 0.30

Effects of initial sugar concentration on lactic acid and biomass production

Effect of initial sugar concentration on lactic acid production and sugar consumption in batch fermentation is presented in Figure 1. The kinetics of sugar consumption and lactic acid production was similar for all samples (Fig. 1), but the highest percentage of theoretical lactic acid yield of 92.3 % was obtained in the sample with the lowest initial sugar concentration of 55.72 g L^{-1}. The highest lactic acid concentration of 75.06 g L^{-1} was achieved in the sample with 85.31 g L^{-1} of initial sugar. However, a lower yield (88.0 %) and productivity (1.29 g L^{-1} h^{-1}) were obtained in this sample as a result of substrate inhibition. Liu et al. (2005) as well noticed a decrease in yield with an increase of initial sugar concentrations in the fermentation performed by *Rhizopus sp*. Also, in fermentations with *Lactobacillus sp*. similar effect was spotted. Bai et al. (2003) reported that lactic acid production on chemically defined media was the most productive with initial sugar concentration of 30 g L^{-1}, and productivity declined by raising the concentrations up to 90 g L^{-1}. In Figure 1, it can be noticed that the rate of sugar consumption slightly decreased after 36 h of fermentation in samples with greater initial sugar concentration, most probably because of the increase in lactic acid concentration and thus its inhibitory effect. Similarly, Gonçalves et al. (1997) observed that ionic form of lactic acid could influence the sugar consumption at pH value maintained above 5.0.

Lactic acid can be produced on triticale, corn and wasted bread liquid stillage with yields of 0.50 g g^{-1}, 0.76 g g^{-1} and 0.80 g g^{-1}, respectively (Djukić-Vuković et al., 2011). A yield of approximately 0.92 g g^{-1} and lactic acid concentration of 50.83 g L^{-1} achieved in this study on the whole wasted bread stillage were higher than previously reported which could be explained by a positive effect of nutrients present in the whole stillage including a solid fraction. Reported lactic acid concentrations and yields obtained on many other waste

substrates were also lower than this obtained on the whole stillage. Coelho et al. (2010) reported a maximal lactic acid concentration of 41.65 g L^{-1} after 48 h of fermentation of cassava wastewater with initial sugar concentration of 50 g L^{-1}. Lactic acid concentration attained on the stillage in this study was pretty high compared to the results reported on other waste substrates, especially taking into account that the stillage was not supplemented with any nitrogen and mineral sources.

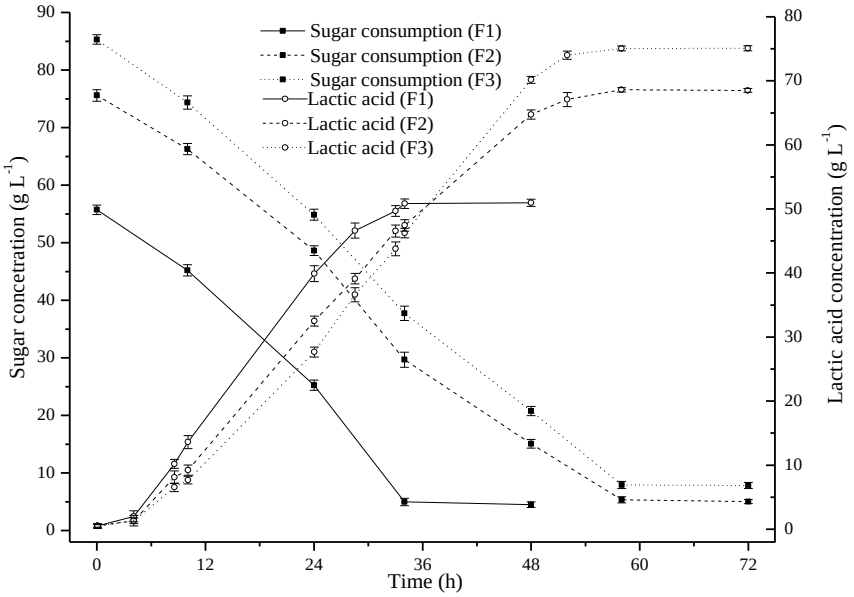

Figure 1. Lactic acid production and sugar consumption in samples with different initial sugar concentrations (F1) - 55.72 g L^{-1}; (F2) - 75.58 g L^{-1}; (F3) - 85.31 g L^{-1})

Spent fermentation media as a biomass enriched animal feed

During the batch fermentation the growth of *L. rhamnosus* ATCC 7469 was intense and it reached a number of 10^9 CFU ml^{-1} at the end of batch fermentation with initial sugar concentration of 50.83 g L^{-1}. Fermented stillage had many advantages over the non-fermented in animal nutrition. Generally, stillage was used in the form of wet distillers grains and in a dried form as Dried Distillers Grain with Solubles - DDGS in EU and USA, respectively, for animal feed (Wilkie et al., 2000). As a result of lactic acid fermentation performed by *L. rhamnosus* the stillage has been enriched with very high number of viable biomass. Scheuermann, (1993) reported improvement in nitrogen digestibility of animal feed rich in probiotic bacteria that qualifies it as a high-value animal feed. On the other hand, probiotic characteristics are strain/species specific and must be proven (Shah, 2000; Gaggia et al., 2010). Beneficial effects of probiotics depend on their survival through harsh gastric conditions of low pH in stomach. The survival of residual *L. rhamnosus* ATCC 7469 biomass of lactic acid fermentation on the stillage is presented in Figure 2. It is important to note, according to European Regulation (EC, 2008), a minimum content of viable bacterial cells (CFU kg^{-1}) in a complete feedingstuff is the one of the major specifications for animal feed enriched with probiotics. The number of *Lactobacillus sp.* and *Enterococcus sp.* cells in a healthy animal intestine amounts 10^5 - 10^8 CFU g^{-1} and their number should be about 10^9 CFU kg^{-1} in complete feed (Anadón et al., 2006; Busch et al., 2004).

Taking into account documented adherence capability of *L. rhamnosus* ATCC 7469 strain (Tuomola and Salminen, 1998) and high viable cell number in the stillage remained after lactic acid removal; it could be a promising animal feed. As shown in Fig. 2, 92.5 % of *L. rhamnosus* ATCC 7469 survive after 3 hours which corresponds to a number of viable cells of 6.6 $\times 10^8$ CFU ml^{-1}. These results are higher than those previously reported for some other *L. rhamnosus* strains (Succi et al., 2005). The pH in stomach is significantly affected by the presence of food (Gaggia et al., 2010), especially proteins which could exhibit buffering capacity. Succi et al. (2005) studied survival in MRS broth with pH adjusted to 2 and 3. Better survival in spent fermentation media in our study could be explained by higher dry

matter content, higher total protein content and presence of solid particles in media. Adaptation of some LAB to low pH affects survival after passage through stomach due to increased expression of stress protein genes (Shah, 2000). Because of the control of pH performed in 4 hours intervals in this study, some adaptation of *L. rhamnosus* ATCC 7469 cells may occur and influence on promoted survival.

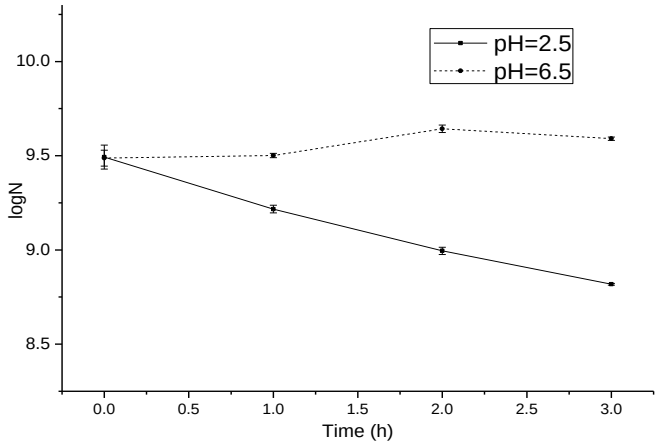

Figure 2. Survival of *L. rhamnosus* ATCC 7469 under the low pH

The European Food Safety Authority established Qualified Presumption of Safety (QPS) status which should be issued to microorganisms with proven safety and no report can be found on safety concerns related to *Lactobacillus sp.* in animals (EFSA, 2007; Gaggia et al., 2010). *L. rhamnosus* is qualified as acceptable for use in animal feed according to QPS and it is one of the most often used species in animal nutrition (Anadón et al., 2006).

CONCLUSIONS

Production of lactic acid and biomass in batch fermentation on the whole distillery stillage as a cheap and abundant substrate could be a new integrated approach to overcome ecologically important problem and improve the economy of bioethanol production. Prospective probiotic characteristics of *L. rhamnosus* ATCC 7469 strain are important for application of spent fermentation as a high-quality animal feed. Furthermore, the stillage was evaluated as a very good substrate for parallel lactic acid and biomass production since high lactic acid yields and biomass concentrations where obtained without nitrogen and mineral supplementation.

ABSTRACT: The aim of this study was selection of appropriate *Lactobacillus* strains for production of functional whey-based beverage. Sixteen strains of different species of *Lactobacillus* genera were studied and their abilities to carry out fast production of the beverage with satisfactory fermentation parameters were assessed.
Preliminary screening was performed by evaluating volumetric productivity of tested strains after 24 h of the fermentation. Further selection was based on determining beverage production parameters such as fermentation time, titratable acidity, cell number and sensory characteristics. The strains showed remarkable differences in cell number and sensory properties, which were particularly useful in the selection.
Based on the obtained results, the strains *Lb. casei* ssp. *casei* ATCC 27139 and *Lb. johnsonii* NRRL B-2178 are good candidates for the beverage production. These strains are rather similar in terms of beverage production ability, but strain *Lb. johnsonii* NRRL B-2178 is a top candidate for functional whey based beverage production. This strain attained titratable acidity of 9.2 °SH after 10 h of fermentation, appropriate odor and cell number of 6.8 log CFU/ml.
Key words: *whey, functional beverages, probiotics, Lactobacillus, fermentation*

INTRODUCTION

Whey which is generated in the process of cheese production is a major by-product of the dairy industry. The excess whey, with failure to processing is becoming a very big pollutant because of high COD (57-75 g/l) (Klasnja and Sciban, 2000) and BOD_5 (35-40 g/l) values (Marwaha and Kennedy, 2007; Anekar and Rao, 2009), what is completely at odds with the potential that such material posses. Discharging of the excess whey is an unforgivable loss of nutritionally valuable raw material. The global production of whey is increasing over the years and has reached the level of 178 million ton in 2010. Long-term predictions estimate that the global whey production will grow more than 2% per year until 2020 (OECD-FAO Agricultural Outlook 2010-2019, 2010), which means that its utilization must be increased. In recent years, the production and export of the whey in Serbia is almost nonexistent. Serbian export of whey has value of 10 thousands dollars, in contrast to the import which has significant value and ranges from 1.9 to 4.7 million dollars (Obućina et al., 2010).
There are many possibilities for whey utilization. In recent years, much attention has been focused on manufacturing of high value products such as lactic acid, ethanol, microbial proteins, β-D- galactosidase, vitamins (Stanzer et al., 2002) Great demands in terms of technological equipment and creating acceptable technological solutions make these processes still very expensive to implement, so most factories are limited to simpler processes of whey utilization (Affersholt, 2007). The production of functional whey based beverages, by fermentation with lactic acid bacteria (LAB), is economically most favorable way of whey processing. In this manner, within a single technological process all whey potentials can be exploited, since whey represents a high biological value material (Smithers, 2008). The role of LAB in functional whey based beverages is to assist in: (a) the preservation of the milk by the generation of lactic acid and possibly antimicrobial compounds; (b) the production of flavor compounds (e.g. acetaldehyde in yoghurt and

cheese) and other metabolites (e.g. extracellular polysaccharides) that will provide a product with the organoleptic properties desired by the consumer; (c) improving the nutritional value of food, as in, for example, the release of free amino acids or the synthesis of vitamins; and (d) the provision of special therapeutic or prophylactic properties against cancer (Reddy et al., 1973; Fernandes et al., 1987; Gilliland, 1990; O'Sullivan et al., 1992) and control of serum cholesterol levels (Lin et al., 1989). Commonly used species of LAB in production of functional whey based beverages are *Lactobacillus acidophilus, Lactobacillus delbrueckii* ssp. *bulgaricus, S. thermophilus* (Pescuma et al., 2010), *Lactobacillus reuteri, Bifidobacterium bifidum* (Hernandez-Mendoza et al., 2007), *Lactobacillus rhamnosus, Propionibacterium freudenreichii* ssp. *shermanii* (Maity et al., 2008), *Lactobacillus casei* (Dragalić et al., 2005), *Lactobacillus plantarum, Lactobacillus helveticus, Enterococcus faecium* (Pavunc et al., 2009), *Bifidobacterium animalis* ssp. *lactis* (Matijević et al., 2009) and *Lactobacillus paracasei* (Matijević et al., 2008). Large number of strains belonging to these species are not explored enough for the production of functional beverages and no information was given could it be used for the production of functional beverages. Most of the research made regarding fermented whey drink formulations was based on the use of probiotic (Drgalić et al., 2005), yogurt starters (Almeida et al., 2009; Gallardo-Escamilla et al., 2007) or kefir grains in reconstituted whey or whey and milk mixtures (Athanasiadis et al., 2004).

The aim of this study was the selection of appropriate *Lactobacillus* strains for the production of functional or probiotic whey-based beverage.

MATERIAL AND METHODS

Microorganisms and media

Sixteen strains belonging to the different species of *Lactobacillus* genera were studied. The strains used in this work (table 1) were obtained from the Collection of Department of Biochemical Engineering and Biotechnology, Faculty of Technology and Metallurgy, Belgrade.

Stock cultures of lactic acid bacteria (LAB) were stored at -20°C in 3 ml vials containing MRS broth and 50% (v/v) glycerol as a cryoprotective agent. For the preparation of laboratory cultures, a drop of stock culture were transferred in 3 ml of the MRS broth and incubated for 18 h under anaerobic conditions at the optimal growth temperature (30 or 37 ºC). All working strains were pre-cultured twice in MRS broth prior to experimental use.

Whey fermentation

Sweet whey powder (Lenic Laboratories, Belgrade, Serbia), with following composition: proteins 12.11%, lipids 1.0%, and carbohydrates 69.62%, was reconstituted in water to contain 8% of dry matter. A volume of 100 ml of the reconstituted whey with pH value 6.2 was poured into sterile glass bottles of 200 ml. Samples were pasteurized at 60 °C for 60 min, cooled at fermentation temperature and immediately inoculated by adding 2% (v/v) of 18 h - old testing cultures grown in MRS broth. All fermentations were performed at 37 ºC, statically. In the experiment of preliminary screening, the samples were incubated for 24 h. Subsequently, the volumetric productivity (P) was determined. In the experiment of evaluation of beverage production performances, fermentation was carried out until pH=4.6 was attained. During the incubation time, the samples were withdrawn every 1 h for determination of pH value. By the time when pH=4.6 was reached, fermentation was stopped by quick cooling. Beverage production performances of tested strains were evaluated by determining the basic fermentation parameters such as fermentation time (h), titratable acidity (°SH), cell number (log (CFU/ml)) and sensory characteristics.

Analytical methods

The volumetric productivity and titratable acidity were determined on the basis of produced lactic acid, by titration of 20 ml of whey samples with 0.1 M NaOH to pH=8.2 in the presence of phenolphthalein as the indicator. Titratable acidity was expressed in Soxhlet-Henkel degrees (°SH), while the volumetric productivity was expressed in g/l·h. These parameters were calculated by the following equation:

$$^{\circ}SH = a \cdot f_{NaOH} \cdot 2$$
$$g/l \cdot h_{(lactic\ acid)} = {}^{\circ}SH \cdot 0.225 / 24$$
$$a = ml\ 0.1\ M\ NaOH$$
$$f = titration\ correction\ factor\ of\ 0.1\ M\ NaOH$$

Cell number was determined by pour plate counting method on MRS agar and expressed in log (CFU/ml). For determination of sensory characteristics a panel group of 5 sensory analysts were evaluating odor with 1-5 grades according to fallowing scale: 1-on sauerkraut, 2-on sourdough, 3-on whey, 4-on mild yogurt, 5-on yogurt.

RESULTS AND DISCUSSION

Preliminary screening based on fermentation activity of tested strains

The fermentation activity of sixteen tested strains was investigated. The fermentation activity was evaluated by determining the volumetric productivity of tested strains. The results are presented in table 1.

Table 1. Volumetric productivities (P) obtained after 24 h of whey fermentation with different strains of *Lactobacillus* sp.

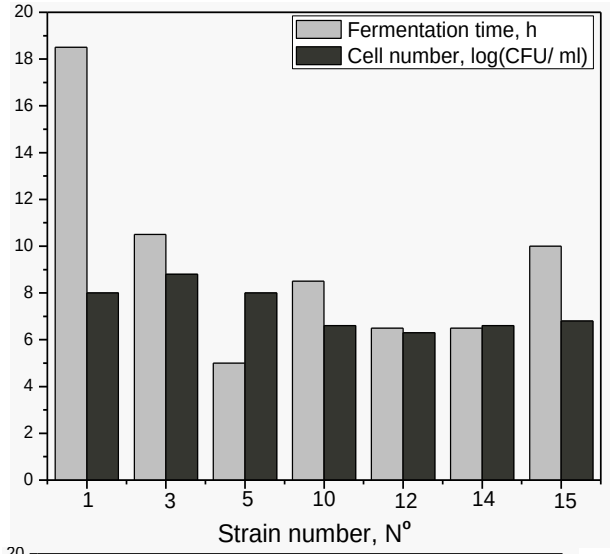
Strain N°	Strains of *Lactobacillus* sp.	P(g/(l·h))
1	*Lb. gasseri* NRRL B-14168	0.124
2	*Lb. gasseri* NRRL B-4240	0.059
3	*Lb. casei* ssp.*casei* ATCC 27139	0.262
4	*Lb. casei* ssp. *casei* NRRL B-441	0.244
5	*Lb. helveticus* ATCC 15009	0.358
6	*Lb. helveticus* NRRL B-734	0.088
7	*Lb. reuteri* ATCC 23272	0.123
8	*Lb. paracasei* ssp. *paracasei* NRRL B-4564	0.083
9	*Lb. rhamnosus* TM1	0.239
10	*Lb. rhamnosus* ATCC 7469	0.280
11	*Lb. acidophilus antibiophilus*	0.262
12	*Lb. acidophilus* ATCC 4356	0.267
13	*Lb. delbrueckii* ssp. *lactis* NRRL B-1942	0.097
14	*Lb. delbrueckii* ssp. *lactis* NRRL B-4525	0.341
15	*Lb. johnsonii* NRRL B-2178	0.207
16	*Lb. delbrueckii* ssp. *bulgaricus* ATCC 11842	0.171

As shown in table 1, the majority of strains (62.5 %) showed an acceptable level of fermentation activity. The highest productivity of 0.358 g/l·h was obtained in fermentation by the strain *Lb. helveticus* ATCC 15009, while the lowest productivity of 0.059 g/l·h was obtained by the strain *Lb. gasseri* NRRL B-4240.

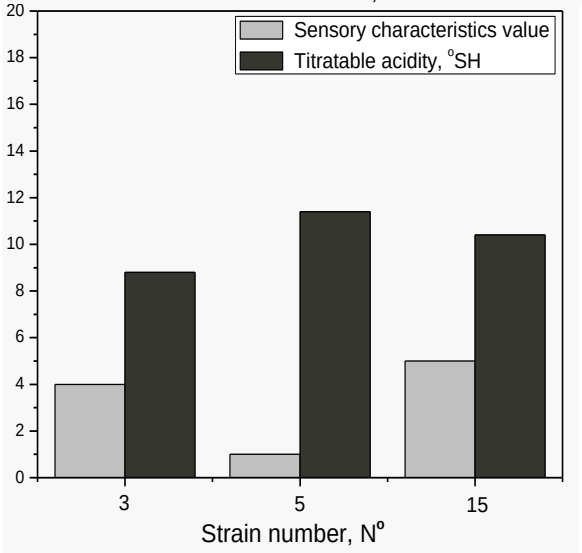
Based on the obtained results, one strain of each species was selected for further testing of the production performances. The preliminary selected strains were *Lb. gasseri* NRRL B-14168, *Lb. casei* ssp. *casei* ATCC 27139, *Lb. helveticus* ATCC 15009, *Lb. rhamnosus* ATCC 7469, *Lb. acidophilus* ATCC-4356, *Lb. delbrueckii* ssp. *lactis* NRRL B-4525, *Lb. johnsonii* NRRL B-2178.

Selection based on beverage production performances

After the preliminary screening, the beverage production performances were investigated. Seven pre-selected strains were characterized on the basis of fermentation parameters which were important in the production of functional beverages.
Time of fermentation was one of the most important parameters which could substantially decrease the beverage production costs and thus valorize whey from the cheese production. In addition, dairy products should contain ≥ 6 log CFU/ml of viable probiotic bacteria to induce beneficial effects on health what is a prerequisite for regular consumption (Tamime et al., 1995; Kailasapathy and Rybka, 1997). Since whey itself has not an acceptable taste, the sensory characteristics are an essential parameter for inclusion of produced beverage in a human consumption. Fig.1-a compares fermentation time and cell number achieved during the fermentation with pre-selected strains. Fig.1-b compares values of sensory characteristics and titratable acidity achieved with three selected strains during the fermentation.



(a) Fermentation time and cell number achieved with pre-selected strains during whey fermentation.



(b) Sensory characteristic values and titratable acidity achieved with three selected strains during whey fermentation

Figure 1. Beverage production performances of strains belong to *Lactobacillus* genera. Strain Number, N° is presented in tab 1.

As shown in Fig.1-a, short fermentation time (5-6.5 h) was obtained with strains *Lb. helveticus* ATCC 15009, *Lb. acidophilus* ATCC-4356 and *Lb. delbrueckii* ssp. *lactis* NRRL B-

4525, but only *Lb. helveticus* ATCC 15009 achieved high cell number of 8.0 log CFU/ml. Strain *Lb. rhamnosus* ATCC 7469 achieved quite short fermentation time (8.5 h) but a cell number of 6.6 log CFU/ml. On the other hand, strains *Lb. casei* ssp. *casei* ATCC 27139 and *Lb. johnsonii* NRRL B-2178 had quite longer fermentation time (10.5 and 10.0 h, respectively) and achieved cell numbers of 8.8 log CFU/ml and 6.8 log CFU/ml, respectively. Strain *Lb. gasseri* NRRL B-14168 had too long fermentation time of 18 h. It is interesting to note that the strain *Lb. delbrueckii* ssp. *lactis* NRRL B-4525 which exhibited the best volumetric productivity and short time of fermentation, didn't achieve the highest cell number at the end of fermentation. This could be due to differences in lactic acid production abilities and growth characteristics. Strains *Lb. casei* ssp. *casei* ATCC 27139, *Lb. helveticus* ATCC 15009 and *Lb. johnsonii* NRRL B-2178 were selected as most promising. These strains were further characterized based on the sensory characteristics and titratable acidity and results are presented in Fig. 1-b.

As shown in Fig.1-b, the strain *Lb. helveticus* ATCC 15009 exhibited very low grade for odor which was like sauerkraut. This is probably a consequence of unpleasant odor substances produced by this strain. This strain was therefore rejected as a possible producer of the beverages. Strains *Lb. casei* ssp. *casei* ATCC 27139 and *Lb. johnsonii* NRRL B-2178 achieved higher grades (4 and 5, respectivly) for odour than the strain *Lb. helveticus* ATCC 15009. These two strains achieved titratable acidity of 8.8 and 9.2 °SH, respectivly and they are rather similar in terms of beverage production ability. The strain *Lb. johnsonii* NRRL B-2178 is a top candidate for production of functional whey based beverage due to much stronger odor like yogurth which was evaluated with grade 5. It is also interesting to note that the strain *Lb. johnsonii* NRRL B-2178 has probiotic characteristics and shows high viability in the presence of whey proteins during the storage (EL-Shafei et al., 2010), which is essential for the beverage shelf-life. In addition, all strains produced residue-free beverages with the sour-salty taste beacuse of high amount of present lactic acid.

CONCLUSIONS

Fermentation of whey by LAB could be an interesting alternative for the production of functional beverages. Our study showed that the strains *Lb. casei* ssp. *casei* ATCC 27139 and *Lb. johnsonii* NRRL B-2178 are good candidates for the beverage production. The strain *Lb. johnsonii* NRRL B-2178, out of 16 tested strains, is a top candidate for the functional whey based beverage production. This strain attained titratable acidity of 9.2 °SH after 10 h of fermentation, appropriate odor and cell number of 6.8 log CFU/ml.

ABSTRACT: The aim of this research was to examine changes in sugar content during production of fermented milk beverages from milk with 2g/100g fat by using 10% (v/v) inoculum of kombucha, cultivated on black tea. Kombucha is a mixed culture of acetic acid bacteria and yeasts with complex metabolic pathways. The traditional carbon source for kombucha fermentation is sucrose. Novel researches showed that application of any other sugar such as lactose is possible.
Temperatures for milk fermentation were 37°C and 42°C. Final pH value was 4.6. Dry matter, milk fat, total proteins and ash were analysed in milk and products by standard methods. Changes in lactose, galactose, glucose and fructose content were investigated during fermentation on pH 5.8; 5.4; 5.1; 4.8 and 4.6. Lactose, galactose, glucose and fructose were detected using specific enzymatic tests.
The obtained results indicated that the pattern of changes of lactose, galactose, glucose and fructose concentration during milk fermentation on two different temperatures were similar.
Key words: *Kombucha, milk fermentation, sugar content*

INTRODUCTION

Kombucha is well-known association of several yeast species and acetic acid bacteria, its metabolic activity on tea sweetened with sucrose produces a pleasant refreshing beverage, containing a number of useful compounds (Malbaša et al., 2008). Previous investigations (Markov et al., 2001) have shown that the applied fungus contained at least five yeast strains (*Saccharomycodes ludwigii, Saccharomyces cerevisiae, Saccharomyces bisporus, Torulopsis* sp. and *Zygosaccharomyces* sp.) and two bacterial strains of the genera *Acetobacter*.
Reiss (1994) investigated application of other sugars (lactose, glucose or fructose) for kombucha cultivation. He has found that kombucha fermentation on other sugars produced beverages slightly different in flavour but significantly different in ethanol and lactic acid quantity, compared to sucrose's sweetened tea. For example, fermentation on lactose gave extremely low quantities of ethanol in comparison to the fermentation on sucrose.
Fermentation is one of the oldest methods practiced by human beings for the transformation of milk into shelf life products. Around 400 generic names are applied to the traditional and industrial fermented milk products manufactured throughout the world (Kurmann et al., 1992). Milk has a very complex structure even though its constituents are mainly water, lactose, fat, proteins and minerals. In cows' milk, milk non fat solid level is 8.5–9.0 g/100g, of which around 4.5 g/100g is lactose, 3.3 g/100g protein (2.6 g/100g casein and 0.7 g/100g whey proteins), and 0.7 g/100g mineral salts. Each of these components is important for the production of a satisfactory yoghurt quality (Fuquay et al., 2011). Nutritional value of fermented dairy products consists, as in milk, in primary essentially ingredients necessary for human body growth, reproduction, maintenance, renewal and fulfill energy needs. These products contain, as well as milk, lactose, lactic acid, protein, fat, minerals and vitamins. The concentration of mentioned components in yoghurt mainly depends of applied starter cultures.

Lactose is the main carbohydrate in dairy products. It contributes 30% energy of whole cow's milk. This disaccharide is composed of glucose and galactose and is the only saccharide synthesized by mammals (Smolin and Grosvenor, 2000). Lactose plays an important role in the formation of the neural system and the growth of skin (texture), bone skeleton and cartilage in infants. It also prevents rickets and saprodontia (Emmett and Rogers, 1997). Lactose fermentation by lactic acid bacteria to lactic acid is widespread in the production of fermented dairy products. In particular, lactose is the principal energy source for the bacteria in the starter culture, while casein, together with calcium and phosphorus gives rise to the basic structure of a gel structure (John W. Fuquay et al., 2011). In general, dairy starter cultures metabolize lactose either through the homo- or hetero-fermentative metabolic pathways. *S. thermophilus*, L. *delbrueckii* subsp. *bulgaricus* and *Lactobacillus acidophilus* possess β-galactosidase (EC 3.2.1.23.) to hydrolyze lactose and fermentation is homofermentative type. Under the influence of lactic acid bacteria, glucose is converted into lactic acid, and alternatively, into ethanol and CO_2 if yeasts are present (Figure 1). Lactose content is reduced during fermentation (by 20–30 g/100g of the level in the original milk), while the concentration of lactic acid and some free amino acids increases, for example, proline, serine, alanine, valine, leucine, and histidine. Even though, after fermentation, the product may contain 4-5g /100g of lactose (Tamime and Robinson, 2004)

Lactose hydrolysis in milk and other dairy products by the enzyme galactosidase is of considerable interest to the dairy industry. It has been estimated that over 70% of world's inhabitants suffer from either lactose maldigestion or intolerance (De Vrese et al., 2001.) Most people who can not consume milk due to allergies on lactose or protein, consume yoghurt and therefore provide the balance of microflora in an intestinal tract.

Application of kombucha in lactose fermentation is still under investigations. Therefore the aim of this research was to compare the changes in lactose, galactose, glucose and fructose content during milk fermentation by non conventional starter-kombucha, at pH 5.8; 5.4; 5.1; 4.8 and 4.6, at two different temperatures 37°C and 42°C.

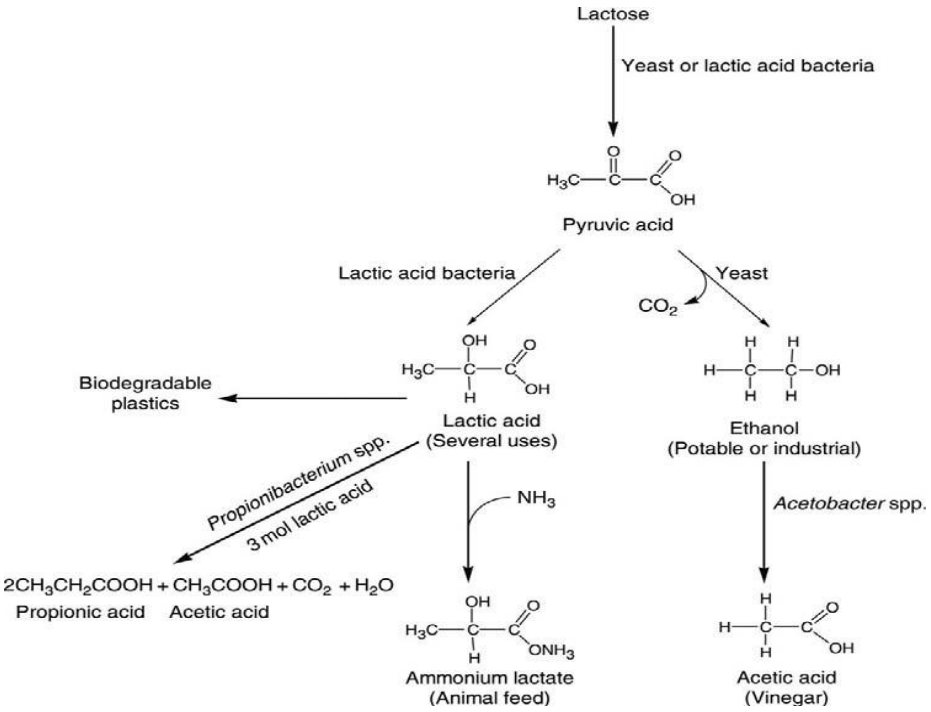

Figure 1. Fermentation products from lactose (Fuquay et al., 2011)

MATERIAL AND METHODS

Milk
Homogenized and pasteurized cow's milk from AD Imlek, Division Novi Sad Dairy, was used for the production of kombucha fermented milk products. The composition of milk was as follows: fat content – 2.0 g/100g, total solids – 10.59 g/100g, total proteins – 3.30 g/100g and lactose – 4.60 g/100g, ash 0.69 g/100g.

Kombucha inoculums
Kombucha inoculum was prepared according to procedure published by Malbaša *et al.,* (2009). Kombucha is cultivated on a black tea (*Camellia sinensis* – oxidized, 1.5 g/L) with sucrose concentration of 70 g/L. The tea was cooled to room temperature, after which inoculum from a previous fermentation was added in concentration of 10 mL/100mL. Incubation was performed at 25°C for 7 days. Inoculum in concentration of 10 mL/100mL was used for milk inoculation.

Samples production
Samples were obtained by addition of 30 mL of kombucha inoculum in 300 mL of milk at 42°C and 37°C simultaneously. Samples were taken at pH values: 5.8; 5.4; 5.1; 4.8 and 4.6.

Methods
Chemical composition: dry matter, milk fat, total proteins and ash of samples was analyzed by methods according to Carić et al. (2000).
The content of lactose and products of milk fermentation at two temperatures were detected in all samples using specific enzymatic tests, such as K-FRUGL 11/05 (D-glucose and D-fructose) and K-LACGAR 12/05 (lactose and D-galactose). The analyses were performed according to the guidelines supplied by the producer (Megazyme, Ireland). Products of the reactions were monitored using spectrophotometer (T80+UV/VIS Spectrometer PG Instruments Ltd.).
Statistical analysis of results was carried out with the computer software program "Statistica 9" and results were expressed as average values with standard deviation.

RESULTS AND DISCUSSION

The obtained results indicate no significant differences in dry matter, fat, proteins and ash content in samples produced at 37°C and 42°C (Table 1).

Table 1. Chemical composition changes in during milk fermentation

	42° C		37° C	
Components (g/100g)	**pH 6.07**	**pH 4.6**	**pH 6.07**	**pH 4.6**
Dry matter	10.34 ±0.02	10.34±0.03	10.34±0.02	9.98±0.24
Milk fat	2.00±0.00	1.98±0.00	2.00±0.00	1.98±0.00
Proteins	3.12±0.12	3.14±0.08	3.12±0.12	2.82±0.17
Ash	0.69±0.69	0.68±0.01	0.69±0.69	0.62±0.05

The biggest changes happened on lactose content. At the beginning of the process lactose content is 4.3900g/100g and further during fermentation it decreased continually. The drop in lactose content was notable between first and second fermentation point at the both temperatures. Lactose content was lower in samples produced at 37°C (3.5931g/100g) than in samples produced at 42°C (3.7483 g/100g) on the end of process - pH 4.6 (Table 2 and Table 3). This could be explained by longer fermentation time for samples produced on 37°C and therefore followed-up with further degradation of lactose.

Table 2. The changes of sugars content in samples obtained at 42°C

pH value

Sugar content (g/100g)	6.07	5.8	5.4	5.1	4.8	4.6
Lactose	4.3900± 0.000	3.9607± 0.0279	3.7910± 0.0080	3.7826± 0.0558	3.7526± 0.0652	3.7483± 0.0254
Galactose	0.0068± 0.0045	0.2017± 0.0075	0.2760± 0.0137	0.2793± 0.0057	0.2890± 0.0095	0.2576± 0.0040
Glucose	0.0155± 0.0155	0.1460± 0.0030	0.1527± 0.0056	0.1536± 0.0020	0.1326± 0.0041	0.0840± 0.0093
Fructose	0.0125± 0.0125	0.0276± 0.0276	0.0232± 0.0034	0.0109± 0.0037	0.0129± 0.0001	0.0233± 0.0035

The galactose and glucose content increased between first and second pH point is caused by lactose fermentation and its hydrolyses on glucose and galactose. Contents of these compounds decreased as consequence of starter culture metabolic activity during fermentation. These results are in accordance with previous research (Iličić et al., 2009). The fructose content at pH 4.6 was higher in samples produced at 42°C compared with samples produced at 37°C, that revealed kombuha's higher fructose affinity at lower temperature.

Table 3. The changes of sugars content in samples obtained at 37°C

	pH value					
Sugar content (g/100g)	**6.07**	**5.8**	**5.4**	**5.1**	**4.8**	**4.6**
Lactose	4.3900± 0.000	3.8523± 0.0881	3.8210± 0.0478	3.7713± 00563	3.6105± 0.1006	3.5931± 0.1388
Galactose	0.0068± 0.0045	0.4097± 0.0534	0.3801± 0.0344	0.3947± 0.0213	0.3272± 0.0295	0.3188± 0.1863
Glucose	0.0155± 0.0155	0.3371± 0.1384	0.2206± 0.0388	0.1948± 0.0518	0.1318± 0.0186	0.0817± 0.041
Fructose	0.0125± 0.0125	0.0964± 0.0145	0.0762± 0.0234	0.1043± 0.0066	0.0752± 0.0077	0.0865± 0.0057

CONCLUSIONS

The changes pattern of lactose, galactose, glucose and fructose concentration during milk fermentation on two different temperatures were similar. The highest increase of glucose, fructose and galactose content was between pH 6.07 and pH 5.8, as well as lactose decrease. Lower lactose and fructose content at pH 4.6 was obtained in samples produced at 37°C compared with samples produced at 42°C.

ABSTRACT: Cinnamic acid and its esters are widespread throughout plant kingdom and therefore, they are common components of our daily diet. Ethyl cinnamate has been approved by FDA for direct addition to food for human consumption. Enzyme synthesis is strongly preferred compared to chemically catalyzed esters synthesis when product quality is a main issue, as is the case for food production. The aim of this study was to examine possibilities for enzyme catalyzed synthesis of cinnamic acid esters and to optimize the synthesis of ethyl cinnamate in terms of selected parameters, including the type of the organic solvent and substrate initial molar ratio.
All reactions were performed batchwise under pH and temperature control in vessels containing 5 mL of reaction medium, using cinnamic acid as limiting substrate (0.167 M). Each reaction mixture was supplemented with 75 mg of commercial immobilized lipase B from *Candida antarctica*, Novozyme 435. The antioxidant activity of obtained ester was measured by using chemical and electrochemical techniques.
We have proven that ethyl cinnamate can be synthesized using lipase B from *Candida antarctica* with very high reaction yields in the simple bioreactor system.The best reaction yield (89%) was obtained in isooctane when substrate molar ratio of 1:3 was used. Both, DPPH assay and cyclic voltammetry measurement has shown that ethyl cinnamate has better antioxidant properties than cinnamic acid itself.
Key words: *Cinnamic acid, Ethyl cinnamate, Enzymatic esterification, Radical-scavenging activity, Antioxidant activity, Cyclic voltammetry*

INTRODUCTION

Phenolic acids, especially cinnamic acid and its derivatives, are inevitable component of our daily diet due to their ubiquitous presence in plant food. These compounds are components of soybeans, cotton seeds, peanuts, coffee and they are proven to be one of the reasons for antioxidant potential of oilseeds (Stamatis et al., 1999). Consequently, these phenolic acids are very interesting substrates for the production of a variety flavor and fragrance compounds such as ethyl cinnamate. There is growing interest in cinnamic acid esters synthesis using free or immobilized lipase in non-aqueous solvents. Although their synthesis can also be chemically catalyzed by acids or bases, enzymatic esterification offers environmental advantages and a reduction in energy consumption. Furthermore, the enzyme synthesis is strongly preferred when product quality is a main issue as is the case for food production.
Guyot and coworkers were first to report enzymatic esterification of phenolic acids and fatty alcohols catalyzed with lipase B from *Candida antarctica* (Guyot et al., 1997; Buisman et al., 1998). Soon afterwards, Stamatis and his research team described enzymatic esterification of cinnamic acid with aliphatic alcohols using lipase from *Rhizomucor miehei* as the catalyst. However data related to enzyme catalyzed esterification of cinnamic acid and its esters are very incomplete and contradictory, making them an interesting topic for research.

Focus of this work was to examine opportunities for lipase catalyzed esterification of cinnamic acid with different aliphatic alcohols and to optimize ester production using ethyl cinnamate as a model reaction. Commercial enyzme preparation of lipase B from *C. antarctica* immobilized on macro porous acrylic resin was used in all experiments. This work also describes attempt to examine antioxidant properties of cinnmaic acid and its esters, thus looking into influence of esterification on antioxidant properties of cinnamic acid.

MATERIAL AND METHODS

Synthesis were performed using commercial immobilized lipase B from *Candida antarctica*, Novozyme 435, obtained from Novo Nordisk, Denmark. Cinnamic acid and alcohols, of analytical grade, were purchased from Sigma Aldrich (*St Louis, MO*, USA), while isooctane and other solvents used in experiments were purchased from Fluka (StQuentin-Fallavier, Switzerland).

Esterification of cinnamic acid

The esterification reactions were carried out batchwise at 55 ºC and 250 rpm in sealed, stirred flasks (100 mL). Typically, reaction mixture consisted of 0.846 mmol of cinnamic acid, and 15 equivalents of alcohol (C2, C4-C7), and was filled with isooctane to reach a total volume of 5 mL. Each reaction mixture was supplemented with 75 mg of enzyme. Control reactions, without enzyme, were performed parallely under the same conditions.

Optimization of parameters for ethyl cinnamte production

In order to maximize production of ethyl cinnamate, series of experiments were performed, in which type of organic solvent and substarte initial molar ratios (1:1, 1:3, 1:5, 1:7, 1:9, 1:12, 1:15, and 1:20) were alternatively varied. The effect of solvent polarity on product formation was examined using solvents with different log*P* values.

Analysis and monitoring of reaction mixtures

Ester formation was monitored by titration of residual cinnamic acid with NaOH (0.05M) in presence of phenolphthalein as indicator. Reaction yields were calculated simply with respect to the limiting reagent (cinnamic acid or its derivatives) by dividing amount of the substrate that was consumed in reaction with the initial amount of substrate.

Antioxidative activity measured by DPPH assay and cyclic voltammetry

Antioxidative activity of cinnamic acid and its esters was measured by their ability to scavenge DPPH radical, which was monitored by decrease of absorbance on 517 nm, as described elsewhere (Blois, 1958). A volume of 200 µL of metanolic ester solution was mixed, in spectrophotometric cuvet, with 1800 µL of metanolic DPPH solution (0.1 mM), vortexed and left in dark and after 30 min absorbance was measured at 517 nm. Appropriate ethyl cinnamate dilutions in methanol were experimentally found in order to satisfy the linear dependence of ester concentration *vs* absorbance. Calculations were done according to method described elsewhere (Gorjanović et al., 2010).

Cyclic voltammetry experiments were performed in a three electrode cell, at ambient temperature. Glassy carbon electrode was used as working electrode, Pt wire as counter, while saturated calomel electrode (SCE) served as reference electrode. The cyclic voltammograms were recorded at scan rate of 50 mV s^{-1}, starting at open circuit potential to potential of 2.0 V (for cinnamic acid) and 1.2 V (for *p*-coumaric acid and ethyl cinnamate). The experiments were performed using SP-200 (BioLogic Science Instruments) potentiostat/galvanostat.

RESULTS AND DISCUSSIONS

Effect of alcohol type on esterification of cinnamic acid

Investigation of the influence of an acyl acceptor on lipase-catalyzed synthesis of cinnamic acid esters was done. For this purposes, cinnamic acid was esterified under the same conditions using aliphatic alcohols of increasing carbon chain lengths: ethanol, *n*-butanol, *n*-pentanol, *n*-hexanol and *n*-heptanol. This assay demonstrated that all of the used alcohols could form esters with cinnamic acid under previously described conditions. Results obtained during this experiment are presented in Table 1.

Table 1. Esterification yields, reaction rates and relative reaction rates obtained with different aliphatic alcohols

Alcohol (acyl acceptore) type	Ester yield, %	Standard deviation, %	Reaction rate, v (mmol/(h cm^3)) ·10^4	Relative reaction rate, v/v_m [a]
ethanol	31	3.4	7.2	1
n-butanol	19	5.2	5.3	0.74
n-pentanol	21	0.8	4.8	0.67
n-hexanol	19	1.2	4.4	0.61
n-heptanol	16	0.4	3.8	0.53

[a]*Relative reaction rate: rection rate normalized to that obtained with optimal acyl acceptore,* v_m

A series of esterifications with alcohol of increasing chain length resulted in a decrease in ester yield, probably because of alcohols react with the acyl-enzyme intermediate formed during the acylation process, the rate of synthesis is determined by the diffusion of alcohol molecules into the active site of the enzyme. Since smaller alcohols are able to diffuse into the active site more readily than bulky ones, an increase of the chain length leads to a decrease of the enzyme activity. Ethanol gave highest reaction yield (31%). This result was somewhat unexpected because literature data showed that esterification of cinnamic acid with ethanol gave very low reaction yields (Guyot et al., 1997). Though results similar with ours were reported for synthesis of ethyl ferulate (Lee et al., 2006). Different amount of ethanol used in esterifications is probably cause of these contradictory results in literature. In fact ethanol in great excess may cause inactivation of enzyme thus making the cinnamic acid/ethanol molar ratio very important parameter in ester formation.

Effect of solvent polarity

Enzyme performances are known to be highly dependent on the properties of the organic solvent. Thus, esterification of cinnamic acid with ethanol was conducted in variety of solvents in order to determine optimal solvent for this reaction. Results obtained in this investigation are presented in Table 2.

Isooctane was proven to be the best solvent for esterification of cinnamic acid with ethanol, as can be seen from Table 2. This result agrees with literature, where has been noted that solvents with log$P$ > 4 are good for biocatalysis since they do not remove essential water layer around the enzyme (Fu and Vasduven, 2010). Conversions up to 85% within 5 days were reported for esterification of cinnamic acid with *n*-butanol, when apolar solvent *n*-pentane was used (Buisman et al., 1998). In solvents with low log$P$ values, that is in polar environments the best results are obtained when *tert*-butanol is used. This result is in accordance with the literature data, where relatively high reaction yields, 52%, have been obtained during esterification of cinnamic acid with *n*-octanol when *tert*-butanol has been used as solvent (Stamatis et al., 1999). This result is probably due to a good solubility of cinnamic acid in polar solvents.

Table 2. Effect of organic solvent on the esterification of cinnamic acid with ethanol catalyzed by immobilized lipase B from *Candida antarctica* at 55 ^{o}C and 250 rpm

Solvent	acetone	*tert*-butanol	chloroform	hexane	heptane	isooctane	hexadecane
log*P*	-0.23	0.35	2	3.5	4	4.5	8.8
Ester yield, %	traces	20	traces	22	23	31	6

Effect of initial molar ratio on reaction yield

Initial molar ratio of substrates is shown to be one of the most important parameters in enzyme catalyzed ester synthesis. Effect of this parameter on the rate of product formation was examined in isooctane, the solvent that was proven to be the best for synthesis of ethyl cinnamate. Increase in initial molar ratio (acid to alcohol) from 1:3 to 1:5 led to decrease in reaction yield for 45%, indicating that ethanol in great excess indeed deactivated enzyme. Further increase in molar ratio did not have such significant effect on product formation.

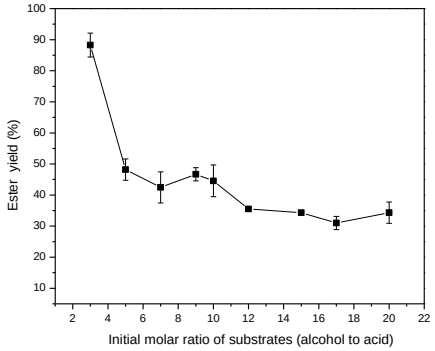

Figure 1. Effect of the initial molar ratio of substrates (alcohol to acid) on ester yield. Reaction mixture consisted of 0.0846 mmol cinnamic acid and alcohol varied according to experimental plan

DPPH assay and cyclic voltammetry results

Cinnamic acid and ethyl cinnamate were tested for their radical-scavenging activity against DPPH in order to elucidate the influence of esterification on the antioxidant activity. It appeared, as showen in Figure 2, that ethyl cinnamate has better antioxidant potential (30% for 0.167M methanolic solution) than cinnamic acid itself (4%), though it is still very low comparing to other natural phenolic antioxidants, such as gallic acid.

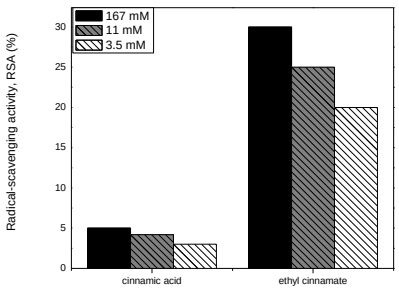

Figure 2. Free radical- scavenging activity of cinnamic acid and ethyl cinnamate

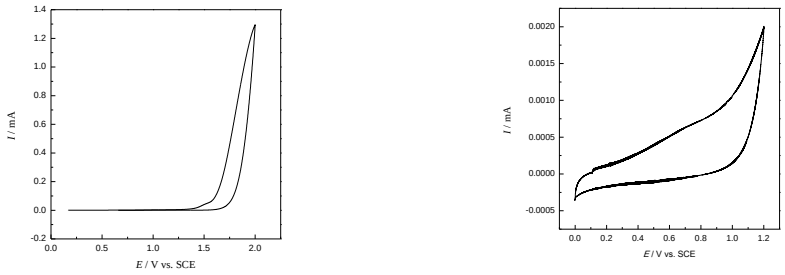
The electrochemical behavior of ethyl cinnamate was investigated by cyclic voltammetry at a scan rate of 50 mV s^{-1} in acetate buffer pH 5.6 on glassy carbon electrode and compared to

native cinnamic acid. It seems that the esterification of cinnamic acid increased its antioxidant activity (Fig 3). It was possible to observe some oxidation process in the cyclic voltammogram of ethyl cinnamate leading to wave broadening compared with that of cinnamic acid as well as appearing of minor anodic peak at E_a 0.7 V.



a) Cinnamic acid (1 mM) in sodium acetate buffer (0.2M)

b) Ethyl cinnamate (1 mM) in sodium acetate buffer (0.2M)

Figure 3. Cyclic voltammetry plots

CONCLUSION

The esterification activity of the commercial immobilized lipase towards cinnamic acids was assayed in different solvents. Isooctane is shown to be the best solvent for this reaction even though solubility of cinnamic acid in this a polar solvent is very low. Highest esterification yield of ethyl cinnamate is obtained when initial molar ratio of substrates 1:3 (cinnamic acid is limiting substrate) is used.

Esterification of cinnamic acid appeared to result in increasing radical-scavenging ability. The effect of esterification of cinnamic acid was also confirmed by electrochemical method using ethyl cinnamate which appeared to enhance the antioxidant activity. These findings should stimulate the application of such lipase-catalyzed reactions for the preparation of food acceptable esters of cinnamic acid as potential lipophilic antioxidants.

ABSTRACT: In the two past decades, there has been a great deal of research on polyphenol compounds and their antioxidant properties. Raspberry as a fruit species is widely grown in Serbia and is well known in the world for its quality. Being very rich in polyphenol compounds, raspberry is a great source of components of excessive biological value.
The objective of this study was to investigate influence of temperature, sulfur-dioxide and selected yeast on fermentation of raspberry pulp and the total polyphenol content of raspberry wine. The pulp of *Meeker*, one of the most abundant varieties of raspberry (*Rubus idaeus*) in Serbia, was fermented at 15°C and 22°C with and without selected yeast cells, and with and without addition of sulfur-dioxide. The total polyphenol content was determined every 24 hours, according to the Folin Ciocalteau method and results were expressed in mg/L gallic acid equivalents (mg GAE/L).
The obtained results indicate that fermentation temperature and addition of sulfur-dioxide significantly influence the extraction of phenolic compounds from raspberry pulp, while the addition of selected yeast cells has no influence. Immediately before fermentation, total polyphenol content in the sample was 1415,7 mg GAE/L. After 72 hours of fermentation, the sample fermented at 15°C with addition of sulfur-dioxide and without selected yeast cells reached its maximum value of 2191 mg GAE/L, whereas the same sample fermented at 22°C reached the value of 2820 mg GAE/L. Other samples had lower values then these two. After 96 and 120 hours of fermentation, in all samples total polyphenol content was slightly lower then after 72 hours.
Key words: *raspberry, fermentation, polyphenol content, raspberry wine*

INTRODUCTION

The production of wine from berry fruits has increased over the last several years in contrast to apples and pears which have been used for wine production since eighteen century. Raspberries, *Rubus idaeus* L*.,* present great source of polyphenolic compounds, particularly flavonoids such as anthocyanin pigments, which give raspberries their characteristic color (Liu, 2007). The phytochemicals such as p-coumaric, ferulic and ellagic acids, are commonly found in raspberries and may have a significant antioxidant and anticancer activity and act as a protector against biological oxidative stress in human cells (Hakkinen et al., 1999). In recent years, increased interest in human health, nutrition and disease prevention has enlarged consumers' demand for functional foods including fruits and their products such as wine (Rupasinghe and Clegg, 2006). Besides polyphenolic compounds, raspberry (cv *Meeke*r) displays specific acid and sugar contents (pH 3.2-3.6 and about 14.5° Brix) that makes it suitable for fruit wine (Duarte et al., 2010). The "*Meeker*" raspberry variety is popular due to high yields, a long harvest season, resistance to root rot, and machine harvest characteristics. "*Meeker*" fruit has a desirable color, firm texture, and good sensorial attributes including aroma, sweetness, and acidity. Raspberry fruits which cannot be used for consumption are used in the production of juices, jam, sweets etc. In some regions, raspberry producers are looking for new alternatives for the use of small and crushed raspberry fruits. One of them is wine (Duarte et al. 2010). Besides polyphenol compounds, the concentration of certain minerals in wine is important due to health impact of minerals on the human organism, their role in the stability of wine, and food regulations. Generally, fruit wines, among which is raspberry wine, contain a significant amount of polyphenols. Range of polyphenols in fruit wines is from 335 mg/L GAE for strawberry to 1830 mg/L GAE for

black currant. Raspberry wine is between these values with total polyphenol content of 1050 mg of GAE/L, which puts it among the top five according to the content of polyphenols in fruit wines (Heinonen et al., 1998).
The objective of this study was to investigate the influence of fermentation conditions on the total polyphenol content and antioxidative power of raspberry wine. Eight samples of the same raspberry pulp was subjected to fermentation at different conditions. Total polyphenol content was measured daily from the beginning until the end of fermentation to obtain the overall picture of polyphenol extraction during fermentation.

MATERIAL AND METHODS

Materials and reagents

Raspberry fruits of the Meeker variety were obtained from the farm in the vicinity of Aleksandrovac town, Serbia. Fruits were stored at -25°C under the processing. The selected yeast, *Saccharomyces cerevisiae bayanus* EC-1118 was purchased from Lallemand (Montreal, Canada). Reagents used in the study were as follows: Folin–Ciocalteau's phenol reagent (2 N) purchased from Merck (Darmstadt, Germany), gallic acid, HCl, $FeCl_3 \cdot 6H_2O$ and sodium carbonate from Aldrich Chemistry (Munich, Germany). 2,4,6-tris(2-pyridyl)-s-triazine (TPTZ, puriss,≥ 99.0%), Trolox (6-hydroxy-2,5,7,8-tetramethylchromane-2-carboxylic acid, a hydrophilic derivative of tocopherol, purum, ≥ 99%, for HPLC), were from Fluka (Buchs, Switzerland). Anton Paar alcolyzer plus, DMA 4500 density meter was used for monitoring of sugar and alcohol content in the samples, and UV/VIS spectrophotometer was used for determination of total polyphenol content.

Raspberry wine production

The raspberries pulp was prepared manually, and pulp without separation of juice, seeds and solid residue was fermented. The initial Brix value was 10.50 and the pH was 3.20. Eight kilograms of pulp was separated in the eight two liter glass bioreactors, and one kilogram of raspberry pulp was added to each of them. At 22°C four samples were fermented: one sample without sulfur dioxide and selected yeast, one sample with selected yeast and without sulfur dioxide, one sample without selected yeast and with sulfur dioxide and one sample with sulfur dioxide and selected yeast. The other four samples were the same as above, but these were fermented at 15°C. Where it was added, sulfur dioxide concentration was 75 mg/l free SO_2, and concentration of selected yeast was 0.4 g/L (dry weight). Fermentation was monitored by measurement of Brix values every 24 hours and it was considered complete when the Brix level was stable. Also, total polyphenol content in the pulp was monitored every 24 hours according to Folin Ciocalteau`s method. At the end of fermentation, seeds and pulp residue were separated from the wine by pressing and wine was transferred to bottles the capacity of 330 ml and stored at 5°C for sedimentation of the biomass. After 24 h, the beverages were transferred without aeration to new bottles and stored for further analysis.

Determination of total polyphenol content and antioxidant power

Total polyphenol content in the sample was determined every 24 hours from the beginning until the end of fermentation by Folin–Ciocalteau colorimetric method (Singleton et al., 1999). Twenty µl of the filtered and centrifuged sample were mixed with 1.58 ml distilled water, followed by addition of 100 µl Folin–Ciocalteau's phenol reagent. After eight min, 300 µl of 20% (w/v) sodium carbonate solution were added, and the mixture was incubated for two hours at 20°C. Absorbance of each sample in triplicate was measured at 765 nm using a spectrophotometer. Total polyphenol content was expressed as mg gallic acid equivalent per liter of sample (GAE). Ferric Reducing Antioxidant Power (FRAP) method (Benzie and Strain, 1996) was modified to a semi microscale. A portion of an aqueous 10 mmol/l solution of TPTZ reagent in 40 mmol/l HCl was mixed with the same volume of 20 mmol/l $FeCl_3 \cdot 6$ H2O and ten times higher volume of acetate buffer of pH 3.6 (3.1 g sodium acetate and 16

ml acetic acid per litre). The mixture was incubated at 37°C for five minutes. 100 µl diluted wine were mixed with 300 µl distilled water, followed by addition 3 ml of the Fe3+-TPTZ mixture and incubated for 40 min (after reaching plateau), and the absorbance at 593 nm was read. Trolox (1 mmol/l) was used for calibration. For statistical analysis, factorial ANOVA and Tukey`s HSD test were applied.

RESULTS AND DISCUSSION

The results of this study are shown in table 1 and 2. As seen in table 2, total polyphenol content (TPC) during fermentation increases, depending on conditions of fermentation. Samples MM1, MM2, MM3 and MM4 were fermented at 22°C, and TPC at the end of fermentation was higher than for samples MM5, MM6, MM7 and MM8 which were fermented at 15°C. In all samples, during the fermentation, TPC was constantly increasing, reaching its maximum values after 72 hours of fermentation. After 72 hours of fermentation TPC was decreasing in all of the samples until the end of the process. It may have been the result of irreversible precipitation caused by polyphenol compounds interactions with proteins in the medium. The highest TPC value was reached in MM3 sample which was fermented spontaneously at 22°C without selected yeast and with sulfur dioxide addition. The lowest TPC values were observed in samples were fermented with selected yeast and without sulfur dioxide. The obtained results indicate that temperature of fermentation and addition of sulfur dioxide have a strong influence on the TPC, while fermentation with selected yeast has the opposite influence. Relatively lower TPC value or samples fermented with selected yeast can be the consequence of absorption of polyphenol compounds on the cellular wall of yeast. At the end of fermentation, only in samples which are obtained after 120 hours of fermentation (final samples), Ferric Reducing Antioxidant Power (FRAP) was measured. Results of FRAP assay are shown in table 1. Results are expressed as mmol/l Trolox equivalents (mmol/l TE).

Table 1. The results of FRAP assay

Sample of wine	MM1	MM2	MM3	MM4	MM5	MM6	MM7	MM8

Figure 1 shows the results of Folin Ciocalteau assay using the box plot, and they are presented as the mean of three replication with standard deviation and standard error.

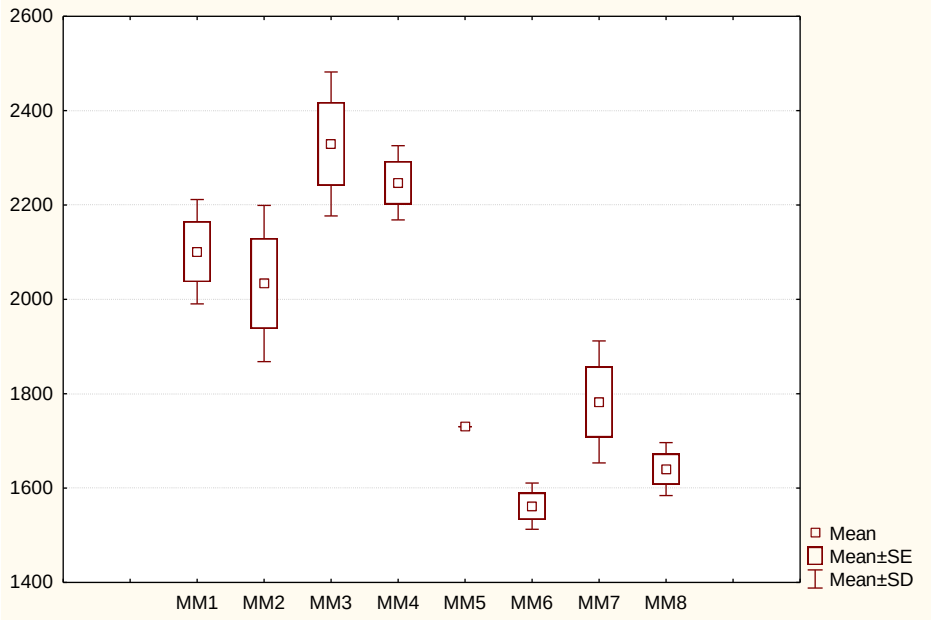

Figure 1. The results of Folin-Ciocalteau assay

The results of statistical analysis are shown in table 3. As shown, there are no statistically significant difference between TPC of samples which are fermented at the same temperature. This may be the results of two different phenomena: very strong influence of temperature on the TPC value and/or the fact that sulfur-dioxide and selected yeast have particularly no influence at all. On the other hand, TPC of samples which were fermented at different temperatures is in the most of cases statistically very significant. This fact supports the conclusion that temperature of fermentation has strong influence on the phenol compounds extraction during fermentation.

CONCLUSIONS

Results of this study show that conditions of fermentation of raspberry pulp have direct influence on the total polyphenol content in raspberry wine. Fermentation temperature strongly influence TPC content of wine. For example, value of TPC in the sample without selected yeast and with sulfur dioxide addition which fermented at 22°C was 2325.8 mg GAE/L, and for sample with selected yeast and without sulfur dioxide addition which fermented at 15°C was 1561.8 mg GAE/L. Statistically, in this study, sulfur-dioxide addition and selected yeast have no influence on the TPC. During fermentation, total polyphenol content in all of samples constantly increases to 72 hours of fermentation whereas reach its maximum.

ABSTRACT: The aim of this study was to establish the impact of initial *F. graminearum* contamination level of barley on deoxynivalenol (DON) and zearalenone (ZEA) content in kilned malt. The influence of applied unit operations during the malt production on development of the above-mentioned fungus and its ability to synthesize DON and ZEA was also considered. Barley samples contaminated with different initial *F. graminearum* contamination levels (0, 10 and 20%) were subjected to micromalting procedure. Barley samples, green malt and kilned malt underwent microbiological and toxicological analyses at which the share of *F. graminearum* contaminated grain and concentrations of mycotoxins were determined. The results show that the strongest proliferation of fungus occurred during steeping and germination, while the drying phase significantly reduced the contamination level. Furthermore, the results indicate that barley with higher initial *F. graminearum* contamination level ensured higher concentrations of mycotoxins in kilned malt. The highest DON concentrations were determined in germ/rootlets samples, while the highest ZEA concentrations were determined in kilned malt.
Key words: *barley, Fusarium graminearum, malting, deoxynivalenol, zearalenone*

INTRODUCTION

Barley is a wide spread commodity used for human consumption. It is used for malt production, as a basic element for beer production. Barley grains represent nutritionally rich substrate and they are therefore suitable for microbial growth and proliferation (Kocić-Tanackov et al., 2005).
The most interesting microorganisms that cause damage on the barley grain are fungi, first of all of genus *Fusarium*. These fungi are naturally present on the grain and they proliferate during the malting process depending on different factors: initial contamination of grain, interaction between species of microbial population, nutritive characteristics of the grain, and most of all, process parameters (temperature, aeration, additives, and humidity) (Noots et al., 1998). Fungi contaminate barley during flowering, in the field, but they can additionally spread during transport and storage. The results of *Fusarium* infection are yield decrease, lower average seed dimensions, decrease in nutritive value, loss of color and changes in smell and taste (Vanne & Haikara, 2001; Siranidou et al., 2001; Kocić-Tanackov et al., 2005). *Fusarium* head blight (FHB) is a severe disease of small grain (Perkowski et al., 2003), that can be partially controlled by crop rotation (highest incidence of *Fusarium* is when barley was grown after corn), tillage, choice of barley cultivar and application of fungicides. Humidity content (rain) during barley anthesis has a huge impact on FHB development (Váňová et al., 2004).
Another downside of *Fusarium* infection are mycotoxins which are accumulating in the grain. Mycotoxins are secondary fungal metabolites that contaminate food and feed and cause toxic effects in humans and animals (Váňová et al., 2004). Being the most prevalent of the *Fusarium* toxins, deoxynivalenol (DON, vomitoxin) is one of the most important indicators of

quality and safety of malting barley (Salas et al., 1999). DON is a potent protein synthesis inhibitor via binding to the ribosomes in eukaryotic cells. In animals, in low or moderate concentrations it can cause anorexia, and higher doses cause vomiting (Legzdina & Buerstmayr, 2004). Mycotoxins from raw material that is used for brewing, like barley or wheat, transfer into malt and from there they can transfer to the final product: beer, which can be detrimental for human health (Vaughan et al., 2005; Lancova et al., 2008). It has been reported that 80-93% of DON from malt ended up in beer (Schwarz et al., 1995). Similar research was conducted by Noots et al. (2003) in which was determined that 80 % of DON was synthesized after steeping.
Noxious effects of zearalenone (ZEA) on humans and animals, primarily reproductive and developmental disturbances (Zinedine et al., 2007), represent a great challenge for the food and feed industry. As a secondary metabolite of *Fusarium* species, ZEA is among the most frequently detected mycotoxins in cereals. Widespread contamination with major fungal producers of this mycotoxin (Krstanović et al., 2005) and its presence (contaminating up to 30% of total cereal production) have also been reported in Croatia (Šegvić Klarić et al., 2008).
This paper refers to how different degrees of *Fusarium* infection influence mycotoxin levels in starting barley, green malt and dry malt.

MATERIAL AND METHODS

The analyses were conducted on barley, artificially inoculated in the field by *Fusarium graminearum,* obtained by the Faculty of Agriculture in Osijek, and non infected barley obtained by the Agricultural Institute in Osijek. Starting contamination of contaminated barley was 34%. To gain three samples with diverse contamination levels (0%, 10% and 20%), starting barley sample was diluted in a way that contaminated and uncontaminated barley were mixed in different scales. Real *F. graminearum* contamination degree was determined in unmalted barley samples according to MEBAK (1997). Manitol agar with antibiotics and fungicides was prepared. To provide surface disinfection of grains, 50 g of barley was soaked in 1% NaOCl for 10 minutes and then rinsed with sterile water. Hundred grains were carefully sorted onto manitol agar in Petri dishes and incubated in dark place at 30 °C. This procedure was conducted in parallels and as a final result, mean value was taken into account. Prepared barley samples with diverse contamination levels were micromalted according to MEBAK procedure (MEBAK, 1997). Hulled barley samples were weighed (250 g) and put into eight malting dishes.
Micro-malting was performed according to MEBAK standard procedure (MEBAK, 1997) in a laboratory incubator (ClimaCell, MMM Medcenter Einrichtungen, München, Germany). The kilning of green malt was also performed according to the MEBAK protocol. After drying, malt was transferred into paper bags and kept at room temperature for three days for moisture equilibration. Real *F. graminearum* contamination degree in malt was determined also according to MEBAK (1997).

Toxicological analysis

Chemicals and apparatus

A Ridascreen® FAST DON fast and ZEA kit for ELISA, competitive enzyme immunoassays, were provided by R-Biopharm (Darmstadt, Germany). Each kit contained a microtiter plate with 96 wells coated with specific antibodies; standard solutions of DON (at concentrations of 0, 0.222, 0.666, 2 and 6 µg/mL) and ZEA (at concentrations of 0, 0.05, 0.15, 0.45, 1.35 and 4.05 ng/mL); peroxidase conjugated DON/ZEA; anti- DON/ZEA antibody; substrate/chromogen solution (urea peroxide/tetramethylbenzidine); stop solution and washing/dilution buffers. ELISA method was performed by ChemWell (Awareness Technology 2910, Inc., USA). DON and ZEA standards were purchased from Sigma Aldrich Chemie GmbH (Steinheim, Germany).

Sample preparation and extraction procedure
Samples (barley, green malt, malt, germ/rootlets) were grounded on an analytical mill (Cylotec 1093, Tecator). After grinding, five grams of each sample was extracted with 100 mL of distilled water for DON analysis and with 25 mL of methanol/water (70/30) for ZEA analysis. The extraction was performed by vigorous shaking for three minutes on a shaker and the extracts were filtered through a filter paper (Whatman, Black Ribbon). The supernatants obtained were appropriately diluted and used for ELISA tests according to the manufacturer's instructions.
Analysis of DON and ZEA
DON: Fifty µL of enzyme conjugate and 50 µL of anti-DON antibody solution were added to 50 µL of standards and prepared samples. Microwell holder was mixed gently and incubated for 5 min at room temperature. After incubation, the wells were washed 3 times with 250 µL of distilled water. Then, 100 µL of substrate/chromogen solution was added to each well and incubated for 3 min at room temperature in the dark.
ZEA: Fifty µL of diluted enzyme conjugate was added to 50 µL of ZEA standards and prepared samples. Microwell holder was mixed gently and incubated for 2 h at room temperature. After incubation, the wells were washed 3 times with 250 µL of distilled water. Then, 50 µL of chromogen solution and 50 µL of substrate solution was added to each well and incubated for 30 min at room temperature.
After these steps, the reactions in both analyzes were stopped by adding 100 µL of stop solution and absorbance was measured at 450 nm. The concentrations of DON/ZEA in samples were calculated by mathematical interpolation from the calibration curve and multiplication with the corresponding dilution factor. Statistical data analysis was performed by use of the Statistica Ver. 6.1. software (StatSoftInc. 1984-2003, USA). All mycotoxin analysis were performed at the Laboratory for Analytical Chemistry, Croatian Veterinary Institute.

RESULTS AND DISCUSSION

Three samples of barley, contaminated with *F. graminearum*, were prepared for the experiment. Samples were contaminated with different degrees of contamination (0%, 10% and 20%). One batch underwent malting with water change during the steeping process and the other batch underwent malting without water change.
Table 1 shows results concerning predicted and actual contamination level determined after microbiological analysis of prepared samples. Actual contamination level was expressed as a number of contaminated kernels (cherry pigment) regarding total number of kernels on selective medium. As expected for this kind of sample, in respect to predicted contamination level, a slight deviation from actual contamination level can be noticed. Microbiological analysis of green malt showed (Table 1**)** that during steeping and germination an increase of microbiological contamination occurred, regarding starting sample. This is in accordance with previous researches (Flannigan et al., 1984; Haikara et al., 1977) which showed that during malting process the starting *F. graminearum* contamination level can increase from 15 – 90%. Cross contamination of kernels with fungi occurs during steeping, when through steeping water, due to release of conidia, mycelium and ascospores, contaminants cross over from contaminated to uncontaminated kernel (Schwartz et al. 1995). No significant difference was noticed between the batch with changed steeping water and the one that had no steeping water change. During kilning, a significant decrease in contamination of all samples occurred, regarding green malt samples and starting barley samples (Table 1). Kilning was carried out in temperatures ranging from 50 – 80 °C, and this lowers the kernel moisture below 5%. This results with decrease in *F. graminearum* contamination level in dry malt.

Table 1. Microbiological contamination of samples collected during the malting process

Batch	Barley		Green malt	Dry malt
	Predicted contamination level/%	Actual contamination level/%	Contamination level/%	
Steeping water change				
0	0	0	0	0
10	10	7	13.5	4
20	20	17.5	52	7
No steeping water change				
0	0	0	0	2
10	10	5.5	10.5	9.5
20	20	19	39.5	7.5

Table 2. Concentrations of DON in samples collected during the malting process

Batch	c(DON) / mg/kg			
	Barley	Green malt	Dry malt	
			Grain	Germ/rootlets
Steeping water change

Tables 2 and 3 show contamination levels of barley, green malt, dry malt and germ/rootlets with mycotoxins DON and ZEA. The results of starting barley analysis indicate that increase of *F. graminearum* contamination level, increases the DON and ZEA concentrations. During the malting process an increase of DON and ZEA concentration occurred in all samples, in respect to starting barley sample.

Toxicological analysis of green malt also showed increase of DON and ZEA concentrations. The increase in DON concentrations can be explained by *de novo* synthesis of DON during the later germination stages. Some researchers have shown that DON concentrations decrease occurs during the steeping phase (Schwarz et al. 1995). This can be attributed to the fact that DON is water-soluble and it transfers into steeping water. Schwartz et al. (1995) have determined that after five-day germination, DON concentrations become significantly higher than the ones in steeped grains (18 – 114%). DON concentrations in both batches slightly decreased in dry malt, in respect to green malt (Table 2), and ZEA concentrations in

dry malt slightly increased in respect to green malt (Table 3). No significant difference has been observed between the batches.

Furthermore, the results indicate that mycotoxins were not equally distributed in dry malt since DON concentrations in germ/rootlets were significantly higher than in dry malt kernel (Table 3). The germ is the place of the most intense fungi growth, so the DON concentrations in germ are the highest. Thus, degermination procedure actually decreases the mycotoxicological malt contamination. ZEA concentrations in the germ were lower than DON. This can be attributed to chemical compounds found in germ. It is presumed that the sugars from the germ react with ZEA and form a "masked" conjugate ZEA-glycoside.
Due to mycotoxins transfer from starting barley to final product – beer, it is important to monitor mycotoxins and to suppress fungi growth during the malt and production processes.

ABSTRACT: The changes of the amount of amino acids in milk fermented with YF-L811 enriched with flakes from biologically activated hull-less barley grain in concentration of 5% and with malt extract in different concentrations (2%, 4% and 6%) were studied. Pasteurized milk, freeze-dried culture YF-L811 (Chr.Hansen, Denmark), flakes from biologically activated hull-less barley grain (Latvia) and malt extract (Ilgezeem, Latvia) were used for experiments. The fermentation process was realized at 43 ^{o}C for 4 hours. The amount of amino acids was determined by Method AS/HPLC-MS.
Results showed that the ability of yoghurt culture YF-L811 (containing *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus*) to produce the amino acids can be promoted by adding flakes from biologically activated hull-less barley grain and malt extract. The amount of amino acids in the fermented milk samples depends on the concentration of added malt extract. The highest content of amino acids was determined in fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4%. It was established significant differences ($p<0.05$) among fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% (the total amino acid content – 11.899 mg·100 g^{-1}) and fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract in concentration of 2% and 6% (the total amino acid content – 4.714 mg·100 g^{-1} and 6.609 mg·100 g^{-1}).
Key words: *amino acids, hull-less barley grain, malt extract, fermented milk*

INTRODUCTION

Dairy products are an important part of functional food. However there are possibilities to find new ways to enrich traditional milk products with bioactive compounds. One of these is to add grain, because it contains high amount of proteins, vitamins, dietary fibre, etc.
Barley is a widely-consumed cereal due to its dietary and technological properties, but mainly (80-90%) barley production is for animal feed and malt (Liu and Yao, 2007). There are growing interests in barley products due to its bioactive compounds, such as β-glucans, tocols (Bonoli et al., 2004; Sharma and Gujral, 2010) and due to its phenolic and amino phenolic compounds (Goupy et al., 1999). The results of research show that the nutritional value of hull-less barley grain can be further increased with biological activation. This includes synthesized vitamin C and increased content of dietary fibre, vitamins B_2, E and niacin during hull-less barley grain biological activation time (Rakcejeva, Skudra, 2007). Therefore biologically activated hull-less barley grain can be used as a good addition for the development of new products.
Barley and malt are now gaining renewed interests as ingredients for the production of functional foods due to their concentration of antioxidant compounds (Qingming et al., 2010). Qingming et al. (2010) have reported that malt contains many phenolic compounds and significant antioxidant activities *in vitro* and *in vivo*. Malt should be considered as a new source of natural antioxidant for dietary needs.
Therefore, both valuable products – biologically activated hull-less barley grain and malt extract were added to fermented milk in order to increase the nutritional value of the final products. The task of the research was to investigate the changes of the amount of amino

acids in fermented milk with YF-L811 enriched with flakes from biologically activated hull-less barley grain and malt extract.

MATERIAL AND METHODS

The research was performed at the microbiological laboratory of the Department of Food Technology of Latvia University of Agriculture and at the laboratory of biochemistry and microbiology of the Scientific Institute "Sigra" of the Latvia University of Agriculture.
Pasteurized milk with fat content 2.5% and the yoghurt culture YF-L811, containing *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* (Chr.Hansen, Denmark), were used for experiments. The culture was stored at -18 ^{o}C.
Flakes from biologically activated hull-less barley grain (Latvia) in concentration of 5% and malt extract (Igezeem, Latvia) in different concentrations (2%, 4% and 6%) were added to milk. The nutrition composition of flakes from biologically activated hull-less barley grain and of malt extract was as follows: protein 13.53 g·100 g^{-1} and 4.00 g·100 g^{-1}, fat 2.70 g·100 g^{-1} and 0, carbohydrate 1.84 g·100 g^{-1} and 73.00 g·100 g^{-1}. Milk samples with flakes from biologically activated hull-less barley grain and malt extract were inoculated with yoghurt culture and fermented at 43 ^{o}C for 4 hours. The control sample was prepared without the flakes from biologically activated hull-less barley grain and malt extract for comparing results.
The content of amino acids was determined by Method AS/HPLC-MS. The differences in the amount of amino acids between the samples were analyzed using the analysis of variance (ANOVA). T-test was applied to compare the mean values, and p-value at 0.05 was used to determine the significant differences.

RESULTS AND DISCUSSION

Lactic acid bacteria can synthesize amino acids; that is determined by the proteolytic character of lactic acid bacteria (Simova et al., 2006). As it is known, these qualities of micro-organisms are genetically determined. In the mixed yogurt culture, *Lactobacillus bulgaricus* has higher proteolytic activity than *Streptococcus thermophilus*, and it has been proven that the free amino acids produced by *L.bulgaricus* are used by *S.thermophilus* (Beshkova, 1998), because *S.thermophilus* has complex amino acid requirement and its growth is influenced by the availability of free amino acids from the growth medium (Guimont, 2002). The primary importance of all amino acids for the growth of *S.thermophilus* is glutamic acid (Neviani et al., 1995). This is one of the factors to shape mixed cultures. The total amino acids content in fermented milk reflects the balance between proteolysis and assimilation by means of bacteria (Wood, 1981).
The content of essential amino acids in fermented milk samples depending on the added flakes from biologically activated hull-less barley grain and malt extract concentration is presented in Table 1.
When evaluating the content of essential amino acids in fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract, it is apparent that the added flakes from biologically activated hull-less barley grain and malt extract affected the amino acids content in the product. Comparing the total content of essential amino acids of control sample (0.409 mg·100g^{-1}) with milk (10.900 mg·100g^{-1}) (Beitane, 2005), it was shown that the obtained results of the experiments confirmed achievements of the research by Oberman and Libudzisz (1998) that lactic acid bacteria require a wide range of amino acids for growth. By adding the flakes from biologically activated hull-less barley grain and malt extract, the content of essential amino acids in fermented milk can be increased. The amount of amino acids in the fermented milk samples depends on the concentration of added malt extract. The highest content of amino acids was determined in fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% (1.508 mg·100 g^{-1}). It was established significant differences ($p<0.05$)

among fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% and fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract in concentration of 2% and 6%, as well as control.

Table 1. The amount of essential amino acids in fermented milk samples with flakes from biologically-activated hull-less barley grain and malt extract, mg·100 g^{-1}

Amino acids	Control	Concentration of malt extract		
		2%	4%	6%
Threonine	0.002	0.002	0.016	0.003
Valine	0	0.001	0.004	0.001
Methionine	0	0	0	0
Isoleucin	0.002	0.001	0.011	0.001
Leucine	0.049	0.088	0.134	0.143
Phenylalanine	0.004	0.006	0.011	0.006
Tyrosine	0.001	0.001	0.007	0.001
Lysine	0.351	0.342	1.325	0.540
Total	**0.409**	**0.441**	**1.508**	**0.695**

Results are given as mean values

Comparing the content of essential amino acids in fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% and control, it appears that the presence of flakes from biologically activated hull-less barley grain and malt extract influence the content of all essential amino acids except methionine.
Similar tendencies can be observed with the content of non-essential amino acids in fermented milk samples (Table 2).

Table 2. The amount of non-essential amino acids in fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract, mg·100 g^{-1}

Amino acids	Control	Concentration of malt extract		
		2%	4%	6%
Aspartic acid	0.007	0.007	0.037	0.012
Serine	0.007	0.001	0.023	0.002
Glutamic acid	0.009	0.013	0.098	0.022
Proline	0.001	0	0.002	0.001
Glycine	0.004	0.001	0.025	0.002
Alanine	0.002	0.001	0.002	0.001
Histidine	3.451	3.494	7.359	4.757
Arginine	0.751	0.756	2.811	1.117
Cystine	0	0	0.034	0
Total	**4.232**	**4.273**	**10.391**	**5.914**

Results are given as mean values

Evaluating the data of Table 2, it was obvious that the highest content of non-essential amino acids had fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% (10.391 mg·100 g^{-1}). It was established that the content of all non-essential amino acids was higher except alanine in comparing with control.
The results of statistical analysis have shown that there were significant differences ($p<0.05$) between fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% and fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 2%, as well as control.
Summarizing the obtained results of the content of amino acids in fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract, it could be concluded that one of the possible ways to promote the ability of yoghurt culture YF-L811 to

synthesize the amino acids in milk in order to elevate the nutritional value of final product, is by the addition of flakes from biologically activated hull-less barley grain and malt extract.

CONCLUSIONS

The ability of yoghurt culture YF-L811 to produce amino acids can be promoted by adding flakes from biologically activated hull-less barley grain and malt extract. The amount of amino acids in the fermented milk samples depends on the concentration of added malt extract. The highest content of amino acids was determined in fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4%. It was established significant differences ($p<0.05$) among fermented milk sample with flakes from biologically activated hull-less barley grain and malt extract in concentration of 4% and fermented milk samples with flakes from biologically activated hull-less barley grain and malt extract in concentration of 2% and 6%.

ABSTRACT: The paper describes i*n vitro* model for evaluation of ability of two adsorbents of plant origin, to adsorb different mycotoxins. Fresh harvested tissues of submerged aquatic plant *Myriophyllum spicatum*, obtained from Sava lake – Belgrade, was washed with HCl solution (3%) and then with distilled water. Plant material was afterwards dried for few days at room temperature, then for 6 hours at 50ºC, crushed and sifted. Peach stones, obtained from "Vino Župa" - Aleksandrovac, were separated from soft fruit residues, washed, dried at room temperature, crushed and separated from kernels. The peach stones were further used as milled shell fractions.
A total of six mycotoxins: aflatoxin B1 (AFL), ochratoxin A (OTA), deoxynivalenol (DON), zearalenone (ZON), diacetoxyscirpenol (DAS) and T-2 toxin were tested *in vitro*. For adsorption experiments crude extracts of mycotoxins were used. The ability for binding mycotoxins was evaluated in the electrolyte 0.1 M K_2HPO_4 (pH 3.0 and 6.9, respectively). Mass ratio of individual mycotoxin and natural mineral adsorbent was 1:5000. The experimental mixtures were incubated for 1 hour on a rotary shaker (185 rpm) at room temperature (22-25^{o}C). The extractions of nonadsorbed mycotoxins from the filtrates were performed with organic solvents, and their quantifications were done by thin-layer chromatography.
M. spicatum bound more (94.7-96.0%) of applied AFL B1 than peach stones (73.3-80.0%). In the case of OTA higher adsorption indexes were observed by peach stones (50.0-66.7%). Binding of DON has been observed only by peach stones. Its adsorption index varied from 25.0 to 50.0% depending on the pH of the used electrolyte. *M. spicatum* adsorbed more ZON at pH 6.9 while peach stones adsorbed more ZON at pH 3.0. In the case of type A trichothecenes (DAS and T-2 toxin) adsorbents of plant origin bound only T-2 toxin. The amount of adsorbed T-2 toxin ranged from 16.7 (pH 3.0) to 33.33% (pH 6.9).
Key words: *mycotoxins, adsorbents of plant origin, in vitro*

INTRODUCTION

Biosorbtion technique for treatment of industrial waste waters by living or non-living biomass has been proven to be an excellent method for removal of toxic contaminants that offers significant advantages: low cost, availability, profitability, easy operating and efficiency (Dhir and Kumar, 2010).
Myriophyllum spicatum (Eurasian water milfoil) is a submerged aquatic plant, native to Europe, Asia, and North Africa, and it was introduced into North America where is invasive species (Couch and Nelson, 1985). *M. spicatum* reproduces primarily by vegetative fragmentation and it can quickly recolonize areas that have been cleared of the species, because of the viability of even small fragments (Aiken et al., 1979). The control methods for growth of *M. spicatum* can be classified as physical (**mechanical harvesters and chopping machines)**, chemical, and biological.
Activated carbon (AC) prepared by pyrolysis of carbonaceous organic compounds (mostly nutshells, wood, paddy husk, etc.) is a general adsorbtive material with a large surface area and excellent adsorbtive capacity. It has been recommended as a general toxin adsorbing agent and is routinely recommended for various digestive toxicities. It is well known that AC

can be used as one of the very effective, non toxic mycotoxin-adsorbing agent (Whitlow, 2006). In order to decrease the costs of adsorbent preparation, which is in preparing of AC inevitable, the authors have tried to explore the possibility of application of raw, untreated lignocelullosic material for adsorption of different types of mycotoxins.
The aim of the presented study was to evaluate *in vitro* the ability of two adsorbents of plant origin, to adsorb six different mycotoxins: aflatoxin B1 (AFL), ochratoxin A (OTA), deoxynivalenol (DON), zearalenone (ZON), diacetoxyscirpenol (DAS) and T-2 toxin.

MATERIAL AND METHODS

Preparation of adsorbents of plant origin

Samples of fresh harvested tissues of *M. spicatum* (**MS**), used for experiment, were taken from Sava Lake. Plant biomass was washed with diluted HCl solution (3%) and then with distilled water three times before drying. Washed plant material was exposed to air and dried for couple days at room temperature and then dried at 50 ºC for 6 hours, crushed and sifted to a particle size less then 100 µm.
Peach stones (**PS**) used as another raw material for adsorption of mycotoxins was obtained from "Vino Župa" Company from Aleksandrovac, where the stones have been disposed as by-product waste from their Juice Factory. After sampling, the fruit stones were separated from soft fruit residues, washed, dried at room temperature, and kept in polypropylene bottles for further treatment. Prior to experiment, all the samples were crushed and separated from kernels, which were discharged, so for further analysis only hard stone part was taken. The peach stones were further used as milled shell fractions with diameter less than 100 µm.
Both adsorbents of plant origin were prepared in the Institute for Technology of Nuclear and Other Mineral Raw Materials, Belgrade.

Production, quantification and isolation of mycotoxins

Aflatoxin B1 (AFL), ochratoxin A (OTA), deoxynivalenol (DON) and zearalenone (ZON) were produced employing solid substrate fermentation per the methods of Bočarov-Stančić et al. (2009a), Bočarov-Stančić et al. (2010) and Bočarov-Stančić et al. (2009b), respectively. Type A trichothecenes (diacetoxyscirpenol - DAS and T-2 toxin) were biosynthesized by submerged fermentation in liquid medium (Bočarov-Stančić et al., 2007). The respective fungal cultures used were: *Aspergillus flavus* GD-2 (leg. prof. dr G. Dimić, Technological Faculty, Novi Sad, Serbia), *A. ochraceus* CBS 108.08, *Fusarium graminearum* GZ-LES (leg. dr J. Lević, Maize Research Institute, Belgrade-Zemun, Serbia), *F. graminearum* D2 (leg. dr A. Bočarov-Stančić, Bio-Ecological Centre, Zrenjanin, Serbia), *F. semitectum* SL-B (leg. dr A. Bočarov-Stančić, Bio-Ecological Centre, Zrenjanin, Serbia), and *F. sporotrichioides* ITM-391 (leg. dr A. Bottalico, Consiglio Nazionalle delle Richerce, Istituto Tossine a Micotossine da Parassiti Vegetali, Bari, Italy).
Isolations of mycotoxins and determinations of single mycotoxin content in solid substrates were done according to standard thin-layer chromatographic method for fodder analysis (The Official Gazette of SFRY, issue 15/87). Isolations of type A trichothecenes were done by ethyl acetate and their quantities were determined by thin-layer chromatographic (TLC) method according to Rukmini and Bhat (1978). Isolated crude toxins were evaporated to dryness and dissolved in following solvents: ethanol (AFL, OTA, ZON), ethyl acetate (DAS, T-2) and methanol (DON). The final concentrations of stock mycotoxins' solutions were 0.1 µg/µl (AFL) and 1 µg/µl (OTA, DON, ZON, DAS and T-2), respectively.

Experimental procedure

For adsorbtion experiments stock solution of AFL was diluted to 0.2 µg/ml, of ZON to 0.8 µg/ml, and of all other mycotoxins to 2.0 µg/ml with electrolyte (0.1M K_2HPO_4). pH value of electrolyte was adjusted with 0.1M HCl or 0.1 NaOH to 3.0 and 6.9, respectively.

The *in vitro* binding ability of *M. spicatum* and peach stones was tested as follows: aliquots (50 ml) of test solutions (containing 10 µg of AFL, 40 µg of ZON and 100 µg of all other tested mycotoxins) were added to Erlenmayer flasks (250 ml) containing 500 mg of single adsorbent in the case of OTA, DON, DAS and T-2 toxin, 200 mg in the case of ZON, and 50 mg in the case of AFL. Controls were prepared by adding of 50 ml of the test solutions without mineral adsorbent. The flasks were stoppered, incubated for 1 hour on rotary shaker (185 rpm) at room temperature (22-25 ^oC) and then filtered. Mycotoxins' concentrations in 25 ml aliquots of electrolyte with adsorbent (C) and without it (C_o) were determined, after extraction with 2 x 15 ml of organic solvents: benzene (ZON), benzene-acetonitrile (AFL), and ethyl acetate (OTA, DON, DAS and T-2) respectively, by TLC methods (The Official Gazette of SFRY, issue 15/87; Rukmini and Bhat, 1978). All analysis were performed in three replications.

The adsorption index of individual mycotoxin in percentages was calculated by the following formula:

$$Adsorption\ index = [\frac{C_0 - C}{C_0}]\ x\ 100$$

RESULTS AND DISCUSSION

Table 1. Chemical composition of adsorbents of plant origin, %

Parameter (%)	*Myriophyllum spicatum* (**MS**)	Peach stones (**PS**)
Dry matter	91.11	92.23
Moisture	8.89	7.77
Crude protein	17.95	1.26
Crude fat	1.28	0.05
Crude cellulose	23.33	58.05
Ash	17.64	0.42
Nitrogen free extracts (NFE)	30.91	32.45
Neutral detergent fiber (NDF)	33.38	71.12
Acid detergent fiber (ADF)	30.96	66.12
Lignin	6.33	16.54

The investigated adsorbents had very different chemical composition (Table 1). In relation to the peach stones *Myriophyllum spicatum* had a significantly higher content of protein, crude fat and ash, while the crude fiber content and lignocellulosic fractions (ADF, NDF and lignin) was noticeably smaller. Chemical composition of *M. spicatum*, (with the exception of ash content) is very similar with composition of some plants of the family *Fabaceae* (*Medicago sativa* and *Trifolium repens*). On the other hand, chemical composition of peach stones is similar or approximate to the composition of the peanuts husks or sunflower husks. Such a chemical composition of the studied mycotoxins adsorbents of plant origin indicates, among others, that they can be used as a feed additive (*M. spicatum*) or energetic material (peach stones) or even as carriers of certain active substances used in agriculture and industry.

Table 2. Adsorption indexes of tested adsorbents of plant origin at different pH values

Adsorbent	pH	Adsorption index (%)					
		AFL	OTA	DON	ZON	DAS	T-2
MS	*3.0*	*96.00*	*50.00*	*0*	*70.00*	*0*	*16.67*
	6.9	94.70	30.00	0	75.00	0	33.33
PS	*3.0*	*80.00*	*66.67*	*25.00*	*53.30*	*0*	*16.67*
	6.9	73.30	*50.00*	50.0	33.33	0	33.33

Aflatoxin B1. By the use of TLC method it was noted that M. spicatum binded more (94.7-96.0%) of applicated AFL than peach stones (73.3-80.0%) (Table 2). Influence of pH value of applied electrolyte on the binding of this mycotoxin was not significant. Obtained results are similar with the results of our previous investigations with natural mineral adsorbents (bentonite – BEN, diatomite – DIA and zeolite – ZEO). We have found that these minerals binded more than 95% of applicated AFL (Bočarov-Stančić et al., 2011).

Ochratoxin A. In the case of OTA higher adsorption indexes (50.0 - 66.67%) were observed by peach stones (Table 2). In both cases adsorbents of plant origin binded more OTA at pH 3.0 than at pH 6.9 as same as the most of mineral adsorbents (Thimm et al., 2001).

Deoxynivalenol. Adsorption of this type B trichothecene (DON) has been observed only by peach stones. Its adsorption indexes varied from 25.0 to 50.0% depending on the pH of the used electrolyte. Contrary to our previous results obtained in vitro with natural mineral adsorbents (Bočarov-Stančić et al., 2011) adsorption of this fusariotoxin was more pronaunced at neutral pH (6.9).

Zearalenone. Effect of electrolyte pH value on the binding of ZON was different. M. spicatum adsorbed more ZON at pH 6.9 while peach stones adsorbed more ZON at pH 3.0 (Table 2). Observed adsorption indexes for MS (70.0 - 75.0) and PS (33.33 - 53.3) were significantly higher then adsorption indexes achieved in vitro with natural mineral adsorbents (BEN, DIA and ZEO), when the largest binded quantity of ZON (12.2 to 37.0 %) was observed by ZEO (Bočarov-Stančić et al., 2011).

Type A trichothecenes. In the case of these fusariotoxins (DAS and T-2 toxin) adsorbents of plant origin (MS and PS) binded only T-2 toxin. The amount of binded T-2 toxin was the same in both cases and ranged from 16.67 (pH 3.0) to 33.33% (pH 6.9). That there is little or no beneficial effect against this type A trichothecene also showed the results of other authors obtained with different mineral adsorbents (Devegowda and Aravind, 2002; Bočarov-Stančić et al., 2011).

Adsorbents of plant origin tested in the present investigation are known as biosorbents of different toxic substances, but not mycotoxins. M. spicatum is capable of regulating salt intake independent of concentration in the aquatic environment (Anderson et al., 1966) and can be successfully used for the removal of heavy metals - lead, zinc and copper (Keskinkan et al., 2003 and 2007). On the other hand peach stones, produced from food industries as solid waste, can also be used for binding of lead ions from polluted water (Rashed, 2006) or aqueuos ammonia (Sotto-Garrido et al., 2003) and some textile dyes (Gercel et al., 2009). It is not surprising that peach stones was better biosorbent of mycotoxins in vitro conditions because it had much higher cellulose content then M. spicatum (Table 1). Although raw, untreated material was used in the present experiments it showed similar adsorption capacities as activated carbon, especially in the case of deoxynivalenol (Döll et al., 2004).

CONCLUSION

Both tested adsorbents of plant origin showed the highest adsorption indexes *in vitro* for aflatoxin B1 (73.3-96.0%).

Rather high adsorption indexes were obtained for zearalenone (33.3-75.0%), and ochratoxin A at pH 3.0 (50% - MS, and 66.67 – PS).

Deoxynivalenol bound only by peach stones (25% and 50%, respectively).
None of the investigated adsorbents adsorbed diacetoxyscirpenol.
The amount of bound T-2 toxin was rather small, although it was the same for MS, and PS (16.67 to 33.33%).
In tested laboratory conditiond the better adsorbent of plant origin was shown to be peach stones because it binded in vitro five (AFL, OTA, DON, ZON and T-2) out of six tested mycotoxins.
Investigated adsorbents, such as they are, can be recommended for the use in ruminants nutrition because ruminants are more tolerant then nonruminants on the presence of higher concentrations of mycotoxins in feed.
Nonetheless in vivo experiments are indispensable to proof the efficacy of investigated adsorbents (MS, and PS) and other ones of plant origin.

ABSTRACT: Over the last decades, there has been an increased interest in studying the potential health benefits of moderate wine and beer consumption. Studies indicate that wine and beer consumed moderately can have a very favorable effect on the overall health condition. The effect can be explained by a high content of antioxidants and other biologically active compounds, particularly polyphenols, which can prevent the occurrence of some diseases, especially cardiovascular disease. In this research, a special type of beer, the grape beer, was produced using three different grape varieties Prokupac, Pinot Noir and Cabernet Sauvignon. Beer samples were fermented using conventional brewer's wort and 20 % w/w and 30 % w/w of crushed grape. The fermentation was carried out using two different yeasts: *Saccharomyces pastorianus* industrial strain obtained from one of the Serbian breweries and wine yeast *Saccharomyces cerevisiae* K1-V1116. The influence of grape variety, the wort-to-grape ratio and yeast strains on the polyphenol content was examined. The total polyphenol content was determined according to the official EBC (European Brewery Convention) spectrophotometric method. The results suggested that grape varieties, their contents, as well as yeast strains had a very significant influence on the total polyphenol content of the obtained beer. The polyphenol content rang in samples went from 95.94 mg/L in beer without grape fermented by brewing yeast and up to 754.40 mg/L in beer with 30 % of Cabernet Sauvignon grape fermented by wine yeast.
Key words: *beer, grape, polyphenol, fermentation*

INTRODUCTION

Over the last decades, numerous studies have dealt with the possibility that certain foods can promote health and improve the prevention of many diseases. The term „functional food" was first introduced in Japan in the mid 1980s and refers to any processed food or food ingredient that may provide additional physiological benefit, such as preventing or delaying onset of various diseases, as well as meeting basic nutritional requirements (Dey et al., 2009). New types of food products with improved healthy function are a growing trend. The utilization of dietary compounds and natural products as potential disease prevention agents in the form of functional foods has become an important task in current health studies (Gerhauser, 2005). Numbers of research works have investigated the possible health benefits of moderate consumption of various alcoholic beverages, such as wine, beer, spirits, liqueurs etc (Corrao et. al., 1999). Many of these studies supports the hypothesis that moderate drinking of any alcoholic beverage, particularly red wine and beer, significantly reduces the risk of cardiovascular diseases (Corrao et. al., 1999). The protective effects of beer and red wine can be explained by a high content of natural antioxidants, particularly phenolic compounds. Antioxidants are "any substance that, when presents at low concentrations compared with those of an oxidizable substrate, significantly delays or prevents oxidation of that substrate" (Halliwell, 2007). Among antioxidants, phenolic compounds are by far the most abundant in the diet. Many of these natural antioxidants, especially flavonoids and stilbenes, exhibit a number of bioactive effects, such as anti-inflammatory, antimicrobial, antiallergic, antithrombotic, anticancerogenic, antimutagenic, antiaging and vasodilatory activities (Jaganath and Crozier, 2010). Dietary antioxidants are able to scavenge of free radicals, thus preventing a number of degenerative diseases caused by oxidative stress (Heim et al., 2002). Beer and wine contain high amounts of

phenolic compounds and other valuable nutrients and can be an interesting basis for development of new functional products.

Beer is a worldwide low-alcohol beverage made from natural ingredients: barley (malt), water, hop and yeast. It has a very complex chemical composition (several hundred compounds have been so far characterized in beer) and may contain significant amounts of nutritional as well as non-nutritional components including carbohydrates, proteins, vitamins, amino acids, minerals and many others phytochemicals. Beer is a rich source of proteins, B type vitamins (B6, B12 and B9), minerals and soluble fibers (a liter of beer contains 20-60 % of recommended daily intake of fiber) (Gromes et al., 2000). In addition, beer is a rich source of bioavailable silicon (Powell et al., 2005). The antioxidant capacity of beer depends on the content of polyphenols and Maillard compounds. Beer polyphenols come mainly from barley (malt) (70-80 %) and hops (20-30 %), which are basic raw materials for its production. However, besides the influence of raw materials, the total antioxidant content of beer significantly depends on the brewing process used. Antioxidants have a very important role in malting and brewing due to their ability to delay and prevent oxidation reactions. Also, various antioxidants (sulfites, ascorbic acid etc.) can be added during the brewing process to improve flavor stability of products (Zhao et al., 2008). However, minimizing the use of additives and increasing the content of antioxidants from natural sources to improve flavor stability and increase the shelf-life of products are growing trend in food and beverage industry.

Wine is probably one of the oldest alcoholic beverages as confirmed by archeological record dating back more than 7.5 thousand years. It has most likely inspired more research and publications than any other beverage or food (Jackson, 2008). The effect of wine consumption on health has been intensively studied over the last several decades. Most studies confirmed that moderate drinking of red wine reduces the risk of cardiovascular diseases and can improve overall health. Such a red wine effect has usually been linked to its high content of polyphenols (Scalbert et al., 2005). The content of phenolic compounds in wines is conditioned by the grape variety and by other factors that influence the grape ripening, such as soil, geographical region and weather conditions. On the other hand, phenolic composition of wines largely depends on the winemaking process, which has the most important role in the extraction process of polyphenols from grapes (Paixao et al., 2007). In addition to their function of antioxidants, phenolic compounds can affect to wine sensorial properties, such as appearance, taste, mouth-feel, fragrance, astringency and bitterness.

Phenolic compounds of wine and beer are quantitatively and qualitatively different because the raw materials used in their production are completely different. Some classes of polyphenols, such as flavan-3-ols and flavonoles are present in similar amounts in both beverages. However, there are phenolic compounds mainly present in red wines (stilbenes and proanthocyanidins), or exclusively in beer (flavanones and chalcones) (Iacomino et al., 2009). The total amount of polyphenols in wine is several times (mainly 2-3) higher than in beer, but absorption of these natural antioxidants by an organism is as important as their presence in beverages. It has been shown that by consuming equal amounts of alcohol from beer and wine, blood contains approximately equal amounts of antioxidants (Baxter and Hughes, 2001). In a previous work, we investigated the possibility of producing a special type of beer by fermenting wort with different proportion of grape must (Veljovic et al., 2010). The obtained results indicated that special grape beer has unique sensorial profile completely acceptable for consumers and significantly higher content of polyphenols. Also, there are some beers on the world market that are produced with the addition of grape such as Vigneronne Cantillon.

The main objective of this study was to investigate the influence of grape varieties, proportions of grape in fermenting medium, yeast strains and conditions of fermentation on total polyphenol content of grape beers.

MATERIAL AND METHODS

Three different grape varieties were used: Prokupac, Pinot noir and Cabernet sauvignon. Prokupac is Serbian autochthonous variety, used for making table and top quality rose and red wines, while Pinot noir and Cabernet sauvignon are one of the best known red grape varieties used for producing top quality wines. Grapes were obtained from experimental school estate "Radmilovac" of Faculty of Agriculture, Belgrade. The wort and a bottom-fermenting industrial yeast strain *Saccharomyces pastorianus* used in this study were obtained from a local brewery. Wine yeast *Saccharomyces cerevisiae* K1-V1116 was purchased from Lallemand (Montréal, Canada). Sodium carboxymethyl cellulose (CMC), ethylenediaminetetraacetic acid (EDTA) and ferric ammonium citrate were purchased from Sigma-Aldrich (Steinheim, Germany). Concentrated ammonia was obtained from Centrohem (Belgrade, Serbia).

Fermentation

Each of the three grape varieties was used to prepare two different media for fermentation, one with 20 % and another with 30 % of grape mash. The grapes were sorted manually, washed in cold water to remove impurities, and the clean grapes were destemmed and crushed by hand. The wort and grape mash were mixed in different proportions (70:30 and 80:20) and the pH of obtained mixtures was adjusted to 5.3 with diluted solution of ammonium hydroxide. The fermentation mediums (4 liter) were poured into 5 L laboratory stainless steel fermenters and seeded with 80 mL of a yeast suspension, corresponding to 10-15 million yeast cells per milliliter of wort. The fermentation process was conducted according to the yeast strain used. Pitching was performed at 12°C or 15°C with *S. uvarum* and *S. cerevisiae* K1-V1116, respectively. When the real extract was decreased to 5 % w/w, the fermenting mixture was sent to a laboratory wine press. After pressing, liquid was transferred into an aging stainless steel vessel equipped with pressure control system. At the end of secondary fermentation, beer was filtered and bottled. Control beer samples were produced in the same way but without addition of grape mash.

Determination of total polyphenols

The total polyphenol content was determined according to the official EBC (European Brewery Convention) spectrophotometric method. Every beer sample (10 mL) was pipetted into a 25 mL volumetric flask where was mixed with 8 mL of CMC/EDTA reagent (10 g/L CMC containing 2 g/L EDTA). Afterwards, 0.5 mL of green ferric ammonium citrate solution (3.5 % w/v) and 0.5 mL of ammonia reagent (concentrated ammonia : water = 1:2) was added to the mixture and vigorously shaken. The total volume was adjusted to 25 mL with distilled water. The absorbance of red-colored solution was measured at 600 nm after 10 minutes. In blank sample, ferric reagent was replaced with distilled water. The content of polyphenols was calculated using the following formula:

$$\text{Polyphenol content (mg/L)} = (A_s - A_b) \times 820 \times F,$$

where A_s, A_b and F are the absorbance of the sample, absorbance of the blank and dilution factor, respectively.

Statistical analysis

All measurements were conducted in triplicate. Analysis of variance and significant differences among means were tested using ANOVA and Tuckey's HSD test.

RESULTS AND DISCUSSION

In our previous research, we found that it is possible to produce a very interesting and pleasant special type of beer made by fermenting mixture of wort and grape must, which was characterized with higher polyphenol content compared with commercial light beer (Veljovic et al., 2010). This is a continuation of the aforementioned research in which the

main aim was to investigate the influence of grape varieties and its proportions in fermenting medium, yeast strains and conditions of fermentation on total polyphenol content of grape beers.

The polyphenol content of analyzed beer samples with basic statistical parameters are shown in table 1. Variations of values for polyphenol content within individual samples were very small. The control beer fermented by *S. pastorianus* had the lowest content of polyphenols, while the highest values recorded in beer with 30 % of Cabernet sauvignon fermented by *S. cerevisiae*.

Table 1. Basic statistical parameters for polyphenol content of analyzed beer samples

Yeast	Samples	Mean (mg/L)	Min.	Max.	Variance	Std.dev.	Coef.var.	Std.err.
S. pastorianus	Cb	95.94	95.08	96.62	0.62	0.79	0.82	0.45
	PN20	154.16	153.73	154.99	0.52	0.72	0.47	0.42

	P30	371.24	371.00	371.69	0.15	0.39	0.11	0.23
	CS20	674.04	673.57	674.59	0.26	0.51	0.08	0.30
	CS30	754.40	754.12	754.86	0.16	0.40	0.05	0.23

Cb - control beer; PN20, PN30 - beers with 20 and 30 % of Pinot noir, respectively; P20, P30 - beers with 20 and 30 % of Prokupac, respectively; CS20, CS30 - beers with 20 and 30 % of Cabernet sauvignon, respectively; Std.Dev. - standard deviation; Coef.var. - coefficient of variation; Std.err. - standard error

Table 2. The results of analysis of variance

Factors	F	p
Grape variety	541487.7	0.000
Proportion of grape	1389661.3	0.000
Yeast strain	1411092.0	0.000
Grape variety*proportion of grape	139332.5	0.000
Grape variety*yeast strain	132800.8	0.000
Proportion of grape*yeast strain	327682.9	0.000
Grape variety*proportion of grape*yeast strain	35278.3	0.000

F - sample values applied test; p - level of significance (p≤0.05, difference is significant)

The results of the ANOVA test are shown in table 2. ANOVA indicates that all observed factors (grape variety, proportion of grape in fermenting medium and yeast strain) influence very significantly on the polyphenol content of samples. The combined effects of factors on the measured values were also very significant, which indicates that the impact of one factor depends on the level of the two other factors. All samples fermented by *S. cerevisiae* had higher amount of polyphenols compared with the appropriate samples fermented by *S. pastorianus*; in some cases, difference between these samples was greater than twice. One of the reason for better extraction of phenolic compounds during fermentation with yeast

strain *S. cerevisiae* K1-V1116 can be slightly higher temperature (15°) in comparison to fermentation with *S. pastorianus* (12°C). The beers produced with Cabernet sauvignon had the highest polyphenol content, while the lowest content was present in the beers with Prokupac. With increasing proportion of grapes in fermenting medium from 20 to 30 %, polyphenol content of obtained beers was also very significantly increased.
In addition, the obtained grape beers were characterized by a pleasant flower-fruit fragrance, enjoyable aroma and high fullness of taste, with prominent freshness and good after-taste.

CONCLUSIONS

The results obtained suggest that all examined grape beers had a higher amount of polyphenolic compounds compared to control beers. The grape variety, proportion of grape in fermenting medium and yeast strain had a significant influence on polyphenols content of grape beer. However, the interactions between factors were also significant, which indicates that these factors did not affect independently, but the impact of any factor depends on the level of the two other factors. The highest polyphenol content had the grape beer produced with 30 % of Cabernet sauvignon and fermented by *S. cerevisiae* K1-V1116, while the lowest value had the control beer fermented by *S. pastorianus*. These results are encouraging for further research and indicate the possibility of obtaining a wide range of special beers with increased polyphenol content.

ABSTRACT: The traditional white brined cow cheese was tested as a delivery medium for probiotic bacteria. The white brined cheese was manufactured by the traditional method. The cheese produced in this way has relatively short period of ripening, large percentage of fat and suitable pH values and therefore provides good conditions for survival of the probiotic culture. Two different initial concentrations of the probiotic bacterium, *Lactobacillus casei*, were used in this study. The traditional and probiotic type of cheeses were produced in a dairy plant in three separate batches. Due to the mild production conditions, the number of survived bacteria in the enriched cheeses was higher than 10^7cfu/g. The quality of the probiotic cheeses was comparable with the traditional product in respect of the dry mass, pH values, titratable acidity, NaCl content, fat content as well as nitrogen fractions. There was no significant difference in almost all quality parameters at the $p < 0.05$ level between the two probiotic cheeses.
Key words: *white brined cheese, probiotic bacteria,* Lactobacillus casei*, traditional food*

INTRODUCTION

White brined cheese, both from sheep and cow milk, is well known traditional dairy product in Balkan countries. Following the current demands for food safety, these types of cheeses are no longer produced from raw milk. Milk is pasteurized just before being used for cheese production. While consumers nowadays ask for traditional food products, they also strive for more nutritive, safer and healthier foods. Their interest in such foods has urged development of probiotic food products. Food and Agricultural Organization of the United Nations and the World Health Organization define probiotics as “live microorganisms (bacteria and yeasts), which when digested or locally applied in sufficient numbers confer one or more specified demonstrated health benefit for the host”. The use of probiotic bacterial cultures stimulates the growth of preferred microorganisms, crowds out potentially harmful bacteria and reinforces the body’s natural defense mechanisms (Anal and Singh, 2007).
The most important probiotic bacteria typically associated with the human gastrointestinal tract, belong to the lactic acid bacteria from the genera *Lactobacillus* and *Bifidobacterium*. These bacteria are Gram positive, rod-shaped, non-spore forming, catalase-negative organisms. Although the number of probiotic bacteria that delivery foods must be able to support to provide a health benefit has not been firmly established, research suggests it should be between 10^7 and 10^9 cfu/g (Sharp et. al., 2008).
Currently the probiotic cultures are successfully incorporated into large number of fermented milk products, especially in yogurts, followed by cheddar cheese, but scarcely in white brined cheese (Yilmaztekin et al., 2004; Burns et al., 2012). In recent years the consumption of cheese has increased rapidly. It is nutritious and ready-to-eat food. It has been reported that the cheese may offer certain advantages as a carrier of probiotic microorganisms, having a higher pH than yogurts and other fermented milk products (Wang et al., 2010). Furthermore, the matrix of the cheese and its relatively high fat content may offer protection to probiotic

bacteria during passage through the gastrointestinal tract (Gardiner et al., 1999; Bergamini et al., 2005).
The objective of this study was to enrich the Macedonian traditional product - the white brined cow cheese with probiotic bacterium *Lactobacillus casei* and to investigate its impact on the cheese composition during ripening.

MATERIAL AND METHODS

Cheese manufacture

The brined white cheese was manufactured from pasteurized cow's milk at industrial scale at the local cheese making company. Three batches, each of 1000 L milk were processed at the same time. A lyophilized mixed culture of *Streptococcus thermophilus* and *Lactobacillus delbrueckii* supps *bulgaricus* (Chr. Hansen Inc.) was used as a starter culture. It was dispersed in the milk according to instructions of the producer. After that, in two of the batches, a lyophilized probiotic culture of *Lactobacillus paracasei* subsp.*paracasei (L. casei)* was directly added and mixed in a dose high enough to achieve 10^{10} cfu/g (200g/1000 L) and 10^{12} cfu/g (300g/1000L). After 20 minutes, 200 ml of chymosin (Chr. Hansen Inc.) were added to each batch. The milk was allowed to coagulate for 25 min then the curd was cut (2x1.5 cm) and allowed to heal 10-15 min then heated to 35^{o}C over 15 min and cured. The curd was separated from whey at pH 6.45 and molded. The molds were first pressed with 1kg per 1kg cheese during 1.75 h, and then again with 2 kg per 1 kg cheese. The cheese was cut in smaller pieces at 30^{o}C, pH 5.4-5.62, and stored at 16^{o}C for 16 h. The cheese was brined in 20% salt solution during 3 h at pH 4.6. The young cheese was then transferred into 5% salt solution and ripened for 20 days at 16^{o}C, and for 20 days at 4^{o}C.

Chemical analysis

Cheese samples were analyzed during ripening period for moisture by drying at 105^{o}C using moisture analyzer Sartorius MA-40, salt was determined by Morh method using $AgNO_3$, titratable acidity (TA) by AOAC method 920.124, fat by van Gulick method (ISO 3433), and total nitrogen (TN) by HACH-8075 Kjeldahl method. The pH of cheese was measured with a pH-meter Mettler Toledo 120. The nitrogen fractions: water-soluble nitrogen (WSN), 12% trichloroacetic acid- soluble nitrogen (TCA) and 5% phosphotungstic acid-soluble nitrogen (PTA) were determined as described by Hayaloglu (2007).

Microbiological analysis

The population of the probiotic bacterium *Lactobacillus casei* was determined by plating sample dilutions on MRS agar and counting plate colonies after 48 h of incubation at 37^{o}C as described by Bergamini *et. al.* (2005).

Statistical analysis

Descriptive statistics and one-way analysis of variance (ANOVA) was performed on the experimental data to evaluate significant differences among the samples at 95 % confidence interval according to Tukey's test using Minitab 15 statistical software. The variables that showed high significance were used in the Principal Component Analysis (PCA) to identify a reduced number of principal components that sufficiently explain most of the information in the starting data.

RESULTS AND DISCUSSION

The gross composition of cheese samples is presented in Table 1. The table shows the mean values of moisture, pH, titratable acidity, salt content, fats-in-dray matter, nitrogen fractions soluble in water, trichloroacetic and phosphotungstic acid, and total nitrogen. Throughout the ripening period, the moisture content of the probiotic cheeses changed within narrow margins. The pH values of the samples decreased gradually during the ripening

period. At the end of the ripening period, pH of the control was 4.6, while both probiotic 1 and probiotic 2 samples had 4.4 which was a statistically significant difference. The addition of the probiotic culture affected the titratable acidity of the cheese. The acidity gradually increased during the ripening period reaching the statistically higher values of 1.6 and 1.7% in the probiotic 1 and probiotic 2 samples compared to 1.33% in the control sample. The salt penetration was fast during the first 20 days and then leveled off in both of the probiotic cheeses. After 40 days the control sample had the highest salt content.

Table 1. Chemical composition of control and probiotic white brined cheeses during ripening

Sample	control			probiotic 1*			probiotic 2**

***Probiotic 2 refers to cheese inoculated with L. casei to achieve 10^{12} cfu/g*
Mean values and standard deviation, (n = 3). Different small letters within a row indicate significant differences due to ripening time within the same sample ($p < 0.05$). Different capital letters within a row indicate significant differences among samples ($p < 0.05$)

The fat fraction of cheese is important for the development of typical flavor and texture. The change in the fat content exhibited in all samples may result from the salt absorption and/or water diffusion of some soluble components between brine and cheese mass (Hayaloglu, 2007). The hydrolysis of triglycerides, which constitute more than 98% of cheese fat, is the principle biochemical transformation of fat during ripening, which leads to production of free fatty acids, di- and monoglycerides and possibly glycerol. The pH of cheese has major influence on the flavor impact of free fatty acids produced by hydrolysis of triglycerides. As Sing et al. (2003) reported, at pH of about 5, a considerable portion of the fatty acids are present as salts, which are nonvolatile, thus reducing the flavor impact.

Proteolysis in cheese involves complex reactions, and to better understand the development of proteolysis in cheese, it is necessary to investigate the nitrogen fractions formed during ripening (Ong and Shah, 2008). The ratio of WSN and TCA to TN in all cheese samples increased significantly throughout 40 days of ripening. At the end of the ripening, the control sample had higher WSN fraction (16.4%) than both probiotic samples (13.9%). At the end of ripening period the PTA levels in probiotic 1 and probiotic 2 samples did not differ significantly but they showed significant difference from the control sample. The results of the increased levels of PTA fraction suggest that *Lactobacillus casei* has an active peptidolytic system. PTA fraction is composed of very small peptides, amino acids, and smaller nitrogen compounds other than dibasic amino acids and ammonia which makes the fraction fair index of free amino acid content (Bergamini et al., 2006). Total nitrogen content increased in the probiotic samples but not in the control sample.

Most publications concerning incorporation of probiotic bacteria into cheese have focused on their survival during manufacture and storage, but few studies have considered the effect of this incorporation on cheese composition and quality. The results of the principle component analysis of the chemical characteristics of the control, probiotic 1 and probiotic 2 cheese samples are presented in Figures 1-3. It can be seen that the components do not affect the overall quality of the cheese samples in same way. In general, the most pronounced effect on the quality of all cheese types had nitrogen fractions and fat content.

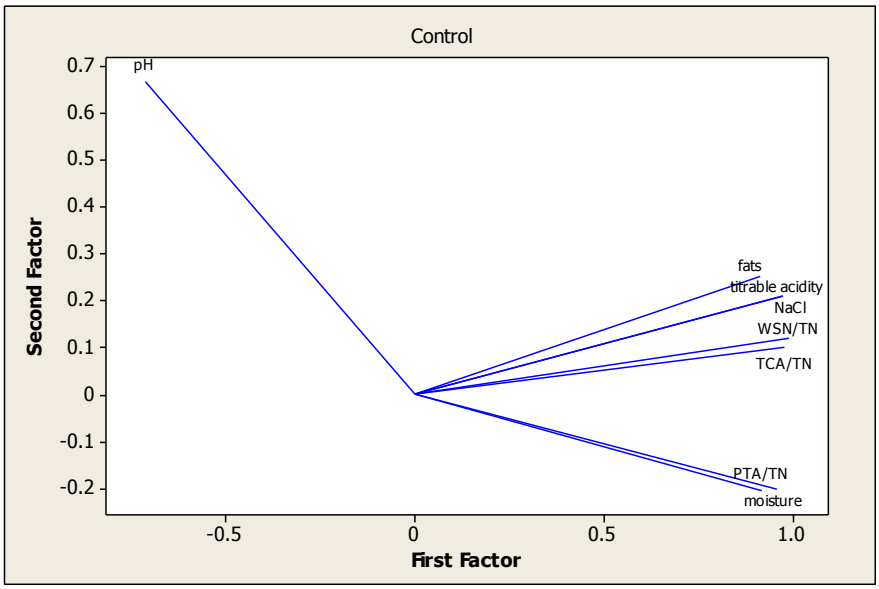

Figure 1. Principle component analysis of chemical composition of control cheese sample

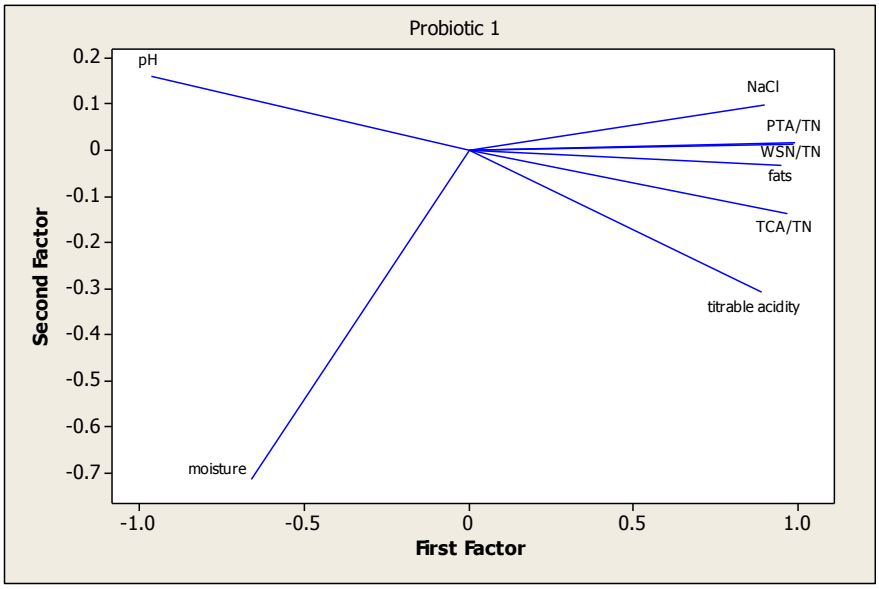

Figure 2. Principle component analysis of chemical composition of probiotic 1 cheese sample

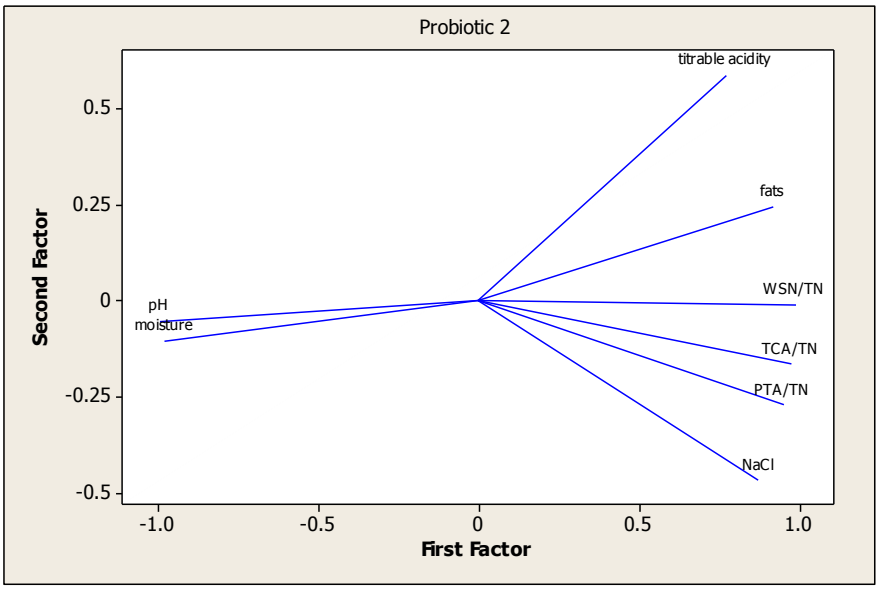

Figure 3. Principle component analysis of chemical composition of probiotic 2 cheese sample

The count of the probiotic bacteria *L. casei* during ripening of white brined cheese is shown in Fig. 4. As can be seen, in the first phase of the cheese manufacture, corresponding to the separation of the whey from the curd, there was about two log reduction in the count of probiotic bacteria in both samples. In the next period, the culture adapted to the conditions and continuously grew reaching a plateau after 30 days of ripening. The counts were about $3 \cdot 10^{10}$ cfu /g (probiotic 1) and about $5.7 \cdot 10^{10}$ cfu /g (probiotic 2). The viability of *L. casei* remained almost constant next 30 days.

Investigating the survival of *L. acidophilus* LA-5 and *B. bifidum* BB-02 in white brined cheese, Yilmaztekin et al. (2004) proved total cell viability to be from 6.8510^8 to $11.90 \cdot 10^8$ cfu /g after 30 days, and from $8 \cdot 10^7$ to $39{,}7 \cdot 10^7$ cfu /g after 60 days. Sharp et al. (2008) incorporated the lactic acid bacteria *L. casei* 334-e, an erythromycin derivative of ATCC 334, in cheddar cheese at approximately 10^7 cfu/g. The number of bacteria remained relatively constant throughout the storage period of 3 months.

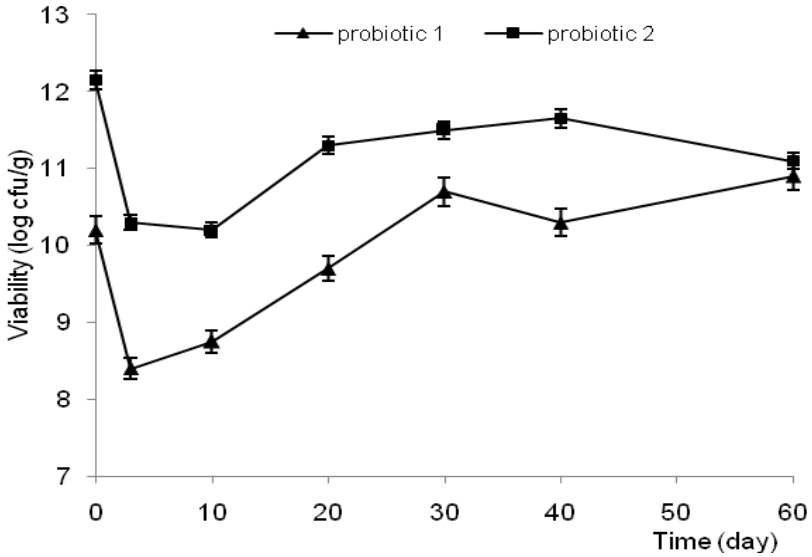

Figure 4. Viability of *L. casei* during ripening of probiotic brined white cheese

CONCLUSIONS

The traditional white brined cow cheese showed to be a very good delivery medium for probiotic culture *Lactobacillus casei*. It provided suitable conditions for the survival of the bacterium in concentrations higher than the critical concentration of 10^7cfu/g. The principal component analysis showed that nitrogen fractions and fat content are the key components influencing the overall quality of the cheeses.

ABSTRACT: Kombucha and fermented milks have again become very popular due to their positive effect on human health. The aim of this work is to investigate possible usage of tea fungus culture as a starter culture for manufacture of fermented milks. Local tea fungus culture was grown on traditional substrate at 28 ºC and 42 ºC. One group of milk samples was incubated without kombucha and another group was inoculated with 10% of local kombucha beverage. Milk-based samples were incubated at 30 ºC and 42 ºC and fermentation was stopped when the pH value of samples reached 4.5. Fermentation process was monitored by determination of basic chemical and microbiological parameters. The samples of traditional kombucha beverage incubated at 42 ºC after 4-day fermentation had the initial pH and titrabile acidity (4.61 and 0.37 g acetic acid/L) and during the first fermentation day number of acetic acid bacteria dramatically decreased from 6.6 x 10^5 (CFU/mL) to <1(CFU/mL). Pasteurized milk-based products, with and without kombucha inoculum, incubated at 42ºC reached the target pH value in almost the same fermentation time. All milk – based samples fermented at 30ºC did not reach the target pH during 24h fermentation. These results suggested that the temperature of 42 ºC is not suitable for kombucha fermentation on used traditional substrate. Lactic acid bacteria from pasteurized milk and/or environmental contaminant bacteria probably had the main role in fermentation of milk-based samples
Key words: *tea fungus, kombucha beverage, fermented milk beverages*

INTRODUCTION

Kombucha is a traditional beverage obtained by fermenting sweetened black or green tea using tea fungus culture. This beverage origins from China and the first records about it dates about 220 B.C. During the past decades, kombucha beverage became very popular in Europe and North America due to the growing awareness of general population about benefits of consuming food with functional properties.

Starter culture for kombucha fermentation is kombucha beverage, kombucha beverage with tea fungus or tea fungus. Although it is usually called fungi, microbiological it represents unique symbiosis of indigenous yeasts and acetic acid bacteria. The most common yeasts in this association belong to *Saccharomyces*, *Zygosaccharomyces*, *Saccharomycodes*, *Brettanomyces* and *Torulaspora* species. The most frequent acetic acid bacteria strains are representatives of *Acetobacter* and *Gluconobacter* species, which are part of *Acetobacteriaceae* familia.

Kombucha beverage is traditionally produced on sweetened black or green tea with sucrose. Apart from this substrate, other authors investigated possibilities for production of kombucha beverage on some alternative substrates. Until now, it is proved that fructose, glucose, lactose (Reiss, 1994), red and white wine with/without added sugar (Janković, 1995), honey (Frank, 1995), malt extract (Cvetković, 2003) and molasses (Malbaša et al., 2008) can be used as only carbon source (instead of sucrose). As far as substitutions for black or green tea are concerned, it is applicable to use sweetened tea beverage made of *Rosa canina*, mint (Janković, 1995), root and herb of *Echinacea purupurea*, as well as tea prepared of *Satureja montana* L. (Cvetković, 2003). Morales and Sánchez (2003) were the first authors who successfully applied tea fungus as a starter culture for fermentation of whey. In addition, Malbaša et al. (2009) produced fermented milk beverages using several kombucha starters.

This paper presents results of an investigation of possible usage of tea fungus culture as a starter culture for production of fermented milk beverages. Apart from that, this paper describes chemical and microbiological characteristics of kombucha fermentation process on traditional substrate at 28 °C and 42 °C as well as fermentation of milk – based samples (pasteurized and sterilized milk) at 30 °C and 42 °C.

MATERIAL AND METHODS

Kombucha fermentation: Traditional substrate for kombucha fermentation was prepared from boiled tap water with 70 g/l of sucrose and 3 g/l of black tea (Fructus, Bačka Palanka, Serbia) which was added into water after it boiled. Extraction of tea lasted 15 min and after that substrate was filtrated and obtained beverage was cooled to room temperature. Cooled tea was inoculated with 10 % v/v of previously produced kombucha beverage. Finally, every bioreactor (total volume of 720 ml, Ø 80 mm) with 330 ml of culture medium was covered with cheesecloth and put on statical incubation under aerobic condition. Traditional substrate for kombucha fermentation was incubated for 4 days at 28 °C and 42 °C. Samples for determination of chemical and microbiological parameters were taken each fermentation day and each analyze was done in two replications.

Milk fermentation

For production of fermented milk beverages two types of commercial milks were used– pasteurized and sterilized homogenized cow's milk with 2.8 % of milk fat. Both types of milk were put in bioreactors (total volume of 720 ml, Ø 80 mm) and warmed to target (incubation) temperature. After warming, samples were prepared and incubated as shown in table 1. After preparation of samples each bioreactor contained 330 ml of culture medium. All fermentations of milk-based samples were stopped when the pH value of fermentation liquid reached 4.5 and after that samples were cooled to 4 °C. One control sample with commercial yogurt starter culture (YC – 381, Christen – Hansen, Denmark) was prepared for each type of milk in order to proving the absence of substances with inhibitor effect.. Every fermentation and analyses was conducted in at least two replications.

Table 1. Plan of experiment for milk fermentation processes

Pasteurized milk with 10 % v/v of inoculum	incubated at 30 °C
	incubated at 42 °C
Pasteurized milk without inoculum	incubated at 42 °C
Sterilized milk with 10 % v/v of inoculum	incubated at 30 °C
	incubated at 42 °C

Chemical analyses

pH values of kombucha beverage and fermented milk products were measured by an electric pH-meter (HI 9321, HANNA Instruments) which was previously calibrated at values 4 and 7. Measuring of pH in samples of kombucha beverage incubated on traditional substrate was conducted after CO_2 was eliminated from sample on ultrasound bath (B-220, Branson Company, Shelton, USA) during 30 seconds. Titrabile acidity in all samples was measured with conductometric titration (OIV method, 1990). Quality carbohydrate profile was determined with thin layer chromatography with silica gel.

Microbiological analyses

All microbiological analyses were done by pour plate method. Total count of bacteria was determined by using MPA grown medium (Himedia, Mumbai, India) and incubation at 28 °C during 48h. For determination of total count of acetic acid bacteria YMP agar was used (Sievers et al., 1995) that was incubated at 28 °C at least 120h. Lactobacilli were isolated with MRS agar (Himedia, Mumbai, India) with incubation under anaerobic conditions provided by anaerobic jar with Anerocult® (Merck, Darmstadt, Germany). Lactococci were

determined with M-17 grown medium (Merck, Darmstadt, Germany). Plates for determination of lactic acid bacteria (lactobacilli and lactococci) were incubated at 37 ºC for 72h. 300 mg/l of actidion (cicloheximid, Sigma-Aldrich, St. Louis, USA) was added in all media for bacteria determination. For yeast number determination the Sabouraud Maltose Agar nutritive medium (Himedia, Mumbai, India) was used that was incubated at 28 ºC during 3 days. 50 mg/l of chloramphenicol (Sigma-Aldrich, St. Louis, USA) was added in Sabouraud Maltose Agar before inoculation.

RESULTS AND DISCUSSION

Fermentation of traditional substrate at 28 ºC and 42 ºC

In order to analyse relations between tea fungus culture and different incubation temperatures, black tea was inoculated on usual way and incubated at 28 ºC and 42 ºC. Usual temperature for kombucha fermentation is in the range 22 - 30 ºC. As Lončar et al (2006) pointed out, Petrović et al. (1995 – 1996) found that optimum temperature for kombucha fermentation is 28 °C. On the other hand, 42 ºC is temperature of yogurt fermentation, which was chosen as possible fermentation model for production of fermented milk beverages with usage of tea fungus culture (Malbaša et al., 2009). Chemical characteristics of substrate and inoculum are presented in Table 2.

Table 2. Chemical characteristics of substrate and inoculum

	sweetened black tea (substrate)		inoculum
	before inoculation	after inoculation	
pH	7.19	4.64	3.25
titrabile acidity (g/l)		0.38	5.64

Development of tea fungus fermentation at 28 ºC and 42 ºC was monitored by measuring pH and titrabile acidity (Fig. 1). Fermentation curves of sample incubated at 28 ºC showed that after 4 – day fermentation pH value decreased from 4.64 to 3.16 (1.48 pH units), while titrabile acidity (hereinafter referred as TA) increased from 0.38 to 6.46 g/l. These results are expected due to the fact that acetic acid bacteria during fermentation process produce acetic acid, gluconic acids and number of other organic acids (Reis, 1994). Comparing with results of other author, presented results for fermentation process are slightly different. For instance, after 3 – day kobucha fermentation at 24 ± 3 °C Jayabalan et al. (2007) detected 0.33 ± 0.07 g/l acetic acid and pH about 4. Apart from that, Lončar et al. (2006) in samples taken after 4-day fermentation at 30 °C detected pH 3.9 and total acid in concentration of 0.7 g/l, while in samples incubated at 22 °C after same fermentation time they measured pH of 4.55 and concentration of total acids of 0.4 g/l. However, these differences between results are quite usual because of the fact that characteristics of fermented tea depend upon the individuality of used tea fungus association (Blanc, 1996; Sievers et al, 1995; Reis, 1994).

On the other hand, fermentation process at 42 °C is quite different because during 4 – day fermentation, samples retained the initial pH and TA values. That can be explained with absence of biological activity of tea fungus culture, particularly activity of acetic acid bacteria which are dominantly responsible for production of acids (Reis 1994).

Quality sugar profile of fermentation liquid during 4 – days incubation period was monitored by TLC method (Fig 2). In sample incubated at 42 °C after 24h glucose was detected in very small amount, while in the samples incubated at 28 °C this amount is much higher. By the end of 4 - days process, amount of sucrose in both substrates was reduced, but in samples incubated at 28 °C that process happened more intensively. These results are consistent with results of other authors (Lončar et al, 2006; Sievers et al 1995) who proved that during kombucha fermentation concentration of sucrose steadily reduce and concentration of glucose increase. This happens because the first step in kombucha metabolic pathway is extracellular hydrolysis of sucrose to fermentable glucose and fructose.

Microbiological profile of kombucha beverage during 4 – days fermentation at 28 °C and 42°C is shown in Fig 1. In samples incubated at 28 °C total count of acetic acid bacteria during 4 – day fermentation increased for about 1 log unit, while the count of yeasts remained at almost the same number (at about 6 log units). Total count of yeasts in samples incubated at 42 °C after the fourth fermentation day was 1.2 x 10^6 (CFU/ml), which was slightly different compared with sample incubated at 28 °C (5.1 x 10^6 (CFU/ml)). Comparing with the results of other authors, a good correlation can be noticed. For example, Sreeramulu et al. (2000) at the fourth fermentation day detected yeasts and acetic acid bacteria in count of about 7 – log units. Chen and Liu (2000) at the sixth fermentation day detected total count of acetic acid bacteria in average about 10^3 (CFU/ml or g) and total count of yeast of about 10^6 (CFU/ml or g).

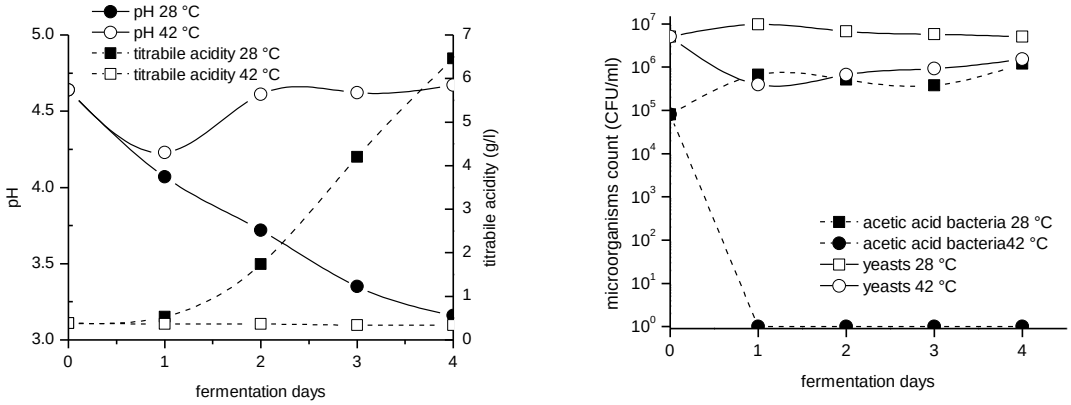

Figure 1. Basic chemical and microbiological parameters of kombucha during fermentation process

On contrary, the total count of acetic acid bacteria in sample incubated at 42 °C during the first fermentation day reduced from initial count to <1 CFU/ml and stayed at that level until the end of fermentation. In addition to that, sample incubated at 42 °C did not have cellulose pelicule on the surface, which is a typical metabolite of acetic acid bacteria and which was produced in samples incubated at 28 °C. This phenomenon can be explained with the fact that optimum temperature for most of acetic acid bacteria is 25 – 30 °C, while the maximum temperature is below 42 °C.

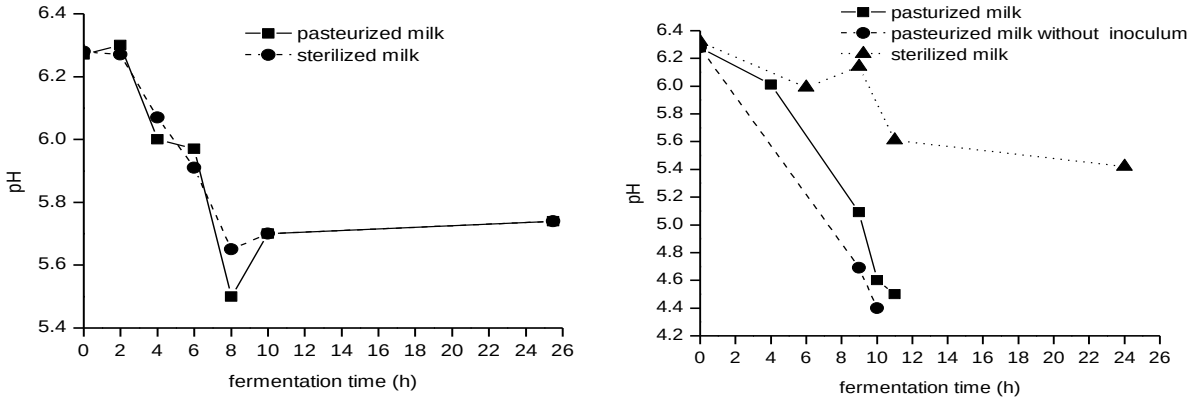
Figure 2. TLC chromatogram of samples incubated at 28 °C and 42 °C

Fermentation of milk – based samples at 30 °C and 42 °C

The development of all fermentation processes of milk – based samples are presented in Fig. 3. All milk – based samples did not contain inhibitor substances because in all control samples fermented milks were produced during the time declared by producer of commercial starter culture. As can be noticed in the Fig 3., all milk – based samples (pasteurized and sterilized) incubated at temperature of 30 °C did not reach the target pH value and during 26h fermentation process pH was only reduced for 0.54 pH units (from 6.28 to 5.74). Results for fermentation process of sterilized milk incubated at 42 °C are similar because after 22h of fermentation pH was still about 5.7 (reduced only for only 0.57 pH units). Although lactose

(as the main carbohydrate source) was presented in these samples, it is obvious that microorganisms did not use it for biotransformation and intensive production of acids.
Results for pasteurized milk incubated at 42 °C are different because fermented milk beverage with pH 4.5 was produced during 10.5h. Our previous work showed that usually fermentation times for milk – based samples with kombucha inoculum are in range 10.5-16h (Ivković, 2011). Comparing with results of other authors, it can be concluded that presented fermentation processes are slower. Malbaša et al. (2009) produced fermented milk beverages with usage of concentrate of kombucha during 6–6.5 h.
Interesting results were gained for samples incubated without kombucha inoculum because the time and trend of milk fermentation was almost the same as for samples inoculated with kombucha beverage.



(a) (b)

Figure 2. Fermentation curves for milk – based samples incubated at 30 °C (a) and 42°C (b)

In Table 3 are presented results of microbiological analyses of produced fermented milk beverages. Dominant microorganisms in microbe association of produced beverages were lactic acid bacteria (lactococci and lactobacilli). They were probably detected in final product in that number because they represented initial contamination of milk or they were environmental contaminants. Initially, milk contained 1.3 x 10^3 (CFU/ml) lactococci, 3.2 x 10^2 (CFU/ml) lactobacilli and 2.4 x 10^3 (CFU/ml) of total bacteria. As can be seen, the biggest increase is detected by lactobacilli (almost 6.5 log units), while lactococci had increase of almost 6 log units. On YMP media, growth of 1.2 x 10^3 (CFU/ml) was detected. However, microbiological analyses of colonies from YMP media showed that present microorganisms were Gram positive and spherical (cocci) bacteria, not Gram negative and rod – shaped, as was expected for acetic acid bacteria. That means that YMP media is not adequate for determination of acetic acid bacteria in samples of fermented milks.

Table 3. Microbiological profile of fermented milk beverages

fermented beverage	**total count of bacteria (CFU/ml)**	**yeasts (CFU/ml)**	**lactobacilli (CFU/ml)**	**lactococci (CFU/ml)**
pasteurized milk with kombucha inoculum	4.8 x 10^7	6.8 x 10^5	9.3 x 10^8	1.4 x 10^9
pasteurized milk without kombucha inoculum	2.7 x 10^7	< 10	1.1 x 10^9	1.9 x 10^9

These results are in certain correlation with results presented by Iličić (2010). In her analyses she concluded that in fermented beverages produced on milk with 0.9 % of milk fat with usage of kombucha culture 80 % of microorganisms are lactic acid bacteria, 10 % are yeast and 10 % are acetic acid bacteria.

CONCLUSIONS

According to these results it can be concluded that acetic acid bacteria lose viability during the first fermentation day at 42 °C and that was the reason why no changes in acidity (tritrabile acidity and pH) of fermented products were detected. On the other hand, yeast from tea fungus, after short adaptation period to 42 °C, continue with their physiological activities which can be detected by reduction of sucrose concentration in traditional substrate and increased total count of yeasts.
According to results for milk – based samples, it can be concluded that kombucha culture is not suitable as a starter culture for fermentation of sterilized milk. Although 30 °C is usual temperature for kombucha fermentation, application of kombucha in milk – based samples at that temperature is not showed as appropriate in this work.
On contrary, in samples of pasteurized milk with addition of kombucha inoculum incubated at 42°C fermented milk beverages were produced. Due to the fact that samples without kombucha inoculum also reached target pH in almost the same time as samples with kombucha inoculum and according to microbiological analyses of final products, it can be assume that fermentation is caused by lactic acid bacteria from pasteurized milk and/or environmental contaminant bacteria.

ABSTRACT: While the nature of antioxidants in sugar cane processing is well documented and understood, little information exist about the antioxidant activity of sugar beet manufacturing products. In this work, besides basic quality parameters, antioxidant activity of A (white) sugar, B (raw) sugar and affinated C sugar, obtained from the process of sugar production was tested. As the antioxidant activity of cane brown sugars was connected with the presence of polyphenol compounds and Maillard reaction products, the content of these compounds was measured, as well.
Apart from the highest sucrose content (99.50 °Z), A sugar was characterized with the lowest invert sugar (0.008%/DM) and coloured matter content (54 IJ/DM). However, A sugar showed no antioxidant activity and also it did not contain a detectable amount of plant phenolics. Contrary to this, sugars B and C contained less sucrose (99.22 and 97.6 °Z, respectively) and more coloured matter (329 and 20366 IJ/DM, respectively). Antioxidant activity of C sugar was higher than that of B sugar, which corresponded with higher total phenolic and coloured matter content of C sugar.
Our results indicate that both, plant phenolics and Maillard reaction products can be associated with the antioxidant activity. Despite the fact that colour of the final product presents a key quality measurement in sugar industries, with regard to the antioxidant activity, consumption of brown sugars can be recommended.
Key words: *sugarbeet, A (white) sugar, B (raw) sugar, affinated C sugar, antioxidant activity*

INTRODUCTION

Colour of the final product is a key quality measurement in sugar industries. While the nature of colouring substances in sugarcane processing is well studied and documented (Bento and Sá, 1998), colour formation in sugar beet manufacture is not much examined and understood. Because of that, it is not possible to predict the content of coloured substances in the final product on the basis of raw material chemical composition. Coloured substances are formed through beet processing as a result of pH changes, thermal and autocatalytic effects. These impurities are of high molecular masses, polymeric and with tendency to occlude within the sugar crystal (Coca et al., 2008). Maillard reaction and alkaline degradation of invert sugars have been considered to be the main mechanisms of colour formation during purification stage (Coca et al., 2008). Melanoidins, as the type of Maillard reaction products, are formed by the reaction of monosaccharides and carbonyl compounds with amino acids, and are recognized as being acidic and polymeric compounds, with a highly complicated structure (Cämmerer and Kroh, 1995; Cämmerer et al., 2002). According to Heitz (1995), up to 80% of colour in sugar beet juice is a result of alkaline degradation of hexoses (HADP). The production of colored HADP takes place at the common pH of a beet sugar factory (8–11) while the formation of degradation products occurs mainly in the purification step where temperature increases up to 85 °C and pH rises up to strong basic values (11–12). The nature and structure of colored HADP have not been elucidated but they are probably due to the extensive aldolisation of intermediate dicarbonyl compounds in alkaline solutions (de Bruijn, 1986). Coloured substances formed through sugar beet processing negatively influence the quality of white sugar. However, Maillard reaction compounds have been reported to possess antioxidant activity (Yanagimoto et al., 2002; Yanagimoto et al., 2004). Payet et al. (2005) reported the antioxidant activity of cane brown

sugars, which was connected with the presence of polyphenol compounds and Maillard reaction products. As the concentration of nitrogen compounds in sugar beet juices is higher than in cane sugar juices, Coca et al. (2004) assumed that the formation of melanoidins in sugar beet processing was more intensive.
The objective of this work was to investigate antioxidant activity of A (white) sugar, B (raw) sugar and affinated C sugar and the molecules that might be responsible for the activity, phenolic compounds, and Maillard reaction products.

MATERIAL AND METHODS

Materials

A (white) sugar, B (raw) sugar and affinated C sugar were obtained from the Sugar factory „Šajkaška“, Žabalj, Serbia. The basic characteristics of the samples were determined according to the methods specified by Reinefeld and Schneider (1978).

HPLC determination of fructose, glucose, raffinose and sucrose

A high-performance liquid chromatographic (HPLC) method was applied to determine fructose, glucose, raffinose and sucrose content of samples previously dissolved in distilled water and diluted to 40°Bx dry matter. The HPLC (HP 1090, Hewlett-Packard, USA) system consisted of a Zorbax Carbohydrate 4.6 × 250 mm, 5 µm column, a solvent system of acetonitrile/water, 70/25 (v/v), a flow rate of 1 ml/min, and a refractive index detector operating in the range od 4×10^{-5} RIU and at the temperature of 35 °C. Prior to injection, all samples were properly diluted in deionised water and filtered through a 0.45 µm Rotilabo-Spritzenfilter CME (Carl Roth).

Scavenging activity on DPPH$^{\cdot}$

Samples were dissolved in deionized water, in an appropriate manner to obtain a series of dilutions. Scavenging activity on DPPH$^{\cdot}$ (1,1-diphenyl-2-picryl-hydrazyl radical) was determined spectrophotometrically following the procedure of Espin and others (2000). The IC_{50} (mg/mL) was defined as the mass concentration of an antioxidant extract which was required to quench 50% of the initial DPPH$^{\cdot}$ under the given experimental conditions. It was obtained by interpolation from linear regression analysis.

Determination of total phenolic content

Total phenolic content of samples, previously dissolved in distilled water and diluted to 40°Bx dry matter, was determined spectrophotometrically at 750 nm by using Folin-Ciocalteu's reagent (Singleton et al., 1999). Gallic acid was used as a standard and results were expressed as gallic acid equivalents (GAE) (µg GAE per g of sample).

Statistical analysis

All analyses were performed in triplicate, and the mean values with the standard deviations are reported. Statistical data analysis software system STATISTICA (StatSoft, Inc. (2011). data analysis software system, version 10.0. www.statsoft.com) was used for analysis.

RESULTS AND DISCUSSION

Basic quality parameters of A (white), B (raw) and affinated C sugars are presented in Table 1. Obtained values are as expected for each of the investigated sugars.

Table 1. Basic quality parameters of A (white), B (raw) and affinated C sugars

	A (white) sugar	B (raw) sugar	C (affinated) sugar
Dry matter content (%)	99.97	99.89	99.82
Sucrose content (°Z)	99.50	99.22	97.6
Invert sugar content (%/DM)	0.008	0.083	0.197
pH value	6.40	6.67	6.81
Coloured matter content 420 nm (IJ/DM)	54	329	20366

The contents of sucrose, fructose, glucose and raffinose in the investigated samples diluted to 40°Bx dry matter are presented in Table 2. In comparison with other investigated samples, A sugar had the highest content of sucrose and the lowest content of fructose and glucose. The content of raffinose in A sugar solution at 40°Bx dry matter was below the limit of detection of the method, while it was higher in affinated C sugar than in raw B sugar. The content of glucose and fructose of C sugar was higher than of B sugar.

As the antioxidant activity of cane brown sugars was connected with the presence of polyphenol compounds and Maillard reaction products (Payet et al., 2005), apart from coloured matter content at 420 nm (Table 1), the total phenolic content of investigated samples was determined (Table 3). The total phenolic content of C sugar was significantly higher than of B sugar, while in the case of A sugar it was below the detection limit of the method. The same stands for the coloured matter content at 420 nm, indicator of Maillard reaction extend. The coloured matter content of C sugar was 62 times higher than of B sugar and 377 times higher than of A sugar.

Due to its convenience, DPPH$^{\cdot}$ scavenging activity test is frequently used to estimate the antioxidant activity of different food matrices.

Table 2. The content of sucrose, fructose, glucose and raffinose in A (white), B (raw) and affinated C sugars at 40°Bx dry matter

Sample	Sucrose (mg/ml)	Fructose (mg/ml)	Glucose (mg/ml)	Raffinose (mg/ml)
A 40 Bx	459.8 ± 2.91	0.25 ±0.022	0.22 ± 0.09	-
B 40 Bx	456.8 ± 3.35	1.10 ± 0.180	1.17 ± 0.28	1.45 ± 0.18
C 40 Bx	450.9 ± 1.68	1.75 ± 0.110	1.97 ± 0.17	2.10 ± 0.25

Scavenging activity against DPPH radicals positively correlated with the total phenolic and coloured matter content of the samples (Table 1. and 3.). Higher scavenging activity corresponds to lower IC_{50} value. As in the case of total phenolics, DPPH$^{\cdot}$ scavenging activity of A sugar could not be established. According to obtained results, both plant phenolics and Maillard reaction products can be associated with the antioxidant activity.

Table 3. Total phenolic content and DPPH$^{\cdot}$ scavenging activity of the investigated samples

Sample	DPPH$^{\cdot}$ scavenging activity IC_{50} ± SD (g/ml)	Total phenolic content mg G.A.E /g
A (white) sugar	-	-
B (raw) sugar	0.676 ± 0.170	0.012 ± 0.001
Affinated C sugar	0.440 ± 0.026	0.494 ± 0.090

CONCLUSIONS

Based on the preliminary results of this experiment, sugar refinement in sugar beet industries, apart from reduction of coloured matter and total phenolic content, leads to drastic decrease in antioxidant activity of the final product (white A sugar). Despite the fact that colour of the final product presents a key quality measurement in sugar industries, with regard to the antioxidant activity, consumption of brown sugars can be recommended.

ABSTRACT: Hominy feed (HF) is a by-product generated by the manufacture of corn meal and is similar to ground corn in appearance. The initial composition (db) of HF is around 60% starch, 14% fibre, 12% fat, 10% protein and 4% cellulose. The market competitiveness and price of HF can be boosted by fermentation of HF starch into ethanol. Before fermentation HF has to be defatted (HF_{DF}). Saccharification and fermentation were performed by three different methods: application of ultrasounds after enzymes addition (US), addition of $CaCl_2$ (Ca) and simultaneous application of two enzymes, α-amylase and glucoamylase, on double quantity (DE). These three different methods, plus a control, were tested using first hydrolysis followed by fermentation (SHF) and in simultaneous saccharification and fermentation (SSF). Fermentation was performed by *Saccharomyces cerevisiae*, at 10^8 cfu/ ml. After 48 h of fermentation of 30% HF_{DF} (% W/V) aqueous solution, ethanol was the main product (from 62 to 97 g/ L), and glycerol (from 8 to 10 g/ L) and acetic acid (from 0.7 to 1.4 g/ L) the secondary products. Highest level of glycerol occurs in simultaneous with highest concentration ethanol, experiments coded DE/HSF and Ca/SSF. Highest level of acetic acid occurred at lowest concentration ethanol in the ultrasonicated experiments. In conclusion, ethanol yields varied from 260 to 500 l/ton HF_{DF}, on the control/SHF and Ca/SSF experiments, respectively. The highest hydrolyzed starch conversion factor into ethanol was 90%. HF showed to be a good sugar source to produce bioethanol.
Key words: *Hominy feed, Ethanol, Separate hydrolysis and fermentation, Simultaneous saccharification and fermentation*

INTRODUCTION

Humankind faces important decisions related to mitigate the impacts of climate change, and reduce greenhouse gas emissions (GHG's) (Tat Tan *et al*., 2008 and Scacchi *et al*., 2010). This situation could be dramatically improved by using renewable and more sustainable fuels to replace fossil fuels (Gnansounou, 2010). Coppola *et al*. (2009) predicts that the European market will increase the consumption of biofuels from its current 2%, up to 25% by 2030. This was the subject of a European Directive n.º 2003/30/CE of 8th May.
Directives of governments accelerated the interest in biofuels, including time bound targets for biofuels consumption (Anonymous, 2009).
In general, biofuels like bioethanol and biodiesel, are produced from agricultural products, e.g. corn, sugarcane, palm oil, rapeseed or soybean. These biofuels, produced from food sources, are known as first-generation biofuels (Tat Tan *et al*., 2008). Biofuel development and production could have a high impact on the structure and distribution of agricultural production, agricultural trade and the welfare of different households (Qiu *et al*., 2010).
Demand for biofuels feedstocks increased world food prices for food and feed cereals by some 140 %, between 2002 and 2007 (Anonymous, 2009).
However, this situation can be minimized if biofuels are produced from the low cost industrial by-products. In today's market, hominy feed (HF) is a cost-effective by-product and represents about 35% of the corn industry production volumes.

In the present study, the HF comes from a protuguese corn milling industry. The conversion of starch into ethanol was evaluated by three different methods using first hydrolysis followed by fermentation (SHF) and in simultaneous saccharification and fermentation (SSF).

MATERIAL AND METHODS

Hominy feed composition

Hominy feed (HF) was obtained from corn milling industry in Torres Vedras – Portugal. Original HF was analyzed in duplicate by Biopremier Laboratories (Lisbon, Portugal). The samples were analyzed for moisture (method PAQF 120.2), starch (method BOE207748), oil (NP 876: 2004), fibre (MI LAQ 103.02), protein (method PAFQ 360.1) and cellulose (method EN ISO 6865: 00).

Oil extraction

Before oil extraction the HF was grounded and was granulometricaly separated to obtain a fraction with 0.5 mm of diameter, to increase the yield of oil extraction. The HF was defatted by Soxhlet extraction with hexane, during 8 h at 80 ºC into HF_{DF} with residual oil.

Fermentation

Separate hydrolysis and fermentation (SHF) and simultaneous saccharification and fermentation (SSF) were conducted to produce ethanol, both combined with the application of ultrasounds after enzymes addition (Mojović et al., 2006 and Nitayavardhana et al., 2010), enrichment with 60 ppm of Ca^{2+} (as $CaCl_2$. H_2O) (Merk, Germany) (Mojović et al., 2006) and double the amount of enzymes (Table 1).

Table 4. Samples codification

	Control	Ultrasound	Ca2+	Double of amount of enzymes
SHF	SHF_Control	SHF_US	SHF_Ca	SHF_DE
SSF	SSF_Control	SSF_US	SSF_Ca	SSF_DE

SHF was carried out by adaptation of work of Mojović (2006) and Sharma (2008), HF_{DF} was mixed with water to obtain 30 % solid content in the slurry. The mixture was treated with enzymes in two steps. The first step, liquefaction was performed at 85 ºC during 1 h at pH 6 (Sharma et al., 2008 and Mojović et al., 2010) with α-amylase (0.5 % v/v) (Liquozyme Supra – Novozymes), and the second step, saccharification, was performed at 55 ºC, 4 h, pH 5 (Sharma et al., 2008 and Mojović et al., 2010) with glucoamylase (0.25 % v/v) (Optimax 4060 VHP, Genencor). The mash was subject to ethanol fermentation by Saccharomyces cerevisiae ISA 1000 (PYCC 4072) (10^8 ufc/ ml), at 30 ºC during 48 h, with mixing rate 350 rpm.

SSF was conducted by protocol of Sharma (2008), similar conditions were used for SHF, but with hydrolysis, saccharification and fermentation at same time.

For HPLC analysis, (Sharma *et al.*, 2008) the mash samples were split into two 1.5 ml samples and centrifuged for 10 min at 12000 rpm, to obtain clear supernatant liquid. Supernatant was passed through a 0.2 µm sterile syringe filter into 1 ml shell vial. Filtered liquid was injected into a chromatography column (Shodex SH 1011, Waters, USA) maintained at 50 ºC. HPLC grade water containing 5 mM sulphuric acid was used as a mobile phase. Elution rate was 0.6 ml/ min. Separated components were detected with a refractive index detector (2410 – Waters, USA). Data were processed using HPLC software (Empower 2).

RESULTS AND DISCUSSION

Hominy feed composition

The composition of hominy feed show in Table 2 is compared with reference values. Ash value was within the range reported by Sharma *et al.* (2008). Protein and starch values are slightly lower than the range reported in the literature, while values of fat and fiber are higher (Raush and Belyea, 2006 and Sharma *et al.*, 2008).

Table 5. Centesimal composition of hominy feed (HF), in dry basis, with 10.3 % ± 0.8 of moisture

	% Dry basis ± SD	Reference values
Ash	3.0 ± 0.1	0.7 - 3.2
Protein	9.8 ± 0.66	9.6 - 12.3
Fibre	13.7 ± 9.3	6.7
Starch	59.6 ± 10.8	56.9
Cellulose	4.3 ± 2.9	____
Fat	12.5 ± 0.2	2.7 - 8.3

Oil Extraction

The optimized oil extraction led to 12 % (in dry basis) of oil. By comparison with results presented before we can observe that yield of oil extraction is close to 100 %.

Ethanol Yield

In SHF it was possible to measure the amount of released glucose. In our conditions we can achieve a yield of glucose extinction between 110 and 130 g/ L (data not shown), at the end of saccharification. This value was higher than value achieved by Mojović (2010) and within the range reported by Khanal (2007), 70g/ L and 160 g/ L.

During SSF the glucose content in the fermentation mash was undetected after 24h indicating rapid sugar utilization by yeasts.

After 48 h of fermentation ethanol yields of 7.8 and 12.5 % (v/v) were obtained from the hominy feed (figure 1). The highest ethanol yields were achieved by samples DE_SSF and Ca_SSF, respectively 12.1% and 12.5% of ethanol (v/v). The lowest ethanol yield was from sample control_SHF (7.8%). The highest values showed a small difference between them, however, if we express the results in L ethanol/ ton HF_{DF} we obtain for DE_SSF and Ca_SSF samples, respectively, 444 L/ ton HF_{DF} and 500 L/ ton HF_{DF}, that correspond to an increase of 11% in yield.

The highest values of ethanol were obtained for SSF, these values were higher than values achieved by Sharma (2008), maximum 380 L/ metric ton, and similar to concentration found by Brethaven (2010), 11 – 12% v/v.

Simultaneously, the secondary products of fermentation were measured, glycerol (Figure 2) and acetic acid (Figure 3), to monitor conditions of fermentation. The range of glycerol was 0.67 – 0.82 % (v/v) and acetic acid 0.07 – 0.14 % (v/v).

Comparing our results with the values found by Sharma (2008), the value of acetic acid was in accordance (< 0.5 % w/v) but the value of glycerol was much higher than the values found by them (< 0.4 % w/v).

Highest level of glycerol occurs in simultaneous with highest concentration of ethanol, i.e. experiments coded DE/HSF and Ca/SSF. Highest level of acetic acid occurred at the lowest concentration of ethanol, in the ultrasonicated experiments.

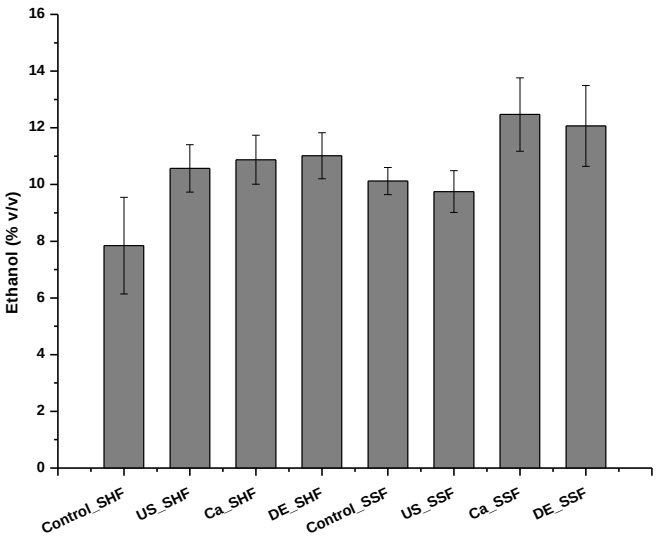

Figure 3. Final ethanol concentration for each tested conditions in separate (SHF) and in simultaneous (SSF) hydrolysis, saccharification and fermentation: control (control_SHF; control_SSF), application of ultrasounds after enzymes addition (US_SHF; US_SSF), addition of $CaCl_2$ (Ca_SHF; Ca_SSF) and application of the double amount of enzymes (DE_SHF; DE_SSF).

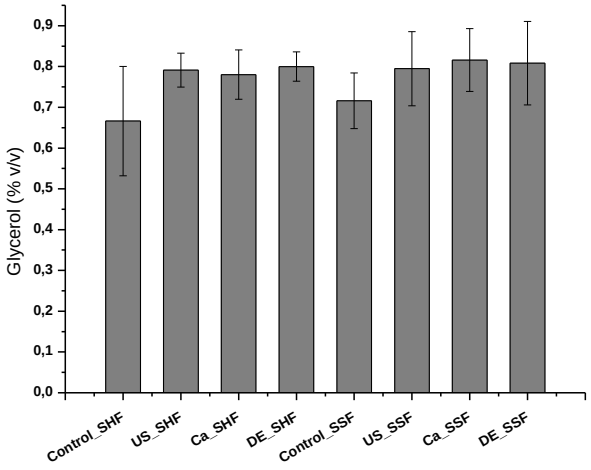

Figure 4. Final glycerol concentration for each tested conditions in separate (SHF) and in simultaneous (SSF) hydrolysis, saccharification and fermentation: control (control_SHF; control_SSF), application of ultrasounds after enzymes addition (US_SHF; US_SSF), addition of $CaCl_2$ (Ca_SHF; Ca_SSF) and application of the double amount of enzymes (DE_SHF; DE_SSF).

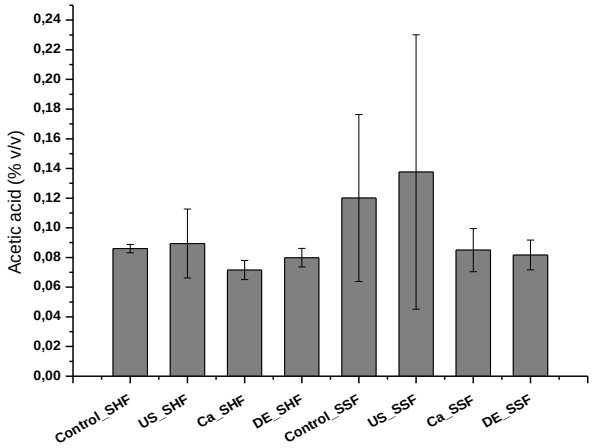

Figure 5. Final acetic acid concentration for each tested conditions in separate (SHF) and in simultaneous (SSF) hydrolysis, saccharification and fermentation: control (control_SHF; control_SSF), application of ultrasounds after enzymes addition (US_SHF; US_SSF), addition of $CaCl_2$ (Ca_SHF; Ca_SSF) and application of the double amount of enzymes (DE_SHF; DE_SSF).

CONCLUSIONS

By centesimal composition, hominy feed have a high value in oil and starch content that could be converted into ethanol. The ethanol yields that were obtained varied from 260 to 500 l/ton HF_{DF}, on the control_SHF and Ca_SSF experiments. These values show that hominy feed has a great potential to be used as a feedstock for ethanol production, and is of secondary source, not competing with food crops.
In conclusion, ethanol yields varied from, 444 L/ ton HF_{DF} to 500 L/ ton HF_{DF} . The highest hydrolyzed starch conversion factor into ethanol was 90%.

ABSTRACT: Increasing health-consciousness among consumers has boosted their interest in added value food products. As a source of biologically active substances including antioxidants and antimicrobials, medicinal plants can be considered as functional food ingredients. In this research, new cookie formulations were developed by supplementing the basic cookie formula with a mixture of medicinal plants, composed to promote digestion. The objective of this study was to investigate the effects of addition on the quality properties of cookies. The medicinal plant mixture was included in cookie formulations at three levels (2%, 4%, 6%) and compared to the control, which was based on wheat flour. Referring to the results, medicinal plant addition caused statistically significant ($P < 0.05$) differences in sensory and instrumentally measured colour and texture parameters of the cookies. Based on their overall good sensory acceptability and previously confirmed antioxidant and antimicrobial properties of the mixture, new cookie formulations can broaden the utilization of this mixture and may be regarded as health-promoting functional foods.
Key words: *cookies quality, medicinal plants, sensory evaluation, colour, texture*

INTRODUCTION

Development of new products by adding functional ingredients to carrier food provides not only new market opportunities for food producers, but also potential benefits for consumers (Krutulyte et al., 2011). Short dough cookies are widely consumed food products, appreciated for their versatility, convenience, conservation, and especially for their attractive sensory attributes (Verbeke et al., 2009), and for these reasons they can be considered to be suitable carrier products for functional bakery formulations. However, there is no previous research on sensory evaluation of specific carrier-ingredients combinations such as cookies enriched with medicinal plant mixture. As a source of biologically active substances including antioxidants and antimicrobials, medicinal plants can be considered as functional food ingredients (Mišan et al., 2009). Their potential application arises from the fact that they contain wide area of secondary biomolecules and pharmacologically active constituents, such as essential oils, antimicrobial substances, which can enhance flavour at the same time, plant phenolics, which are powerful antioxidants, organic acids, resins, pigments, vitamins and minerals (Willbrandt, 1989). However, the addition of some functional ingredients could result in changes in the sensory attributes which may lead to changes in consumers' acceptance (Glanz et al., 1998). Concerns about the reductions in taste quality can interfere with the adoption of healthy diets, since consumers emphasize sensory experiences during consumption (appearance, texture, flavour), with the pleasure derived from consumption as an important motivator in eating (Westenhoefer and Pudel, 1993). In respect of the above facts, descriptive sensory analysis remains an important method in the evaluation of different foods, including cookies which are usually applied before the usual consumer tests (Stone and Sidel, 1998). When integrated within the product development process, sensory testing allows cost-effective delivery of acceptable products to consumers and thus reduces the risk of failure (Lawless and Heymann 1998).

Referring to all mentioned above, the aim of this research was to evaluate the ability of sensory evaluation, instrumental colour and texture analysis as descriptive quality attributes of cookies.

MATERIAL AND METHODS

Materials

The commercial plant mixture 'Vitalplant' was obtained from the Institute for Medicinal Plants Research 'Dr Josif Pančić' (Belgrade, Serbia). It was provided in three packages, each containing 500 g of material. The mixture was in the form of powder with granulation of up to 3 mm. Presence of herbal drugs in the composition of the 'Vitalplant' mixture was: *Frangulae cortex* 35%, *Petroselini fructus* 25%, *Menthae pip. folium* 20%, and *Carvi fructus* 20%.

Preparation of cookies

Bake trials were conducted under laboratory conditions. Dough mixing, processing and baking were performed on laboratory-scale equipment. The basic cookie dough formulation (control sample) contained 100 g of refined wheat flour, 40 g of vegetable fat, 30 g of powdered sugar, 1 g of salt, 1 g of baking powder. Plant mixture was added at three doses 2, 4, and 6% (flour basis). The amount of water added varied to obtain cohesive dough suitable for the production of mold-cut cookies. Ingredients were mixed in Diosna mixer as per "all-in" method. All ingredients were mixed together in one phase for 15 min. The formed dough was packed in polyethylene bags and left to rest 0.5 hour at ambient temperature (22-24ºC Following the rest time, the dough was sheeted to a final thickness, approximately 5 mm on a pastry break, and cut out using a rectangular cutter. Dough pieces were baked for 12 min in a deck oven at 170°C. After cooling, the cookies were placed in polyethylene bags and stored at ambient temperature until further examination (Mišan et al., 2009).

Physical characteristics and sensory evaluation

Cookies were evaluated for different parameters. Five, randomly chosen cookies were taken to measure width and thickness. Spread was calculated from the ratio of width and thickness. Sensory evaluation was performed 24 h after baking by six experienced panellists (35-50 years old). The samples were evaluated on two occasions. Sensory profiling was performed using a generic descriptive analysis technique, included the selected representative attributes of cookies (Tang, et al., 1999; Sikora et al., 2007). The attributes were evaluated using a 5-points method. Each mark was described with words, using previously prepared standard cards (Pajin, 2009; Sikora et al., 2007; Sedej et al., 2011). In order to obtain the overall cookies quality, prior to sensory evaluation, importance coefficients (IC) for each sensory attribute were standardized and fixed by the panel. The importance coefficients were balanced that their sum equals to 4.0. The obtained marks were multiplied by the following importance coefficients: IC = 0.8 for appearance (shape and surface); IC = 0.8 for structure, and break; IC = 0.8.0 for chewiness; IC = 0.6 for odour; and IC = 1.0 for taste. Applying the importance coefficients, a quantitative expression of the total product quality is obtained as the 'weighted' mean value of the scores for each evaluated attribute.

Cookie surface colour measurements

Surface colour of cookies was determined by chromameter MINOLTA, CR-400 (Minolta Co., Ltd., Osaka, Japan) with illuminate D-65, and standard observer function 2°. Colour values of top and bottom surfaces, at five measured points (centre and at the corners of cookies), were recorded for 10 randomly chosen cookies per batch and averaged. The results were expressed as lightness (L^*), redness-greenness (a^*), and yellowness-blueness (b^*), according to CIE $L^*a^*b^*$ system.

Textural analysis
Textural analysis of cookies was conducted by using a TA.XTPlus Texture Analyzer (Stable Micro Systems, England, UK), equipped with 3-point bending rig (HDP/3PB), and a 5 kg load cell. Texture analyzer settings were: mode – measure force in compression; pre-test speed – 1.0 mm/s; test speed – 3.0 mm/s; post-test speed – 10.0 mm/s; distance – 5.0 mm; trigger force – 50 g. Ten measurements per each cookies type were made.

Statistical analysis
Results were expressed as the mean of replications ± SD for all measurements. Analysis of variance (ANOVA) and Duncan's multiple range test were used to compare means at 5% significance level by using the statistical data analysis software system STATISTICA (StatSoft, Inc. (2008), version 10.0 (www.statsoft.com).

RESULTS AND DISCUSSION

Data on the physical characteristics of cookies are presented in Table 1. There were significant differences in the thickness of cookies. The thickness was significantly increased by the addition of medicinal plant mixture, at all levels compared to the control sample. The width of cookies was reduced significantly except in the case of cookie enriched with 2% of the plant mixture.

Table 1. Pysical characteristics of cookies

Sample	Width (W) (mm)	Thickness (T) (mm)	Spread ratio (W/T)
Control (K)	53.75 ± 1.08^{b}	9.34 ± 0.79^{b}	5.75
2%	51.93 ± 0.79^{a}	7.99 ± 0.41^{a}	6.50
4%	52.84 ± 3.12^{ab}	7.70 ± 0.24^{a}	6.86
6%	52.39 ± 0.58^{ab}	8.92 ± 0.22^{c}	5.87

Values are means ± SD of ten measurements.
Values with the different superscript within a column are statistically different (P < 0.05).

The cookies exhibited a decreased spread ratio, which ranged from 6.86 (cookie with 4% enrichment) to 5.75 (control sample). Previous studies indicated that two factors affect the spread ratio: expansion of dough by leavening and gravitational flow (Gurjal et al. 2003). Dough flow mostly depends on its viscosity: the higher the viscosity the lower the spread rate (Filipčev et al., 2011). Fuhr (1962) suggested that any ingredient that absorbs water during dough mixing will decrease the spread ratio. According to Jacob and Leelavathi (2007), the type of fat does not make a difference in spread value in the case of cookies made of margarine and bakery fat. On the other hand, cookie dough containing the hydrogenated fat had significantly less spread ratio (Jacob and Leelavathi, 2007). Finney et al., (1950) and later Abboud et al., (1985) concluded that fat type is not an important variable for cookie spread. On the basis of the above mentioned facts, it could be concluded that the addition of 'Vitalplant' in the form of powder, with more coarse particles held less water in comparison to the fine particles of wheat flour (Filipčev et al., 2011), which contributed to larger extend of cookies' spreading (Table 1, Figure 1).

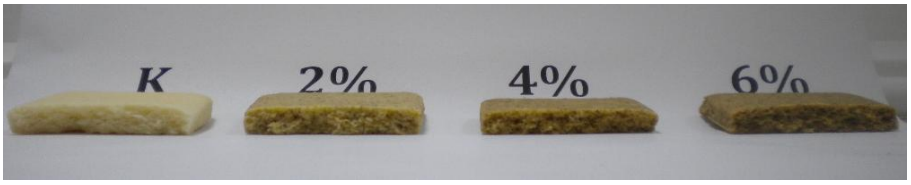

Figure 1. Cross-section of cookies

Sensory evaluation

Sensory quality of produced cookies was defined on the basis of evaluation of appearance, texture, odour and taste. The obtained results are shown in Table 2. Quality category was determined in dependence on scores: unacceptable (<2.5), good (2.5 - 3.5), very good (3.5 - 4.5) and excellent (>4.5).

Table 2. Sensory evaluation of cookies

Attributes	Control	2%	4%	6%
Appearance (surface, shape)	4.25 ± 0.62^{a}	4.50 ± 0.52^{a}	4.42 ± 0.51^{a}	4.55 ± 0.52^{a}
Structure and break	4.17 ± 0.83^{a}	4.33 ± 0.49^{a}	4.50 ± 0.67^{a}	3.73 ± 1.35^{a}
Chewiness	4.33 ± 0.78^{ab}	4.75 ± 0.62^{b}	4.33 ± 0.98^{ab}	3.91 ± 1.04^{a}
Odour	2.67 ± 0.89^{a}	3.92 ± 0.90^{b}	4.33 ± 0.65^{b}	4.55 ± 0.69^{b}
Taste	3.25 ± 0.97^{a}	4.25 ± 0.62^{b}	4.67 ± 0.49^{b}	4.64 ± 0.50^{b}
Weighted mean value	**3.76**	**4.37**	**4.47**	**3.92**

Values are means ± SD of six panellists. Values with the different superscript within a raw are statistically different (P < 0.05). Scores: 1 - unacceptable, 2 - acceptable, 3 - good, 4 - very good, 5 - excellent

Sensory evaluation of the representative attributes of cookies, done by the points-based method showed that the cookie enriched with 4% of the medicinal plant mixture had almost excellent overall quality (Table 2). Scores for individual sensory attributes, except for odour and taste of control sample, indicated very good or excellent quality of all cookies. In addition, data analysis of the odour and taste scores revealed a statistically significant difference between the control sample and all enriched cookies, while no significant differences between the samples were found for the appearance, structure and fracture. The addition of 2% of the medicinal plant resulted in significantly softer product, which was rated the highest for chewiness. Also, 'Vitalplant' mixture applied at three levels of supplementation significantly improved the odour and the taste of the cookies. In general, referring to the results of sensory quality of the cookies, 'Vitalplant' mixture in the form of powder may be used in cookie formulations without producing a negative impact on the sensory attributes.

Colour determinations

The surface colour of a baked product is, together with texture and taste, a very important attribute for the initial acceptability of baked goods by consumers (Zucco et al., 2011). The colour of the cookies' top surface was generated in the baking process possibly due to non-enzymatic browning (Maillard reactions) in the reaction between reducing sugars and amino acids, but also possibly as a results of starch dextrinisation and sugar caramelisation (Chevallier et al., 2000). CIE Lab colour values were determined for cookie samples and presented in Table 3.

Table 3. Colour values of cookie samples

Sample	L*	a*	b*
Top surface			
Control	80.07 ± 0.47^{d}	-1.22 ± 0.44^{a}	25.64 ± 1.16^{a}
2%	65.59 ± 0.76^{c}	1.28 ± 0.64^{b}	29.90 ± 0.75^{b}
4%	57.98 ± 0.88^{b}	2.55 ± 0.45^{c}	31.56 ± 0.91^{c}
6%	54.36 ± 0.78^{a}	2.89 ± 0.33^{d}	30.89 ± 0.69^{d}
Bottom surface			
Control	74.92 ± 1.58^{d}	1.86 ± 1.60^{a}	30.32 ± 2.59^{a}
2%	62.39 ± 1.40^{c}	3.02 ± 1.17^{b}	32.19 ± 1.16^{b}
4%	56.19 ± 0.90^{b}	3.54 ± 0.65^{b}	33.39 ± 0.64^{c}
6%	53.24 ± 0.84^{a}	3.44 ± 0.51^{b}	32.86 ± 0.76^{bc}

Values are means ± SD of twenty-five measurements.
Values with the different superscript within a column are statistically different (P < 0.05)

The analysis of *L** (top and bottom surface) (Table 3) showed that lightness decreased significantly ($P < 0.05$) with the increase in the level of supplementation of the cookies. The obtained results are in accordance with previously published results of the other authors (McWatters et al., 2003; Singh and Mohamed, 2007; Sudha et al., 2007), who found that the incorporation of different composite ingredients may contribute to darker top surfaces (Table 3). Since 'Vitalplant' mixture contained green herbal drugs, significant increase ($P < 0.05$) in red tonality (positive *a** values) was not expected in the case of the both cookie surface colours. However, increase in the level of supplementation was followed by the increase in red tonality. Also, yellow tonality (positive *b** values) significantly ($P < 0.05$) increased with the increase in the mass portion of the medicinal plant mixture in the cookies. Finally, "Vitalplant" mixture addition significantly changed their colour. The acceptability of obtained cookies yellow tonality should be evaluated by consumers.

Textural analysis

Textural properties of cookies were analyzed applying 3-point bending rig which allows measurement of the hardness and resistance of cookies to bend or snap. The hardness refers to the maximum force needed for cookies' fracture, while the fracturability relates to the resistance of cookies to bend. According to many authors (Bourne, 2002; Sudha, 2007; Wekwete and Navder, 2008; Mamat et al., 2010) among the most important factors influencing the mechanical properties of hardness are shape, size and type and amount of fat in the formulations. The measurements showed that cookies containing 4% of the medicinal plant mixture were significantly softer in comparison with other investigated cookies (Table 4).

Table 4. Textural properties of cookies

Property	Control	2%	4%	6%
Hardness, g	1630.7 ± 395.42^{b}	1442.6 ± 249.73^{b}	1198.5 ± 186.63^{a}	1670.4 ± 136.01^{b}
Fracturability, mm	83.02 ± 0.67^{c}	82.44 ± 0.30^{b}	82.05 ± 0.21^{a}	82.95 ± 0.24^{c}

Values are means ± SD of ten measurements.
Values with the different superscript within a raw are statistically different ($P < 0.05$)

On the other hand, hardness of the cookies supplemented at 2 and 6% level was not significantly different between them and the control sample. Since wheat cookies were control ones, and were prepared with the same amount of fat, difference in hardness could have been addressed to the difference in size (width and thickness) as well as spread ratio. Cookie's fracturability, reported as a distance at the point of break is the resistance of cookies to bend, expressed in mm (Table 4). Smaller distance denotes higher fracturability. The obtained results of fracturability indicated statistically important differences ($P < 0.05$) between all investigated cookies. The most fracturable cookie was the sample with the addition of 4% medicinal plant mixture while the control sample was the least fracturable. The obtained results may support above mentioned observation.

CONCLUSIONS

Development of new products by adding 'Vitalplant' mixture in the form of powder to carrier foods such as cookies may provide new market opportunities for bakery producers. Sensory evaluation, colour and texture measurements were found to be sensitive as quality attributes. The addition of the medicinal plant mixture may be used in the cookie formulations without adversely affecting their sensory attributes. Cookies supplemented at 4% of the medicinal plant mixture were estimated by sensory evaluation and instrumental measurements to be the best. Further research needs to be done in order to examine consumers' acceptance of the new products, especially in terms of colour.

Based on their overall good sensory quality, and previously confirmed antioxidant and antimicrobial properties of the mixture, new cookie formulations can broaden the utilization of this mixture and may be regarded as health-promoting functional foods.

ABSTRACT: The level of worry against food additives is higher in Hungary (81%), than in Spain (54%) (Eurobarometer, 2010), probably as a result of different level of knowledge and attitudes.
Results of a previous survey carried out by the authors in Hungary and Spain ($N_{Hungary}$= 437, N_{Spain}= 348) showed a strong demand for artificial additive-free products in both countries, even at higher prices. Thus, the aim of our work was to analyse and compare the willingness to buy (WTB) and preference of foodstuffs containing natural and artificial food additives in Hungary and Spain.
For this purpose a conjoint analysis was done. Conjoint cards were created from two groups of food additives (preservatives and packaging gases), and from two "model foodstuffs". One foodstuff expected high additive content (chips) and one expected low additive content (pre-packed sliced cheese). These foodstuffs were used to stimulate shopping situation. Three factors were selected: "preservatives" (artificial/natural), "packaging gases" (contains/does not contain) and "price" (average+10%/average+20%). For the conjoint analysis six cards were selected. Results were collected via Internet.
On the basis of the conjoint analysis the presence of "natural preservatives" was the most important factor in case of cheese in both countries. Regarding chips the "natural preservatives" were the most influencing factor in Hungary, while the presence of "packaging gases" in Spain. With the help of cluster analysis 3 clusters were created in each country. Respondents were sensitive to the "prices" of the foodstuffs in both countries, so it must be taken into consideration during product development and the production of new foodstuffs.
Key words: *food additives, conjoint analysis, preservatives, packaging gases, willingness to buy*

INTRODUCTION

Nowadays consumers expect the foodstuffs they buy and eat to be safe and convenient as well as tasty, pleasant to eat and healthy. These exceptions require ingredients to be used improving the appearance of foodstuffs and increase their health benefits. In order to fulfil these consumer demands, the food industry uses different food additives.
According to the Eurobarometer survey of 2005 when concerns about a range of listed risks/problems associated with food were analysed, the rate of worry about "additives like colours, preservatives or flavourings used in food or drinks" in Hungary was really high (76%), while in Spain lower (46%) (EU mean: 57%) (Eurobarometer, 2006). Similar results were detected in 2010, when 81% of the Hungarian participants worried, while in Spain this proportion was lower (54%) (EU mean: 66%) (Eurobarometer, 2010). Based on our survey conducted in 2011, Hungarian respondents judged "food additives" to be more hazardous (mean: 3.15; on a 1-5 Likert scale, where 1: not hazardous at all – 5: really hazardous; N= 437) – although not significantly – than Spanish participants (mean: 3.08; N= 348). In the just now mentioned survey a strong demand was expressed for additive-free foodstuffs in both countries. In Hungary 80.1% of the participants, in Spain 73.3% would buy foodstuffs without food additives, even if they had different colour or consistence than it used to. Furthermore, these consumers were ready to pay extra money for these products, 10% (in Hungary 15.1% of the respondents and 20.7% in Spain) or 20% more frequently (in Hungary 21.7% of the respondents and 10.9% in Spain). Thus, the aim of our work was to analyse and compare

the WTB and preference of foodstuffs containing natural and artificial food additives in Hungary and Spain.

MATERIAL AND METHODS

According to the authors' previous survey Hungarian respondents judged "preservatives" ($p \leq 0.001$) to be more hazardous than Spanish people, while in case of "packaging gases" the opposite tendency was observed ($p \leq 0.001$). Furthermore, unambiguous consumer demand was found for foodstuffs free of food additives even at a higher price in both countries. The most frequently mentioned acceptable extra rates in case of common products (e.g. bread, cold cuts) were 10% and 20%. Thus for the conjoint study three factors were chosen: "preservatives" (artificial/natural), "packaging gases" (contains/does not contain) and "price" (average+10%/average+20%). Average prices were determined on the basis of market data. On the basis of the selected factors conjoint cards of two "model foodstuffs" were created and used to simulate a shopping situation. One foodstuff expected high additive content (chips) and one expected low additive content (pre-packed sliced cheese) (Figure 1). In order to avoid the effect of the order of the selected foodstuffs two questionnaires were designed in both countries (one started with cheese and continued with chips, and the other in reversed direction). For the conjoint study six cards were chosen, which were set out in a fix order (Table 1). The selected foodstuffs' consumption frequency was asked in the conjoint questionnaire. Results were collected via Internet with the help of an e-mail list – compiled from previous studies – furthermore participants were asked to forward the link if they could. The data collection period was between autumn 2011 and winter 2012. 250 questionnaires were collected in Hungary, and 211 in Spain, but not all of them were suitable for the conjoint analysis (Hungary: 167, Spain: 147). Data were analysed with the help of SPSS 17.0 statistical software (conjoint analysis, K-means cluster analysis and Chi^2 test).

Table 1. The applied conjoint cards in order

	Preservatives		Packaging gases		Price	
	artificial	natural	contains	does not contain	+10%	+20%
1		X		X	X	
2		X		X		X
3	X			X	X	
4		X	X		X	
5	X			X		X
6		X	X			X

Figure 1. Samples from the conjoint cards (Spain)

RESULTS AND DISCUSSION

Utilities and relative importance of the analyzed factors

According to the Spanish results small difference was found between the utility of "artificial/natural preservatives" and the "presence/absence of packaging gases" regarding cheese. However, in both countries the most preferred aspect was the presence of "natural preservatives". In case of "packaging gases", higher relative importance rates were perceived in Spain, than in Hungary. In case of Hungary the utilization of "packaging gases"

was rejected in chips and certain indifference was observed regarding cheese. Increasing "price" had negative influence on the utility. In case of cheese the "price" was more important for Hungarian respondents, than for Spanish ones (Table 2).

Table 2. Relative importance of each factor and utility for each level (Cheese)

Factor	Level	Utility		Relative importance (%)	
		Hungary	Spain	Hungary	Spain
Preservatives	**Natural**	0.675	0.595		
	Artificial	-0.675	-0.595	42.765	40.696
Packaging gases	**Presence**	-0.076	0.588		
	Absence	0.076	-0.588	26.421	39.836
Price	**+10%**	-0.607	-0.388		
	+20%	-1.214	-0.776	30.814	19.468

Analyzing the results regarding the chips it was found that one of the most important factors of rejection was the presence of "artificial preservatives" in both countries. "Packaging gases" attracted higher interest in Spain. Presence of "packaging gases" was a less important factor for Hungarian participants; however Spanish respondents preferred the utilization of these substances mainly in case of chips. The WTB is decreasing with the increasing of the "price" in both countries (Table 3).

Table 3. Relative importance of each factor and utilities for each level (Chips)

Factor	Level	Utility		Relative importance (%)	
		Hungary	Spain	Hungary	Spain
Preservatives	**Natural**	0.964	0.578		
	Artificial	-0.964	-0.578	**55.984**	40.533
Packaging gases	**Presence**	-0.174	0.619		
	Absence	0.174	-0.619	25.197	**41.251**
Price	**+10%**	-0.210	-0.293		
	+20%	-0,419	-0.585	18.819	18.216

Cluster analysis

In order to explore differences amongst the consumers' decisions and to determine similar consumer groups, on the basis of the utilities, a K-means cluster analysis was performed, and 3-3 clusters were created in both countries (Table 4).

Hungary

Informed price sensitive: Members of this cluster prefer cheese and chips with "natural preservatives" and without "packaging gases", but they do not want to pay extra money for these foodstuffs. Thus these consumers are price sensitive.

Inert: Most of the Hungarian respondents belong to this cluster. These consumers prefer "natural preservatives", and they do not care about the presence of "packaging gases". They are price sensitive.

Aspire to health: Participants of this cluster show reference marks to health, but at the same time they want to enjoy the consumed foodstuffs. They prefer chips with "natural preservatives" and without "packaging gases", but they do not want to pay too much extra money for these foodstuffs.

The presence of "natural preservatives" is the most important factor for the "informed price sensitive" cluster regarding pre-packed sliced cheese, while in case of chips for the "aspire to health" cluster (Table 4).

Spain

Lover of natural: The most important factor for this cluster is the use of "natural preservatives" instead of artificial ones. Nevertheless members of this cluster do not take

care about the presence of “packaging gases”, furthermore they do not want to pay more money for these foodstuffs.
Convenient: Participants of this cluster like pre-packed and easy-to-handle foodstuffs like the pre-packed cheese and chips. They prefer foodstuffs with “natural preservatives”, but practicality is more important for them. At the same time they are moderately price sensitive, they do not want to pay extra money for these foodstuffs.
Inert: Most of the Spanish participants belong to this cluster. They prefer cheese and chips with “natural preservatives” and with “packaging gases”, however they do not want to pay extra money for these products. This cluster is the most price sensitive.
Presence of “packaging gases” got positive acceptance by the members of the clusters, mainly by the “convenient” cluster. “Natural preservatives” got also favourable judgement, and this was the most important thing for the “lover of natural” cluster in case of both foodstuffs (Table 4).

Table 4. Cluster utilities of each level

Foodstuff	Factors		Clusters					
			Hungary				Spain	
			Informed price sensitive (N= 58)	Inert (N= 68)	Aspire to health (N= 41)	Lover of natural (N= 38)	Convenient (N= 34)	Inert (N= 75)
Cheese	Preservatives	Natural	1.09	0.28	0.75	1.61	0.18	0.27
		Artificial	-1.09	-0.28	-0.75	-1.61	-0.18	-0.27
	Packaging gases	Presence	-0.53	0.33	-0.11	0.07	1.94	0.24
		Absence	0.53	-0.33	0.11	-0.07	-1.94	-0.24
	Price		-0.98	-0.05	-1.00	-0.12	-0.24	-0.59
Chips	Preservatives	Natural	0.69	0.58	1.98	1.34	0.21	0.36
		Artificial	-0.69	-0.58	-1.98	-1.34	-0.21	-0.36
	Packaging gases	Presence	-0.28	0.16	-0.58	0.29	1.98	0.17
		Absence	0.28	-0.16	0.58	-0.29	-1.98	-0.17
	Price		-0.47	-0.16	0.08	-0.10	-0.20	-0.44

Cheese and chips consumption in the clusters

Hungary

Only 37.8% of the Hungarian participants consume pre-packed sliced cheese “1-3 times per month” or more often. Members of the “informed price sensitive” cluster consume pre-packed cheese the most frequently (39.6% at least “1-3 times per month”), closely followed by the “aspire to health” cluster (39.1% at least “1-3 times per month”) (Figure 2).
35.9% of the participants consume chips “1-3 times per month” or more often, and 59.3% “less than once per month”. Like in case of cheese, members of the “informed price sensitive” cluster consume chips the most frequently (44.8% at least “1-3 times per month”), closely followed by the “aspire to health” cluster (43.9% at least “1-3 times per month”) (Figure 3).

Spain

Spanish participants consume pre-packed sliced cheese (83.7% “1-3 times per month” or more often) and chips (81.7% “1-3 times per month” or more often) more frequently than Hungarians (Figure 2, 3).
Regarding cheese, amongst the members of the “once a week or more often” consumers the “lover of natural” cluster have the highest rate (73.7%), while in sum the members of the “inert” cluster consume it the most frequently (86.6% at least “1-3 times per month”) (Figure 2).
Consumers of the “lover of natural” cluster have the highest rate amongst the “once a week or more often” chips consumers (42.1%), but the members of the “inert” cluster are the highest chips consumers (89.4% at least “1-3 times per month”) (Figure 3).

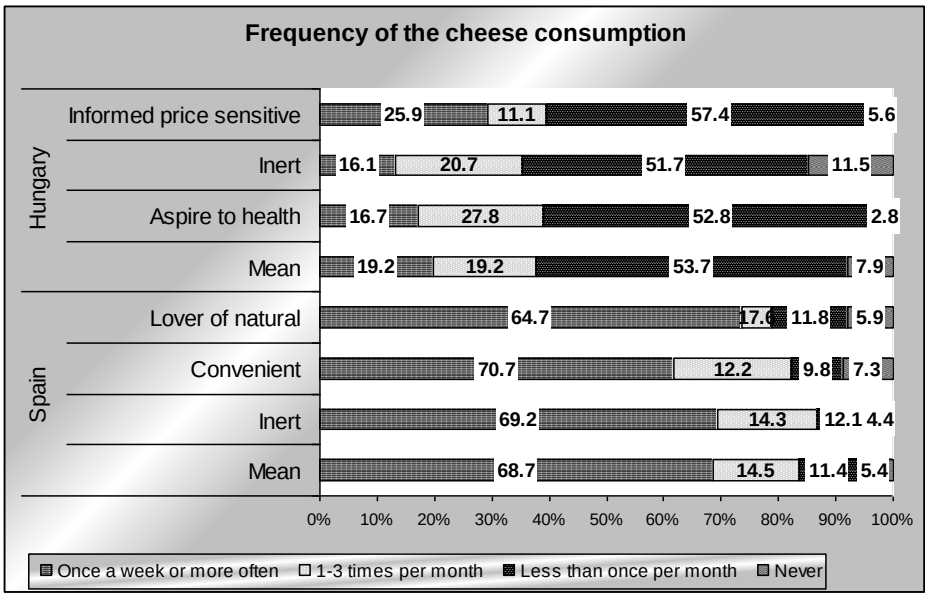

Figure 2. Cheese consumption of the three clusters in Hungary and Spain

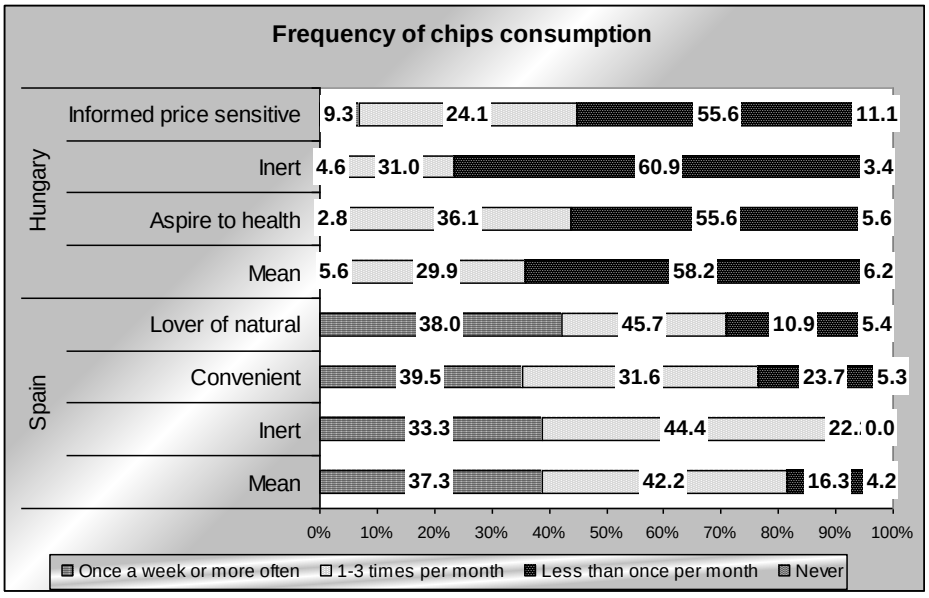

Figure 3. Chips consumption of the three clusters in Hungary and Spain

CONCLUSIONS

According to the results of the cluster analysis in case of pre-packed sliced cheese the most important factor influencing the preferences was the presence of “natural preservative” in both countries. The presence of “natural preservatives” was the most influencing factor regarding chips in Hungary, while the presence of “packaging gases” in Spain. Results of a previous study carried out by the authors were not confirmed by the findings of this conjoint analysis, since strong rejection against the presence of “packaging gases” was not observed in Spain. Spanish consumers probably agree with the utilization of gases in these foodstuffs, thus they become easier to handle and more practical. By means of a cluster analysis three clusters was designed in each country which had different characteristics. Most of the participants belong to the “inert” cluster in both countries – the most frequent cheese and chips consumers in Spain – where the members prefer “natural preservatives”, do not care about “packaging gases”, and they are price sensitive. Members of the “aspire to health”

cluster – which were frequent cheese and chips consumers – can be influenced by new information and trends in Hungary and in case of Spain participants of the “lover of natural” cluster. Both countries’ respondents showed price sensitive attitude so it must be taken into consideration during the development and production of new foodstuffs.

ABSTRACT: Due to the rushing lifestyle and the constantly rising demands for convenience food, additives became important ingredients of foodstuffs.
According to the results of the Eurobarometer survey (2010) there were differences between the reported level of worry against food additives in Hungary, Spain and Romania. In order to get more information about the main reasons for these differences a self administered questionnaire was developed in 2009 in CFRI to evaluate Hungarian consumers' knowledge and judgement about food additives. In the frame of a "pilot study" 400 respondents' data were collected. Following the analysis of the data a concise and more targeted questionnaire was designed, which was translated into Spanish and Romanian. This questionnaire was filled out in these three countries via Internet.
On the basis of the results, differences were found in the judgement and knowledge of food additives amongst the countries, and on the basis of the socio-demographic factors, too. These differences can be caused by consumers' mixed and ambiguous knowledge, furthermore by the countries' different communication about these ingredients.
Key words: *food additives, knowledge, risk perception, questionnaire*

INTRODUCTION

Thanks to the continually changing lifestyle and consumption habits, utilization of food additives became widespread and common. According to the Eurobarometer "Risk issues" survey conducted in 2005, 7% of the respondents mentioned "food additives" as a risk associated with food in an open-ended question (where response alternatives were not presented) (Eurobarometer, 2006). In the "Food-related risks" survey in 2010 this rate was a little bit higher, 9% (Eurobarometer, 2010). In the above mentioned surveys when people's concerns about a range of named risks/problems associated with food were analysed (prompted responses) against "additives like colours, preservatives or flavourings used in food or drinks" higher rates of worry were found (57% in 2005 and 66% in 2010).
In Hungary the prompted response against "additives like colours, preservatives or flavourings used in food or drinks" in both Eurobarometer surveys were very high, 76% in 2005, and 81% in 2010. In Spain these rates were much lower, 46% in 2005, and 54% in 2010. Romania participated only in the last Eurobarometer survey (2010). According to the Romanian respondents' results the rate of concern about food additives was high 74%.
On the basis of the results of the mentioned surveys differences were found in the rate of concerns against food additives in Hungary, Spain and Romania.
The aim of our study was to try to collect more detailed information in order to gain knowledge about these differences.

MATERIAL AND METHODS

A self-administered questionnaire was developed to evaluate the knowledge and judgement of Hungarian consumers' about food additives, from which in the frame of a "pilot study" 400 respondents' data were collected. Following the analysis of the data a concise and more

targeted questionnaire was designed, which was translated into Spanish and Romanian, too. Participants in the questionnaire were asked to judge different risk factors on a 1–5 Likert scale (1: not hazardous at all, 5: really hazardous), questions related to knowledge "Do you know the meaning of food additives used by food industry?" and "Do you know what "E-numbers" mean on food packaging?". Respondents' detailed knowledge was analysed with the help of six statements. Some socio-demographic data were asked, too. This questionnaire was filled out in Spain on paper (with the assistance of a nearly representative sample, N= 200) and via Internet. In Hungary and in Romania the questionnaire was filled out only through Internet, which is a comfortable and cost effective too however the sample is restricted to Internet users, who as a group may not be representative of the population as a whole (Fox et al., 2003). Altogether 437 fully completed questionnaires were collected in Hungary, 348 in Spain (200 paper and 148 internet based) and 386 in Romania. Results were collected in 2011 (Hungary: spring-summer, Spain: summer-autumn and Romania: autumn-winter). Data were analysed by means of SPSS 17.00 statistical software.

Distribution of socio-demographic factors

Female respondents were in majority in the examined countries. In Hungary and Romania the distribution of respondents' age was similar; however in Spain it was different – partly due to the nearly representative 200 consumers' sample. Most of the participants were from big cities in the three countries, and less from villages or other settlements. Because of the different education systems equal groups can be formed only in case of Hungary and Romania (Table 1).

Table 1. Distribution of socio-demographic factors in the analysed samples of the three countries

		Hungary	Spain	Romania
Gender	Female	69.3%	59.5%	75.6%
	Male	30.7%	40.5%	24.4%
Age	18–24 years	30.4%	7.2%	47.7%
	24–44 years	52.9%	48.3%	40.9%
	Over 45 years	16.7%	44.5%	11.4%
Place of residence	City with more than 20.000 inhabitants	71.4%	74.1%	75.9%
	City with less than 20.000 inhabitants	13.3%	10.3%	13.2%
	Village, other settlements	15.3%	15.5%	10.9%
Highest level of education	Lower than school leaving examination	14.2%	11.5%	15.3%
	School leaving examination		34.5%	
	Bachelor degree	32.0%		66.6%
	Master degree	53.8%	54.0%	18.1%

RESULTS AND DISCUSSION

Risk perception

Based on the polled people in the three countries the most hazardous risk factors were different from food additives. In Spain (4.68) and Romania (4.79) "chemical residues (e.g. pesticides)" ended up in the first place, while in Hungary (4.51) it was the "chemical substances from environmental pollution". Factors considered to be the less hazardous were also different in the countries. In Hungary "gases of the modified atmosphere" (2.65), in Spain "other food additives (e.g. gelling agents)" (2.97) while in Romania "preservatives" (3.46) were the less hazardous factors. Regarding the "gases of the modified atmosphere" a high aversion was detected in Romania (3.77), while significantly ($p \leq 0.001$) less in Spain (3.34) and in Hungary (2.65). Romanian respondents reported significantly higher ($p \leq 0.001$) risk against "food additives", "E-numbers" and "GMO foodstuffs", than participants in Hungary and in Spain. Furthermore it was found that Romanian participants perceived higher risk

against the different groups of food additives listed amongst the risk factors, than respondents in Hungary and Spain.
Significant difference ($p \leq 0.001$) was found between the judgement of "food additives" and "E-numbers" in Spain and Romania, but not in Hungary. This proves that Spanish and Romanian participants were not at all aware of the fact that these two terms cover the same substances.
"Sweeteners" and "preservatives" with the term "artificial" presented a significantly ($p \leq 0.001$) higher level of worry in the three countries' participants than the same factors without the term "artificial".
Results showed that Hungarian participants felt the biggest difference between the listed risk factors, while Romanian respondents the smallest (Table 2).

Table 2. Perceived risk levels in three European countries (1: not hazardous at all, 5: really hazardous)

Risk factors	Hungary (a)	Spain (b)	Romania (c)	SD
Gases of the modified atmosphere	2.65	3.34	3.77	a-b, c; b-c
E-numbers	3.09	3.35	4.23	a-b, c; b-c
Sweeteners	3.13	3.07	3.69	c-a, b
Food additives	3.15	3.08	3.79	c-a, b
Other food additives (e.g. gelling agents)	3.26	2.97	3.67	a-b, c; b-c
Preservatives	3.38	2.97	3.46	b-a, c
Artificial sweeteners	3.43	3.27	4.04	c-a, b
GMO foodstuffs	3.46	3.48	4.29	c-a, b
Flavourings	3.49	3.19	4.00	a-b, c; b-c
Substances migrating from packagings	3.79	4.11	4.03	a-b, c
Artificial preservatives	3.80	3.56	4.13	a-b, c; b-c
Pathogenic microorganisms	4.04	4.50	4.52	a-b, c
Antibiotics and hormones in meat and milk	4.27	4.56	4.31	b-a, c
Pathogenic mould and mycotoxins in foodstuffs	4.37	4.58	4.44	b-a, c
Chemical residues (e.g. pesticides)	4.48	4.68	4.79	a-b, c; b-c
Chemical substances from environmental pollution	4.51	4.67	4.55	b-a, c

Risk perception on the basis of socio-demographic factors

It was difficult to find unambiguous tendency regarding the three countries. Some outstanding observations will be demonstrated hereinafter, with special regard to the judgement of "food additives" and "E-numbers".
Most of the risk factors were judged to be more hazardous by females than by males in Hungary and Romania. Furthermore female participants linked higher level of risk to "food additives" and "E-numbers" than male respondents.
In Hungary and Spain the same trend was found regarding the age groups. In most of the cases younger respondents (18-24 ys) reported lower hazardous level than older ones (over 45 ys). In Romania the opposite was observed. Related to the knowledge of "food additives" and "E-numbers" significant connections ($p \leq 0.05$ and $p \leq 0.001$) were found amongst the age groups only in Hungary. Young Hungarians (18-24 ys) thought these factors less hazardous than older participants (over 45 ys).
Respondents from big cities (over 20.000 habitants) reported higher hazardous level regarding most of the listed risk factors ─ food additives and "E-numbers" too ─ than habitants from smaller settlements (village or other settlements) in Spain and Romania. The opposite tendency was observed in Hungary, where participants from smaller settlements linked higher level of hazard to most of the risk factors.
Judgements of the listed risk factors were different even within one country on the basis of the highest level of education. Differences were detected between the evaluation of the

hazardous levels of “food additives” and “E-numbers”. In Romania respondents with the lowest level of education (school leaving examination or lower educated) reported the lowest risk level against these factors, while in Hungary these participants perceived the highest one ($p \leq 0.001$). Spanish participants with the highest level of education (Master degree) perceived the lowest risk level in case of both factors ($p \leq 0.001$ and $p \leq 0.05$).

Knowledge of food additives

Romanian participants reported the highest knowledge (92.5%) about food additives, while Spanish participants the lowest (84.2%). Regarding “E-numbers” Hungarians (72.5%) and Romanians (70.5%) were self-confident, however Spanish people were more uncertain (45.4%).

Knowledge of food additives on the basis of socio-demographic factors

There were more Hungarian and Romanian females ($p \leq 0.05$) who answered that they knew food additives and “E-numbers” than males. In Spain a similar tendency was not observed.
The level of knowledge of food additives was rising with the age ($p \leq 0.05$) in Romania. Middle aged Spanish respondents (25-44 ys) had the highest level of knowledge ($p \leq 0.05$), however in Hungary this group had the lowest ($p \leq 0.05$).
According to the place of residence significant differences were not observed.
The knowledge of food additives and “E-numbers” was in parallel with the rising of the highest level of education ($p \leq 0.05$, and $p \leq 0.001$) in Spain. Respondents with Bachelor degree had the highest knowledge, and those who had Master degree had the lowest (food additives: $p \leq 0.05$) in Hungary.

Detailed knowledge of food additives

On the basis of the results, Hungarian participants reported the highest knowledge, while Spanish respondents the lowest (Figure 1). Compared the answers given to the previous questions about the knowledge of food additives and “E-numbers” to the answers about one of the statements “Every food additives can be linked to an “E-number”, it can be said that respondents previously overestimated their knowledge in the three countries. Only 27.6% of the Spanish participants knew that “Natural additives also have “E-numbers” and 37.9% that “the role of “E-numbers” is to easily identify food additives”.

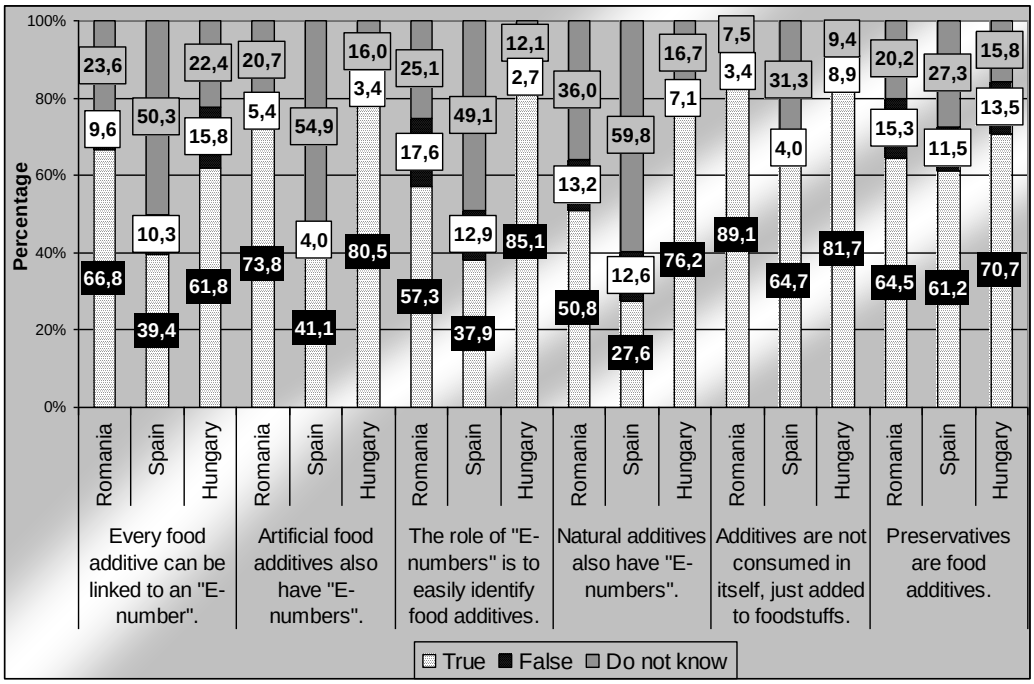

Figure 1. Knowledge of food additives and “E-numbers” on the basis of statements in the three European countries

Detailed knowledge of food additives on the basis of socio-demographic factors

Regarding gender mixed knowledge levels were perceived in Spain and Hungary. Romanian women were a little bit more informed about food additives than men.

According to the age groups in Spain and Romania an explicable tendency was not observed. The youngest group (18-24 ys) had better knowledge about food additives – those who previously linked the lowest risk levels to most of the listed risk factors – than the oldest ones (over 45 ys) in Hungary.

Spanish respondents from small cities (city with less than 20.000 inhabitants) had the less detailed knowledge about food additives, while in Romania – except one statement "the role of "E-numbers" is to easily identify food additives" which was significantly ($p \leq 0.05$) less known by participants from cities with less than 20.000 inhabitants, than others – and Hungary inhabitants of villages or other settlements had the lowest.

In case of some statements the level of knowledge was rising in parallel with the level of education, but it was not overall in Spain. Hungarian participants with Bachelor degree had the best detailed knowledge of the statements. Occasionally respondents with Bachelor degree had the highest knowledge level, while in all cases respondents with Master degree had the lowest in Romania. It is important to note that more Hungarian and Romanian consumers had higher education level than Spanish ones.

CONCLUSIONS

On the basis of a self-administered questionnaire it was found that according to the Hungarian, Spanish and Romanian participants the most hazardous factors were independent from food additives. The leaders of the hazard list were the "chemical substances from environmental pollution" and the "chemical residues (e.g. pesticides)". Romanian respondents reported higher level of hazard to factors in connection to food additives, but – together with the Spanish participants – thought "E-numbers" to be significantly more hazardous than "food additives". Thus they did not know the exact connection between these two terms. Hungarian participants made the biggest difference during the judgement amongst the listed factors, while Romanian participants the least.

It was difficult to determine unified tendencies in the three examinded countries on the basis of the socio-demographic factors. It can be highlighted that females perceived higher risk against the different risk factors, and Hungarian and Romanian females had better knowledge (not detailed) of food additives and "E-numbers". Hungarian and Spanish young respondents (18-24 ys) linked lower hazardous level to most of the listed risk factors. Furthermore in Hungary this group had the most detailed knowledge about food additives. Inhabitants from smaller Spanish and Romanian settlements reported lower level of hazard against the listed risk factors, and Romanian participants had the lowest detailed knowledge about food additives. The highest educated (Master degree) Spanish participants linked the lowest hazardous level to food additives and "E-numbers" as risk factors, furthermore these people reported the better knowledge of both factors, and the most detailed knowledge too.

On one hand differences in the judgement of food additives can be due to consumes' mixed and ambiguous knowledge, and on the other hand to the different types of communication about these ingredients. Food additives are one of the most well-known food ingredients in the Hungarian media, while in Spain and Romania this is not typical at all.

ABSTRACT: The aim of this paper was to select the most acceptable housing system of broiler meat production evaluating consumers attitudes and to investigate quality of raw type sausages made of chicken meat, applying quantitative descriptive sensory analysis.
Based on the survey conducted among consumers of different sex, age and education, it was concluded that majority of consumers of both sexes finds that the price of broiler meat produced in free range production is justifiably higher because of the quality of meat provided. Meat should be labelled according to production system and quality of meat should be controlled by scientific institution according to the opinion of female consumers, whereas male consumers stated that meat quality should be controlled by producers and inspection. Compared sausages samples are made with different chicken meat type: A – commercial broiler, B – commercial broiler and Naked Neck chickens (50:50 ratios) and C – Naked Neck chicken. In all three variants of sausages 20% of pork fat was added. Sensory evaluation was done after roasting. System of 9 points was used for sausages quality attributes (parameters) scoring: 1-exceptionally unacceptable to 9-exceptionally acceptable. Following attributes were evaluated/scored: external appearance, cross-section appearance, colour, smell, taste and texture. Thirty untrained panellists participated in scoring. The appearance of all examined sausage was very good. The colour of group B and C were evaluated as acceptable, but not the usual for this sausage type. Sausages from group A had lighter colour than expected and assessed as too pale. Group B had the highest scores for smell and taste. As a result of conducted sensory analysis, sausages from variant B were selected as the best of compared samples, with overall scores of 7.87.
Key words: *Broiler meat, product, consumer, attitudes*

INTRODUCTION

It is general knowledge that in each production chain the most important is the last link – consumer. For every production it is very important to know why the consumers are purchasing the product and what are their preferences in that regard. In countries with developed poultry production, first and few studies of the consumer attitude towards poultry products appeared in the sixties. However, in the eighties, these studies have become more prominent and intensive, so, today, topics dealing with consumer attitudes have the most prominent place on all poultry meetings.
Favourable circumstance is that in our country, considerable attention was paid on studies of the consumer attitudes towards poultry products. From seventies to late eighties, there were several studies focused on different directions. The questionnaire poll was used as investigation method, which included predominantly consumers from Belgrade as the largest market of poultry products in our country (Mašić and Pavlovski, 1984; Mašić and Pavlovski, 1991; Pavlovski, 1981a; Pavlovski, 1981b; Pavlovski, 1982; Pavlovski and Mašić,1993; Pavlovski et al., 1980; Pavlovski and Mašić,1994; Pavlovski et al., 2002). Studies of the consumer attitudes towards poultry meat originating from extensive rearing system in our country were carried out by Rodić et al., 2003.
The aim of this paper was to select the most acceptable housing system of broiler meat production evaluating consumers' attitudes and to investigate quality of sausages made of chicken meat, applying quantitative descriptive sensory analysis.

MATERIAL AND METHODS

Study of the consumers attitudes towards poultry meat coming from free range system of production comparing to the commercial broiler included survey of consumers of different sex (100 female and 100 male), ages 21-64 years, and level of education (high school-HSE and faculty-FE .Survey was carried out on the territory of the city of Belgrade on a simple random sample of 200 respondents using a questionnaire. Data were analized by SPSS 15.0.
The aim of the second part of investigation was to select the most acceptable raw type sausage made of chicken meat (from free range system), applying quantitative descriptive sensory analysis. Compared sausages samples are made with different chicken meat type: A – commercial broiler, B – commercial broiler and Naked Neck chickens (50:50 ratios) and C – Naked Neck chicken. In all three variants of sausages 20% of pork fat was added. Sensory evaluation was done after roasting. System of 9 points was used for scoring: 1-exceptionally unacceptable to 9-exceptionally acceptable. Acceptability of following attributes was valuated/scored: external appearance, cross-section appearance, colour, smell, taste and texture. Thirty untrained panellists participated in scoring .Data bases were analyzed using software program SPSS 15.0 All significant differences established based on variance analysis were evaluated using T test.

RESULTS AND DISCUSSION

In regard to the question “How important in the process of production are the following: welfare, environment, profit? (offered answers were: very important, important, not important, no opinion) “, male respondents answered that the environment were very important (76.9%), also animal welfare (46.1%), whereas 46.2% answered that profit was important. Respondents of female sex found animal welfare to be important (62.5%) and environment very important (50.0%) and important (41.5%), whereas the profit was on second place with score (54.2%). Based on analyzed answers of male and female respondents, it could be concluded that the influence of sex/genus, age and level of education on what could not be established.
In regard to the question “Which type of poultry meat, coming from which system (floor system with free range, organic production) should be the most expensive or the cheapest from conventional system or floor system without range?“ Respondents of different sex, age and level of education answered in following way: 100% of male respondents and 83.4% females, age from 21-35 years (100%) and high education level (92.4%) thought that the meat produced in the organic system should be the most expensive. Interesting is that lot of respondents of both sexes (46.2 % males and 29.2% females) from 51-64 years of age, 50% and 45,4% of respondents of medium education level, had no opinion about the production system from which the poultry meat should be the cheapest.

Table1. Question "Should the meat on the market have the indication of the system of origin?" and answers grouped according to the sex, age and education level

Question/Answer		**Sex**		**Age**			**Education level**	
		M	**F**	**21-35**	**36-50**	**51-64**	**HSE**	**FE**
Should the meat on the market have indication of the rearing system	yes (%)	92.3	83.3	80.0	86.7	87.5	81.8	88.5
	no (%)	7.7	16.7	20.0	13.3	12.5	18.2	11.5

Table 2. Question " Who should issue the certificate of origin of meat?" and answers grouped according to the sex, age and education level

Question/Answer		Sex		Age			Education level	
		M	F	21-35	36-50	51-64	HSE	FE
Who should issue the certificate of origin of meat	Producers	7.7	4.2	0	0	12.5	0	7.7
	Producers but with present inspection	46.1	12.5	40.0	33.3	12.5	9.1	30.8
	Government inspection	0	12.5	20.0	6.7	6.2	0	11.5
	Specialized certification firms	23.1	20.8	0	13.3	31.3	27.3	19.2
	Scientific inspections	23.1	50.0	40.0	46.7	37.5	63.6	30.8

From table 1, it is obvious that 92.3% of male and 83.3% of female respondents, 87.5% from 51-64 years of age and 88.5% of respondents of high education (faculty degree) thought that meat placed on the market should have the indication of the system of production .
Table 2 shows anwers to the question: „Who should issue the certificate of origin"? Most of male respondents (46.1%) thought that producers with present isnpection should issue the certificates of origin, whereas 46.7% of female respondents thought that scientific inspections should be responsible for this.

Table 3. Consumer attitudes on meat from free range system

Question/Answer		Sex		Age			Education level	
		M	F	21-35	36-50	51-64	HSE	FE
Is the meat produced in free range system healthier that meat produced in conventional system	yes	61.5	50.0	60.0	26.7	75.0	63.6	50.0
	no	30.8	20.8	20.0	46.6	6.2	18.2	26.9
	no opinion	7.7	29.2	20.0	26.7	18.8	18.2	23.1
Should the price of meat coming from different production systems also be different	yes	69.2	79.2	100	66.7	75.0	54.5	84.6
	no	15.4	8.3	0	20.0	6.2	9.1	11.5
	no opinion	15.4	12.5	0	13.3	18.8	36.4	3.9
Reasons for difference in prices	Meat quality	53.8	50.0	40.0	33.3	68.7	63.6	46.2
	Production costs	30.8	25.0	60.0	26.7	18.7	19.2	30.8
	Quality and costs	15.4	8.3	0	20.0	6.3	9.1	11.5
	No opinion	0	16.7	0	20.0	6.3	9.1	11.5

Consumers prefer poultry meat produced in free range system. In regard to the question: „Is the meat produced in free range system healthier that meat produced in conventional system"?, 61.5% of male and 50.0% of female consumers thought that it was, 60.0% of consumers from 21-35 years of age and 63.6% of consumers with high school education. 69.2% of male and 79.2% of female consumers thought that prices of poultry meat from different production system should differ and this attitude was mostly influenced by the age (21-35) and education level (FE).
Qaulity of meat was the most improtant factor influencing the difference in prices of meat produced in different production systems.
The appearance of all examined sausages was very good. The colour of groups B and C was evaluated as acceptable, but not the usual for this sausage type. Sausages from group A had lighter colour and assessed as too pale. Group B had the highest scores for smell and taste. As a result of conducted sensory analysis, sausages from variant B were selected as the best of compared samples, with overall scores of 7.87.

Table 4. Results of sausages sensory evaluation (mean ± standard deviation)

Sensory characteristics	A	B	C
External appearance	6.59^{a} ± 0.52	7.62^{b} ± 0.47	7.83^{b} ± 0.63
Cross-section appearance	6.91^{a} ± 0.44	7.37^{b} ± 0.62	7.25^{b} ± 0.38
Colour	4.88^{a} ± 0.21	6.14^{b} ± 0.18	6.57^{c} ± 0.25
Smell	7.93 ± 0.62	7.56 ± 0.74	7.74 ± 0.77
Taste	8.29^{ab} ± 0.76	8.61^{b} ± 0.51	7.88^{a} ± 0.45
Texture	7.35 ± 0.89	7.76 ± 0.62	7.80 ± 0.92
Overall acceptability	7.03^{a} ± 0.20	7.87^{b} ± 0.32	7.56^{b} ± 0.35

Means within rows bearing different letters are significantly different at P<0.05

CONCLUSIONS

Sex of respondents had no significant influence on the consumers attitudes towards meat produced in different production systems, Age and education level influenced different attitudes of consumers. Group B had the highest scores for smell and taste. As a result of conducted sensory analysis, sausages from variant B (commercial broilers and nacked neck) had the highest scores for smell and taste and were selected as the best of compared samples, with overall scores of 7.87.

ABSTRACT: Understanding consumers' buying habits and motives for selecting high-fat products and their low-fat alternatives is useful in launching new reduced-fat food items.
In order to collect information on the most commonly chosen fat-reduced products available on the Serbian market and identify motives for their consumption, a survey among 250 randomly selected consumers in Vojvodina, Serbia was conducted. The participants could have chosen between high- and low-fat milk, yoghurt, margarine and mayonnaise and different statements referring the apprehension of these alternatives. The study also assessed the socio-demographic influence on motivation for choosing full- or low-fat food versions. The data were analysed using chi-square analysis.
In contrast to mayonnaise, participants chose low-fat milk, yoghurt and margarine in preference to their full-fat version. The results also showed that taste was the infinitely preferable attribute for choice of full-fat food, while the healthiness factor was the most crucial for selection of low-fat products. Different age as well as educational level groups showed different preferences to taste, while the consumption of low-fat food due to healthiness was more frequent among women.
The obtained results indicated the necessity to improve the taste of low- or reduced fat products in order to be competitive with its high-fat alternative.
Key words: Consumers' attitudes, low-fat, full-fat products, questionnaire

INTRODUCTION

Modern human nutrition is often related to an increasing amount of reduced fat, low-fat or light products on the market (Visschers and Siegrist, 2010). According to numerous previous researches, it was found that consumers rated taste of reduced-fat products as less pleasant than products labelled as regular-fat (Stubenitsky et al., 1999) or than reduced-fat without label (Solheim, 1992). Moreover, according to Kähkönen and Tuorila (1998), reduced-fat labels decrease people's expected pleasantness of products in comparison to regular-fat labels. The choice of food represents complex process which is influenced by a number of factors related to the product (intrinsic and extrinsic), the consumer (knowledge, beliefs, attitudes) and the consumption context (occasion, cultural environment) (Jaeger and Rose, 2008; Mela, 1999; Pollard et al., 2002). Moreover, knowledge, beliefs and attitudes to foods are the results of cultural background, eating habits and constant flow of information in everyday life (Lappalainen et al., 1998). The most important aspects which influence food choice is health and weight control. Also, motives for food choice can be related to consumers' personality and lifestyle, sensory pleasure, ideological reasons, price or familiarity (Brunsø et al., 2004; Lindeman and Sirelius, 2001). Moreover, food choice is often influenced by gender, age, social class and income (Johansen et al, 2011).
The aim of this work was to identify consumers' motives for choosing reduced-fat or fullfat products and to determine their preferences between reduced fat milk, yoghurt, margarine and mayonnaise and their full-fat versions.

MATERIAL AND METHODS

Consumers' attitudes investigations

A questionnaire was developed to collect data concerning consumers' profile, their eating habits and motives for choosing full-fat or reduced-fat product. Also, the consumers were asked to choose between various fat replacements levels of milk, yoghurt, mayonnaise and margarine which they most commonly consume. The data collection comprised 250 consumers in Vojvodina region, both in urban and suburban areas. Special attention was given to include different socio-demographic categories of consumers.

Statistical analysis

Collected data were analyzed using descriptive statistics and Pearson $\chi 2$-test, at 0.05 significance level. The statistical analyses were performed using the Statistical Analysis System software package Statistica 10.0 (Statsoft Inc., SAD).

RESULTS AND DISCUSSION

Distribution of demographic characteristics of the 250 randomly selected consumers is presented in Table 1.

Table 1. Profile of tested conumers

Characteristic	Category	Percentage of respondents (%)
Gender	man	34.4
	woman	65.6
Age group	< 30	35.2
	30 - 50	37.2
	> 51	27.6
Education	Primary and high school	40.4
	University	59.2
	no answer	0.4
Household size	1 - 2	35.6
	over 2	62.4
	no answer	2
Monthly household income	< 500 €	33.2
	500 – 1000 €.	47.2
	> 1000 €	18.8
	no answer	0.8
Profession related to nutrition and/or health	yes	15.6
	no	84.4
Body mass index (kg/m^2)	< 18.5	4
	18.5 - 25	56
	> 25	40

According to consumers' profile, it can be observed that percentage of respondents in all categories, except the BMI < 18.5, were more or less evenly distributed, which gave the representative number for giving the conclusions regarding consumers attitudes, motives and preferences. However, the obtained BMI data, which was extremely low for category < 18.5 was in accordance to the investigation performed by "Institut za javno zdravlje Srbije" (Gudelj-Rakić, 2008).

According to Budimović et al. (2010) milk consumption in Serbia was found to be roughly 180 l per person and according to data obtained by Statistical Office of the Republic of Serbia the consumption of margarine was about 2.6 kg per person in 2009 (http://webrzs.stat.gov.rs/WebSite/), while consumption of mayonnaise in Balkan countries, in 2009 and 2010 was cca 500 g per person (www.nielsen.com).
Firstly, consumers were asked how frequently they chose reduced fat versions of different food products available on the market. Accordingly, it was determined that low-fat milk, yoghurt and margarine were bought more frequently than mayonnaise (Figure 1). Moreover, it can be concluded that the answer "never" was at least frequently used for low-fat margarine. This might be due to the fact that consumers perceive margarine as a product which contains significant amount of saturated fats. Namely, according to investigation of Wansink (2003), acceptability of certain products is not only related to decrease in its energetic value but also to product type and how unhealthy is that product perceived even without decreasing its fat content. However, in the case of mayonnaise, which is a product with high fat content, the majority of tested consumers (35%) decided not to consume it at all.

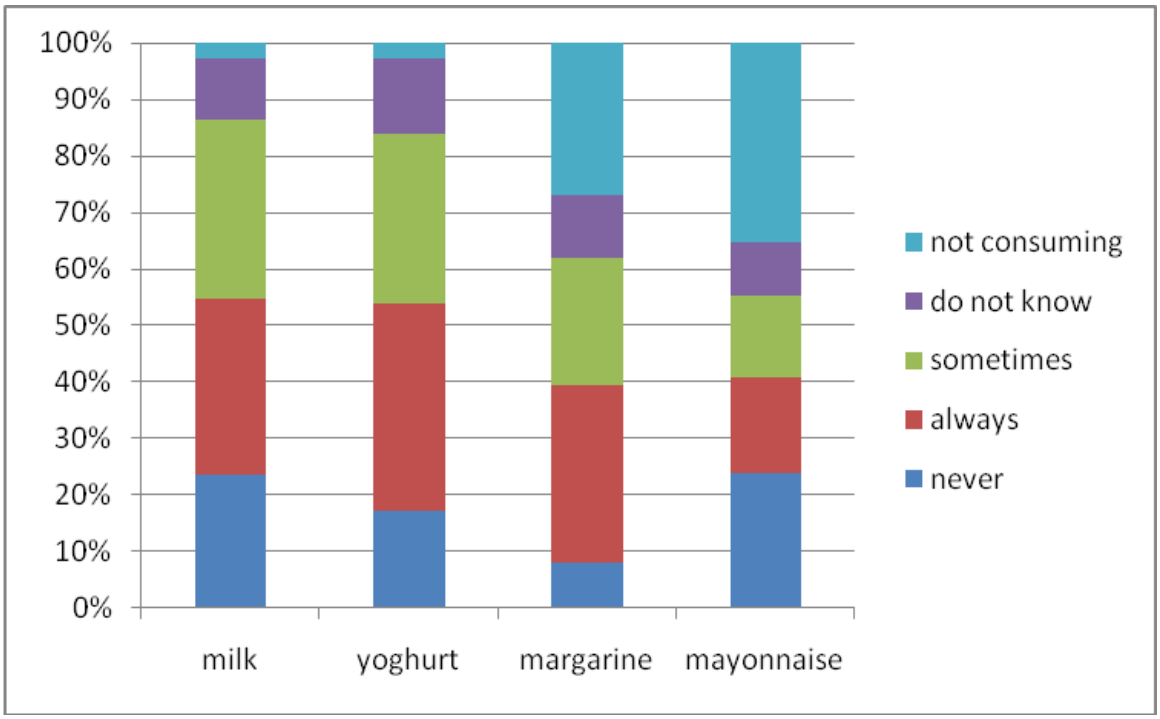

Figure 1. The presence of examined food products with reduced fat content in daily nutrition

The reasons and agreement percentages for consuming full-fat products or their low-fat alternatives are presented in Table 2.
The most important factor in consuming full-fat products was its taste followed by its availability in the supermarkets, its favourable price, etc. The most frequent answer for consuming low-fat products was that they were healthier, followed by helping in reducing weight, recommendation by a friend or from the information given by the mass media, way of life style, etc.

Table 2. Statements used in sorting test in evaluation the reasons for consuming full fat and lowfat products

Statements pro full fat products	%	Statements pro low-fat products	%
It tastes good	47.10	It tastes good	3.87
It looks nice	0.36	It looks nice	0.64
It has pleasant texture	4.35	It has pleasant texture	0.33
It is cheap	6.89	It is good value for money	2.26
It is easily available in shops and supermarkets	8.33	Recommended by medical staff or nutritionist	4.19
It is healthier	0.36	It is healthier	33.87
Not consuming	20.29	Not consuming	10.97
Do not know	12.32	Do not know	10.32
		It suits my lifestyle	8.39
		It helps me control my weight	14.52
		Recommendation by friend or information given by he mass media	10.64

According to Pearson χ2-test, at 0.05 significance level, it was determined that different age and education level groups showed different preferences to taste of full-fat products. Namely, younger people and those with the higher educational level marked the taste of the full fat product as a crucial factor in consuming these products. However, it was also determined that women consume more frequently low-fat products due to its health effects than the men do, which was in agreement with the findings of Rozin et al. (2002) and Steptoe et al. (1995).

CONCLUSIONS

The results of this study showed that between full-fat milk, yoghurt, margarine and mayonnaise and their low-fat alternatives consumers preferred all reduced fat products except the mayonnaise. Moreover, it was determined that the taste was most dominant factor in consuming full-fat products, whereas the health effect was for low-fat products. Also, different age groups as well as educational level groups expressed different preferences to taste, while the consumption of low-fat food due to healthiness was more frequent among women in comparison to men. Since it was found that taste is most important parameter in consuming full-fat products, it can be concluded that taste of low-fat products must be improved in order to be competitive with its high-fat counterparts.

ACKNOWLEDGEMENTS

This research is a part of the project funded by Ministry of education and science, Republic of Serbia (Project No 46001).

ABSTRACT: The growing consumer concern with the obesity and diabetes has led to the quest for alternative sweeteners that can replace sucrose. A sweetener that fulfills many of the consumers' demands is steviose. It is natural, intense and with zero calories. Steviose or steviol glycosides accumulate in the leaves of *Stevia rebaudiana*, a plant native to South America, and commonly known as stevia. In 2008 the Food and Drug Administration approved GRAS status for purified stevia extracts while in November 2011 the steviol glycosides were declared to be safe for use in foods and beverages in all EU countries.
In this study, steviol glycosides were used as sucrose substitute in industrially manufactured apple and peach juices. The manufacturing process of the stevia-based juices followed the regular procedure of juices containing sucrose as sweetener. Pasteurized juices were aseptically packaged in 250-mL containers and stored. As an essential component of a product development process a quantitative descriptive sensory evaluation was conducted to assess the color, sweetness, texture, aroma, aftertaste and other attributes relevant for these types of fruit juices. The overall acceptance of the juices was tested by consumer panelists according to the 5-point hedonic scale.
Key words: *stevia, steviol glycosides, sugar substitute, apple juice, peach juice*

INTRODUCTION

The leaves of *Stevia rebaudiana* Bertoni, also known as stevia, contain a group of compounds identified as steviol glycosides. More than 100 compounds have been identified in *Stevia rebaudiana*. The most commonly known compounds are the steviol glycosides, particularly stevioside and rebaudioside A, which are also the most abundant (Wölwer-Rieck, 2012).
Stevia glycosides possess valuable biological properties and their consumption could be beneficial for human health. They are noncariogenic and non-caloric sweeteners. Regular consumption of these compounds decreases the content of sugar, radionuclides, and cholesterol in the blood, improves cell regeneration and blood coagulation, prevent ulceration in the gastrointestinal tract, and can act anti-inflammatory and antihypertensive (Lemus-Mondaca et al., 2012). Studies conducted with patients proved steviosides effective in diminishing plaque formation (Blauth de Slavutzky, 2010).
Another application of stevioside is as scavenger of reactive oxygen species. Recent findings point to a prominent role of sugars or sugar-like compounds as an oxidative stress defense in plants (Stoyanova et. al., 2011).
Oliveira et al. (2012) reported recently on using stevioside as a substitute for sugars in Malay apples. In a first stage, high calorie sugars (sucrose, fructose and glucose) are partially removed from the fruit samples and in a second stage, low calorie sugars (stevioside and rebaudioside) are incorporated to the fruit to maintain its sweetness. However, such substitution does not seem economically feasible.
In 2008 the Food and Drug Administration approved GRAS status for purified stevia extracts. Although stevioside and extracts of *Stevia rebaudiana* leaves were commercially available and used as sweetener for foods and beverages in Japan, USA, and several South American countries, until recently it was not approved in the EU (Hermann, 2009). In November 2011,

the final hurdle in the EU regulatory process was lifted and steviol glycosides were declared to be safe for use in foods and beverages in all EU countries. Steviol glycoside sweeteners have been assigned the number E-960 for labeling purposes (Scardigli, 2011).
Until recently, not much data were available on the practical application of stevioside in foods and beverages. Furthermore, there is a lack of detailed information on the stability of the stevioside during different processing and storage conditions as well as its interaction with other food ingredients (Kroyer, 2010).
For the judgment of the fruit juices, a sensory evaluation is crucial. Whether the juices will be accepted or not depends on the integration of the consumer's perception of their characteristics into overall impression of quality. Although very important, chemical, physical and microbiological tests cannot provide this type of information. The objective of this study was to use steviol glycoside as sucrose substitute in industrially produced apple and peach juices and to evaluate its effect on the taste and overall acceptability of the juices by the consumers.

MATERIAL AND METHODS

Apple and peach juices

Apple and peach juices were manufactured from the fruit pulp as commercial products following the recipes of the company (Devolli group). Pasteurized juices were aseptically packaged in 250-mL containers and stored. Originally, both types of juices contain sucrose as sweetener. A commercial product Rebaudioside A with 97% purity, a product of NOW-foods, USA, was used in the experiments with steviose as substitute for sucrose. The production of all juices, standard and with steviose, was on industrial scale.

Sensory evaluation of juices

The methods used throughout the sensory evaluation of the juices were discrimination test, quantitative descriptive analysis and hedonic test (Lawless and Heymann, 1998). Sensory attributes were scored on a scale from 1 to 5 points, where higher score meant more intense attribute. A total of 92 untrained panelists, 42 women and 50 men participated in the study, all from middle class background and age range between 21 and 68. Before the evaluation started, they were briefed on the use of the sensory evaluation techniques. Each panelist tasted every sample. One sample for both descriptive analysis and hedonic test was used. The juice samples were presented in plastic cups of 150 mL. About 50 mL of juice were poured into coded cups just prior to sensory evaluation and served at room temperature. The samples were assigned three digit random codes for identification.

Statistical analysis

Descriptive statistics and one-way analysis of variance (ANOVA) was performed on the parameters to evaluate significant differences between the means at 95 % confidence interval ($p \leq 0.05$) according to Tukey's test using Minitab 15 statistical software.

RESULTS AND DISCUSSION

The sensory assessment of the juices started with a discrimination, paired comparison test. The panelists got two samples; one sample was regular juice, and the other one contained stevioside instead of sucrose. The "chemical" difference between the juices was sensory perceivable to all panelists who noticed the difference both in apple and peach juices.
The sensory properties of the apple juices are presented in Figure 1. The apple juice with sucrose tasted sweeter and fresher than the apple juice with stevioside. The apple juice with stevioside was evaluated as overpasteurized, and surprisingly with higher color score and less pronounced aftertaste than regular apple juice. The aroma attribute was almost the same for both samples.

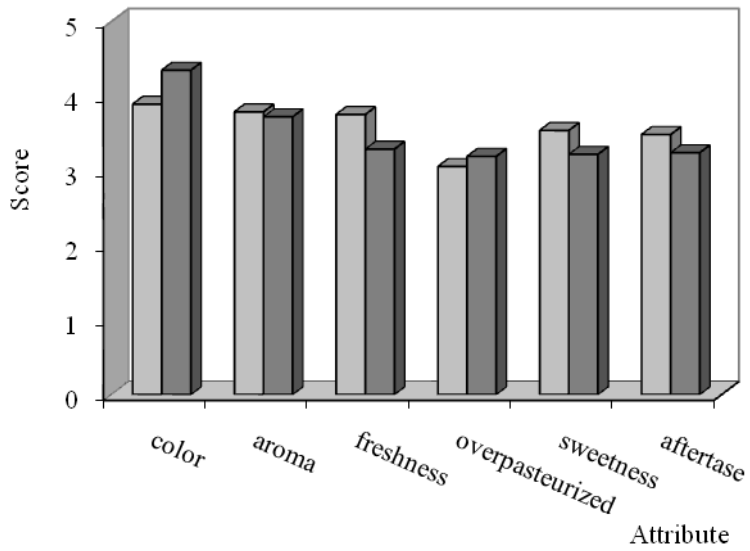

Figure 1. Descriptive sensory analysis of standard apple juice (□) and juice with stevia (■)

As can be seen from Figure 2, color and over-pasteurization of peach juice with sucrose and peach juice with steviol glycoside do not differ significantly. The peach juice sweetened with sucrose was evaluated with higher scores for aroma, freshness, sweetness, but also for aftertaste.

To better illustrate the differences of selected sensory attributes of the juices with stevia, apple juice with stevia and peach juice with stevia, the average attribute intensities of both samples are depicted in the spider web graph (Figure 3). It can be clearly seen that the apple juice with stevia has been perceived as significantly sweeter, fresher and with intenser aroma than the peach juice with stevia. However, the apple juice with stevia had more pronounced aftertaste than the peach juice with stevia. Only the feeling of over-pasteurization was the same for both juices.

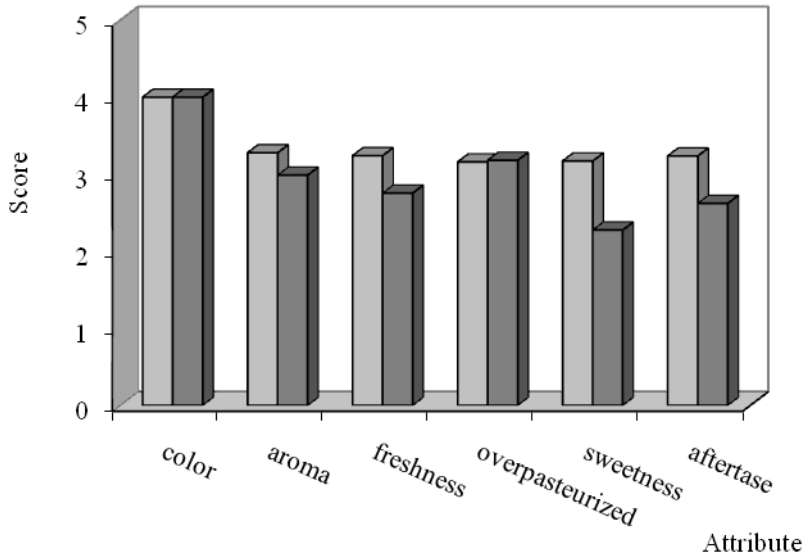

Figure 2. Descriptive sensory analysis of standard peach juice (□) and juice with stevia (■)

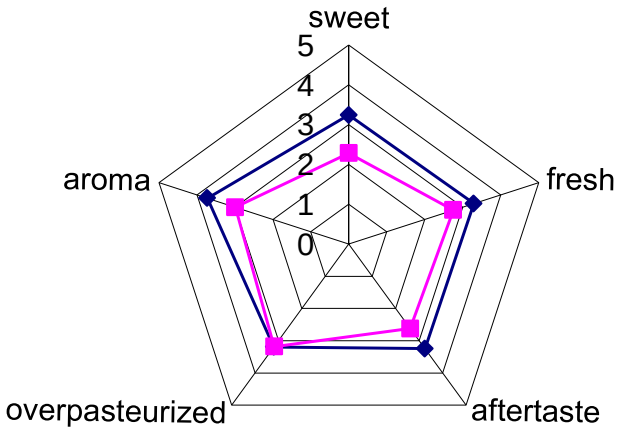

Figure 3. Spider web graph of apple (◆) and peach (■) juices with stevia

The overall acceptance of the juices was tested according to the 5-point hedonic scale used to assess liking or disliking of the panel group (Table 1). 32% of the panelists labeled the apple juice with sucrose as “like very much” followed by 25% of the panelists who gave this attribute to the apple juice with stevia. With 37% of the panelists who labeled peach juice with stevia with “neither like nor dislike”, and 17% of them who chose “dislike”, the peach juice with stevia displayed the lowest level of acceptance. The percentage of panelists who labeled the juices with “dislike” varied from 8% (peach juice with sucrose) to 4% (apple juice with sucrose).

Table 1. Hedonic judgment of the juices manufactured with and without stevia

Hedonic judgment		**Apple juice**	**Apple juice with stevia**	**Peach juice**	**Peach juice with stevia**
Nr.	Attribute	Panelists (%)			
1	Dislike	4	7	8	17
2	Neither like nor dislike	7	21	15	37
3	Like slightly	20	18	28	19
4	Like moderately	36	29	27	17
5	Like very much	32	25	22	10

CONCLUSIONS

The interest in natural sweeteners has significantly increased over the last decade.
The stevia-based juices manufactured at industrial scale were evaluated using descriptive sensory analysis. The overall acceptance of the juices was tested by consumer panelists according to the 5-point hedonic scale. Apple juice containing stevioside was accepted by the panelists while they were reluctant towards peach juice with stevioside.
The future work should be also focused on educating the consumers on the health benefits of this sweetener.

ABSTRACT: Wine varietal aroma is one of the most important parameters of sensory quality and it is influenced by vintage, temperature and volume of alcoholic fermentation and several other vitivinicultural practices. In recent years the importance of yeast starter culture used for alcoholic fermentation has been highlighted. The aim of the present study was to investigate the influence of three commercial wine yeast starter cultures on aroma and chemical composition of Sauvignon Blanc wine together with three different fermentation volumes and two fermentation temperatures. The main chemical parameters, volatile thiols (GC-MS), metoxypyrazines (HS-SPME GC-MS), glutathione (HPLC-FLD) and hydroxycinnamic acids (HPLC-DAD) were determined in produced young wines. Sensorial evaluation of young wines was also performed. The results showed significant differences in the concentrations of some measured parameters and in the sensorial quality of the wines with regard to the yeast strain, volume and temperature of the alcoholic fermentations. It can be concluded that all three parameters could be an important tool for producing wines with enhanced varietal aroma and better overall quality.
Key words: *oenology, wine, Sauvignon Blanc, yeast starter culture, alcoholic fermentation, sensory quality*

INTRODUCTION

Sauvignon Blanc is a wine variety with numerous precursors for aromatic compounds, which define its typical varietal aroma. One of important aromatic compounds in Sauvignon Blanc wine are volatile thiols with tropical fruity aroma, reminiscent of passion fruit, grape fruit, mango and such. The most important volatile thiols in wine are 4-mercapto-4-methylpentan-2-one (4MMP), 3-mercaptohexan-1-ol (3MH) and 3-mercaptohexyl acetate (3MHA). They possess a very strong aroma with perception thresholds low as 3 ng/l for 4MMP, 60 ng/l for 3MH and 4 ng/l for 3MHA. Usual contents of volatile thiols in Sauvignon Blanc wines are 4-40 ng/l of 4MMP, 200-5000 ng/l of 3MH and 0-500 ng/l of 3MHA (Tominaga et al., 1998). Grape must contains non-volatile, non-aromatic precursors for volatile thiols 4MMP and 3MHA, which are released to become volatile during alcoholic fermentation with yeast enzyme lyase (Darriet et al., 1995). Volatile thiol 3MHA is formed from 3MH through the action of the yeast ester forming enzyme, alcohol acetyl transferase. Different yeast strains have a different ability to release volatile thiols 4MMP and 3MH from grape must and to convert 3MH into 3MHA, which is of great importance for wine sensory quality (Swiegers et al., 2006, 2009). Studies have shown that higher fermentation temperatures can increase content of volatile thiols in wine (Masneuf-Pomaréde et al., 2006).
Another important varietal aromatic compound of Sauvignon Blanc wine is the group of methoxypyrazines, which are responsible for the green character of wines produced in cooler climates. The most important methoxypyrazines in must and wine, deriving from grapes, are 3-isobutyl-2-methoxypyrazine (IBMP) and 3-isopropyl-2-methoxypyrazine (IPMP). Their content in must and wine mostly depends of vitification factors and vintage. In concentration around their perception threshold (2 ng/l for IBMP) they have a positive contribution to varietal aroma and complexity of wine (Lacey et al., 1991).
Glutathione (GSH) (γ-L-glutamyl-L-cysteinylglycine) is one of the most important antioxidants in wine, since it protects it from oxidation and by that prolongs its shelf life and preserves its aromatic potential (Rollini and Manzoni, 2006). Content of GSH in wine is largely dependent

of its content in grapes and the way of pressing the grapes, but in recent years numerous studies confirmed the importance of yeast strain used for fermentation on content of GSH (Du Toit, 2007). At the beginning of fermentation the content of GSH decreases, because yeasts are using it as a nitrogen source. Towards the end of fermentation and in the first few months of wine maturing on lees, the GSH is released back into the wine with yeast autolysis (Dubourdieu and Lavigne-Cruege, 2004). Selection of appropriate yeast strain for fermentation therefore greatly influences the final content of GSH in wine, as different strains have different ability to preserve, synthesize and release GSH (Du Toit, 2007; Lavigne et al., 2007).
The aim of the presented study was to investigate the influence of yeast strains, volume and fermentation temperature on chemical, aromatic and antioxidative composition of Sauvignon Blanc wine and on sensory quality as well.

MATERIAL AND METHODS

Sauvignon Blanc grape must was obtained from a winery in Podravje winegrowing region of Slovenia, where grapes were destemmed, crushed and pressed in inert atmosphere. Grape juice was settled over the night at 6 °C, without any further treatments. Must was divided into 25, 35 and 2500 l tanks as shown in Figure 1. Two fermentation temperatures were used – optimal (adjusted) temperature of each yeast strain and the temperature of the cellar itself. The two experiments (first in 35 l tanks and second in 2500 l and 25 l tanks) were held in two cellars. Wine yeast strains (starters), used in this study, are listed in Table 1.

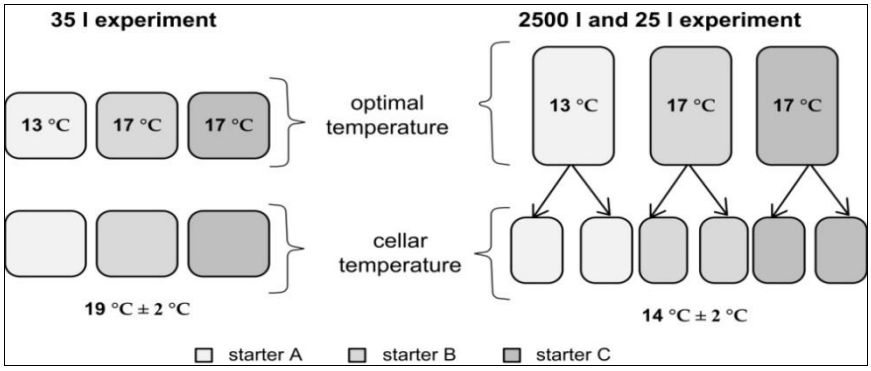

Figure 1. The schematic presentation of the experimental design

Table 1. Yeast strains used in this study

Starter culture	Commercial name of the yeast strain	Yeast strain	Producer	Dosage (g/l)
A	VIN 7 Lalvin QA23®	*S. cerevisiae* *S. bayanus*	Anchor Yeast, Cape Town, South Africa Lallemand S.A., France	0.15 + 0.15
B	Level2™ TD	*T. delbrueckii* (1st level) *S. cerevisiae* (2nd level)	Lallemand S.A., France	0.25 + 0.25
C	Exotics SPH	*S. cerevisiae*/ *S. paradoxus*	Anchor Yeast, Cape Town, South Africa	0.30

After alcoholic fermentation no fining was performed on young wines, the samples were taken from the tanks and stored in a freezer at -20 °C. In those samples the concentrations of volatile thiols, metoxypyrazines, and hydroxycinnamic acids were determined within 6 months. The determination of the main chemical parameters and glutathione was performed immediately after alcoholic fermentation. After sampling wines were racked with addition of SO_2 in concentration of 50 mg/l.

Determination of main chemical parameters
The main chemical parameters in wine (reducing sugars, alcohol, total acidity, volatile acidity and pH value) are determined by the recommended methods of European Union (Commission regulation (EEC) 2676/90 and Commission regulation (EC) 355/2005).

Determination of glutathione content
The determination of glutathione content in wine was done by the method described in Janeš et al. (2010). An Agilent 1200 Series HPLC with fluorescence detector and high-performance auto sampler for on-line derivatization controlled by Agilent Chemstation Rev. B.03.01 from Agilent Technologies (Palo Alto, CA, USA) was used for glutathione detection and quantification. Separation was performed at 25 °C using a Synergi Fusion-RP 80A column (4 µm, 150 mm × 2.0 mm i.d.) from Phenomenex (Torrance, CA, USA).

Determination of hydroxycinnamic acids
The determination of hydroxycinnamic acids content in wine was done by the method described in Vanzo et al. (2007). An Agilent 1100 HPLC with DAD connected to an Agilent NDS ChemStation (Agilent Technologies, Palo Alto, USA) was used for hydroxycinnamic acids detection and quantification. Separation was performed using an ODS Hypersil C18 column 2.1x250 mm (5 µm) with an ODS Hypersil guard column 2.1 × 20 mm (5 µm) (Agilent Technologies, Palo Alto, USA).

Determination of methoxypyrazines
The determination of methoxypyrazines IBMP and IPMP in wine was performed using modified and optimized method by Parr et al. (2007) described in Lisjak et al. (2011). A headspace solid phase microextraction (HS-SPME) with gas chromatography and mass spectrometry (GC-MS) was used for methoxypyrazines detection and quantification. Extraction was performed using divinylbenzene/carboxen/polydimethylsiloxane (DVB/CAR/PDMS) fiber. Separation was performed using series of columns HP-1MS and HP-INNOWAX (Agilent Technologies, Palo Alto, CA, USA) and the detection was done using mass spectrometer with selective ion monitoring mode.

Determination of volatile thiols
The determination of volatile thiols 4MMP, 3MH and 3MHA was in wine was performed using modified and optimized method by Tominaga et al. (1998) described in Lisjak et al. (2011). A GC-MS was used for volatile thiols detection and quantification. Separation was performed using HP-INNOWAX column (Agilent Technologies, Palo Alto, CA, USA) and the detection was done using mass spectrometer with selective ion monitoring mode.

Sensory evaluation of young wines
Sensory evaluation of young wines was made two months after end of alcoholic fermentation with a group of five experts who are well experienced in wine evaluation. Wines were coded and served at 12 ºC. An evaluation test (0-5 points) was used for the following attributes: tropical fruity flavour, green pepper flavour, fermentation flavour and overall quality.

RESULTS AND DISCUSSION

Basic chemical parameters of young wines as well as content of glutathione, hydroxycinnamic acids and methoxypyrazines are presented in Table 2. It can be seen that the reducing sugars content did not differ much between wines, with the exception of wines fermented with starter C, which had the highest content in almost all cases. There were no differences between wines in alcohol content and pH value. Wines fermented with starter A had the highest contents of total and volatile acidity in all cases, while the lowest content of volatile acidity was determined in wines fermented with starter B. Fermentation with starter A at higher (cellar) fermentation temperature and smaller volume resulted with an increase in wine volatile acidity.

Table 2. Main chemical parameters and glutathione (GSH), hydroxycinnamic acids (HCA) and methoxypyrazines (IBMP and IPMP) content in young wines

Volume	**35 l**						**2500 l**			**25 l**		
	Yeast strain/combination											
	A	**A***	**B**	**B***	**C**	**C***	**A**	**B**	**C**	**A***	**B***	**C***

IPMP (ng/l)							nd	nd	nd	nd	nd	nd

**denotes cellar fermentation temperature. Results for 25 L volume are given as mean (n=2); nd – not detected*

The content of GSH was the highest in wines fermented with starter B in all cases, which might be a contribution of a non-*Saccharomyces* yeast strain in the starter culture B. The lowest contents of GSH were determined in wines fermented with starter C. Higher GSH content was determined in wines fermented at optimal temperature and in a larger volume. On the contrary higher hydroxycinnamic acids (HCA) content was determined in wines fermented at higher fermentation temperature and smaller volume. Also in most cases wines fermented with starter C again had the lowest content of HCA.
The concentration of methoxypyrazine IPMP was below the limit of quantification (1.6 ng/l) in all investigated wines. Higher contents of methoxypyrazine IBMP were determined in wines fermented in smaller volume at higher temperature. Yeast starter cultures did not affect on the content of methoxypyrazines.

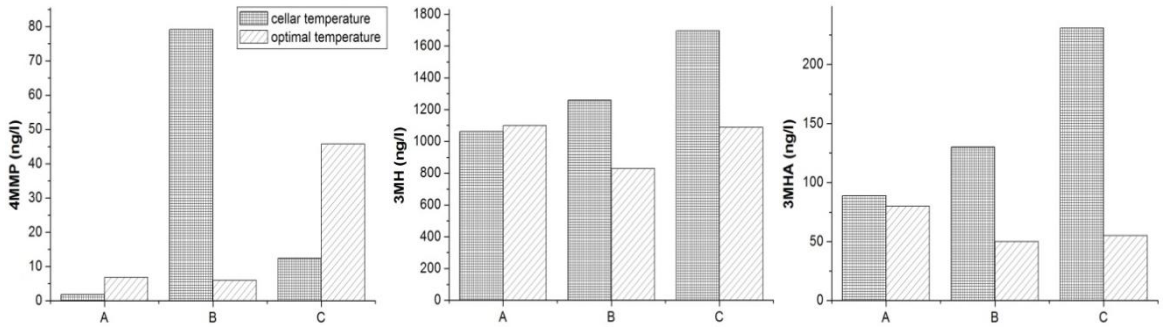

Figure 2. Content of volatile thiols (4MMP, 3MH and 3MHA) in young wines, produced by different yeast starter cultures (A, B, C) and different fermentation temperature in 35 l tanks

Fermentation temperature greatly influenced the content of volatile thiols in produced young wines (Figure 2). Lower temperatures increased the content of 4MMP in wines fermented with starter A and C, while wines fermented with starter B had an extremely high

concentration of 4MMP at higher temperature. Higher temperature also resulted in increase of 3MH and 3MHA in almost all cases, especially in wines fermented with starter C with the highest concentration of mentioned thiols. Fermentation temperature itself had the least influence on volatile thiols in wines fermented with starter A. At optimal temperature wines fermented with starter A had the highest contents of 3MH and 3MHA, while wines fermented with starter C had the highest contents of 4MMP. The conversion rate of 3MH into 3MHA was higher at higher fermentation temperature, especially in the case of starter C. At optimal temperature starter A had the highest conversion rate of 3MH into 3MHA.

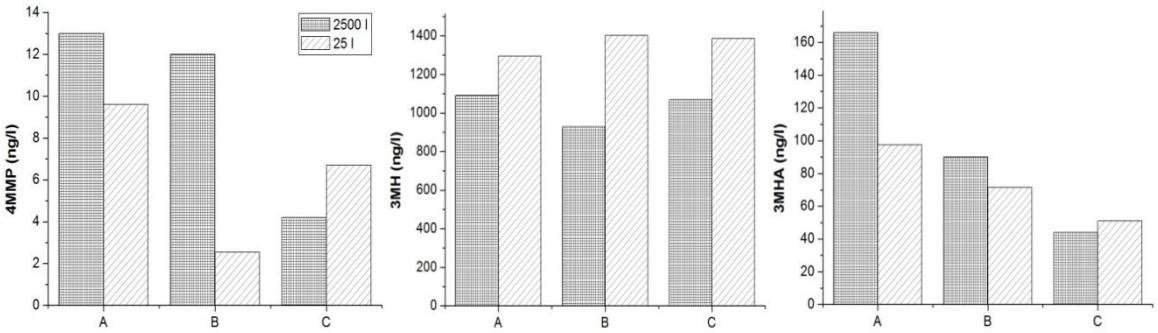

Figure 3. Content of volatile thiols (4MMP, 3MH and 3MHA) in young wines, produced by different yeast starter cultures (A, B, C), in different fermentation volume and at different fermentation temperature (2500 l tanks - optimal temperature, 25 l tanks - cellar temperature).

Influence of volume of alcoholic fermentation on content of volatile thiols is shown in Figure 3. Larger fermentation volumes resulted in higher contents of 4MMP and 3HA in wines fermented with starters A and B, while the fermentation with starter C in larger volume had the opposite effect. On the other hand, smaller fermentation volumes resulted in higher content of 3MH in all cases. In larger fermentation volumes wines fermented with starter A had the highest contents of all three volatile thiols, while the lowest contents of 4MMP and 3MHA were detected in wines fermented with starter C. In smaller fermentation volumes again wines fermented with starter A had the highest contents of 4MMP and 3MHA, but in this case the smallest content of 3MH.

Sensory analysis performed on wines fermented in 35 l tanks showed that higher fermentation temperature resulted in wines with lower ratings of all evaluated sensory attributes. Between wines, fermented at optimal temperature, the once fermented with starter A were rated the highest for attributes tropical fruity flavour and fermentation flavour. The highest rated for attribute overall quality were wines fermented with starter B. In the case of wines, fermented in 2500 l, wines fermented with starter A were again rated highest for attributes tropical fruity flavour, fermentation flavour and overall quality, while attribute green pepper flavour was rated highest in wines fermented with starter B. On the other hand, wines fermented in 25 l were relatively similarly ranked for evaluated sensory attributes. With a small difference, wines fermented with starter C were ranked highest in all evaluated sensory attributes.

CONCLUSIONS

As different fermentation parameters did not influence much on basic chemical parameters, with the exception of higher volatile acidity in wines fermented with starter A, they had a greater impact on varietal aroma and antioxidative state of wine in terms of GSH and HCA content. The content of volatile thiols and GSH in wines varied greatly in dependence of the used yeast strain, which also reflected on sensory quality of wine that was in general the best in wines fermented with starter A. Higher fermentation temperature resulted in higher content of volatile thiols, but lower content of GSH, which led to lower sensory quality of wines due to oxidation. Larger volume of fermentation generally resulted in higher content of volatile thiols (4MMP, 3MHA) and GSH, but lower content of methoxypyrazine IBMP. It can be concluded

that yeast starter culture, volume and fermentation temperature have an influence on wine varietal and fermentation aroma and therefore on overall wine quality.

ABSTRACT: The aim of this paper was to give an overview of up-to-date papers covering sensory evaluation and consumer preference research that can form a basis for user-oriented food product development in Small and Medium Enterprises (SMEs). The paper points out the most important factors with impact on food products fail, that may arise as a consequence of not matching consumers' needs. Collecting of appropriate information concerning consumers' needs and expectations are essential requirements of a consumer-oriented product development. Consumer's sensory tests can provide sensory information related to food product quality and consumers preference, useful and important for product quality control and improvement. The elements with impact on consumers' food products preferences are identified and discussed. Success and survival of SMEs on the market could be expected if producers identify and satisfy current and future needs of consumers. Management and policy makers of the enterprise should support development and implementing sensory programs within an enterprise, and use it as a tool for ensuring quality of product and competitive food manufacturing. Consumer-oriented food product development should be considered as a tool for building competitive advantage and long-term enterprise success in the market and for prevention of negative changes in product quality and acceptability, consumers' complaints and product rejection.
Keywords: *food product development, sensory evaluation, consumers*

INTRODUCTION

Small and Medium Enterprises (SMEs) are an important contributor to growth and employment in the European Union, and they are much greater in number than large companies. Enterprises face the challenge of being competitive on a global scale and SMEs continue to face with limited capacity to expand to markets beyond their home country (Commission Recommendation 2003/361/EC; European Commission Proposal, 2011/0394 COD). SMEs are often said to be responsible for driving innovation and competition in many economic sectors. As major factors that distinguish the SMEs as growers and non-growers Hansen and Hamilton (2011) emphasize: their opportunistic perceptions of the environment; controlled growth ambition within their own needs and financial, intellectual or personal capabilities; a developed culture of innovation referring to new ways of doing things commonly associated with new products or processes; flexibility that refers to agile approaches to products, product markets and customer services; and use of extensive private business networks. SME performance is directly associated with and affected by the procurement system, by logistics, and particularly by the general attitude and behaviour adopted by enterprises towards their customers and suppliers (Orfanos et al., 2010). Considering the effect of various management practices on performance of small business enterprises in manufacturing industry Gadenne (1998) found that small retail and manufacturing firms may be able to successfully compete in the open marketplace with good quality, pricing products lower than competitors, acquiring knowledge of competitors' activities, and with better customer relations.
Most SMEs play a key role as innovators in EU economy, although they are not exercising research and development activities, as officially defined. Innovation in SMEs relies to a large extent on qualified entrepreneurs and employees and on cooperation with suppliers

and customers (UEAPME, 2009). The economic success of the food processing enterprises in a competitive environment depends on their capability to improve their products, identify and satisfy consumers' requirements (Grunert et al., 2008; van Trijp and van Kleef, 2008). Transformative consumer research is studying the role that consumption plays in the major social problems of our day, with the goal to do practical research that can be used by consumers' activists, policy makers and businesses to improve consumer well-being (Ozanne et al., 2011). Nowadays consumers' requirements regarding food products are more diverse than ever before, thus challenging the producers to design and produce food products that are perfectly tuned to the wishes of individual consumers (Benner et al., 2003). For SMEs is very important to assess its strategic position, challenges and to identify opportunities performing continuous improvement of user-oriented product quality, food product development, increasing productivity and competitiveness and staying in a mature market.

The aim of this paper was to give an overview of up-to-date papers covering sensory evaluation and consumer preference research that can form a basis for user-oriented food product development in SMEs. The paper points out the most important factors with impact on food products fail, that may arise as a consequence of not matching consumers' needs. The paper is organized as follows. First, an overview of up-to-date papers covering sensory evaluation and consumer preference research has been given. Second part of the paper offers a brief review of the literature related to the food product development, with impact on activities which SME should assess for improving current methods and practices in a consumer-oriented food production and products fail prevention. Third part of the paper emphasizes importance of the food product quality control and quality control sensory programs implementing, as a tool for ensuring high and consistent quality of final products and competitive food manufacturing in SME. Finally, some conclusions are provided.

Sensory evaluation and consumers' research

Collecting of appropriate information concerning consumers' needs and expectations are essential requirements of a consumer-oriented product development. Researches on consumer behaviour, demand, expectations and consumption of food generally are important the same as analysis and understanding of consumer preferences (Van Kleef *et al.*, 2006; Gielens and Steenkamp, 2007; Miljkovic and Effertz, 2010). The key determinant of success in product development is the degree to which a product coincides with consumer needs and expectations (Sijtsema *et al*., 2004; Bahamonde et al., 2007). Consumer's sensory tests can provide sensory information related to food product quality and consumers preference, useful and important for product development and quality control.

The areas or growth and opportunities for improvement companies' success in the market include awareness of the importance and support for quality control sensory programs within an organization and involvement of sensory scientists in it (Munoz, 2002; Moskowitz et al., 2006). Adequate information exchange throughout the complete food production chain is a vital element in the realisation of an efficient and effective product development process in SMEs. The sources of information and knowledge, mostly used for innovative ideas by SME in the food area, are in their direct surroundings (Benner et al., 2003).

Food producers must know that consumers have concerns about influence of the foods they eat on their health. Their personal values, especially those related to sensory quality characteristics and nature of food may be strong predictors of consumers' concerns about food preference, acceptability and choice (Linnemann *et al.*, 2006; Worsley and Lea, 2008). A range of factors have influence on special categories of consumers or children, youth and teen population lifestyles, food choice and diets (Pescud and Pettigrew, 2010; Roberts and Pettigrew, 2010; Luchs et al., 2011; Mason et al., 2011). The visual design parameters should be considered in the food product development process. The packaging colour and shape may influence food product quality evaluations. Package appearance is important, it may be specifically designed with particular symbolic meanings, related to the selected sensory properties and impact on overall product evaluations and price expectations (Becker et al., 2011).

Consumer-oriented products have to deliver nutrition performance, function, convenience, but most importantly, sensory characteristics related to the product acceptability (Moskowitz and Hartmann, 2008). A quality control function is an operation closely aligned with the food manufacturing process, with emphasis mainly on instrumental and chemical analyses. Most companies have well defined and established quality control programs, but no quality control sensory programs. The quality of food products is correlated with their sensory properties, and implementing quality control sensory program may have a vital role in the consumer-oriented food production (Munoz, 2002). The experienced specialists in sensory analysis and quality control, with strong personal networks can play a fundamental role in supporting SMEs, creating stable and continuing relations communicating between SMEs and universities, institutions and science laboratories.

Food product development

Small and Medium Enterprises (SMEs) were important developers of radical innovations (Massa and Testa, 2008). Enterprise should assess its current situation and implement new or improve current methods and practices. Food product development is a continuous process that is of great concern to producers, because of the fact that tomorrow's consumers needs are changing with time and they may not want the products that were in great demand yesterday (Costa and Jongen, 2006; Linnemann *et al.*, 2006; Grujić and Cantalejo, 2009).

Small enterprise may achieve long-term survival through timely strategic and management changes, encouraging close relationships among core shareholders and core customers (Ng and Keasey, 2010). In food product development, SME should established food quality and sensory standards and incorporate it in specifications for final products QC. It should include results of consumers' preference research. Food product development process in SMEs can use available external sources of inputs and expertise from suppliers, research institutes, universities, partner companies, and customers.

Innovation and product developments in SMEs are permanent process driven by small entrepreneurs and their staff. These kinds of activities include new and improved products, new processes, new markets and management concepts and play an important role for economic growth. New food products often fail, because they are not designed according to consumers' wishes or not produced efficiently. SMEs need qualified staff or adequate support services to design and handle products development projects, especially if bigger changes in production process are involved. That could be solved using external sources of expertise from research institutes, universities and customers. The reasons for the low innovation rate in the food industry are numerous. The qualitative customer requirements should be translated into design parameters of the product during development process. Parameters are measurable attributes and quality determinants of the food product. The approach of Mattsson and Helmersson (2007) illustrated a method to cluster consumer attribute preferences and to transform that text about certain food product, spontaneously written by consumers, in directions for work on food product development. In order to reach a stage of sustainable development, firms need crucial resources, such as a large enough market, an accepted product or service, purchasing customers and a supportive network. Furthermore, the firm has to be able to utilize these resources in a satisfactory way that is, through its motivation, competence and organization (Norrman and Bager-Sjögren, 2010). Each of mentioned factors have role in matching consumers' needs and impact on food products success or fail.

Quality of food product as competitive advantage

Many SMEs are facing with lack of capacity, human and financial sources for food product development, but consumers require and expect quality and safety of food products in the market (Costa and Jongen, 2006; Mattsson and Helmersson, 2007; Grujić and Cantalejo, 2009; Pescud and Pettigrew, 2010). Most companies have well defined and established quality assurance and quality control programs to pursue and maintain the products' quality and prevent negative changes in product quality, consumers' complaints or product rejection. The emphasis is mainly on instrumental and chemical analyses, many enterprises have

some type of quality control sensory programs, but only a few have sound quality control sensory programs (Munoz, 2002). Management and policy makers of the enterprise should support development and implementing sensory programs within an enterprise, and use it as a tool for ensuring high and consistent quality of final products and competitive food manufacturing.
The research work of Arulselvan et al. (2008) provides a practical approach for classify food industry products, to understand characteristics of the food industries and structure of the food industry market. Success and survival of SMEs could be expected if producers identify and satisfy current and future needs of consumers. Status consumption is the consumption of goods for displaying status. It could be used as quality characteristic for products development, s obzirom na to da as modern status orientation has a positive impact on status consumption and satisfaction with life in general (Nguyen and Siok, 2011).
The success of a product is determined by the profit a company and by selling the product (Benner et al., 2003). For the products survival on the market, the consumers have to buy the product once, and if it fulfils certain expectations they will buy it again. The product also has to be better in fulfilling these requirements than similar products available on the market.

CONCLUSIONS

Success and survival of SMEs on the market could be expected if producers identify and satisfy current and future needs of consumers. Collecting of appropriate information concerning consumers' needs and expectations are essential requirements of a consumer-oriented product development. Consumer's sensory tests can provide sensory information related to food product quality and consumers preference, useful and important for product development and quality control. Management and policy makers of the enterprise should support development and implementing sensory programs within an enterprise, and use it as a tool for ensuring quality of product and competitive food manufacturing. Consumer-oriented food product development should be considered as a tool for building competitive advantage and long-term enterprise success in the market and for prevention of negative changes in product quality and acceptability, consumers' complaints and product rejection.

ABSTRACT: Food product quality and stability during storage is very important for the successful manufacturing. It is known that different factors during processing have impact on quality characteristics of final product. The aim of the study was to investigate influence of selected food additives with antioxidant and stabilising functional characteristics on quality of finely comminuted boiled chicken sausages "parizer" type, during storage. Samples were produced in industrial conditions, five experimental model samples with selected additive blends added separately to each: (a) 0.04% GUARDIAN Rosemary Extract 08 (Natural rosemary extract, E471, E472a, E1520); (b) 0.10% (based on the fat content) GRINDOX 539 Antioxidant (E304, E306, E322, rapeseed oil); (c) 0.30% GRINDSTED Carrageenan CC 310 (E407, E410); (d) 0.30% GRINDSTED MEATLINE 345 A Emulsifier and Stabiliser System (E401, E516, E470a, E450); (e) 0.30% GRINDSTED MEATLINE 333 Stabiliser System (Carob germ flour, E466) and (f) control sample, according to the producer's specification. The samples had adequate chemical composition. Sensory evaluation of selected sensory characteristics was done 7 days and 35 days after samples production: (1) by the descriptive sensory analysis - scoring method, and (2) by discriminatory sensory analysis - ranking method, after assessment and comparison of the overall quality of sausages model samples. The results of the sensory analysis indicated differences between model samples dependent on added additives. On the basis of descriptive sensory evaluation results, it was found that the best quality of compared had sausage sample produced with addition 0.30% GRINDSTED MEATLINE 345 A Emulsifier and Stabiliser System (E401, E516, E470a, E450). Discriminatory sensory analysis – ranking confirmed that finding.
Key words*: sensory analysis, chicken sausages, quality*

INTRODUCTION

Food industry has an important position in the processing industry, especially when we talk on the manufacturing of meat products. Meat and meat products are very important ingredients in human nutrition because they are an excellent source of protein with a well-balanced composition of amino acids, B vitamins and mineral components (Borowski, 2007).The most important tasks of meat industry include the development of products that identify and satisfy consumer needs and expectations and have relatively long shelf life.
Quality control is an essential component of any food processing business. Accurate and objective chemical and physical methods should be used in the food quality control, but despite of progress in this area, the human senses are still more efficient than instrumental methods in evaluation of flavour and texture, and provide more rapid responses. The reliability of information obtained through the human senses can be increased by selection and training of assessors, providing suitable environment for evaluation, and using appropriate testing procedures. Therefore, sensory evaluation should be an integral part of product quality defining and controlling process (Krysztofiak, 2005; Savanović and Grujić, 2008; Vasilev et al, 2011). The importance of sensory analysis is great and it is applicable in different areas: for improve quality of the products throughout the development process, for describe products sensory characteristics and for comparing products with competitors' products (Leppard et al., 2004; Živković et al, 2011; Maughan et al., 2012). Methods of sensory evaluation are unavoidable and applied for development of meat products and as tool for detailed sensory characteristics describing. Assessors have to be tested and trained

according to the standard methods (ISO 8586-1:1993). In such cases, during realisation of sausages quality improvement process, different aspects of sensory evaluations are considered, using visual, olfactory, gustatory and palpatory techniques that enable detailed judgment of particular quality characteristics (Leppard et al., 2004; Giboreau et al., 2007; Savanović and Grujić, 2008). That approach could create a base for designing of model for products quality improvement in the meat industry.

Today the market offers a large number of meat products from the category of boiled sausages. All generations of consumers like to eat and appreciate quality of finely comminuted boiled chicken sausages "parizer" type as they have pleasant and mild flavour. It is known that different factors during processing have impact on quality characteristics of final product. Product quality could be defined in many ways. For sensory quality of parizer, important attributes are: outside appearance, cross section appearance, colour of cross section, smell, aroma and taste, and consistency (Savanović and Grujić, 2008). Sensory characteristics of sausages depend on the type of meat, ways and length of storage of meat, then the aroma and chemical composition of meats, as well as used additives and spices (Bilska, 2007; Grujić et al., 2008). In aim to improve the quality of meat products various food additives can be used (Serdaroglu and Yildiz-Turp, 2004; Bilska, 2007; Hong et al., 2008; Garcıa-Garcıa and Totosaus, 2008).

The aim of the study was to investigate influence of selected food additives with antioxidant and stabilising functional characteristics on quality of finely comminuted boiled chicken sausages "parizer" type, during storage.

MATERIAL AND METHODS

Boiled chicken sausages "parizer" type, were used as a model-product in the experiment. Samples were produced in industrial conditions according to the producer's specification. The following ingredients were used (percentage shown in descending order): mechanically deboned chicken meat (60%), lean chicken meat (15%), vegetable oil, water, salt, isolated soy protein, dextrose, spices, stabilizers, antioxidants, flavour enhancer, preservative. Five experimental samples were produced with selected additives added separately to each (Table 1). The sixth model-sample (P6) is produced according to the manufacturer's recipe and it was also used as a control sample. Sausages were packed in tight artificial casings (diameter 60 mm; average mass of sausage pieces was 500g) and after heat treatment were chilled and labelled appropriately. Until the moment of test samples were stored in a dark and cold place, at +4°C to +8°C.

GRINDSTED MEATLINE 333 Stabiliser System (Carob germ flour, E466)	-	-	-	-	0.30	-

** - quantity expressed based on the amount of fat in the finished product*

Analysis of chemical composition was carried out in Laboratory for food analysis on Faculty of Technology, University of Banja Luka. The following parameters were determined according to AOAC (2006) procedures: moisture content (drying at 105 °C to constant mass),

the fat content (according to the Soxhlet method), protein content (according to the Kjeldahl method), the content of sodium- chloride (according to the Mohr method), and the content of nitrite (expressed as $NaNO_2$, according to the method ISO: 2918:1975), the content of phosphates (expressed as P_2O_5, according to the spectrophotometric method ISO: 13730:1996).

Individual sensory evaluation was carried out by 10 trained assessors (ISO 8586-1:1993), in the Laboratory for sensory analysis of food on Faculty of Technology, University of Banja Luka, 7 and 35 days after production. Six labelled different model samples (five samples in which selected additives were added and the sixth control sample) were twice delivered to assessors during the sensory analysis. Water and cubes of white bread were served to assessors for cleaning the mouth between samples evaluation. Descriptive sensory analysis - scoring method, and discriminatory sensory analysis - ranking method were used for evaluation of sausages quality.

In initial preparation of sausages sensory evaluation by the scoring method (ISO 4121:2003; Radovanović and Popov-Raljić, 2001), coefficient of significance (Cs) was determined for each selected sensory attribute (sum of them are 20). Appropriate Cs was multiplied with score given after sensory evaluation of each selected attribute (in scale from 5 for very good quality, to 1 for very bad quality). Addition of all results of evaluated sensory attributes multiplied with Cs, gives overall score, expressed as percentage of maximum possible products quality, or 100% for the best quality. For boiled sausages the most important sensory attributes were evaluated: odour, aroma and taste (Cs=6), colour of cross section and consistency (Cs=4), outside appearance and cross section appearance (Cs=3). The scoring forms with description of the sensory attributes and possible defects for each quality level were delivered to the assessors (Grujić et al., 2008; Savanović and Grujić, 2008).

Discriminatory sensory analysis – ranking of six model samples of sausages were realised on the basis of to the 20 judgements of overall acceptability: the most acceptable (on the first place), the least acceptable (on the last place). The rank sums were determined and statistical comparisons (α=0.05) were carried out by the Friedman test (ISO 8587:2006) for demonstrating and recognition by assessors differences among evaluated samples.

RESULTS AND DISCUSSION

The average chemical composition of the tested sausage samples is shown in the Table 2. The content of the tested compounds in all samples were in accordance with the requirements defined by the Regulation on the quality of poultry meat products (Official Journal SFRJ No. 55/91), valid in Bosnia and Herzegovina, where production was realized.

Table 2. The average chemical composition of the boiled chicken sausages

	Sausages sample code					
	P1	**P2**	**P3**	**P4**	**P5**	**P6**
Moisture (%)	58.61	58.50	58.06	57.65	58.71	58.07
Fat (%)	20.12	21.03	18.49	17.87	17.36	19.23
Proteins (%)	16.09	15.51	15.89	15.40	15.66	15.71
NaCl (%)	2.64	2.45	2.49	2.31	2.43	2.57
Phosphate (P_2O_5) (%)	0.29	0.27	0.29	0.28	0.29	0.27
Nitrite (mg/100g)	0.025	0.024	0.021	0.025	0.026	0.027

The results of the sensory analysis indicated differences between model samples depending on added additives. Outside appearance of all six chicken sausage samples were on acceptable quality level, without any noticeable defects (Table 3). Selected food additives with antioxidant functional characteristics had positive impact on colour of finely comminuted boiled chicken sausages “parizer” type during storage. After 7 days of storage it was found that between produced samples the most acceptable colour score (4.70) had sample P1, produced with addition of natural rosemary extract, and after 35 days of storage the most acceptable colour score (4.85) had sample P2, produced with addition of ascorbyl palmitate

and tocopherols (Table 3). These results are in agreement with previously published papers, confirming the positive effect of antioxidants on colour stability of meat products (Serdaroglu and Yildiz-Turp, 2004; Bilska, 2007; Mancini et al., 2007).
The scores for evaluation of the cross section appearance of sausage samples were relatively lower than expected. Partial annular layers of colour shade and larger pieces of ingredients were observed at the cross section of some sausage samples, and affected sensory scores, as shown in Table 3. That did not significantly affect on the overall acceptability of the product, but it is more pleasant to eat particles of sausages ingredients of uniform size. For cross section appearance, after 7 days of storage, scores were from 4.55 for P3 sample, to 3.85 for P5 sample. Similar average values of these quality characteristic were assigned after 35 days of storage (Table 3).

Table 3. Results of the descriptive sensory evaluation for the boiled chicken sausages

		Average scores for quality parameters (n=20 assessments)					
Sample code	**Storage time (days)**	**Outside appearance (Cs=3)**	**Cross section appearance (Cs=3)**	**Colour of cross section (Cs=4)**	**Odour, aroma and taste (Cs=6)**	**Consistency (Cs=4)**	**Evaluated overall quality* (%)**

P6	35	5.00	4.65	4.45	4.20	3.90	87.55

*Cs – coefficient of significance; * Evaluated quality – percent of maximum possible quality*

Among the many sensory characteristics, the odour and taste sensations take particular place when eating food products. Manufacturing of model chicken sausages samples and a control sample were performed according to the same recipe, from identical basic ingredients, and that results in approximately uniform odour, aroma and taste of all samples (Table 3). Most samples were evaluated by score higher than 4 and with the comment that the aroma of the product were weaker than expected, and odour of fat and other ingredients were slightly more perceptible than it is desirable.
The consistency of processed meat products depends on the structure of the matrix formed by the proteins gel, the solutes and particles entrapped in the gel and the moisture content. Therefore, the matrix forming depends on factors such as protein water binding ability, salt content, pH, fat content and the addition of nonmeat ingredients (Flores et al., 2007). Comparing the consistency of the control sample, and produced models of chicken meat sausages, differences in the structure of the products after 7 days of storage were determined by sensory evaluation. Consistency of control sample was defined as mild finely granular, powdered, with gentle glimpses and hardly noticeable release of fat droplets. Compact mass and chewiness of the control sample were satisfactory. Consistency of samples P1, P2 and P3 were evaluated as appropriately and described as a persistent, slightly elastic-plastic and contents did not release water or fat under pressure (Table 3). The best scores for consistency were assigned to the samples P4 and P5 (Table 3). Consistency of these samples were described as elastic, sausages were sturdy and juicy, connectivity of components were good and compact, chewiness were satisfying, neither too hard nor too soft. Scores of consistency, after 35 days of storage, showed that the control sample P6 produced according to the producer's specification, had the lowest value of the mean score, followed by the sample P1, while samples P3, P4 and P5 produced with additives with of

emulsifying and stabilizing functional properties, were evaluated with the highest scores (Table 3). Hydrocolloids are currently added to meat products to improve cooking yields, increase moisture retention and modify consistency of product (Garcıa-Garcıa and Totosaus, 2008). Many studies have been carried out on these products and their application in comminuted food products. They are added as another gelling system to improve yield, textural properties and also reduce cost of the meat formulation. The addition of potato starch has a positive impact on the consistency, improvement the emulsion stability and reduction the jelly and fat separation in cooked meat products (Flores et al., 2007; Aktas and Genccelep, 2006). Hong et al. (2008) have found that carrageenan and glucono delta lactone (GDL) have high binding characteristics and minimal discoloration of restructured pork, even if a low salt concentration was used. Garcıa-Garcıa and Totosaus (2008) reported that carrageenan-locust bean gum interaction improved texture and water retention, with only a minor effect on sausage colour.

Comparing the overall quality of the produced sausages, expressed as a percentage of the maximum quality, after 7 days of storage was found that the sample P4 had the highest overall quality (91.40%), followed by the sample P3 (89.75%), and the samples P5, P6, P2 and P1 (Table 3). The similar quality of products was evaluated after 35 days of storage. Sausage P4 was the best with 92.50% of the expected overall quality, then the samples P3, P2, P6, P5 and sample P1 with relatively the lowest score (80.05%), as shown in Table 3. It should be noted that all samples had relatively high scores for overall quality and can be characterized as products with very good quality level.

Table 4. Rank sums calculated based on the overall acceptability of boiled chicken sausages

Sample code	Rank sums after 7 days storage	Rank sums after 35 days storage
P1	70	58
P2	85	79
P3	70	80
P4	58	47
P5	73	85
P6	64	71

Ranking is method for discriminatory sensory evaluation with the aim of placing a series of test samples in rank order. Based on the overall acceptability of the sausages model samples ranking were realised after 7 and 35 days of storage, for recognition by assessors of differences among the samples (Table 4). Critical table value for the Friedman test is 10.92, for the 6 samples and 20 judgments (significance level α=0.05). Calculation of the rank sums evaluated after 7 days of samples storage, results in value 5.91 for Friedman test (F_{test}<F) and indicated that there are no statistically significant differences (α=0.05) between compared products. Comparing the rank sums obtained after 7 days of storage showed the lowest value of the rank sums (58) for the sample P4 and that it had the highest quality of compared sausages (Table 4). After 35 days of storage calculated value for Friedman test was 15.43 (F_{test}>F), and it was concluded that there were statistically significant difference (α=0.05) in the quality between compared samples of sausages. After 35 days of storage sample P4 had the rank sums 47 and the best quality comparing to the other samples (Table 4). Sample P4 with modified composition by adding of 0.30% additives blend GRINDSTED MEATLINE 345 A Emulsifier and Stabiliser System (E401, E516, E470a, E450), could be characterised as sausage with the best improved sensory acceptability of the compared.

CONCLUSIONS

Sensory quality characteristics of the finely comminuted boiled chicken sausages “parizer” type depends of method of manufacturing, quality, quantity, chemical composition and aroma of used meat, spices, other ingredients and functional property of food additives. The results of the sensory evaluation of sausages model samples indicated that addition of selected

additives blends could impact on quality and improve overall acceptability of sausages. On the basis of descriptive sensory evaluation results, it was concluded that the best overall quality of compared, had boiled chicken sausage sample produced with addition 0.30% additives blend GRINDSTED MEATLINE 345 A Emulsifier and Stabiliser System (E401, E516, E470a, E450). Discriminatory sensory analysis – ranking based on overall acceptability of the sausages, confirmed that finding.

ABSTRACT: Public perceptions relating to fruit and vegetable as functional foods was investigated using a survey. The cross-relation of their perceptions was examined according to the gender, age and educational level. The main aim was to identify the public acceptance of the concept of functional food as well as possibilities of the marketing in this filed.
In this paper a convenience sample was used and data were collected using a self-administrated questionnaire. The questionnaire was designed to assess opinions and attitudes about consumption and about fruit and vegetables as functional foods. Individuals of both genders (N = 628) aged from 19 to 65 with different education levels were interviewed. Stratification of the units from the sample has been made according to gender, age and educational structure as well as social-economic status of respondents in the sample.
The study showed that over 45.7% of female consumers are familiar with the term functional food which is more than male consumers (36.5%). Results also indicate differences regarding education level and age because the majority of younger consumers with higher education are interested to pay more (34.6%) for vegetables and fruits. The consumers consider as most important the origin (67.5%) of fruits and vegetables and their quality (77.9%). The place of sale and the brand of the product seem not to be as important as expected (49.6%). The opinions are especially divided ($p<0.05$) according age and education level and not to the gender ($p>0.05$). The results have shown that general familiarity with functional food varies systematically as a function of age, gender and education level.
Key words: *vegetable, functional food, consumers*

INTRODUCTION

Food provides essential nutrients for normal function of body, but unbalanced diet over a long time increases the risk of developing nutritional diseases and involves expensive medical treatments. Phrase “functional food” was introduced in Japan (1980s), for food products that were fortified with special constituents with advantageous physiological effects (Wootton-Beard & Ryan, 2011). Numerous study have reaffirmed that functional foods may improve the general conditions of the body (Chen, 2011; Bhat & Bhat, 2011), decrease the risk of some diseases, and could even be used for curing some illnesses (Ngo et al., 2011). It was recognized that there is a demand for these products in all age and gender groups. Functional food products typically include health claims on their label describing their benefits: for example for vegetables: "Vegetable is a significant source of fibre” (JHCI, 2002) which has been proven to provide health benefits over and above basic nutrition (Elleuch et al., 2011). Consequently, the fruit market faces great opportunities. In recent decades, research has confirmed that the consumption of fresh fruit products has a positive effect on a person’s health (WHO, 2003). The World Health Organization (WHO) recommends eating at least 400 g of fruits and vegetables per day (WHO, 2003). National recommendations for fruit and vegetable have adopted similar intake levels throughout the European Union. Examples of these governmental recommendations are five a day campaigns in the UK, Spain and France and two plus two campaign in the Netherlands. However, despite governmental intervention strategies, general fruit consumption in EU countries does not meet the

recommended level. Average consumption of vegetables and fruits in Croatia is 350 grams per day (GfK, 2011), what is under the recommendation.
The inclusion of physiologically active natural components with beneficial effects on health strengthens the nutritional value of fresh vegetables (Sanzana et al., 2011; Wootton-Beard and Ryan, 2011). A health diet should include at least five portions of fruit and vegetables a day according the Food Standards Agency (FSA, 2009) but the majority of the population do not consume the recommended portions for fruit and vegetables (FSA, 2010). Diverse fresh food like vegetable and fruits, convenient, value-added, ''healthy'' food are trends in new lifestyles. Higher incomes and consumer awareness are creating consumer demand for a year-round supply of high quality products (Onwezen and Bartels, 2011).
Responsibility for inadequate daily intake of fruit and vegetables obviously lies with the consumer, but there is also an inherent challenge to the food industry to develop new, exciting and convenient food products to help inspire people to make a positive change to their diet (Wootton-Beard and Ryan, 2011). Fresh fruit and vegetables consumption can lower the risk of diseases such as coronary heart disease and specific types of cancer and are preferable in the human nutrition regarding their richness of antioxidant what is a benefit for the public health. Antioxidants differ in their efficacy against differing substrates; some are potent free radical scavengers whilst others have stronger metal chelation effects (Niki & Noguchi, 2000). It is however widely accepted that many compounds traditionally thought of as antioxidants have important non-antioxidant functions including maintenance of redox balance (Formanet al., 2002; Hensley et al., 2000; Valko et al., 2007). It has been suggested that some molecules which are traditionally thought of as antioxidants (such as polyphenols) may also have pro-oxidant effects in certain issues (Azam et al., 2004).
Main idea of this study was to investigate familiarity with the term functional food and is the vegetable and fruit recognised as functional food.

MATERIAL AND METHODS

This research was conducted in the spring 2010 and the sample frame consisted of participants aged over 18 years (N=628; 45.7% women, 54.3% men) from Croatia (Table 1).

Table 1. Socio-demographic characteristics of the data set

Characteristic		%
Gender		
	Female	45.7
	Male	54.3
Age (y)		
	18-30	50.6
	31-50	39.6
	51-60	9.8
Education level		
	Elementary school	7.3
	High school	56.9
	University degree	37.8
Income		
	< 4.000 kn	16.6
	4.001 – 6.000 kn	29.7
	6.01 – 10.000 kn	33.1
	> 10.000 kn	20.6

1 € = 7.6 kn

Data were collected using a self-administered questionnaire distributed among respondents. The questionnaire included questions about the functional food knowledge, attitudes regarding functional food as well as the socio-demographic variables (Table 1).
From the collected data two different matrices were developed – one for those who know the meaning of functional food and the other one for those that are not familiar with the term

"functional food". From the first matrix (those who are familiar with functional food) were developed two new matrices regarding the (i) vegetable consumption and (ii) fruit consumption.
Data were analysed using SPSS (Statistical Package for Social Science, v.15). The ANOVA (Two-Factor without Replication) was used to determine differences between observed variables. Crosstabs from the descriptive statistics were used to observe interactions for at least 2 variables.

RESULTS AND DISCUSSION

In the total data set, familiarity with the term "functional food" was expressed by 40.7% (N=628) of the participants and almost 52% of them were female consumers. The female consumers were fewer in the total population of participants what is in accordance with previous publications (Markovina et al., 2011; Chen, 2011). Over 42% of interviewed Croatian consumers are familiar with the concept of functional food, what was also observed in other European countries where the familiarity with the term "functional food" is ranged from 25% in United Kingdom, Germany and France to 49 % in Belgium (Annunziata and Vecchio, 2011).
One of the aims was to determine similarities and/or differences in the gender affiliation. According ANOVA, the difference in global perception of functional food is confirmed ($p<0.001$) and is matching with results of the study of Markovina and co-workers (2011). In the paper were also investigated the differences in perception of vegetables and fruits as functional food ($p<0.05$) as well as the influence of the education and income level on the perception which food is concerned as functional food ($p<0.005$).

Table 2. Participants' opinion regarding fruits and vegetables as functional food products

	%		
Characteristic	**Fruits**	**Vegetables**	**Total (fruits & vegetables)**
Gender			
Female	28.3	17.4	45.7
Male	32.0	22.3	54.3
Age (y)			
18-30	34,8	21.2	56,0
31-50	15,1	20.6	35,7
51-60	8.3	4.0	8.3
Education level			
Elementary school	18.7	18.0	36.7
High school	36.1	20.1	56.2
University degree	3.6	3.5	7.1
Income			
< 4.000 kn	10.6	5.9	16.5
4.001 – 6.000 kn	17.3	12.6	29.9
6.001 – 10.000 kn	19,8	13,6	33.4
> 10.000 kn	11.8	8.4	20.2

1 € = 7.6 kn

The results of this study, regarding fruits and vegetables considered as functional food, are in accordance with some studies (Santosa et al., 2010) where was concluded that vegetables and fruits are staple food for most countries in the Mediterranean region (i.e. Spain, Italy, and Greece). Numerous studies have pointed out the health benefits associated with rich intake of vegetables and fruits that helps to lower cardiovascular risk (Martinez-Gonzales et al., 2004) because of their richness in dietary fibres. 39.7% from all participants consider vegetable as food with functional properties what can be related with richness in antioxidants (Forman et al., 2002; Hensley, et al., 2000) or dietary fibres (Elleuch et al, 2011). It is questionable if this attitude is a consequence related to the food choice preferences or to the nutrition richness of food.

Vegetables and fruits are considered as healthy food because this is the food which can deliver natural antioxidants and other bioactive phytochemicals in a small volume but offering a convenient method of consumption and contribute significantly to overall vegetable consumption (Wootton-Beard and Ryan, 2011). Also, high share of fruits and vegetables in the daily food intake may play an early protective role against the development of cardiovascular diseases, (CVD) as a consequence of high amounts of fibers and antioxidants (Thomson et al., 2007).

As expected, higher level of education and higher incomes are critical in classification of fruits and vegetables in the category of functional food. Most informed age group regarding fruits and vegetables as functional food is group from 18-30 years. They are young people on the peak of their working life and it is important for them to take care about their health. Those results are in accordance with those presented by Annunziata and Vecchio (2011) where the functional food users are more often more educated.

The functionality of fruit and vegetable is generally recognized by the consumers. In order to be more familiar with their buying habits the analysis of their place of purchase was tested (Fig. 1) on all age and gender groups as well as in different education and income.

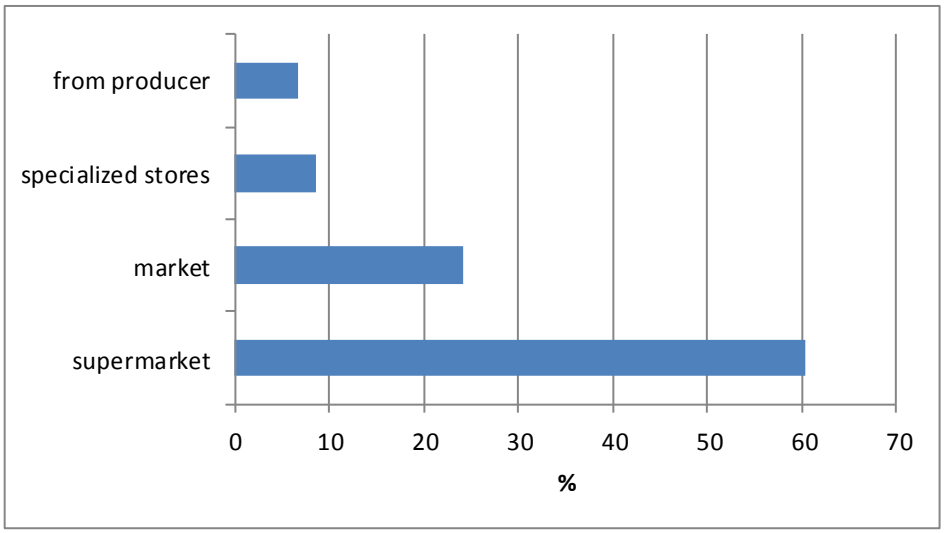

Figure 1. Consumers' preferred places of purchase of vegetables and fruits

The places of purchase of vegetables and fruits are presented in Figure 1, and, as it can be seen, supermarkets have earned the trust of the consumers (60% of the interviewed consumers believes that the vegetable and fruit purchased there has functional properties. 45.3% of buyers are not sure should they pay more for functional food products and that should be a challenge for the producers and industry.

In order to make more detailed analysis of presented result, place of purchase has been additionally analysed according to socio-economic parameters (table 3).

Female consumers are more oriented on buying on the market, specialized stores followed by supermarkets. Opposite of them man chose to by fruit and vegetables (considered as functional food products) direct from the producer (68%), what is also the first choice of those aged 31-50 (48%) and with higher incomes (6.001-10.000 kn) where almost 40% of them would prefer to by direct form the person that has produced the vegetable and fruit considering it that as functional food.

Table 3. Participants' opinion regarding place of purchase and main features of fruits and vegetables.

Characteristic	%						
	Specialized stores	Super-market	Market	From producer	Origin	Brand	Quality
Gender							
Female	55.6	49.1	56.0	32.0	77.1	51.8	65.6
Male	44.4	50.1	44.0	68.0	78.6	49.4	69.2
Age (y)							
18-30	47.4	61.2	52.7	34.0	77.5	43.9	66.5
31-50	40.5	34.9	38.9	48.0	72.9	58.1	67.9
51-60	12.3	4.0	8.4	18.0	92.0	76.0	88.0
Education level							
Elementary school	31.7	36.3	42.3	48.0	76.9	55.8	66.8
High school	66.7	56.3	54.4	47.9	78.4	47.0	68.2
University degree	1.6	7.5	3.3	4.1	79.1	51.2	66.7
Income							
< 4.000 kn	16.7	15.4	15.3	20.8	76.0	48.5	70.0
4.001 – 6.000 kn	16.7	31.5	31.3	22.9	75.4	44.4	67.2
6.001 – 10.000 kn	28.3	31.9	35.8	39.6	80.7	45.5	68.3
> 10.000 kn	38.3	21.2	17.6	16.7	77.2	66.1	63.8

1 € = 7.6 kn

Both genders have considered the origin and the quality as the most important characteristics of fruits and vegetables. This fact is especially evident by the oldest participants (92% for origin and 88% for quality).

CONCLUSIONS

Over 42% of Croatian consumers are familiar with the concept of functional food but the perception of the foods that are considered as food with functional properties differ with the socio-demographic characteristics of the consumers. Female consumers were more familiar with the functionality of food, in general.

Consumers' recognition of fruits (over 51%) and vegetables (42%) in a group of functional foods has differed, especially regarding the education level and age. Presented findings could be an indicator of a successful marketing approach in sale of vegetables and fruits. Majority of the consumers choose fruits and vegetables as a food that will improve their health, especially male consumers (54.3%) aged under 30 (56%), with finished high school (33.4%) and middle (29.9%) or higher incomes (33.4%).

The findings of this work also imply that the impact of the gender, age and education level is not negligible.

ABSTRACT: The association between dietary fibre, health benefits and healthy food has been studied in recent years. The food industry, to accompany the strong interest shown by consumers, has placed at their disposal new products, rich in dietary fibre. In order to meet this huge interest and demand for these products, this work was elaborated, which had as main objective to evaluate the degree of knowledge of the Portuguese population about fibre and its effects on health, as well as evaluating the their consumption habits in respect of fibres. To achieve this goal an inquiry was carried out by questionnaire to 182 adults. The most relevant results indicate that only 13% of the inquired eat two meals a day with vegetables and/or salads and 9% eat at least 3 pieces of fruit. Whole grains are never consumed by 41% and 18% do so at least once a week. The vast majority (90%) of respondents have the notion that fibre intake contributes to the prevention and treatment of diseases. With this work it was concluded that respondents' knowledge about dietary fibre is insufficient, and that although they give great importance to their role in treatment and prevention of diseases, the level of intake is too low.
Key words: *fibre, food habits, fibre intake, fibre rich food*

INTRODUCTION

Food plays an important role in the maintenance of human life by providing the caloric and nutritional elements necessary for the body functions. Among these elements, dietary fiber has attracted great interest in the last decades, having been produced several studies in this area (Kendall *et al.*, 2010). The theme "dietary fiber" was one of the most attractive in nutrition and public health in the second half of the 20th century, and it was the stimulus for a large number of researches at many levels: epidemiological, physiological, analytical and technical. In that context, it was the incentive for the development of knowledge about the causes of several diseases, especially those dealing with the large intestine and diabetes, and has contributed for the governments and the food industry to establish valuable goals to a healthy diet (Cummings *et al.* 2004). Since then there have been a growing number of studies about dietary fiber, not only related to their diet aspects, but also on its economic recovery, resulting in increased knowledge of its chemical, nutritional and functional properties (Rodríguez *et al*., 2006).

At present, this issue continues to awaken interest and it is clear the growing concern that people have about health. Epidemiological studies have shown a correlation between diets rich in fibre and a lower incidence of some chronic diseases such as cardiovascular disease (Honda *et al*., 1999), colon cancer (Bobek *et al*., 2000, Honda *et al*., 1999) and breast cancer (Park *et al*., 2009). Also fiber intake has an effect on the absorption of glucose, and in general, the consumption of fibres induces a lower risk of disease (Gallaher & Schneeman, 2003).

Although it is known that dietary fibers play an important role in preventing various diseases, and that diets high in fiber, such as those rich in cereals, fruits and vegetables, have a positive effect on health (Kendall *et al*. , 2010), often this is not taken into account in the current daily intake of food. The stress of modern life, has led to increased demand for processed foods with predominance of refined products rich in saturated fats and low in

dietary fiber. The increased consumption of these foods, combined with the stress and the reduction of physical exercise, led to an increase in several human health disorders such as obesity, hypertension and heart problems (Kendall *et al*., 2010).
Besides the growing importance that has been attributed to dietary fiber, there have also emerged new sources of fiber and a better understanding of the technological functionality of fibres, which allowed offering new opportunities for its use in the food industry. In addition to the nutritional effect, the fibers can be used for economic and technological purposes as well. As technology agents, their use may range from a bulking agent to a substitute for fat (Guillon & Champ, 2000), and have been used in bakery products, beverages, candy, milk, frozen dairy products, pastas, meats and soups . In recent times, the production of products rich in fiber is "fashionable". At the technological level there has been interest in order to improve the sensory characteristics of products, so as to make them not only healthier but also more "attractive" from the organoleptic point of view.
Dietary fibres have been studied, particularly in recent years, for the positive effects that they have on people's health. To understand what is the level of knowledge that a group of the Portuguese population demonstrate about the benefits of their intake and also what are their motivations and habits of consumption, a survey was conducted and a statistical analysis of the results was consequently performed.

EXPERIMENTAL METHODOLOGY

To achieve the objectives of this study, it was conducted a survey by mix questionnaire, with open and closed questions to obtain some more qualitative information to complement the quantitative information. The questionnaire was divided into various topics in order to obtain data related to consumption habits, knowledge about dietary fiber, and ways of disseminating information, food labeling, the relationship between fiber, variety of foods and disease.
The survey was conducted between April and June 2011, having been obtained in total 182 completed questionnaires. For the treatment of data two software programs were used: SPSS (Statistical Package for Social Sciences - version 18) and Microsoft Excel (version 2007).

RESULTS AND DISCUSSION

182 people were surveyed of which 54% were female and 46% were male. Approximately 70% had between 18 and 40 years, university frequency and lived in urban areas.
To link the consumption of fiber with some of the eating habits of those surveyed, were asked questions related to weekly frequency of consumption of vegetables, salads, fruit, fast food, whole grains and number of meals outside the home. About 39% of those surveyed make more than one meal a day with a salad and/or vegetables, and only 2% do more than two. These numbers are far below those recommended by the current food wheel published by the Directorate General of Health in 2005, which indicates that we should eat vegetables at least in the two main meals every day. The results indicate that only 13% of those surveyed do satisfy this requirement. Regarding the number of times they eat meals away from home per week, 31% report eating five meals, which may be related to the number of days a week that people are normally absent from home, mostly for reasons of work or school. This is reinforced by the fact that the vast majority of those surveyed are old enough to be in working life. Approximately 90% eat meals such as "fast food" once a week or simply do not consume them al all, and this information somehow goes against the present tendency to increased consumption of such foods (Kendall *et al*., 2010). The whole foods do not seem to be part of the daily diet of respondents because 41% said not to eat whole grains and food products. One meal a day with them is made by more than 12% and 82% do not eat whole foods every day.
The results presented in Table 1 allow to verify the level of information of the regarding their knowledge about fibres.

Table 1. Relative frequency of the answers regarding knowledge of those surveyed about fiber.

	Relative Frequency (%)				
	Totally disagree	**Disagree**	**not agree or disagree**	**Agree**	**Totally agree**
1. Only plant foods have fiber	13.2	35.7	14.3	22.0	13.7
2. Foods of animal origin such as meat, eggs and dairy products have no fiber (except if added)	11.0	22.5	23.1	28.0	14.3
3. According to World Health Organization, an average adult should eat 25g of fiber per day	2.7	7.1	56.0	26.9	5.5
4. The whole foods (pasta, bread, rice, cereals, ...) have the least amount of fiber than non-integral	33.5	33.5	17.0	10.4	3.8
5. The unpeeled fruits have less fiber than peeled	34.1	39.6	15.4	7.7	1.6
6. Dietary fibers are classified into soluble and insoluble	3.3	4.4	45.1	24.7	21.4

When asked if the fibers are of animal or vegetable origin, the responses are confused, suggesting that this area is not known to the majority of those surveyed. In relation to the recommendations of the World Health Organization and the Directorate General of Health (Candeias, n.a.), the majority of respondents (56%) did not know how much fiber should be consumed each day (25 g/day). This data reveals that the importance of fiber to the diet is not known to the majority of respondents, since only 5% are completely sure of their answer. The largest quantity of fiber present in whole foods is known to 67% of respondents, revealing that there is an association between whole foods and a higher amount of fiber. The same relationship is observed with the skin of fruit because 74% of those surveyed said that the fruit with skin has more amount of fiber compared to that peeled. The answers to the last question show that 45% of people had no opinion about the solubility of fibers and equivalent percentage of respondents agree with the statement.

There are several ways to pass and give information that keep the general pubic informed about various topics, including about fibers. In this way, questions were asked about the means to get more information related to fibers and their consumption and, in the opinion of those surveyed, the means that would be most appropriate are shown in Figure 1.

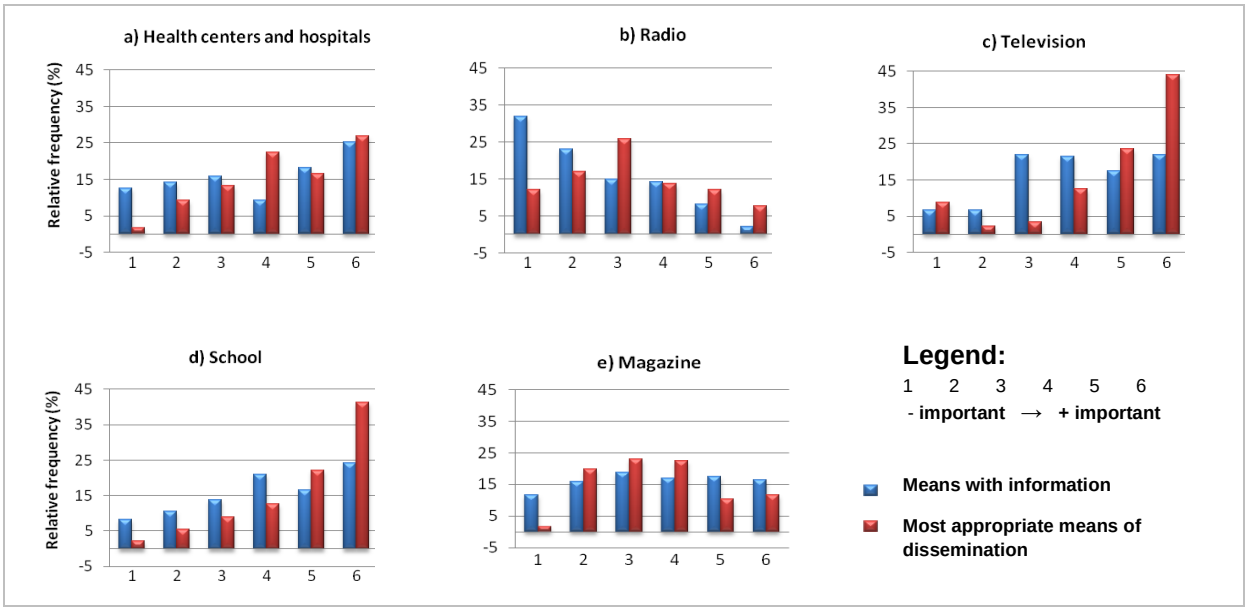

Figure 1. Means of dissemination for information about dietary fibre

From the analysis of the responses, one can highlight two media considered more appropriate to encourage the consumption of fibre: television (44%) and school (41%), but none of these was identified as where there is usually more information on fibres. In fact, the respondents considered most important the health canters and hospitals as the places with available information on this subject. To the radio was given little importance, because this media was referred less often. It should be noted that health centers, hospitals, television and school are the means of transmission of information considered the most important.

Foods have different fiber contents and some of it is not part of the natural food constitution. In this context, it was designed a group of questions in order to evaluate the respondents' knowledge about the food groups that have higher fibre contents (Table 2). The analysis of the responses indicates that respondents do not have consolidated knowledge concerning the origin of the fibers, taking into account that the fiber source is of plant origin and both the results in Table 1 and Table 2 do not evidence this in a clear way.

As it can be seen in Table 2, nearly half of the enquired responded that the fibers have nutritional value. However, this high percentage obtained may not due to effective knowledge about the recent legislation (just over one year) which indicates that the fibers have an average energy value of 8 kJ/g (2 kcal/g) (Dl nº. 54/2010 28/05), but due to the lack of information. Most respondents agreed that legumes, cereals and fruits are rich in fiber. Studies described by Slavin (2008) and Martins *et al*. (2006) among many other corroborate the opinion of those surveyed. Furthermore, the results did now allow establishing a relationship between fiber intake and the environment of living (rural or urban).

Table 2. Relative frequency of responses concerning the relation between fiber and variety of food

	Relative Frequency (%)				
	Totally disagree	**Disagree**	**not agree or disagree**	**Agree**	**Totally agree**
1) Dietary fibers have their origin only in plant foods	12.1	33.5	15.9	22.0	13.7
2) Dietary fibers have their origin only in animal foods	36.3	45.1	15.4	0.5	0
3) Dietary fiber can come from in food animals and plants	12.1	20.3	22.0	34.1	9.3
4) The fiber have calories, ie, they provide energy to the body when ingested	12.1	20.9	19.2	40.1	4.9
5) Leguminous plants (beans, peas, beans, ...), cereals and fruits are foods rich in dietary fiber	1.6	5.5	13.2	45.6	31.3
6) The consumption of dietary fiber is higher in urban than in rural áreas	18.7	37.9	31.3	7.1	1.6

Another group of questions was delineated to investigate whether the respondents relate the fibre intake with health benefits associated to some types and diseases. According to Figure 2, about 90 % of respondents agree with the fact that fibers can prevent and treat disease.

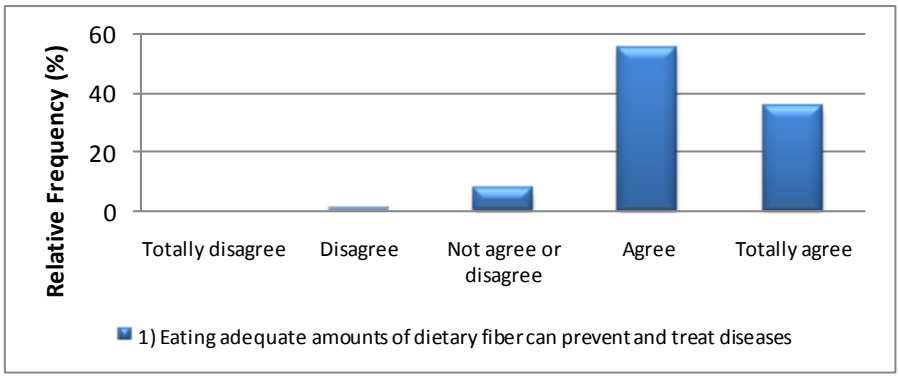

Figure 2. Relationship between fibre intake and disease

Other questions aimed that respondents could eventually establish a relationship between fiber and some diseases. The prevention and treatment of deficiency in vitamins and minerals or vision problems were the illnesses most commonly mentioned as not having to do with the intake of fibre. On the other hand, the most common diseases related to the benefits of fiber intake were: constipation; (86%), obesity (80%), cardiovascular disease and cholesterol (70%), bowel cancer (69%).

Food labels and nutrition information were also examined. These are consulted by most respondents when buying food products, however there are few that give relevance to the amount of fiber that a food product contains when making their purchase.

CONCLUSIONS

The most relevant results indicate that just over 10% of those surveyed eat two meals with vegetables and/or salad a day and at least three pieces of fruit (recommended intake to achieve the recommended intake is 25 g of fibre/day). Whole grains (bread, pasta...) also showed low levels of consumption, despite the respondents revealing knowledge about their higher fibre contents.
The consultation of food labels is of interest for the majority of respondents, about 80%, but little more than half show curiosity to know the fiber content that the food actually has.
The vast majority of respondents have the notion that fiber intake contributes to the prevention and treatment of diseases. Of the various diseases listed, the most cited were constipation (86%), obesity (80%), cardiovascular disease and cholesterol (70%) and bowel cancer (69%).
With regard to the means of dissemination for information on dietary fiber, school and television were considered the most appropriate media to encourage consumption, but in the opinion of respondents, health centers and hospitals are those where more information is at present available.
This study also revealed that knowledge about fibres and the amounts eaten should be higher than they are now. Furthermore, and despite being given high importance to the fibers in the treatment and prevention of diseases, the intake is actually still very under the recommended amounts.

ACKNOWLEDGEMENTS

ABSTRACT: In the framework of the NovelQ EU FP6 project, the consumer acceptance of novel technologies was studied by qualitative and quantitative methods. According to the research results the name 'Pulsed Electric Field' (PEF) evokes the fear of electricity, thus not widely accepted. Prof. Dietrich Knorr, Chairman of the NovelQ Scientific Advisory Board thus proposed a new expression to replace PEF, namely „micro pulse".
The acceptance of the new terminology was studied focus group interviews. Three focus groups were organised with consumers (elderly age consumers, young adults and health conscious consumers) and one more focus group with experts of food sciences, specialised in technology, legislation, food policy, consumer sciences and nutrition sciences.
The results of the focus group interviews with consumers highlighted, that name 'micro pulse' evokes better associations than the pulsed electric field and 'micro pulse' is in no way associated with 'electricity'. Consumers expressed their definite need of getting informed about the new technologies even if this leads to distrust because of the lack of comprehensive knowledge. Consumers' judgment about the change of the technical term is diverse: according to the opinion of two focus groups, it is not misleading to use the name 'micro pulse' instead of PEF, though the electrical feature of the treatment should be mentioned. According to the respondents of the health conscious focus group, change of the name is misleading, because the aim is the reduction of consumers' fears. The most important issues rose by the expert focus group, namely that clear communication is essential for the consumers, and the electrical feature of the technology has to be expressed. The term 'pulsed electric field' is threatening and 'micro pulse' is not informative. The term 'micro electrical pulse' might be acceptable according to the experts. It is important from the market point of view a new technology that it has to offer unambiguous benefits for the consumers. A communicational campaign is needed for the introduction of novel technologies.
Key words: *food processing technology, Pulsed Electric Field (PEF), focus groups*

INTRODUCTION

Our present research was carried out in the framework of the NovelQ (Novel Processing Methods for the Production and Distribution of High-Quality and Safe Foods) EU FP6 integrated project. The aim of the Sub Project 3 was to study the consumers' acceptance of novel food processing technologies and novel products, and the perceived benefits and costs. Secondly, to develop guiding principles for the implementation of novel technologies to be used mainly SMEs in various regions in Europe.
Several findings underpinned, that comparing the Pulsed Electric Field (PEF) technology to the HPP, there are more negative attitudes and less positive attitudes towards the PEF process and products, than towards the HPP process and HPP products. (Butz et al., 2003; Cardello et al., 2007; Mireaux et al., 2007; Nielsen et al., 2009; Sonne et al., 2012).
We carried out a qualitative study on consumer attitudes towards Pulsed Electric Field (PEF) and high-pressure processing (HPP). 12 focus groups were organised with 97 adults in Slovenia, Hungary, Serbia, Slovakia, Norway and Denmark. Participants were generally positive towards these novel technologies as the processes are seen to be environmentally friendly and result in natural products with high vitamin content. Besides, consumers were sceptical toward PEF because of being uncertain about the risks. The name Pulsed Electric Field generated a fear of electricity (e.g. 'I just cannot imagine this high voltage. I'm afraid of

it. It sounds bad. Electricity is not for me.' Female, 29 years old, Hungary). In addition, PEF products were seen as negative as they are believed to trigger allergic reactions. Another difference between the two technologies is that only PEF is associated with the well known processing methods like microwave oven and irradiation, which technologies were not favourable for the consumers. (Nielsen et al., 2009)
The likelihood of choice for novel processed (PEF, HPP) apple juice with conjoint analysis by was also examined by our network 609 consumers in Norway, Denmark, Hungary and Slovakia. The results show, that consumers in all four countries perceive PEF and HPP treated juices to be a better choice than pasteurized juice if the price and taste are right, although the acceptance of HPP treated juice was much better, than that of the PEF products. (Olsen et al., 2011)
According to Olsen et al. (2010) familiar technologies are easier to accept than unfamiliar ones like PEF. In case of PEF products information and benefit statement about the technology may reduce the uncertainty associated with the technology and improve its expected liking. Moreover, tasting is affect consumers' acceptance of HPP and PEF-treated products. Hence, experience with the products and more information about the technologies can be the key to achieving consumer acceptance of products made by novel technologies. This is especially important in case of PEF products, since many consumers associated the name of the technology with electricity, and they were sceptical. It is important, that food producers and food scientists must provide the evidence that this technology is safe to use in connection with food processing (Olsen et al, 2010).
Because of the threatening name of PEF Prof. Dietrich Knorr, Chairman of the NovelQ Scientific Advisory Board proposed a new expression „micro pulse" to replace the name Pulsed Electric Field.
In the framework of the present study, our aim was to investigate the acceptance of the new terminology. We examined

- the suitability of the proposed terminology,
- the consumers' concerns about the rename of the technology.

MATERIAL AND METHODS

A qualitative method, focus group interviews, was conducted, to discover consumers' emotions, motivations and attitudes. 6-12 respondents are needed for a focus group, what is moderated by a trained moderator. There is a main topic in the focus of the discussion. Focus groups must have to be homogenous regarding for example the respondents' demographic data, lifestyle or other. The benefit of the focus group interview is the interaction between the respondents within the group, what creates real life situation during the discussion.
In the framework of our research, a preliminary focus group was organized with the participation of 6 respondents. The aim of the preliminary focus group was to design the guide for the consumer focus groups.
For the examination 3 consumer focus groups were organised, altogether with 21 respondents:

- one group with respondents 45 < years (6 respondents),
- one group with young adults 25-40 years (8 respondents),
- one group with health conscious respondents, as the target group of novel products (7 respondents).

The guideline of the consumer focus groups consists of three parts:
1. Review of the discussion objectives in general, introductory question
2. Attitudes toward PEF, 'micro pulse', HPP, pasteurization terminologies

- Associations based on the expression
- Attitudes based on the description of the technologies
- Intention to buy products made of the technologies

3. Opinions, judgements about the alternative name of the PEF technology and the rename of the technology.

Descriptions of the technologies applied in the consumer focus groups, to give information for the respondents. To define the descriptions of the technologies we consulted with Prof. Knorr. The descriptions were short and easily understandable, as product labels in general, as follows:

- **Preserved by pasteurization:** After a short heat treatment the product is quickly cooled down increasing its durability in this way. This process nearly preserves the fresh taste and vitamin content of the product. Refrigerating is required!
- **Preserved by 'micro pulse' treatment:** The product undergoes a short-term electric impulse treatment. Product treated in this way will have longer shelf life in comparison with the pasteurized ones. This process nearly preserves the fresh taste of the product and the heat sensitive vitamin content. The procedure is energy saving, treated products should be refrigerated.
- **Preserved by high pressure treatment:** Durability is provided by applying with extreme high pressure for a short time; shelf life exceeds that of the pasteurized product. This process nearly preserves the fresh taste of the product and the heat sensitive vitamin content. The product should be refrigerated.
- **Preserved by Pulsed Electric Field technology:** The product is given a high-voltage alternating electric field treatment assuring in this way increased durability related to the pasteurized products. This process nearly preserves the fresh taste of the product and its vitamin content. The procedure is energy saving, treated products should be refrigerated.

After the consumer focus groups an **expert group** was organized with 13 experts, to discuss the concerns related to the change of the name of PEF technology. The experts represented the different fields of food sciences: technology, legislation, food policy, consumer sciences, nutrition sciences and decision makers.

A flow chart (Figure 1) shows the procession of the of the focus group interviews.

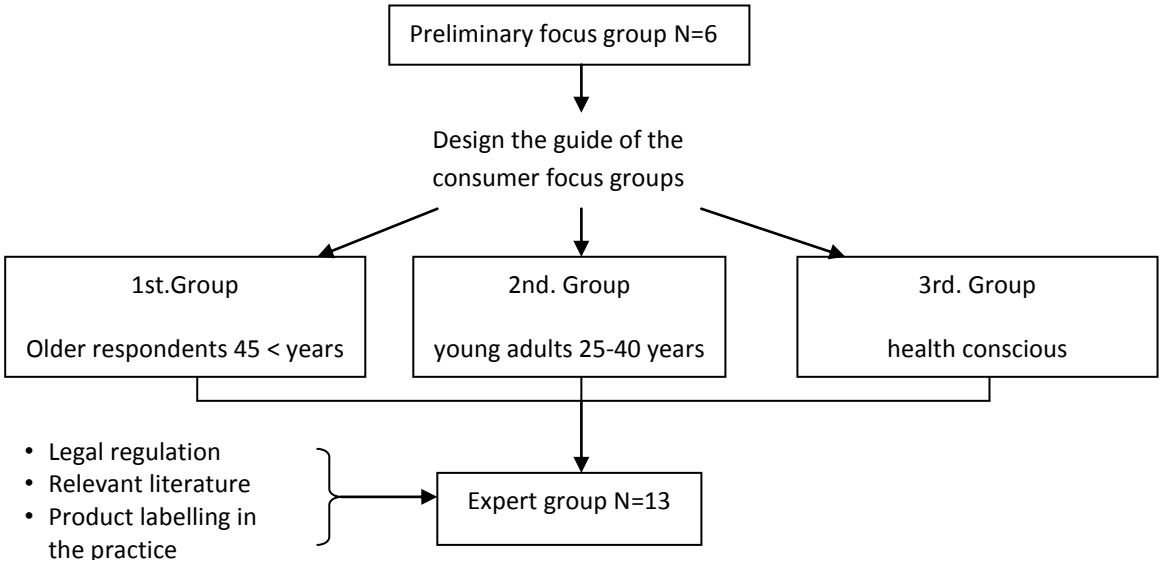

Figure 1.The procession of the focus group interviews

RESULTS AND DISCUSSION

Results of the consumer focus groups

In the first part of the consumer focus groups, associations and feelings evoked by the names of the technologies were collected.

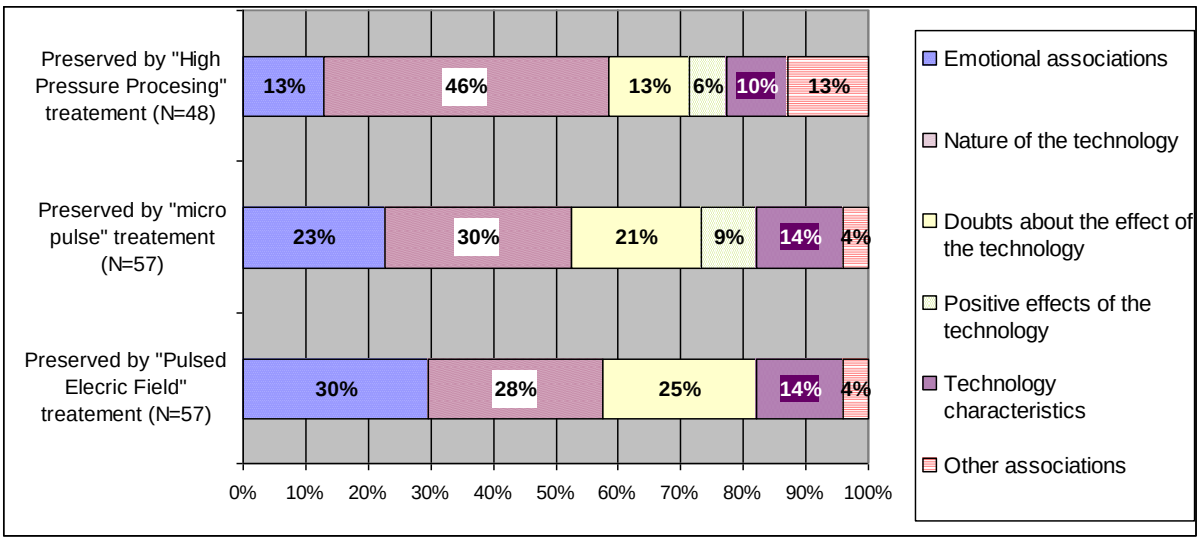

Figure 2. Categories based on associations mentioned (N= number of the mentioned associations)

Figure 2 show the mentioned association categories by the consumers. The most frequent associations mentioned about HPP were related to the nature of the technology (46%), like ‘pressure’, ‘heat treatment’, ‘gas’, ‘vacuum’, ‘homogenization’. Emotional associations ‘higher confidence toward this technology’ and doubts about the technology, like ‘it could be harmful for the nutrients’ were equally frequent mentioned (13%). 10% of the associations were related of the technology characteristics, like ‘simple’ ‘natural’. 6% of the associations related to the technology’s positive effects, like ‘increase the shelf-life”, ‘fresh product’, ‘microbes are destroyed’

More emotional associations (30%) were mentioned regarding the terminology Pulsed Electric Field, than for HPP and these were mostly negative associations, like ‘distrust’, ‘uncertainty’ and ‘fear’. The associations related to the nature of the technology were also negative, like ‘radiation’, ‘roentgen’, ‘electricity’. There were more doubts mentioned (25%) about the effect of the technology, than in case of the other two terminologies (‘unhealthy’, ‘changes in the product’s structure’). Regarding the characteristics of the technology mainly negative associations were mentioned also, like ‘complicated’, ‘expensive’, ‘dangerous’.

In case of the new terminology ‘micro pulse’ more neutral associations were mentioned, than in case of the Pulsed Electric Field technology. The most frequent associations (30%) were related to the nature of the technology, like ‘microwave’, ‘heating’, ‘vibration’. 23% of the mentioning were emotional associations, like ‘inquisitiveness’, ’accepting’, ’uncertainty’. The judgement of the characteristics of the technology was mostly positive or neutral: ‘technology of the future’, ‘small effect’, ‘rapid’, ‘complicated’, ‘expensive’. 9% of the associations were positive associations about the effect of the technology: ‘tactful’, ‘minimal’, ‘less changes in the product’.

To summarize the associations, more positive mentions were related to ‘micro pulse' than to Pulsed Electric Field. The name ‘micro pulse' is in no way associated with 'electricity', but the judgment of HPP was more positive, than that of the ‘micro pulse’ – according to the associations and the descriptions, too.

Young consumers are more open toward the novel technologies, while elder consumers usually more conservative. The group of health conscious consumers was the most risk sensitive – although they are the target group of the novel processed products. On the other hand, the avoidance of food additives is a benefit for them.

Consumers in all groups expressed their definite need to be informed about the technologies, even if this leads to uncertainty and distrust because of the eventual lack of comprehensive knowledge.

Consumers’ opinion about the name changing is divided:

According to two focus groups, it would not be misleading to rename PEF into ‘micro pulse’, though the electrical feature of the treatment should be mentioned.

According to the respondents of the health conscious focus group, changing the name of the technology is misleading, because the aim is the reduction of consumers' fears. A deterrent technology name makes consumers more careful and motivates more conscious product choice.

Main results of the expert focus group

According to the experts of food sciences, the description of the technology should be explained to consumers on the product label, or with the help of other communication tools. Clear and easily understandable communication about the novel technologies is very important. The electrical nature of the technology might have been communicated, because consumers expressed their need to be informed. The name ‘pulsed electric field’ is threatening the term ‘micro pulse’ is not informative. The terminology ‘micro electric pulse’ is acceptable.

Novel technologies have to offer unambiguous benefits to the consumers what is facilitating the marketability of the novel processed products.

The product label is not enough in itself for adequate information providing. A communication campaign is needed in order to introduce novel technologies: besides the product labels the use of other communication tools is needed.

Communication between the experts and the opponents of the technology might be an efficient solution to release doubts related the novel technologies.

CONCLUSIONS

In case of the market introduction of a novel food technology, consumers’ conservatism should be taken into account. The main problem is that although consumers need information it is difficult to explain clearly the nature of the technology clearly.

Consumers expressed their definite need of getting informed about the technologies even if this leads to uncertainty and distrust. Clear communication is important for consumers; the description of the technology should be explained for them.

The term 'micro pulse' creates better associations than pulsed electric field and 'micro pulse' is in no way associated with 'electricity'. However, according to the respondents of the health conscious focus group (the target group of the novel technologies), changing the name of the technology is misleading. The name ‘Pulsed Electric Field’ is deterrent and ‘micro pulse’ is not enough informative. The name ‘micro electrical pulse’ would be acceptable, according to experts.

It is essential for the marketability of a novel technology that it has to offer unambiguous benefits for consumers. Besides the information provided via the product label a communicational campaign is needed in order to introduce novel technologies.

ABSTRACT: Consumption of fresh fruit products increased during the last decade, probably as a consequence of the public awareness regarding the importance of healthy eating habits and consumer's tendency for eating ready-to-eat fresh cut fruits (Olivas G.I., et al. 2005).
The objective of this study was to develop a jellified fruit product based on mango puree and gellan gum. The effect of type of gellan (low acyl and high acyl), concentration (1% and 2%) and dissolution temperature (70 ºC and 90 ºC), on gels setting temperature, was investigated.
Gels prepared with mango puree and low acyl gellan have shown higher values of dynamic moduli than those with high acyl gellan. The heating temperature was determinant on the physical properties of the mango puree-gellan: gels produced after heating the mixtures to 90 ºC for 1 min have shown higher dynamic moduli and higher gel setting temperature (Tg≈ 65 ºC), than those obtained after heating at 70 ºC for 1 min (Tg≈ 45 ºC).
Future work will be focused on the optimisation of the product formulation (e.g. use of low acyl and high acyl in different proportions) and production process, in order to design a fresh fruit product with an improved sensorial acceptance.
Key words: *jellified mango puree, gellan gum, viscoelastic properties*

INTRODUCTION

Ready to eat fresh fruit products became an important area in the food industry due to their characteristics of freshness, low caloric content and convenience, enabling their use in the promotion of fruit as a basic component of a healthy diet (Corbo et al., 2000).
Gellan gum is an approved gelling agent, available in two forms with different characteristics (low acyl-LA and high acyl-HA), having interesting properties that are applicable to a wide variety of food systems. It is an extracellular polysaccharide secreted by the bacterium *Pseudomonas elodea,* which can produce a gel at a concentration as low as 0.2% in the presence of cations. The gellan gum structure is based on a tetrasaccharide repeating unit composed of (1-3)-β-D-glucose, (1-4)-β-D-glucuronic acid, (1-4)-β-D-glucose, and (1-4)-α-L-rhamnose as the backbone (Noda et al., 2008). The gelation process is generally considered to involve two separate thermo-reversible steps. Molecules of the gellan gum adopt a disordered coil (single chain) upon heating in aqueous solutions. Upon cooling the molecules adopt an ordered double helical conformation followed by associations between the helices through weak interactions such as hydrogen bonds and van der Waals forces (Matsukawa et al., 2007).
Its multi-functional properties, its synergy with other polysaccharides and between the two gellan forms (LA/HA), allows the production of a wide range of textures, which make gellan gum an attractive additive to be used in the food industry (Chandrasekaran et al., 1995).
Tropical fruits, particularly mango (*Mangifera indica L*.), have a high content of antioxidant compounds, including carotenoids, vitamin C, vitamin E and phenolic compounds (Vijaya Kumar et al., 2010; Xianli et al., 2004). Thus, the consumption of mango may provide significant amounts of bioactive compounds with antioxidant activity. Due to its pleasant

colour, taste, good texture, and flavour, mango attracted attention for minimal processing as a fresh-cut product (Gonsález-Aguilar et al., 2008).
The interactions between gellan gum and mango puree depend on their physical-chemical properties and on processing conditions, such as temperature, mango puree/gellan proportion, ions concentration and pH. To have a better understanding regarding gelation mechanism and physical properties of mango puree with gellan gum, the effect of type of gellan (low acyl-LA or high acyl-HA), LA/HA mixture (50/50) and gellan dissolution temperature (70 ºC and 90 ºC), on the gel-setting temperature and viscoelastic properties, was studied.

MATERIAL AND METHODS

Materials

Low-acyl gellan gum (Kelcogel® F) and High-acyl gellan gum (Kelcogel® LT) were provided by CP Kelco U.S., Inc. (Wilmington, DE, USA).
Mature mangoes (Mangifera indica L. cv. Palmer) were purchased from a local supermarket in Lisbon, Portugal.

Preparation of the samples

Before processing, mango was stored at 4±1 ºC. The fruit was washed, peeled, cut into small pieces, and pureed in a food blender for 10 minutes. The puree obtained was heat treated for 5 minutes at 70 ºC, in order to induce the enzyme deactivation. pH was measured using a pH meter calibrated with standard buffers. The total concentration of soluble solids (TSS) was determined with a digital refractometer PAL-1, calibrated with distilled water.
Gellan gum (1%wt and 2%wt) was dispersed in the mango puree by stirring and adding the powder slowly to the vortex. Samples were also prepared with 50/50 LA/HA proportion at overall polymer concentration of 1%wt and 2%wt.

Dynamic oscillatory measurements

Rheological measurements were performed on a controlled Stress Rheometer, RS 75 Rheostress HAAKE. The sample was placed between two parallel stainless steel serrated plates (gap of 1 mm), with a diameter of 35 mm. Paraffin oil was applied along the border of the plates to prevent sample dehydration.
The experimental procedure consisted on 2 steps : (i) heating at 90 ºC (or 70 ºC) and holding at that temperature for 1 min, (ii) oscillatory cooling temperature sweep to 20 ºC at a rate of -2 ºC/min (f = 0.1 *Hz*, τ = 1 *Pa*).

RESULTS AND DISCUSSION

Fig.1 shows the gelation profile of mango puree/gellan mixtures upon cooling. When Low Acyl Gellan was used (Fig. 1a and 1b) a rise of G' and G'' was observed, which was attributed to gel setting process. However, the gel setting temperature (Tg) was dependent on the temperature at which the mixture was heated. Mango puree/gellan mixtures heated at 90 ºC show a Tg around 65 ºC upon cooling, while a Tg≈45 ºC is observed when the mixture was heated at 70 ºC. In addition, stronger structures were obtained upon cooling from T=90 ºC, since higher values of dynamic moduli were reached in this case. It may also observed that, the increase of Low Acyl Gellan content from 1% (Fig 1a) to 2% (Fig 1b), does not induce an improvement in gel structure formation.

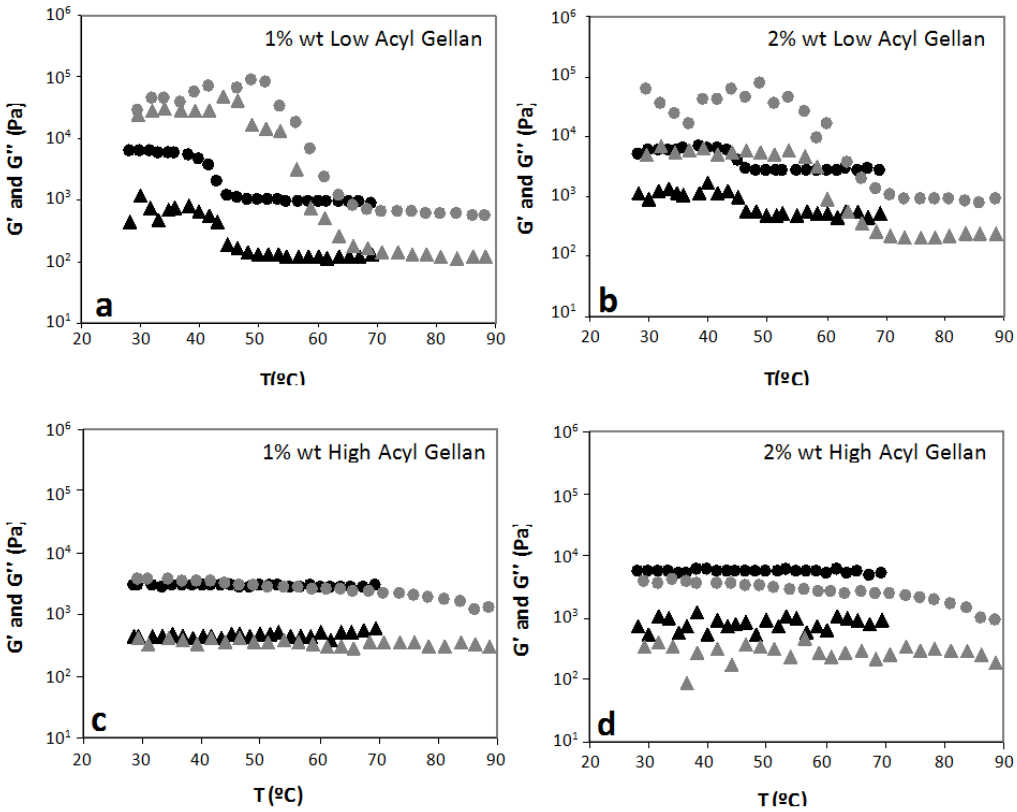

Figure 1: Dynamic moduli of gellan gum/mango puree mixtures, G' (●, ●) and G'' (▲, ▲), as a function of temperature during cooling from 90ºC (gray symbols) and from 70ºC (black symbols).

When High Acyl Gellan was used as jellifying agent, no marked increase on dynamic moduli was noticed over the temperature sweep (Fig. 1c and 1d). Furthermore, High Acyl Gellan has shown to be less effective on structure creation, as in the end of the temperature sweep the values of G' and G'' were much lower when compared to those obtained with Low Acyl Gellan.

The formulations having LA/HA (50/50) mixtures, have shown a gelation profile similar to the one observed only with Low Acyl Gellan (Fig.2). Low Acyl Gellan is known to produce more firm and brittle gels, while the texture of high acyl gels is more soft and flexible (Philips, G., 2000). It is expected to obtain texturized mango puree with intermediate properties by using gellan mixtures.

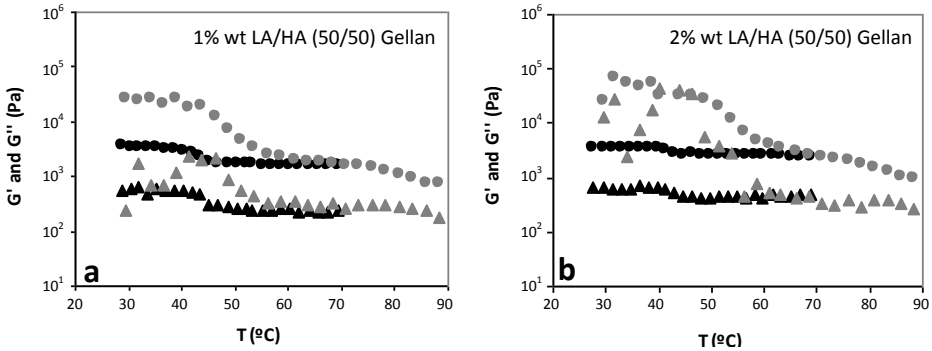

Figure 2: Dynamic moduli, G' (●, ●) and G'' (▲, ▲), of mango puree texturized with HA/LA (50:50) mixtures, during cooling from 90ºC (gray symbols) and from 70ºC (black symbols).

CONCLUSIONS

The effect of type of gellan (low acyl-LA or high acyl-HA) and LA/HA gellan mixtures, on the gel properties was studied using a stress controlled rheometer which monitored the variation of G' and G'' under cooling temperature sweeps. It was observed that: (i) Low Acyl Gellan has shown to be more effective as texturizing agent of mango puree than High Acyl Gellan, (ii) the increase of gellan content from 1% to 2%, does not induce any improvement in gel structure formation, (iii) the heating temperature was determinant on the physical properties of the mango puree-gellan structure: gels produced with Low Acyl Gellan after heating the mixtures at 90 ºC have shown higher dynamic moduli and higher gel setting temperature, than those obtained after heating at 70 ºC, (iv) the formulations having LA/HA (50/50) mixtures have shown a gelation profile similar to the one observed only with Low Acyl Gellan.

ACKNOWLEDGEMENTS

This paper is a result of the research within the Grant (SFRH/BD/64341/2009), financed by Fundação para a Ciência e a Tecnologia. The authors thank to CP Kelco company for providing the gellan.

ABSTRACT: The aim of this study was to investigate if young people, and in what way and to what extent, use the Internet as the source of information about food, its composition and dietary habits. The sample consisted of students of Faculty of Economics University of Mostar (BiH). Young people use the Internet very often, mostly up to 3 hours per day. They read news, play games and socialize on social networks. A lot of respondents consider that food and dietary habits affects human health. Most of them talk about food with family and friends, but very few of them read the laws on food and food products. Students think that there is enough information about the food available on the Internet. A small number of respondents use Internet to find out something about food, and could specify the web site with the theme of food or purchase food through the Internet. The results show that searching the Internet with the aim of discovering new knowledge about food and its beneficial impact on human health is not sufficiently affirmed among young people and the environment should work to encourage the aforementioned.
Key words: *Internet, food ingredients, young people, dietary habits*

INTRODUCTION

The food is the „fuel“ of the people and has significant impact on the human health. Therefore, it is necessary to be familiar with the quality and the composition of the food products. Primarily source of the information about the composition of the food are the declarations on the food package, but this is rapidly changing, due to the development of the new media. Fast development at the area of information and communication technologies led to the fact that in the last 20 years the Internet has become a new important source of the information for the customers, so some, before unimaginable and incomprehensible, information have became readily available and known.

Internet is an interesting phenomenon and people approach it in different ways. For some, it's the place of many information, news and knowledge, for others, it's the place of pure fun and amusement, yet for others it's the place of making business and earning money and even for some it's the place of bad or evil behavior. From the social point of view, Internet is becoming essential part of the everyday life whether it's used during free of working time. It's inexhaustible source of information from and for all areas of human life which makes it a good foundation for various research about the frequency, purpose and benefit of its usage.

At the review of the available materials, not many researches connecting food and the Internet were found. There are many papers that research the consumer awareness about the nutrition data at the packaging of food products (Sharf et al., 2012), how consumers assess the product based on logo (Hoogland et al., 2007), the impact of nutrition data available on the product to the relation of consumer and healthy diet (Barreiro-Hurlé et al., 2010) and the importance of the standardization of the information at food and its availability to every consumer in the world (Bell et al., 2011).

Bearing in mind the importance of the awareness about the consumed food, and under the influence of the information-communication technologies, it’s not possible not to wonder if the Internet is used for the purpose of spreading the knowledge about food and food products. This issue was the foundation for defining the aim of the conducted research.

The aim of this study was to investigate if young people, and in what way and to what extent, use the Internet as the source of information about food, its composition and dietary habits.

MATERIAL AND METHODS

The survey was conducted among students of the Faculty of Economics, University of Mostar in November 2011. A random sample included 140 respondents in all years of study (from first to fifth), with age range 19 – 24. Before implementing the survey, students were informed about the object and purpose of the research. The survey process lasted 15 minutes. After the technical and logical control of the questionnaires, 132 of them were accepted for further analysis. Questionnaire was used as the survey instrument. It contained questions about the purpose and frequency of Internet usage, attitudes about food, and the usage of the Internet as a source of information on food products. Questions were formed as closed form questions, allowing respondents to answer by choosing one or more answers.
The results are expressed in relative frequencies (one decimal place). SPSS version 12.0. was used for statistical analysis.

RESULTS AND DISCUSSION

The survey included 132 respondents, 42.4% men and 57.6% women. 88.6% of the respondents live in their town of study, and 69% of them live with their parents and others in student dormitory or private housing. The rest of the students travel daily to their faculty by personal car or bus, and they mostly live with their family or relatives.

Internet

- Nearly 80% of the respondents use the Internet daily (78.8%), 18.2% do so several times a week, while other 4 respondents stated that they do it even rarer.
- For the majority of the respondents one Internet session lasts 1-3 hours (47.7%), 27.3% of them finish all their activities within one hour, while 6.1% of respondents are almost dependent to the Internet, spending more than 5 hours in one session. Other respondents use the Internet in the continuum between 3 and 5 hours.
- Half of the respondents believe that only 25% to 50% of the time they spend on the Internet is useful for them, 25% believe that the usefulness percentage is less than 25% and only 5.3% of respondents considered that all the time spent on the Internet is useful (100% efficiency).
- Most of the respondents only partially believe the information available on the Internet, (70.5%), while only 5.3% of respondents stated that they believed completely. Other respondents take all of the available information with caution.
- 58.3% of the respondents had at least once checked the accuracy of the information found on the Internet, while the others never did so.
- The most common activities on the Internet are: socialization at social networks, playing games, watching movies, listening to the music...

Food products

- Preferences of the students by type of food they consume are usually quite colorful. The proposed responses are represented as follows: healthy foods - 32.6% of the respondents, junk/fast food - 21.2% of the respondents, traditional food - 28% of the respondents. The remaining 18.2% of the respondents stated that they eat something else; thereby indicating the combination of previously mentioned three categories or the indecision to declare what they prefer.
- With regard to the criteria of choice of food/food products, students mostly go for flavor (66.7%), followed by the composition of ingredients (20.5%) while the price and packaging are poorly represented.
- Slightly more than half of the respondents consider their eating habits to be average (neither good nor bad - about 55%), about 30% thought that their eating habits were very good or excellent, while the rest of them find their eating habits more bad than good. None of

the respondents choose the answer “bad”, while 5 respondents felt that their eating habits were excellent.

- 99.2% of respondents believe that food can affect health, and 96.2% consider this to be the case for diet regime.
- 92.4% of the respondents consider that it is important to be well informed about the composition (ingredients) of the food products, but they are less interested in the composition of the food products they consume (68.9%). 72.7% of the respondents read the composition of food they consume, and 75.8% of them talk about it with people from their environment. Only 14.4% of the respondents read the applicable state laws related to food products.

Internet & food products

- Slightly more than half of the respondents (56.7%) stated that they at least once searched the Internet to obtain new information about food, or to put it differently: they were in a situation where they heard something new about the food and they used the Internet in order to know the importance of the new terms.
- Nearly ¾ of respondents believe that the Internet is a good source for the information related to food in general, food products and diet.
- Less than half of respondents use the Internet to gather information about food in general (40.9%) or specific food products (42.4%).
- When it comes to the information about food and food products that respondents search the Internet for, it turns out that it mostly comes down to recipes (instructions) for the meal preparation (61.4%), followed by information on the impact of food on health and which food is good for what (at 48% of respondents). Method of preparation of certain foods is a topic of research on the Internet for 37.1% of the respondents, 20% and 25% of them search the safety and composition of food products respectively, 24.2% of them compare people's experiences, while the method of storage and process of manufacture of food products are interesting to less than 10% of respondents.
- The results showed that most respondents only partially believe the information from the Internet (67.4%), 25.8% do not believe in the information at all, and only 6.8% of the respondents consider that the information found on the Internet is completely accurate.
- Even though respondents distrust the information on food available on the Internet, only 32.6% respondents check the accuracy of the same.
- Very few respondents use the Internet as a communication media that is to exchange information about food and food products with others. 12.9% of the respondents confirmed that they receive various and useful food related e-mails from their friends, and 10.6% were forwarding these e-mails to others so that can get familiar with the benefits.
- When asked if they knew and could specify the address of a Web site whose primary theme is the food a few respondents indicated www.coolinarka.com page. If the collection of information about food can imply different cooking recipes then the study found that 61.4% of respondents use the Internet for these purposes. Only 7.6% of respondents, namely only 10 of them, are included in certain groups on the Internet that deal with the theme of food.

DISCUSSION

What is the reason for using students for the research, especially because they're such young population? The reason is because young population is most frequent and most common consumer of the Internet when it’s used as the communication media and source of information.

The research results of the students’ Internet habits have demonstrated that Internet is very present among them and that, in most cases; they spend around 3 hours per day browsing. The most common activities that they get involved in when using Internet are socializing in social networks, reading news, playing games and exploring of different subject areas that are of great interest to them. Most respondents feel that even though they use lot of time at the Internet, that time is not well spent. Besides, Internet is an inexhaustible source of the information that respondents use in everyday life, but on the other hand they are familiar with the fact how quality control of available information is not fully guaranteed and so they take

Internet information, which they operate with, with caution (as being partially correct), and accordingly they are familiar with the activities of verification of gathered information.
Analysis of issues related to the eating habits of students has produced a lot of colorful responses. All offered types of foods are equally represented, and it is not possible to identify student population with just one kind of food. It was expected that students would be choosing an answer junk/fast food in more cases, due to the strengthen influence of the western culture, but this was not the case and the results negated the presumption. The reason for this can be found in the fact that most students live with their parents in their place of study and due to the local tradition they are guaranteed with daily homemade (cooked) meal. Despite low percentage of students who prefer a healthy diet, almost all respondents believe that food and diet affect health, which is positive, but is in contrast to their criteria of selection of food (taste). Why is this in contrast, it's because "unfortunately" ingrained notion that healthy food is tasteless. Further on, young people believe that one should be informed about food, but the results suggest that very few of them read food composition of ingredients, legislation or even discuss the topic of food with others.
As the research showed, Internet is still a place of fun for young people, and not the primary source of information. Actually, for them it is the source of information, but information that are usually not important for the daily functioning of the organism. The Internet is just slightly presented as the source of information about food, food products and diet even though young people consider that it offers enough of such information. The question that arises here is: On what basis does youth form such attitude. It can be assumed that the answer is: logical thinking. Since the Internet abounds with "all and everything" it can be assumed that enough information about food products can be also found and thus: the students' opinion. In fact young people right about it, the Internet abounds with information related to food, but they are also unmistaken for taking that information with doubt, not trusting it completely. Abovementioned attitude towards quality of information is correct and further analysis should investigate the quality of information available about food, with special emphasis on the reasons for their presentation on the Internet. The reason for this skepticism lies in the fact that nowadays the Internet is the mean of communication with interested parties, in most cases with the primary aim of making profit. This applies primarily to the economic sector, because when the results of the conducted research are being analyzed in respect to the Internet as a communication medium, they are not so attractive because very few respondents states that the Internet is used for the exchange of information about the food with their environment.
Neither familiarity of respondents with existing web pages that deal with food issues has shown interesting results. Specifically, since asked to name a web page with the theme of food, they mostly stated www.coolinarka.com, and bearing in mind that the primary purpose of this site is sharing recipes for the preparation of various foods, it can be concluded that food web pages are considerable unknowns to them.
Despite the frequent use of the Internet it turns out that respondents do not think about purchasing some groceries via the Internet (online shopping), which coincides with their unfamiliarity and under-utilization of the Internet as an information resource. The reason for the above lies in the fact that electronic commerce in BiH has not been realized in full swing, it's still at the stage of growth and great distrust of the consumers for the mentioned form of trade is present. Perhaps it's a little strange to discuss the purchase of food through the internet, but sometimes it is simply necessary, especially in the case of territorial limits for production of some foods. On the other hand, however, the increasing number of Internet users leads to "internetisation" of all daily activities and most of the big shopping malls that are present on the Internet offer online shopping options. Consumer purchases in the virtual store, and after a period of time, all purchased goods get delivered to his/her address. These services every day stronger and the online food shopping will soon be something we take for granted, and soon, thanks to lifestyle and practice for many. These services are getting stronger by every day and the online food shopping will soon be something we take for granted, and thanks to fast lifestyle also a common practice for many.

Results showed that very few respondents used thematic website (this refers to sites which don't have sales and promotion of some products as their primary goal, but education, or approaching some unknown facts to the common man) and forums for exchanging their personal experiences and discussion.
Given the above facts it is easy to conclude that the segment of young consumers is most convenient for the promotion of food through the Internet, whether it is promoted with the goal of increasing sales (as viewed by the company) or the goal of encouraging healthy lifestyle.

CONCLUSIONS

The obtained results indicate that education on Internet possibilities should be strengthen, and quality of information on the Internet put in focus in order for young people to acquire habits of Internet search and of checking the available information since it is obvious that the frequency and degree of implementation of the Internet in everyday life will continue to grow with no clear indication of the opposite.
Given the fact that young people are aware of the positive impact of food, intensifying the promotion of healthy food should be worked on, and student ways of Internet usage should be utilized as the basis for all promotional activities to promote awareness of healthy eating and essential knowledge of food products of, but also to promote the positive characteristics of the Internet in general.
In order to intensify the usage of the Internet for "health" causes, it would be very convenient and educational to organize forums and workshops at which young people could get acquainted with ways to search online information and ways to assess its quality, accuracy, authenticity and acceptability. These events should be organized with joint efforts of student organizations, doctors, nutritionists and course teachers (and teaching assistants) who are specialized in the field of Internet, electronic business, food and its effect on human. Synergy effect of all mentioned areas of expertise would help create appropriate image of Internet-food correlation and its meaning for healthier and better quality life in the minds of young people. All of this could lead to even more detail understanding of student habits and could trigger them to share this newfound, interesting and useful information through e-mail, but also through online forums or social networks which are, according to current research, unavoidable accessory to personal and business life.
The limiting factor of this study is the fact that these are the students of economic faculty. Continuing the above mentioned research would involve the participation of students from other faculties, especially the Agriculture and Food Technology and Biotechnology Faculty in order to analyze the intensity and frequency of their Internet usage. This could then be compared with other students in order to draw conclusions about the possible impact of study area to the use of the Internet for research in the area of food and food products.
In addition, research should be enhanced with questions about socio-demographic and health features followed by comparison of different sub-samples. Further on, analysis of web sites, which are focused on food, should be conducted, analyzing the quality of available information and the quality of web pages themselves.
This and future, as recommended, researches would create a good foundation for the creation of appropriate strategies of action in an environment that includes young people, Internet (technology) and food as the driving force behind it all.

ABSTRACT: A significant component of new food development process is precise identification of consumer preferences and expectations. In this paper we empirically show that findings form a preliminary research, can be used for development guidance, however, when more objective research techniques are applied, suggested managerial decision could critically differ. The new food product is dessert topping based on traditional Slovenian wine teran, which is highly valued among consumers and perceived as a national speciality. We assumed that these positive elements of consumers' perception about wine teran will be transferred to new developed product and will form central marketing elements.
The research involving consumers combined semi-structured interviews, focus groups and questionnaire with consumer sensory test. The third phase aimed at product fine-tuning, applying consumers' sensory tests; hedonic evaluation and preference testing, where four commercial toppings were included besides the newly designed one. Questionnaire gave important inputs to the marketing strategy, elucidating the purchasing behaviour and consumer expectations regarding the products in target market segment.
We found out that the market is in highly mature phase. As distinguished from the quantitative stages of the research, the questionnaire reviled consumers' preference for established topping flavours, particularly chocolate. Consumer sensory test disconfirmed high expectation, since the average score in preference testing was in lower end for teran's topping, being surpassed by the standard topping tastes. Market acceptance of the new product is below the threshold to continue the outlined product development strategy without risking business failure that is why we suggest product concept redefinition.
Key words: *new food product development, consumer sensory testing, preference test, hedonic test, prototype optimization*

INTRODUCTION

New food product prototypes that include consumer needs and wants have a greater chance for success on the market. However, in reality smaller food companies often neglect that phase and launch the new products without detailed market and consumer analysis. This specific research field stresses the necessity to attack problems in an interdisciplinary way, which is still rare in both sensory and consumer research (Köster, 2009).
Successful new products are usually result of comprehensive market research, planned product development program and an organized marketing effort (Side, 2002). Consumers want to be able to choose the products that consistently meet their needs and desires (Perry and Cochet, 2009). It is a generally accepted fact that far too many food product introductions fail (Costa and Jongen, 2006; Linnemann et al., 2006). Side, 2002 estimated a failure rate of over 90%. The majority of innovations (approximately 65%) are line-extensions aiming at variation (Linnemann et al., 2006). According to Lord (2000), 72% of true new products and 55% of line extensions fail. For non-leading, smaller companies a success rate is only 12% (Lord, 2000). Most part of the food industry has relied on an incomplete knowledge of consumer preferences (Moskowitz and Hartmann, 2008).

We noticed that Slovenian food companies in last few years didn't show significant innovative progress. Slovenian food industry is one of the most important manufacturing sectors and lack of innovation and new product development can have significant effects on the market position of Slovenian companies. One of the major deficits is certainly a decline in industrial research and development processes, which includes the development of new products. To ensure success in developing new food products is necessary to include, in early stages, findings obtained with different consumer analysis techniques. Consumer sensory testing of prototypes is a method which allows the optimization of a new product and ensures a greater chance of commercial success.

Sensory characteristics should not be overlooked, because they almost always have a significant weight in the final decision (Combris et al., 2009), particularly in the new product development, much of the success or failure of a food product in the marketplace results from consumer perception of sensory quality (Moskowitz et al., 2006). Sensory test on consumers attempt to quantify the degree of liking or disliking of a product, called hedonic or affective test methods (Lawless and Heymann, 1998). In studies about food acceptability, four critical questions arise: how consumers perceive the sensory characteristics of food; to what extent the variation in perceived sensory characteristics influences consumer response; how certain consumer habits, attitudes, or beliefs affect hedonic ratings and purchase intention and to what extent hedonic ratings are influenced by the expectations created by different types of information (Costell et al., 2009). Innovation for mass markets is characterized by the lack of personal interaction between the innovator and the users or, at least, most users (Grunert et al., 2008). Sensory evaluation and market research are two separate but related activities that complement one another and rely on different testing methods (Resurreccion, 1998). The primary role of sensory analysis is to provide information about how the sensory characteristics of products, ingredients, or other related information and services relate to perceived quality characteristics and to consumer liking. Once the quality attributes important to the consumer have been determined, appropriate design for systematic product optimization can be developed (Moskowitz et al., 2006).

There are two approaches to consumer sensory testing, first is acceptance test, which is a valuable and necessary component of every sensory evaluation program; it measures consumer's acceptance or liking of a product (Moskowitz et al., 2006). In contrast, preference tests measure the appeal of one food or food product over another (Stone and Sidel, 1993). The consumer panel gives opinions on all product characteristics, not just sensory qualities but others such as safety, nutrition, size, ease of use, transport, storing and convenience. They can also be involved in the design of the package. (Earle and Earle, 2000).

New food product is dessert topping made from traditional Slovenian wine, which is highly valued among consumers and perceived as a national speciality. We wanted to see consumer response to the new product and test the market potential. Research was carried out in three stages: semi-structured interviews, focus groups and a questionnaire with consumer sensory test.

MATERIAL AND METHODS

First qualitative phase – interviews and focus groups

The most popular qualitative research methods for the design stage are focus groups and in-depth interviews (Costa, 2003), they are good tool for the critical properties of the product, which can be modified and adapted during process of development (Resurreccion, 1998). Qualitative methods are ideal in the early fuzzy-front-end of the innovation process, where the objective is, for example, to gain a deeper understanding of user needs (manifest or latent) in order to be able to formulate a product concept, but knowledge about consumers' experience, their beliefs and understanding may also be valuable in later phases of product development (Grunert et al., 2011). They generate oral-descriptive, non-numerical information, and are usually carried out within small groups of people (Costell et al., 2009).

In our research we used semi-structured interviews, where questions are predefined, but we can adapt flow of conversation to the situation. The advantages of in-depth and detailed

responses can be queried for, which may provide the researcher with new insights and ideas for the new product development process (Kleef et al., 2005). We interviewed twenty consumers, male and female, different statuses and age groups on a fair in Ljubljana. Next step were two focus groups, where 14 consumers were involved. The function of the focus group may be to suggest ideas, to clarify potential options, to react to ideas, to recommend a course of action, to make a decision, to plan or to evaluate (Krueger and Casey, 2000).

Second quantitative phase – questionnaire and consumer sensory

The third phase was therefore aimed at product fine-tuning applying consumer sensory tests and to get the further insight for marketing and distribution strategy. Sensory analysis was conducted in three different locations in Slovenia and it based on 126 respondents. With obtained data we studied consumer behavior, preferences and expectations about desert toppings. Two sensory techniques were used; namely preference testing and hedonic evaluation. In preference test we compered newly formed teran's dessert topping with four commercial toppings that are available on the market. We used traditional 9-point hedonic scale, which is performing equally well as comparable scales (Lawless et al., 2010). Methods that include a set of competing alternatives available in the market have the advantage, because they represent the task that consumers typically perform in the market (Kleef et al., 2005). Part of the hedonic test was JAR (just about right) scale for evaluating the degree of liking for sweetness, colour and thickness of the new product.

RESULTS AND DISCUSSION

Results gained with interviews and focus groups were formed into specific categories; the main findings are written and shown in table 1. Conclusions from the first two stages gave us qualitative data which was highly encouraging, since the response of the consumers was supportive for the product concept and the expected market potentials were substantial.

Table 1. Results of a qualitative research methods, semi-structured interviews and focus groups

Aspect	Meanings	Aspect	Meanings
Desserts	Associating desserts with different occasions (after lunch, celebration, snack in front of a TV…). Different motives for desserts consumption (happiness, award, sadness…). Lack of time – ready to eat desserts. Desserts prepared home differ on season.	Wine teran	Good, red wine with rich flavour Slovenian, traditional, highly valued. Associating with seaside.
		Packaging for new topping	Natural, ecological. Small, convenient. Material – glass.
Dessert toppings	Used very rarely, few times per year. Unfamiliarity of the dessert toppings available on the market. Lot of ideas for combining topping with different dishes. Curious to try new topping flavor.	Description of the taste	Good impression. Pleasant unknown taste. Intense colour. Presence of alcohol is not distracting.

The statistical analysis of the questionnaire was used to determine consumer habits regarding food, desserts and dessert toppings. Almost three-quarters of respondents want to test new foods that they do not know. Another important factor when choosing a food is the Slovenian origin, since two thirds of the respondents would chose food from Slovenian companies, if this is possible. In turn, the results of the real food choice experiment revealed that activating domestic origin cognitively actually results in favouring foreign food products while activating domestic origin affectively leads to favouring of domestic food products (Luomala, 2007). Concern for the body weight is not the most important factor when choosing food. Only thirty per cents of the respondents fully or partially pay attention on their weight. More than half of respondents have no bad conscious after eating a dessert.

Consumers who participated, eat dessert toppings very rarely; half of them only few times per year. One fourth of respondents are regular users, which consume dessert toppings several times a month and the other quarter almost never eat dessert toppings (less than once a year). The most common reason to not consume dessert toppings is that they don't remember to buy it and use it and also high additive content and high calorific value. They think that there are not enough offers in the market.

Extrinsic factors, like packaging material, commonly have no direct influence on the characteristics of the product, but they can be of overriding importance in the purchasing policy of some consumers (Linnemann et al., 2006). Most of the respondents recommended glass packaging.

Results of preference test are showed in figure 1. Highest average of scores received chocolate dessert topping (6.86) and the new teran's topping (5.28) reached fourth place.

All results have a high standard deviation, which shows the dispersion of ratings on a large scale around the arithmetic mean. The maximum standard deviation (2.65) has teran's dessert topping, as shares of scores are very evenly distributed.

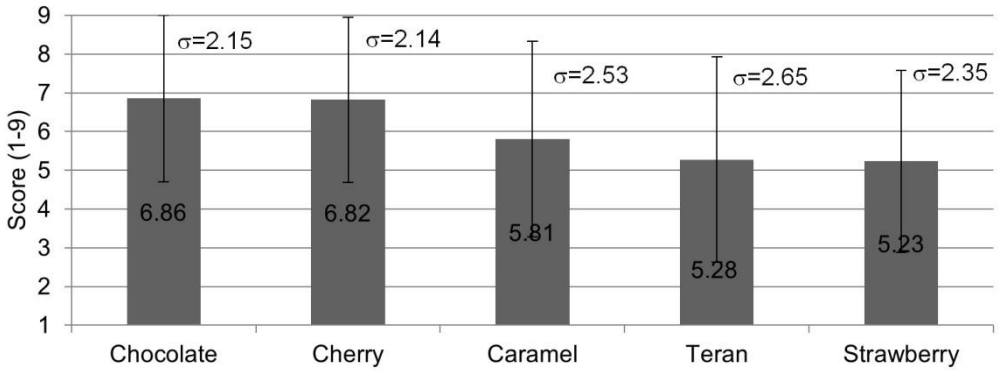

Figure 1. Results from preference testing

In hedonic test teran's dessert topping scored higher average (5.95) than in preference testing. We assumed that could occur because of the inscription "new" in the hedonic test, which lead to a psychological, leniency error. That is when panellists rate the product on the basis of their feelings toward the group or individual that developed the product (Resurreccion, 1998). Particularly increasing was the percentage of best estimates. Sensory attributes from JAR (just about right) scale showed results that were rather favorable for the new product. Product could be better adapted to consumer preferences if it would be a little thicker.

We made three categories of consumers depending on score they gave to teran's topping in hedonic test: enthusiastic, undecided and unfavorable. A variable may be categorical because categories are investigated, but may also have been made categorical by splitting a continuous axis up into subgroups (Næs et al., 2010). With contingency tables and chi-square test we compared and analyze the relation between two categorical variables. In table 2 are chi-square values from comparing hedonic scores with scores of some statements which show statistical significance ($p<0.05$).

Table 2. Comparison of hedonic test scores with certain statements scores that show statistical significance ($p<0.05$)

Hedonic test score	Chi square value	Statistical significance
It's fun to try new foods.	10.608	0.031
If it's possible I choose food from Slovenian companies.	9.963	0.041
I don't have bad conscience when eating a dessert.	10.274	0.036

There is a statistical significant (0.031) connection between degree of liking of new dessert topping and degree of agreement with a statement which indicates neophilia (affinity for novelty). There is a statistical significant result when comparing hedonic scores to degree of loyalty to Slovenian food industry and degree of liking sweets in general.

CONCLUSIONS

Findings form a preliminary research, can be used for development guidance, however, when more objective research techniques are applied, suggested managerial decision could critically differ.

A shortcoming of in-depth and detailed responses research is that the in-depth and idiosyncratic information obtained does not lend itself for direct use in subsequent analysis. A categorization and quantification step is required on the basis of subjective interpretation on the part of the researcher. As such, the personal view of the researcher may affect the way the data are interpreted and a researcher bias can occur as a result from selective observation and recording of information (Kleef, 2006).

The respondents liked the new product, but they preferred the classic. The final results indicate that the market acceptance of the new product is below the threshold to continue the outlined product development strategy without risking business failure. Therefore the process of the product concept redefinition should be initiated in order to better respond to the specific consumer segment or marketing channel. It was find out that the market is in rather highly mature phase with consumers behaving primarily habitually with low involvement in purchasing decision process. Despite the clearly demonstrated inclination towards the diversity when looking for a “sweat threat” behavior in the area of sweet desert toppings, is much more standardized. Next marketing strategy would be evaluating a different distribution channel, like gastronomy and hotel business, catering companies, restaurants and confectioneries.

ABSTRACT: In a research aiming to improve lamb meat quality and quantity of 8 different genotypes were examined. Various lamb meat foods were developed based on genotypes to study the differences among them: Wiener sausage (8 kinds); marinated, smoked and cooked ham (8 kinds); kitchen ready, seasoned, marinated, sliced and roasted lamb meat (8 kinds); whole roasted (restaurant style) lamb leg (4 kinds).
Altogether 285 (60% male and 40% female) randomly selected heads of consumers were included in sensory evaluation/ judging of the products. The consumers represented different age groups: below 20 years; between 21-30; 31-40; 41-50; 51-60; 61-70, and above 70 years. The groups of consumers were involved in: sheep farming; other animals' farming; other agriculture; industry; catering, education, student, other service; administrative department of the state, and others.
The stringiness, flavour and smell were judging in food sensory evaluation. In stringiness and flavour five (from 1 to 5), and concerning smell three (from 1 to 3) categories were created according to decreasing quality.
Analyses of variance were calculated to estimate the effects of lamb genotype; the gender, age, and occupation of judging consumers on sensory evaluation of the various meat foods.
In conclusions, it was stated that new lamb meat foods were highly appreciated by consumers. Consumers made definite distinctions among genotypes according to flavour, stinginess and smell. There were significant interactions between gender, age and occupations of consumers as well as sensory evaluation of various lamb meat foods.
Key words: *lamb genotypes, meat products, consumer, sensory evaluation*

INTRODUCTION

The various authors stated that the most dominant effects modifying the sensory values of the lamb meat are the genetics (Fahmi et al, 1992; Horcada et al, 1998; Ducket and Kuber 2001; Hofmann et al, 2003; Brzostowski et al, 2004; Teixeira et al 2005; Osman and Aldosari 2006), the feeding regime (Melton ,1990; Fischer et al, 2000; Sanudo et al, 2000; Corraiz et al, 2000; Bunch et al, 2004; Revilla et al, 2009), the slaughter weight (Horcada et al, 1998; Berian et al, 2000), and the gender of lambs (Teixeira et al, 2005; Lind et al, 2011).
Consumers could distinguish lambs according to their origin and their preferences. Dominantly well trained panellists were making sensory examinations of various kinds of meat (including lamb meat), but even on family level the untrained panellist could make differences among breeds of lamb according to their preferences. The cultural background and previous experiences or knowledge affect the preferences of the panellist (Ward et al., 1995). The flavour ratings appear to be largely related to the panellist's preference and previous exposure to lamb (Sanudo et al., 1998, 2000).
In many studies stated that the gender of the lamb has significant effect on meat quality, but the acceptance of the lamb meat according to gender of the panellist has not been studied. Also limited information is available about the effect of age and the profession of the panellist on the ratings of sensory attributes of lamb meat.
In Hungary, lamb meat and mutton are dominantly consumed as stew, or rarely a kind of soup, but other kinds of foods are not really made. The main aim of this present study was to examine the acceptance of various kinds of foods made from lamb meat by the not well

trained panellists. The other aim of this study was to investigate the ability of panellist to distinguish breeds; as well as the effect of gender, age and profession of panellists on the sensory evaluation.

MATERIALS AND METHODS

The animals

In a part of experiment serial, lambs belonging to different genotypes were indoors fattened ad libitum on pelleted feed with limited grass hay supplement: Transylvanian Racka ewes were harem mated by rams of following terminal breeds: Transylvanian Racka (1), British Milksheep (2), Charollaise (3), Ile de France (4), German Blackhead Mutton Sheep (5), German Mutton Merino (6), Suffolk (7) and Texel (8). Forty lambs (20 males + 20 females) per genotypes were fattened up to 27-30 kg of live weight category, on approximately 60 days after weaning at 16-18 kg body weight. Half of the lambs (10-10 male and female) from each group were slaughtered.

The preparation of samples

The carcasses were classified using S/EUROP grading system and kept 24 hours after slaughtering at +4 ^{o}C temperature. The carcasses were halved and the right halves were dissected, boned and measured. Meat were handled by genotypes, samples for different products were separately packed into plastic bags, and after slow cooling they were frozen and kept at -20 ^{o}C temperature until preparation.

The meat was gradually de-frosted and three products were developed and manufactured at Biharnagybajom Slaughterhouse and Meat Processing Ltd: Wiener sausage (8 kinds); marinated, smoked and cooked ham (8 kinds); kitchen ready seasoned, marinated, sliced and roasted lamb meat (8 kinds). The manufacturing process was the same in all genotype.

The prepared meat products were aged for three days, four weeks and two days, respectively in the previous order. The hams were smoked for 24 hours following four weeks of aging, and after two days of rest they were cooked, than cooled down and kept at 8 ^{o}C until presentation.

The developed products were promoted and tasted at Farmer Expo Exhibition (Debrecen). The Wiener sausages were boiled only before sensory study and kept served at 40 ^{o}C. The seasoned and sliced lamb meat were roasted on 170 ^{o}C right before sensory test and offered at 40 ^{o}C to the participants of the sensory panel. The lamb hams were warmed up naturally and served at 18 ^{o}C.

For the preparation of the whole roasted lamb leg (restaurant style) two heads of purebred Transylvanian Racka, British Milksheep F_1, Charollaise F_1, and Texel F_1 were slaughtered two days prior presentation and sensory study, and prepared in the oldest and most famous restaurant in Debrecen (Arany Bika Restaurant). The legs were kept at 60 ^{o}C until offer to sensory evaluation.

Samples (3 x 1.5 x 2.0 cm cubes) were made from various products and put on a preheated plate. These samples were coded with a randomized three-digit number.

The sensory panel and examination

The sensory panels were created from visitors of the abovementioned exhibition. The first three products were sensory examined every days around midday by 80 (44 male + 36 female – Wiener sausage); 82 (50 male + 32 female - marinated, smoked and cooked ham); and 64 (37 male + 27 female – marinated, seasoned, sliced and roasted lamb meat) persons. The fourth product was qualified one hour before the official reception of exhibition by 39 (27 male + 12 female – whole roasted lamb leg) panellists.

The members of panels were educated about quality examination of various meat products. Three traits were requested to be rated as follows: ***stringiness*** /1 very soft; 2 soft; 3 nether soft nor stringy; 4 stringy; 5 very stringy/; ***flavour*** /1 very delicious; 2 delicious; 3 satisfying; 4 not satisfying; 5 foul flavour/; and ***smell*** /1 perfect; 2 sufficient; 3 insufficient/.

The panellists individually filled in a form concerning kinds and number of products, including the following information about panellists: gender (male, female); age (under year 20; between 21-30; 31-40; 41-50, 51-60; 61-70, above 70); as well as profession (sheep farmer/shepherd; involve in other kind of animals' farming; other agriculture; industry, catering; education; student, other service; administrative department of the state, and others).
Analyses of variance were calculated to estimate the effects of lamb genotype, age, occupation and gender of judging consumers on sensory evaluation of various meat foods.

RESULTS AND DISCUSSION

The three developed new lamb meat products and the whole roasted lamb leg made in restaurant style were evaluated separately (Table 1-3).

Table 1. Sensory evaluation by gender of judging consumers and by breeds (average of scores)

Different superscript means significant differences (P<0.05) between genders (a) between breeds (A,B,C,D)

Wiener sausage

The gender, age and profession of panellist had definite effects on judgements concerning stringiness, flavour and smell of various kinds of sausages. Reasonable deviations were observed among studied genotypes. In the case of stringiness the British Milksheep F_1, in flavour the Ile de France F_1, and in smell the purebred Transylvanian Racka reached the best result.
Bigger differences were observed concerning stringiness and flavour among studied genotypes, while smaller deviations found in smell according to gender of panellists. On the contrary, significant difference was only received in smell between judgements of male and

female panellists. These data were modified by breeds (Teixeira et al 2005; Osman and Aldosari 2006).
It seemed that the age of panellists essentially modified values of scores regarding stringiness and flavour. The judgements of older panellists fundamentally differed from scores given by younger panel members in smell, as for the latter ones the lamb meat was dominantly unfamiliar.
The profession definitely modified judgements. In flavour there was strong difference between scores given by shepherds and other professions. However, concerning smell judgements of panellists working in industry, education, and others services were significantly different from other members of panel.

Table 2. Sensory evaluation by occupation judging consumers (average of scores)

Food	1	2	3	4	5	6	7	8
Wiener sausage								
stringiness	2.71a	2.25b	2.56a	2.65a	2.56ab	2.83a	2.96ac	2.30b

flavour	2.21a	1.79b	2.05ac	2.13ac	1.75ac	2.09a	2.08ac	1.82c
smell	1.79a	1.43bc	1.90a	1.67ac	1.25b	1.62a	1.43b	1.52bc
Roasted leg								
stringiness	2.42a	2.41a	2.00ab	-	1.38b	2.63a	2.50a	2.35a
flavour	2.52a	2.09b	2.00abc	-	1.13c	3.00a	2.30ad	2.15ad
smell	1.96a	1.68b	1.25b	-	1.50ab	1.88ab	1.60b	1.80ab

Different superscript in a row means significant differences (P<0.05)

Marinated, smoked and cooked lamb ham

There were significant differences among studied genotypes in stringiness, flavour and smell. In all three traits differences were observed between opinions of male and female panellists, however, these differences were only significant in smell, but in the case of comparing breeds significant differences could be observed (Teixeira et al 2005; Osman and Aldosari 2006).
The age had strong effects on scores in stringiness and flavour. The judgements of age category 21-30 and above 70 years definitely deviated from scores given by others. In smell differences were observed among age groups, and score values were higher in older member of panel.
There were significant differences between shepherds and other professional groups. This tendency could also be observed in smell, however, judgements of other agriculture group were closer to shepherds.

Kitchen ready, seasoned, marinated, sliced roasted lamb meat

Bigger differences were observed among genotypes in stringiness and flavour, while concerning smell smaller deviations were found. The gender concerning summarised values had strong effect on stringiness and flavour, and in smell the differences could also be observed. At the same time, these differences were only significant in smell. Apart from them, there were significant breed differences among the scores (Horcada et al, 1998; Ducket and Kuber 2001; Hofmann et al, 2003; Brzostowski et al, 2004).
Studying age panelists below 30 years gave different judgements than other age groups concerning stringiness and flavour. Apart from these, effects of age groups could also be followed in smell scores.

The profession of panelists resulted less determining effects on stringiness and flavour as it was experienced concerning Wiener sausages. On the contrary, there were big differences among professional groups concerning smell.

Whole roasted lamb leg (restaurant style)

Differences among genotypes could also be followed in this product concerning all three quality traits. The gender definitely modified score values of stringiness and flavour, and differences were also found in smell in the cases of summarised values. However, because of high standard deviations gender effect were not significant. Apart from them there were significant differences among breeds (Teixeira et al 2005; Osman and Aldosari 2006).
Comparing age groups no significant differences were found in stringiness. On the contrary, in smell definite age group differences were observed. Concerning smell scores groups above 40 years were significantly different from those ones originated from other age groups. In stringiness and flavour judgement of catering group (like cooks) was significantly different from other profession groups. Concerning smell scores of shepherds significantly deviated from other profession groups.

Table 3. Sensory evaluation by age of judging consumers (average of scores)

Food	1	2	3	4	5	6	7
Wiener sausage							
stringiness	2.09a	2.46bd	2.49bd	2.80c	2.54d	2.57bcd	2.38abd

flavour	-	2.60a	1.75b	2.75a	2.20ab	1.94b	-
smell	-	1.80a	1.75a	2.06ab	1.70ac	1.59ac	-

Different superscript in a row means significant differences (P<0.05)

CONCLUSIONS

Summarising the results of examinations we could draw the following conclusions down. The general acceptance of the various lamb meat foods was much higher than the expectations; the acceptance of the lamb meat could be improved by introducing new kinds of foods. Strong differences could be followed in the evaluations of stringiness, flavour and smell according to the gender of the panelists. The age and the profession of the panellists have significant effects on the score given to various foods, as their preference and knowledge about various kinds of meats were different. There were significant differences among the panellists in evaluation of stringiness, flavour and smell values. The panellists were able to distinguish the various breeds in the evaluation of foods.

ACKNOWLEDGEMENTS

This paper is a part of the results within the project GVOP-3.3.1.-2004 "*Bio-juhhús termelés fejlesztése"* (Development of bio lamb meat production), financed by the National Research and Technology Office, Hungary.

ABSTRACT: The research is based on the consumer quantitative survey performed on general population 18+ in six Western Balkan Countries (WBC - Bosnia and Herzegovina, Croatia, Macedonia, Montenegro, Serbia and Slovenia) at the end of September – beginning of October 2010. The instrument used in this survey was a structured questionnaire. The stratified three-staged random representative sample was applied (N=3085). Based on reported frequency heavy traditional food consumers - who simultaneously reported lower level of functional food consumption (N_t=723), and heavy functional food consumers - with lower level of traditional food consumption (N_f=400), were identified. Descriptive analysis (parametric and non-parametric) was conducted with the aim to investigate statistically significant differences between two profiles of identified consumers' groups in WBC. The study addresses the opposite consumers' profiles. The recommendations for food marketers are emphasized in the concluding remarks.
Key words: *traditional food, functional food, motives, socio-demographics, consumer profile, WBC.*

INTRODUCTION

The concept of traditional food is multidimensional. Seen from different points of view and recognized in different forms, this concept links tradition with food consumption. Traditional food is usually defined as a typical food of local origin, home-made or on-farm produced (Ricketts et al., 2006; Vogt and Kaiser, 2008; Wilson and Fearne, 2000; Hamermesh, 2007). Additionally, traditional products constitute an important element of European culture, identity and heritage, which has been recognised both at scientific and political levels (Committee of the region 2010, Communication of the European Parliament 2011). At the same time, the urban diet changes the occasions and the frequency of consumption of the traditional food. Additionally traditional food is reputed as not so healthy in some regions (Ambelard et al, 2010).

On the other hand, functional food gains in importance recently. Marketed as novel, this food type has been often seen as an opposite to the traditional food. Produced by leading multinational companies, functional food is considered as a much more global concept. Simultaneously, there is an increasing importance of health aspects in food consumption (Diplock et al, 1999; Sijtsema et al, 2003, De Jong et al, 2003; Niva & Mäkelä 2005). This paper aims to investigate differences regarding motives toward food choice and main socio-economic and demographic characteristics between two groups of consumers in Western Balkan Countries (WBC) – heavy traditional and heavy functional group. The food choice motives were analyzed by Milosevic and others (Milosevic et al, 2012). However, profiling of chosen consumer groups can improve understanding of contemporary food consumption and possible dynamics which are of crucial importance for policy makers.

THE SAMPLING PROCEDURE, RESEARCH INSTRUMENT AND METHODS

Consumer quantitative survey was performed on general population 18+ in WBC (Bosnia and Herzegovina, Croatia, Macedonia, Montenegro, Serbia and Slovenia). The sampling was based on the data from Census and estimated population dynamics. The stratified three-staged random representative sample was applied. The primary sampling units (PSU) were polling station territory, the secondary sampling units (SSU) households and the tertiary sampling units (TSU) respondents – the adult member per each chosen household. The Troldahl and Carter (1964) modification (T-C) of the Kish technique was used for data collection. The total sample was 3085, whereas the valid sample for our study was 1123 respondents who stated high frequency of traditional or functional food consumption.
The instrument used in this survey was a structured questionnaire consisting of several separate sections, including motivation toward food in general (Food Choice Questionnaire - FCQ), some specific questions about traditional and functional food and general consumer's socio-economic and demographic characteristics. The motivation was measured by 36 items divided into nine groups (*health, mood, weight control, natural content, convenience, sensory appeal, price, familiarity and ethical concerns*) on a five points' Likert scale. As the concept of functional food is a new on the emerging WBC market, the respondents were previously advised on what was typically assumed under this term. Also, several examples were presented before respondents were asked to complete the survey. Consumers' socio-economic and demographic characteristics relevant for this study includes their gender and age, level of education, number of household members, type of settlement (rural/urban), employment, height and weight - body mass index (BMI), as well as their self-assessed economic and health statuses. The dependent variable was self-reported frequency of consumption of the studied food categories.
In order to find out differences between heavy traditional and functional consumers in WBC, the final sample was reduced: consumers who simultaneously stated high consumption of both foods were eliminated. Consequently, the relevant sample consists of consumers who stated higher consumption of one food group than other – e.g. the *heavy traditional* profile represent consumers who reported higher traditional food consumption and simultaneously lower functional food consumption (Nt=723), and the *heavy functional* group *visa versa* (Nf=400). A descriptive statistical analysis is conducted aiming at investigating all statistically significant differences between both consumers' profiles. The differences between the two groups related to a number of socio-demographic and attitudinal variables were measured by parametric (One-Way ANOVA) or non-parametric (Chi Square) statistical tests.

RESULTS AND DISCUSSION

Heavy traditional are more represented than *heavy functional foo*d consumers in our sample (Table 1). Almost 2/3 of all respondents belong to the first, while 400 respondents were found in the second group. Generally, when compared with the *heavy functional*, the *heavy traditional food* consumer is more frequently man than women, slightly older on average (44 and 48 years old respectively), significantly more accessible to agricultural resources, secodnary or less educated in general and more exposed to problem of overweight, even obesity (percent of people with BMI=>32 is recorded at 8.44% in this group). The *heavy functional food* consumer profile is obviously completely different, like a picture in a mirror. However, this analysis supports our study with higly rough description of two consumers' profiles in WBC. Additionally, the consumers' profiles might differ on the national level which was not in the focus of this paper analysis.
Further statistical analysis indicates the opposite characteristics of two 'heavy consumers' groups in WBC. Differences were found at the highest level in almost all attributes (Table 2). Obviously two consumer groups are significantly different regarding gender, age, type of household and settlement, level of education and sophisticated characteristics such as self-

perceived economic status, health status (measured by self-reported current state and BMI) as well as importance of social influences (rated by the immediate environment interactions).

Table 1. The sample structure

The sample characteristic	Heavy traditional food consumers		Heavy functional food consumers	
	Total	%	Total	%
No of respondents	723	64.38	400	35.62
Gender				
Male	317	43.85	138	34.5
Female	406	56.15	262	65.5

Slovenia	41	28.67	102	71.33

**Unemployed group includes pensioners*
***Calculated based on self-reported weight and height*

Differences in employment were found at 5% significant level. Namely, *the heavy traditional food* consumers are more often unemployed than the *heavy functional food* consumers in WBC. It is also important to emphasize that unemployment in our case also signifies that people are retired which is again linked to their age. Additionally, pensioners are slightly more represented in the sample of the *heavy traditional* than *functional food* consumer group in WBC (28.91% and 25.25% respectively). However, it is equally important to emphasize the structure of unemployed *heavy functional food* group. It comprises more of pupils and students (10.75%) compared with the structure of *heavy traditional food* consumer group (6.64%). It might indicate a food consumption pattern dynamic in WBC.
The rank of motivations toward food consumption was almost the same for both consumers groups in WBC. After ‘health’ - ‘mood’, ‘sensory appeal’, ‘convenience’, ‘natural content’ and ‘price’ were most important. The least important factor was ‘ethical concerns’ for both groups. Slight difference was noticed when importance of ‘weight control’ and ‘familiarity’ had been considered as the motives for food choice.

Table 2. Differences in consumers` profile in the Western Balkans, 2010

Variables	Definition	Heavy traditional food consumers	Heavy functional food consumers	Statistical tests
		Mean (standard deviation)		One-way ANOVA
Age	In years	48.30 (17.275)	44.42 (17.880)	F=12.677***
Economic status	5 point scale	3.08 (0.853)	3.33 (0.804)	F=23.029***
Health status	5 point scale	3.59 (0.962)	3.78 (0.888)	F=9.932***
BMI	self-reported	25.73 (4.123)	24.68 (4.091)	F=16.574***
Social influences /functional food	5 point scale	0.22 (0.974)	0.70 (0.938)	F=63.244***
Social influences /traditional food	5 point scale	1.28 (0.810)	0.81 (0.864)	F=82.073***
		Frequencies (share)		Chi-Square
Gender	0 = male	317 (43.85%)	138 (34.50%)	9.332***
	1 = female	406 (56.15%)	262 (65.50%)	
Education	0 = secondary or less	600 (82.99%)	284 (71.00%)	22.090***
	1 = college/university	123 (17.01%)	116 (29.00%)	
Type of settlement	0 = urban	405 (56.02%)	285(71.25%)	22.225***
	1 = rural	318 (43.98%)	115 (28.75%)	
Type of household	0 = non-agricultural	556 (77.32%)	365 (91.25%)	36.174***
	1 = agricultural	167 (22.68%)	35 (8.75%)	
Employment	0 = unemployed	445 (61.55%)	221 (55.25%)	4.234***
	1 = employed	278 (28.45%)	179 (44.75%)	

Significant at 10% significant level. ** Significant at 5% significant level. * Significant at 1% significant level*

However, in order to find out if the significant differences exist in motivation toward traditional and functional food consumption, one-way ANOVA test was applied. The results are presented in Table 3. Differences between two consumers groups were found to be significant at 1% level in 'health' motivation, and 'convenience'. Functional food consumers were more oriented toward 'health' motive and 'weight control' while choosing food than traditional consumers in WBC. Simultaneously, they do care more about 'convenience' in food consumption. Contrary to these findings, both consumers groups insist equally on hedonic aspects - 'mood' and 'sensory appeal' while making food choices. Moreover, heavy traditional food consumers express less favoured attitudes toward 'ethical concerns' – food origin, environmental protection and small-scale production. Regarding this motive, statistically significant difference was found at 5% level. Finally, the heavy traditional consumer group insisted more on 'familiarity', while heavy functional consumer group was more oriented toward naturalness. However, the finding might be controversial: the local, on-farm production of traditional food usually relays on strong consumer ethical orientation, while functional food is more exposed to new technologies which might not insist on pure naturalness.

Table 3. Differences in motivations toward food consumption in WBC, 2010

Motivation	Heavy traditional food	Heavy functional food	Test
	Mean (standard deviation)		One-way ANOVA
Factor 1—Health	8.56 (3.656)	9.75 (3.335)	F=28.826***
Factor 2—Mood	5.41 (4.367)	5.51 (4.963)	F=0.108
Factor 3—Sensory Appeal	5.33 (2.345)	5.42 (2.313)	F=0.402
Factor 4—Convenience	4.48 (3.785)	5.13 (3.573)	F=7.681***
Factor 5—Natural Content	3.60 (2.212)	3.85 (2.115)	F=3.385*
Factor 6—Price	3.44 (2.255)	3.48 (2,264)	F=0.088
Factor 7—Familiarity	2.68 (2.337)	2.41 (2,553)	F=3.195*
Factor 8—Weight Control	1.91 (2.726)	2.60 (2.709)	F=16.559***
Factor 9—Ethical Concern	0.47 (2.992)	0.94 (2.982)	F=6.184**

Significant at 10% significant level. ** Significant at 5% significant level. * Significant at 1% significant level*

CONCLUDING REMARKS

Our research addresses the most important marketing issues of creation of competitive and safe food products by introduction of new technologies in traditional food production in the Western Balkans. The findings are based on comparison of heavy consumer profiles – traditional *versus* functional food (the later represents the approximation of novel food in the region). The analysis is based on identification of heavy consumers, important in profiling of marketing diffusion strategies.

Differences between two consumer profiles were confirmed to be significant in each socio-demographic and economic attribute applied in our research. Simply, two consumer groups seem to be completely opposite: (1) younger, educated, urban, female and more employed are the main socio-economic characteristics of WBC *heavy functional food* consumer group; (2) older on average, secondary or less educated, rural, more often mail, members of agricultural households and unemployed represent *heavy traditional food* consumer profile. Although so different, two consumer groups almost identically rank the motivations toward food choice. While choosing food, both groups in WBC were motivated by health, mood and sensory appeal, followed by convenience, natural content and price. No matter whether they choose traditional or functional food, consumers are simply convinced about healthiness and tastefulness of their choice, including hedonic aspects. Additionally, while insisting on product naturalness, both groups consider the specific food convenient (easy to prepare/buy/consume).

However, the important differences between consumers were found in health motivation, weight control and convenience (at 1% significant level), as well as due to ethical concerns (significance at 5%), familiarity and natural content (at 10% significant level). *Heavy functional food* consumers are more oriented toward health, weight control and convenience. They do more care about naturalness and ethical concerns in food production than *heavy traditional food* consumers in the region. Food marketers should take care about the 'natural content' of food as consumers in the region do not want to leverage between "artificial" foods ingredients and other motives while consuming food. On the other hand, lower ethical concerns of heavy traditional food consumers might indicate lower potentials for promotion of regional food concept. The traditional food might be used as a term for low marketed goods home-produced by traditional recipes. However, the meaning of traditional food for consumers in different countries of the Western Balkans is highly debatable (Stojanovic & Barjolle, 2012). The further research should also contribute explanation of term "traditional food" in the region.

ACKNOWLEDGEMENTS

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7 2007-2013) under grant agreement n°212 579 – FOCUS-Balkans Project and the Republic of Serbia Ministry of Science under Project no. III 46001 (2011-2014).

ABSTRACT: Sensory properties of fermented beverages are an important quality indicator. The taste and aroma of the products are formed not only from the raw material, but also important is the added yeast, since it affects on the sensory properties of the finished product. The aim of current research is to evaluate the influence of different yeast strains on the sensory properties of cider. Apple variety 'Lietuvas Pepins' juice was fermented with four different commercial yeast strains *Saccharomyces bayanis* yeasts 'EC-1118'and 'Cider yeast', *Saccharomyces cerevisiae* yeasts '71B-1122' and 'K1V-1116'. The sensory evaluation of samples was carried out by experts and intensity of sensory properties (namely, clarity, apple, fruit and yeast aroma, apple, yeast, sour, astringent and bitter taste) using line scale was evaluated. The data obtained in present study shows that yeast strains has a significant influence to the sensory properties of cider. Higher intensity of apple and fruit taste and aroma characteristics showed samples fermented with '71B-1122' and 'K1V-1116' yeasts, whereas samples fermented with 'EC-1118'and 'K1V-1116' showed higher intensity of yeasts aroma and taste. Generally better results showed sample fermented with '71B-1122' yeast. Results of current research approve that choice of the yeast strains are very important for developing technology of the cider.
Key words: *cider, yeast strains, sensory properties*

INTRODUCTION

Apple production is one of the largest fruit-growing sectors of Latvia. Most apples are sold fresh, but part of the apple, which does not meet the requirements of the market, has to be processed and therefore, fermented apples beverage production could be good perspective. The quality of fermented drinks like cider is a characteristic originated from the presence of aroma compounds in a product (Mangas et al., 1996), that are influenced by several factors, namely apple variety, yeast strains, fermentation conditions, the production process and fining treatments (Hidalgo et al., 2004; Martınez-Rodrıguez and Polo, 2003). The fermentation of apple must is a complex microbial reaction involving the sequential development of various strains of yeasts and bacteria (Duenas et al., 1994). Among these micro-organisms, yeasts are primarily responsible for alcoholic fermentation. The different yeast species developed during fermentation and their dynamics and frequency of appearance determine the taste and flavour characteristics of products (Cabranes et al., 1997). Ethanol and glycerol are quantitatively the dominating alcohols, followed by higher alcohols and esters. The main ester produced during alcoholic fermentation is ethyl acetate, but other esters of fusel alcohols and medium chain fatty acids also appear. Two main species, *Saccharomyces cerevisiae* and *Saccharomyces bayanus*, are currently recognized among wine yeasts (Masneuf-Pomarède et al., 2007; Naumov et al., 2000). Different strains of *Saccharomyces cerevisiae* can produce significantly different flavour profiles when fermenting the same must. This is a consequence of both, the differential ability of wine yeast strains in releasing various volatile compounds from grape precursors, as well as the differential capacity to synthesize new yeast-derived volatile compounds (Swiegers et al., 2006; Ugliano et al., 2006). Also in our previous investigations significant influence of the yeast strain on the final chemical and volatile composition was observed (Riekstina-Dolge et al., 2011). Formation of a new product should be designed with high-quality beverage taste of the consumer sensory evaluation. In order to match the instrumental analysis with the consumer requirements, a sensorial profile of the cider is necessary. Sensory quality is

related to consumer acceptance and confidence in the product, being defined by the interaction between the food and the consumer. Thus, sensory quality depends on both the sensory characteristics of the food and how consumers perceive them (Cardello, 1995; Costell, 2002; Ares et al., 2009). Sensory descriptive analysis is a primary tool of food scientists, which involves the evaluation of both the qualitative and quantitative sensory characteristics of products (Meilgard et al., 1999).
The aim of current research is to evaluate the influence of different yeast strains on the sensory properties of cider.

MATERIAL AND METHODS

Raw materials

In these experiments apples of variety 'Lietuvas Pepins' grown in the Latvia State Institute of Fruit and harvested in October 2010 were used. Juice was obtained by mechanical press *Voran Basket Press 60K* (Voran Maschinen GmbH, Austria). For stabilization of juice before fermentation 'Tannisol' (Enartis, Italy) was added. Tannisol capsules consist of potassium metabisulphite (added amount to juice – 9.5 g 100 L^{-1}), ascorbic acid (0.3 g 100 L^{-1}) and tannin (0.2 g 100 L^{-1}). Sulphites have various permitted uses, their primary function is as a preservative and antioxidant to prevent or reduce spoilage (Fazio and Warner, 1990) and they help to stabilize product colour and inhibit discolouration, thereby improving the appearance and flavour of many foods during preparation, storage and distribution (Adams, 1997).

Fermentation conditions

Fermentation was performed using four commercial yeasts – *Saccharomyces bayanis* yeast EC-1118 (Lalvin, Canada), *Saccharomyces bayanis* 'Cider yeast' (Youngs Home Brew., UK), *Saccharomyces cerevisiae* yeast 71B-1122 (Lalvin, Canada) and *Saccharomyces cerevisiae* yeast K1V-1116 (Lalvin, Canada). Fermentation was carried out at 16±1 °C for 28 days. The apple juice was fermented in a glass bottles (n=5) with a volume 750 ml in the laboratories of Latvia University of Agriculture, Faculty of Food Technology. For analysis purpose the average juice samples were combined from 5 bottles in equal proportions. All of ciders were performed immediately after 28 day fermentation. Chemical parameters of cider are presented in Table 1.

Table 1. Chemical parameters of ciders

Yeast variety	Abbreviation	Titratable acidity, g L^{-1}	Soluble solids, g L^{-1}	Alcohol, % vol.
EC-1118	SB1	9.40±0.04	7.70±0.02	5.4±0.05
Cider yeast	SB2	8.40±0.08	6.40±0.03	5.6±0.06
71B-1122	SC3	8.02±0.06	5.14±0.01	5.9±0.03
K1V-1116	SC4	8.32±0.08	15.40±0.02	4.3±0.08

Sensory analysis

Sensory evaluation of cider was carried out with experts (nine women and two men, aged 21 to 51 years). Experts are specialists in the field of beverage technology and experienced in sensory analysis of beverages.
Two methods of sensory analysis were used:
1) identification of cider flavours using characteristic descriptors divided in 12 classes (Table 2) developed by Willams (1975);
2) line scale method for measuring intensity of sensory attributes.

Table 2. Characterization of cider flavours (Williams, 1975)

Class	General characterization	Characterization of subclasses
1	Sour, acidic	Acidic, apple (sharp) acid, vinegar, lactic (soft) acid, citrus sour
2	Aromatic, fragrant, fruity, floral	Alcoholic (fusel), solvent-like (plastics, can-liner, acetone), estery (pear drops, apple-like with aniseed note, light fruity), fruity (citrus fruit, banana, blackcurrant, melon, pear, forest fruit, culinary apple, bittersweet apple), acetaldehyde, floral (rose-like, perfume-like, geranium
3	Spicy, nutty, grassy	Spicy (resinous, woody, spicy bittersweet), nutty (walnut, almond), grassy
4	Caramelised, toasted	Caramel (molasses, raisins), burnt (toasted, rubbery)
5	Chemical	Phenolic (tarry, carbolic, antiseptic, iodoform), plastic, oily (mineral oil, vegetable oil), indole
6	Soapy, fatty, diacetyl, rancid	Fatty acid (soapy, cheesy, rancid butter), butterscotch, rancid
7	Sulphury	Sulphury, sulphur dioxide, sulphidic (rotten egg, drains, autolysed, burnt rubber, shrimp-like, cooked vegetable, cooked cabbage), yeasty
8	Oxidised, stale, musty	Stale, catty, papery, leathery, sherry-like, mouldy (earthy, musty), biscuit
9	Sweet	Honey, artificial (saccharin), vanilla, syrup
10	Bitter	Bitter
11	Mouthfeel	Alkaline, metallic, astringent (drying), powdery, creamy, carbonation (flat, gassy), warming
12	Fullness	Body (watery, characterless, satiating, thick)

Experts also evaluated all samples using 12 cm line scale to rate the intensity of nine descriptors: clarity, apple aroma, fruit aroma, yeast aroma, apple taste, sour taste, yeast taste, astringent and bitter taste. Scale of clarity was defined as clear (on left side of line) and cloudy (on right side of line). For other parameters left side was described as 'attribute not perceptible' and the right side 'attribute strongly perceptible'.
Analysis of variance was performed by ANOVA procedure and $p<0.05$ was considered as statistically significant and principal component analysis was performed with the software SPSS 17.00 for Windows.

RESULTS AND DISCUSSION

Identification of cider flavors

In analyzed samples experts identified descriptors of eight classes of cider flavours: 1) sour, acidic, 2) aromatic, fragrant, fruity, floral, 3) soapy, fatty, 4) sulfury, 5) oxidased, stale 6) bitter, 7) mouthfeel, 8) fullness (Table 3).
In all analysed samples experts identified following flavours: vinegar acidity, citrus sour, apple like esters, astringency and satiating body. Only for two descriptors – citrus fruit flavour and bitterness, differences between *Saccharomyces bayanis* and *Saccharomyces cerevisiae* yeasts can be distinguished. Experts identified sharp acidity in samples SB1 and SC4 and soft acidity characterized by lactic acidity in samples SB2 and SC3. Lactic acid is one of the major acids in ciders and succinic acid is the main acid produced by yeasts during the course of the alcoholic and glycerol-pyruvic fermentation, both present in Asturian natural ciders (Suarez and Picinelli, 2001).

Table 3. Cider flavours identified by experts

Class	General characterization	Characterization of subclasses	Identified characterization in juices samples			
			SB1	SB2	SC3	SC4
1	Sour, acidic	apple (sharp) acid	+	-	-	+
		vinegar	+	+	+	+
		lactic (soft) acid	-	+	+	-
		citrus sour	+	+	+	+
2	Aromatic, fragrant, fruity, floral	alcoholic (wine, fusel)	+	+	+	-
		solvent-like	-	+	+	-
		esters (apple-like)	+	+	+	+
		esters (pear like)	-	-	+	-
		citrus fruit	+	+	-	+
6	Soapy, fatty	fatty acid	+	-	+	-
7	Sulphury	sulphury, yeasty	+	-	-	+
8	Oxidised, stale,	stale, mouldy	+	+	+	-
10	Bitter	bitter	+	+	-	-
11	Mouthfeel	astringent	+	+	+	+
12	Fullness	body(satiating)	+	+	+	+

+ expert identified flavours in cider
– expert not identified flavours in cider

All samples were characterized with apple like esters and in sample SC3 also pear notes were identified. Alcohol, wine, fusel notes were identified in ciders SB1, SB2, and SC3.

Evaluation of the intensity of sensory properties

Significant differences ($p < 0.05$) among the yeasts for following evaluated sensory properties: clarity, yeast aroma, apple taste and sour taste (Fig.1) were observed. For clarity significantly higher results for cider SC4 was identified and also for this sample had higher intensity of yeast aroma. Significant differences ($p < 0.05$) among samples in apple taste and higher results show cider SC3, followed by SC4 and SB2. In previous investigations volatile compounds of ciders were analysed using solid phase microextraction followed by gas chromatography (Riekstina-Dolge et al., 2011).

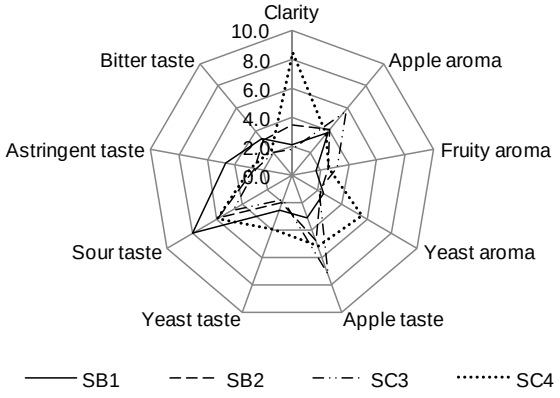

Figure 1. Spider plot for sensory properties of cider

2-methylbutyl acetate, hexyl acetate, hexan-1-ol was identified as main volatiles of apple juice. According to these results, correlation between content of volatile substances and evaluation of intensity of fruit aroma, apple taste and aroma were performed (Table 4).

Table 4. Correlation between sensory properties and content of volatile compounds

Parameters	2-methylbutyl acetate	Hexyl acetate	Hexan-1-ol	Sum of three compounds
Apple aroma	0.92	0.15	0.50	0.99
Fruit aroma	0.49	0.63	0.40	0.72
Apple taste	0.59	0.60	0.51	0.82

Experts evaluation of apple aroma intensity correlated very close with 2-methylbutyl acetate (r=0.92) and with sum of 2-methylbutyl acetate hexyl acetate hexan-1-ol content (r=0.99) in cider. Generally closer correlation between sum of three analyzed volatile components and sensory properties were observed.
Also correlation analysis was performed to determine interactions between different sensory properties. Moderate correlation ($p<0.001$) between yeast taste and yeast aroma (r=0.689), clarity and yeast aroma (r=0.688), clarity and yeast taste (0.555) were observed. Principal Component Analysis (PCA) with rotation was applied to all flavour terms data to obtain a more simplified view of the total flavours characters of the cider (Fig.2).

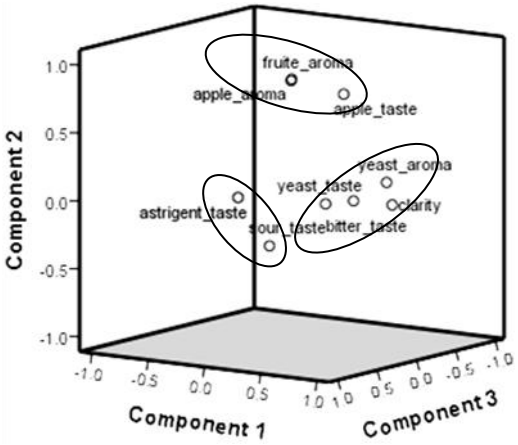

Figure 2. The diagram of factors by rotation

The first three PCs accounted for the highest variation, with 31.3, 23.5 and 12.1% out of total of 66.9 variations that could account for. The first factor contains characterising indicators as clarity, yeast aroma, yeast taste and bitter taste. In the second factor three parameters are included - apple aroma, apple taste and fruit taste. The third factor contains two descriptors - astringent and sour taste.

CONCLUSIONS

Selection of yeast is very important factor that influence final quality of cider. Four descriptors were significant for characterization of differences of ciders fermented by different yeasts, namely, sour taste, apple taste and yeast aroma and clarity. Apple taste and aroma, and also fruit aroma are important quality parameters of ciders and taking into account these evaluations as the best cider SC3 was observed.

ABSTRACT: Extrusion cooking is used in the food industry, to produce direct expanded snacks; the nutritional value of these extruded snacks usually increases with the addition of high-value food ingredients. The objective of the present study was the determination of the effect of process conditions on the structural and textural properties of rice extrudates enriched with carrot. Extrudates were prepared using a twin-screw extruder, operated at different conditions, including screw speed (150-250 rpm), extrusion temperature (140-180 ºC), feed moisture content (14-20%) and carrot-rice flour ratio (5-10%). True density of the products was measured using a helium stereo-pycnometer and apparent density was obtained by measuring their dimensions with a caliper. The expansion ratio was determined as the ratio of the diameters of the extrudates to the die. The textural properties (maximum stress, maximum strain and elasticity modulus) of extruded products were obtained using a universal testing machine. A stereomicroscope was used in order to visualize the macrostructure of selected extrudates. Simple mathematical models were used in order to correlate the examined properties with the extrusion conditions. Apparent density increased with moisture content and material ratio and decreased with temperature and screw speed, while porosity presented the opposite trend. Expansion decreased with moisture content, material ratio and temperature, while a screw speed rise increased the expansion. Moisture content and extrusion temperature affected positively the textural properties. The increment of carrot concentration led to the increment of maximum stress and elasticity modulus and the decrement of maximum strain, whereas screw speed caused opposite trend.
Key words: *carrot, extrusion, modelling, rice flour, structural properties, textural properties*

INTRODUCTION

In recent years, there is an increasing trend for the consumption of high-value ready-to-eat products which preserve their nutritional characteristics. Among the processes which are used in the food industry, extrusion cooking is a continuous, high temperature-short time process, that produces direct expanded materials, with high quality (Ding et al., 2006). Food materials are cooked in a screw-barrel assembly by a combination of moisture, pressure and temperature in order to be mechanically sheared and shaped (Rodriguez-Miranda et al., 2011). Product quality depends on the extruder type, feed moisture, temperature profile, screw speed and feed rate (Thymi et al., 2005).

Nowadays, consumers have increased interest to the Mediterranean diet and the consumption of functional foods with high nutritional value. The nutritional value of the extruded snacks can be increased with the addition of high-value food ingredients, such as vegetables, which must be dehydrated in order to obtain the appropriate powder structure. Among the drying methods that are used in food industries, freeze drying is considered one of the most advanced methods, since it produces materials with high porosity, unchanged nutrition quality, superior taste, aroma, flavours and colour retention, as well as better rehydration properties (Krokida et al., 1998).

Structural properties, such as density and porosity, characterize the texture and quality of expanded products by controlling their taste and appearance, as well as they are indexes of the extent of puffing (Hagenimana et al., 2006). Expansion is also desirable for successful product development and is the primary quality parameter which determines the extrudate structure and texture. It is also associated with other important properties of the produced

snacks, such as crispness, water absorption, etc. (Chen and Yeh, 2001; Jyothi et al., 2009; Rodriguez-Miranda et al., 2011). In addition, the textural properties of foods are related with their sensorial characteristics, and finally with the quality and acceptance of the product by the consumers. The most common method in determining the texture of foods and especially of extruded products is compression (Mazumder et al., 2007; Vincent, 1998).
However the extrusion cooking is a widely studied process, the addition of high nutritional ingredients on the extrudates, has not been extensively examined. In addition, the determination of the effect of process conditions on the properties of extruded snacks is based on generalized models. As a result, the objective of the present study was the determination of the effect of process conditions and material characteristics on the structural and textural properties of extruded rice snacks enriched with carrot. Simple mathematical models were selected in order to predict structural and textural properties correlated with process conditions and material characteristics.

MATERIALS AND METHODS

Materials preparation and extrusion cooking

Rice flour was provided from Agrino Ev.Ge. Pistiolas S.A. and carrots were purchased from the local market. Carrots were preliminary dehydrated in a laboratory freeze dryer (Leybold-Heraeus GT 2A, Koln, Germany) for two days, and were ground to powder. Rice flour and carrot powder were mixed in different ratios, ranging from 5 to 10% (carrot concentration) and equilibrated to three moisture levels: 14, 17 and 20%. Extrusion was performed in a co-rotating double screw extruder (Prism Eurolab, model KX-16HC, Staffordshire, UK), consisting of five independent temperature control zones. The diameter of the die was 3 mm. Extrusion temperature varied from 140 to 180 ºC and the screw speed ranged from 150 to 250 rpm. Extruded materials were stored in laminated bags until required for analysis.

Measurement of structural properties

The true volume of the samples, ground to powder to remove most of the internal pores, was estimated using a helium stereopycnometer (Quantachrome multipycnometer MVP-1). The true density (ρ_{ts} (kg/m^3)) was expressed by the ratio of the mass of dry solids to the volume of dry solids. The extruded snacks were cut in cylinders and the apparent volume was obtained by measuring their actual geometric characteristics (diameter, length), using a digital Vernier caliper. The apparent density was determined using the equation:

$$\rho_{ap} = \frac{4 \cdot m_s}{\pi \cdot d^2 \cdot h} \quad (1)$$

where ρ_{ap} (kg/m^3) is the apparent density, m_s (kg) the mass of the extrudates, d (m) the diameter and h (m) the length of each extrudate.
The porosity, ε, was estimated using the equation:

$$\varepsilon = 1 - \frac{\rho_{ap}}{\rho_{ts}} \quad (2)$$

and the expansion ratio, *Exp*, was determined according to the equation:

$$Exp = \frac{d}{d_o} \quad (3)$$

where d (m) is the diameter of the extrudates, d_o (m) the diameter of the die.
The macrostructure of the samples was visualized using a stereomicroscope (Olympus, SZ). The samples were cut at a thickness of 2 mm and photographed at 10x magnification.

Measurement of textural properties
The textural properties of extrudates were obtained using a universal testing machine (Zwick model Z2.5/TN1S, Germany-Ulm). The uniaxial compression tests were performed at room temperature, using a 100 N load cell. Constant deformation rate of 5 mm/min was used for all the materials. Extrudates were cut in cylinders and their dimensions were measured, prior to each experiment, using a caliper. Force and deformation were recorded electronically and the resulting stress–strain compression curves were constructed according to the equations:

$$\sigma = \frac{F}{A} \tag{4}$$

$$\varepsilon_n = \frac{\Delta L}{L_o} \tag{5}$$

where σ (Pa) is the stress, ε_n (mm/mm) is the strain, A (m^2) is the cross section area, L_o (m) is the initial thickness of the samples, F (N) is the force and ΔL (m) is the deformation.

Mathematical modelling
A simple power model, containing parameters with physical meaning, has been selected in order to correlate the structural and textural properties with process conditions and materials characteristics, and is expressed with the equation:

$$I = I_o \left(\frac{X}{X_o}\right)^{i_X} \left(\frac{100-C}{100-C_o}\right)^{i_C} \left(\frac{T}{T_o}\right)^{i_T} \left(\frac{N}{N_o}\right)^{i_N} \tag{6}$$

where I is the measured property, X (% w.b.) the feed moisture content, C (%) the carrot concentration, T (ºC) the extrusion temperature, N (rpm) the screw speed, I_o, X_o, C_o, T_o, N_o, the corresponding values of the experimental parameters at reference conditions, i_X, i_C, i_T, i_N are parameters dependent on the materials.

Statistical Analysis
Regression analysis was used to estimate the models' parameters, as described by Maroulis et al. (1988). The analyses were performed using Statistica software (Statistica Release 7, Statsoft Inc, Tulsa, OK, USA). Significant differences were considered when $p<0.05$.

RESULTS AND DISCUSSION

The true density of all extrudates was taken as a constant equal to the density of the solid material. True density was estimated equal to 1480 kg/m^3 with a standard deviation of ±18 kg/m^3.
The apparent density of the extrudates increased with the increment of moisture content and concentration of carrot in the mixture. The increased moisture content of extruded products changes the molecular structure of amylopectin contained in starch, reduces the viscosity and increases the density. The increment of carrot concentration is characterized by high protein and fiber content and when it is added to starchy products, causes an increase in density, as expected from the literature (Sacchetti et al., 2004). The increment of extrusion temperature decreases the melt viscosity of the mixture, leading to bubble growth during extrusion and creating a less dense structure. The increment of screw speed caused the reduction in density of extrusion products. This phenomenon is attributed to the reduction of the viscosity, the increment of the elasticity of the dough and the gelatinization of starch. The

corresponding results are presented in Fig. 1, where solid lines represent the predicted values of apparent density. The calculated parameters of Eq. 6 are presented in Table 1.

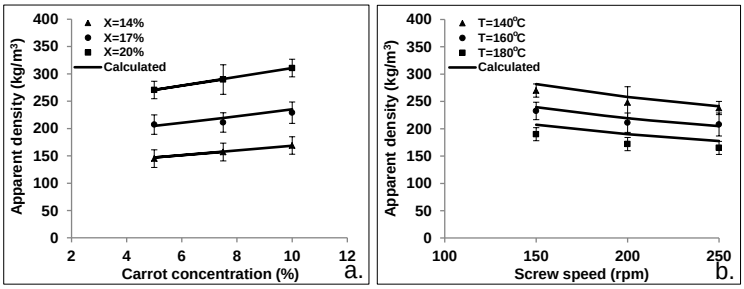

Figure 2. Effect of a) moisture content and carrot concentration, (*T*=160ºC, *N*=200 rpm) and b) extrusion temperature and screw speed, (*X*=17%, *C*=7.5%) on apparent density of extruded products

Table 1. Parameters estimation for structural and textural properties of extruded snacks.

	ρ_{ap}	*Exp*	σ_{max}	ε_{max}	*E*
I_o	219.330	2.394	161.683	0.243	605.609

i_T	-1.218	-0.770	2.702	0.378	1.953
i_N	-0.306	0.248	-0.541	0.412	-0.387

**for all the estimated parameters p<0.001*

As shown in Fig. 2, porosity presented the opposite trend, as expected, according to Eq. 2.

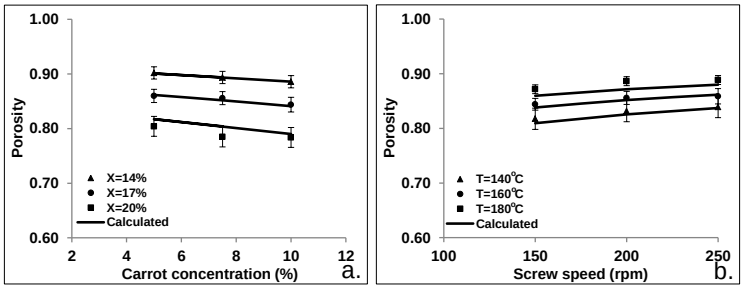

Figure 3. Effect of a) moisture content and carrot concentration, (*T*=160ºC, *N*=200 rpm) and b) extrusion temperature and screw speed, (*X*=17%, *C*=7.5%) on porosity of extruded products

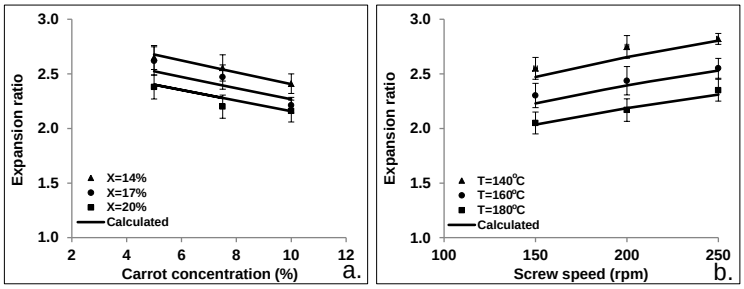

Figure 4. Effect of a) moisture content and carrot concentration, (*T*=160 ºC, *N*=200 rpm) and b) extrusion temperature and screw speed, (*X*=17%, *C*=7.5%) on expansion ratio of extruded products

Expansion of extrudates decreased with increasing moisture content, carrot concentration and temperature, while it increased with increasing screw speed, as shown in Fig. 3. The increment of moisture content reduces the viscosity, leading to more compact structures. Higher levels of carrot resulted in significant reduction of the expansion. The increased concentration of protein and fibres caused the formation of less expanded products due to the interaction between these components and starch. Fibres can also cause rupture of cell walls and prevent air bubbles to expand (Lue and Huff, 1991). The decrease in expansion with increasing temperature is possibly attributed to greater degradation of starch

(Hagenimana et al., 2006). The increase of screw speed caused an increase in expansion, due to the reduced viscosity and the increased elasticity of the dough. These observations were enhanced with stereomicroscopy. Fig. 4 illustrates that expansion ratio of extrudates decreased with increasing temperature, while it increased with increasing screw speed.

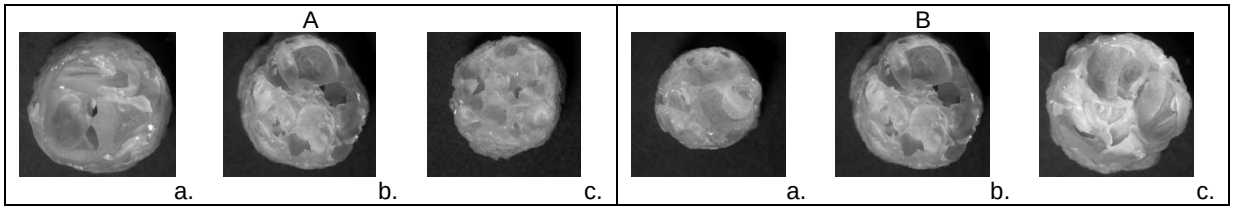

Figure 5. A) Effect of extrusion temperature on the structure of extruded products (*X*=17%, *C*=7.5%, *N*=200 rpm) a) *T*=140 ºC, b) *T*=160 ºC, c) *T*=180 ºC), B) Effect of screw speed on the structure of extruded products (*X*=17%, *C*=7.5%, *T*=160ºC) a) *N*=150 rpm, b) *N*=200 rpm, c) *N*=250 rpm

Fig. 5 presents a typical stress strain curve. Fig. 6 shows the effect of material characteristics on the maximum stress (σ_{max}), maximum strain (ε_{max}) and elasticity modulus (E) of extruded products. It can be observed that maximum stress and elasticity modulus increased with the increment of moisture content and carrot concentration, whereas maximum strain increased with feed moisture content and decreased with carrot concentration.

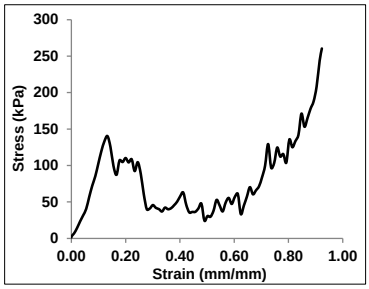

Figure 6. Typical stress strain curve

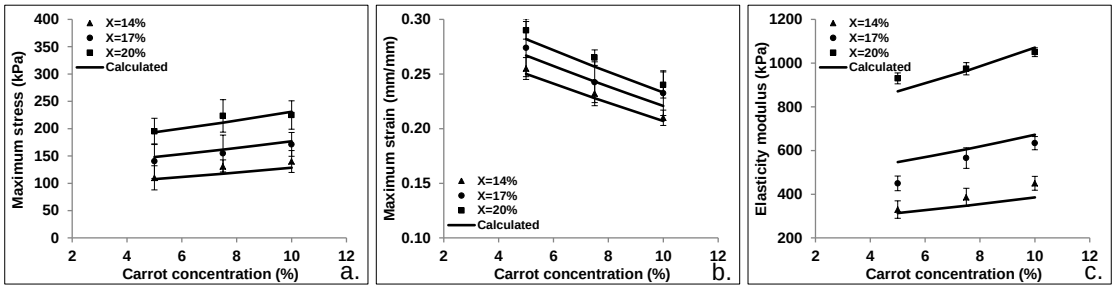

Figure 7. Effect of moisture content and carrot concentration, (*T*=160 ºC, *N*=200 rpm) on a) maximum stress, b) maximum strain and c) elasticity modulus of extruded products

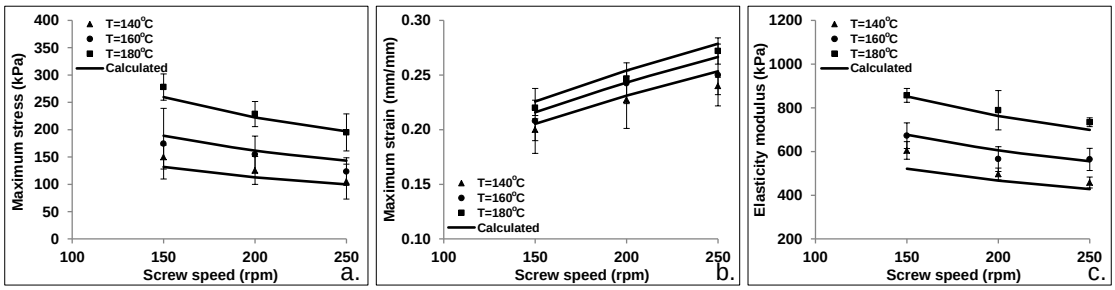

Figure 8. Effect of extrusion temperature and screw speed, (*X*=17%, *C*=7.5%) on a) maximum stress, b) maximum strain and c) elasticity modulus of extruded products

Fig. 7 shows the effect of process conditions on the textural properties of extrudates. Maximum stress and elasticity modulus decreased with screw speed and presented opposite

trend with porosity. The less dense extrudates presented lower values of maximum stress. The increment of stress with temperature, where the density of the products is reduced, may be attributed to the formation of more solid cell walls due to the high temperature (Agbisit et al., 2007). Maximum strain increased with temperature and screw speed.

CONCLUSIONS

Extrusion conditions affected the structural and textural properties of the extruded rice snacks enriched with freeze dried carrot powder. Apparent density increased significantly with moisture content and material ratio and decreased with temperature and screw speed, while the opposite trend was observed for porosity. The extrudate expansion decreased as the moisture content, material ratio and temperature increased, while a screw speed rise resulted in products with higher expansion ratio. The above-mentioned results were enhanced with the images obtained from the stereomicroscope. The textural properties were also significantly affected by process conditions. The denser extrudates presented higher values of maximum stress and elasticity modulus. The most desirable extruded products with higher expansion ratio were those contained 14% initial moisture content and were produced at medium temperatures. Information about the structure and texture of foods is very useful for the process design and the production of high-value foods with desirable properties.

ACKNOWLEDGEMENTS

The authors would like to thank the Research Committee of the National Technical University of Athens (NTUA) and the Alexander S. Onassis Public Benefit Foundation for their financial support. We would also like to thank Agrino Ev.Ge. Pistiolas S.A for providing rice flour.

ABSTRACT: Sensory analysis is an indispensable part of the development, characterisation and quality control process, respectively. It is a scientific discipline applying principles of experimental design and statistical analysis. The need for education in sensory analysis of food was recognized in Slovenia as early as 1975. The courses in sensory analysis became a part of B.Sc. and post-graduate study programmes at Department of Food Science and Technology of Biotechnical faculty. Sensory courses and trainings are also organized for various audiences i.e. beekeepers, school teachers, farmers, consultants and winemakers. The majority of Slovenian food producers nowadays employ internal sensory assessment of products as a part of quality control. At the Department panels of sensory assessors were formed, whose members collaborate with food industry in product developments and quality controls as well as they participate as lecturers in sensory courses and expert assessors in sensory evaluations of products for various clients. The importance of sensory quality of food was also found important for consumer protection and is therefore applied in quality testing of food products performed in collaboration with Slovenian consumer association.
Key words: *sensory analysis, education, food, assessors, consumers*

INTRODUCTION

Sensory evaluation is preformed instinctively every day. Humans have used their senses to discriminate between good and spoiled, safe and unsafe foods for several thousands of years. Over the centuries various methods of food assessment were developed, incited by early trade (Drake et al., 2009). In Slovenia, we have about two hundred years old documented source of sensory evaluation, a cook book, in which the author wrote about the smell, colour and taste as parameters of water quality as well as they are important indicators of the quality of food in relation to human health (Vodnik, 1834).

Although professional tasters and consultants were employed in food and beverage industry since the early 1900s, the field of sensory evaluation advanced rapidly not earlier than with the expansion of processed foods in the second half of the 20th century (Lawless and Heymann, 1998; Meilgaard et al., 1999). In Scandinavian countries a triangle test, a difference test method, was developed in about 1940, while in other European countries modern sensory analysis was employed not until 1950. Although the first book on sensory analysis was written in Polish in 1957 by Tilgner, and the second one by Japanese authors in 1962 (Jellinek, 1985), the definition of sensory evaluation, as cited nowadays, was determined in 1985. Sensory evaluation has been defined as a scientific discipline used to evoke, measure, analyse, and interpret responses to those characteristics of foods and materials as they are perceived by the senses of sight, smell, taste, touch and hearing (Stone and Sidel, 1985). As such, it enables determination of the sensory properties of a food product and provides noteworthy information about sensory characteristics of the product to food technologist and to others involved in the product development and sales (Lawless and Heymann, 1998). Sensory analysis is nowadays indispensable in food industry. It is employed in a development of a new product, as well as in the quality control process. However an early survey revealed that food producers often utilized inappropriate test methods in the development of their product, as they were confused about the purpose of the chosen method and the type of information such method provided (Brandt and Arnold, 1977).

Biotechnical faculty of University of Ljubljana has been running courses in food science and technology since 1961. At the time when the first generations of students graduated and

started their professional careers in the food industry, various studies from the field of sensory analysis have already been conducted abroad and results published. However the accessibility of professional and scientific journals was quite limited at that time and language constraints were often present. The first "*Živilski dnevi*" (engl. *Food Days*), a form of postgraduate education for food technologists, organized in 1975 and dedicated to sensory analysis of food, is considered as the beginning of systematic work in this field in Slovenia. Until then there wasn't any professional literature available in Slovenian language, neither was sensory evaluation methodically introduced into the process of evaluation of food quality in our country. Presented topics published as papers in the proceedings comprised did not only broaden the aspect of food quality and opened new possibilities in product development, but also introduced the Slovenian vocabulary in sensory analysis of food (Bučar, 1975).

METHODS AND MATERIALS

Sensory analysis is used for different purposes of a food product evaluation. It is used to establish difference among similar products, or to characterize and measure sensory properties of a product. Moreover, it is used to ascertain whether product differences are acceptable or noticeable to consumers.

Sensory assessors

A group of sensory assessors, i.e. a sensory panel is consisted of individual members of the panel. Similarly as it is important to calibrate an apparatus, an instrument, it is necessary to properly select, train and monitor the performance of the panel members, since the results of the sensory analysis depend on them. A sensory assessor is a person, who is involved in sensory evaluation, irrespective of the competence and qualifications obtained. Regarding their abilities of perception, discrimination, training level and experience, sensory evaluation is carried out by three types of assessors (ISO 8586-1:1993; ISO 8586-2:2008):

1. Naïve – those who have had no training or beginners who have only been introduced in sensory methodology;
2. Selected – have been screened for their abilities, selected and trained for sensory evaluation by a certain method, and to work in a specific field (e.g. evaluation of dairy products);
3. Expert – assessors who have undergone an extensive training and are able to reliably detect and measure sensory properties of a food product.

The process of selection and training of assessors is comprised of several stages:

- recruiting and preliminary selection of the candidates, naïve assessors,
- training of the novices (naïve assessors),
- selection of the novice regarding their abilities and performance in certain sensory tests,
- selection of candidates, who have passed the previous stage, with regard to their ability of discrimination, memorizing and expression of perceived sensory stimuli (for descriptive sensory analysis),
- further education and training of candidates, who have fulfilled requirements in all stages of the selection of assessors.

Sensory methods

Different sensory methods are applied in the evaluation of sensory characteristics of foods. The sensory tests used are divided into two main types:

1. Affective tests that are used for determination of preference or level of acceptability. The questions raised in these tests are "How pleasant is the product?", "Which of the two products do you prefer?" The attributes evaluated by these tests are preference, suitability and image of the products.
2. Analytical tests that are applied to identify differences in sensory properties and to measure selected property. The methodologies used are rigorous in order to minimise

external influences and assure objective, precise and reproducible descriptions of sensory properties. These tests are further classified into:

- Discrimination tests, which allow detection and determination of small differences between the two products.
- Tests using scales for classifying samples into categories or classes, or to determine the intensity of an attribute or of the difference between the products (ISO 4121:2003; ISO 8587:2006).
- Descriptive analysis, which is performed only by a panel of experts. The result is a complete description of all perceived sensory properties in the order as they are perceived (ISO 11035:1994; ISO 11036:1994).

Education

Education in sensory analysis, which is carried out for students of Biotechnical faculty and of other schools as well as for participants of various seminars, is based on today already reach and diverse literature (Jellinek, 1985; Lawless and Heymann, 1998; Piggott, 1988) and applying all available ISO standards. The later give general guidance on the use of sensory analysis (ISO 6658:2008), for the design of test rooms (ISO 8589:2007), for selection, training and monitoring of different types of assessors (ISO 8586-1:1993; ISO 8586-2:2008) as well as on the implementation of various sensory methods.

Different sensory methods are used for education and training in sensory analysis. The number and types of tests applied depend on the purpose of the education, on the candidates as well as on the nature of the samples presented:

- *Discrimination tests* befit the education and training process and are quite easy to carry out. They are used to train the candidates in detecting the difference between the two samples, when the difference is very small or non-existent. Among the five discrimination tests: Paired comparison test (ISO 5495:2005), Triangle test (ISO 4120:2004), Duo trio test (ISO 10399:2004), Two out of five test and “A” - “not A” (ISO 8588:1987) the first two are the most suitable and commonly used. The Paired comparison test is the most simple and rapid test, while the Triangle test is the most sensitive one.
- During the training candidates are familiarized with the importance of different *scales* (nominal, ordinal, interval, and ratio scales) and their types: category scales, line marking scales, magnitude-estimation scales (Lawless and Heymann, 1998). The scales are distinguished in four groups on the basis of the ordering and distance properties inherent in measurement rules: classification, ranking, measuring magnitudes, assuming equal distances between points on the scale, and measuring magnitudes, assuming equality of ratios between points (Stone and Sidel, 1985). In ISO 6658:2005 four different types of measurement with scales are distinguished: classification, grading, ranking, and rating and scoring. Ranking and rating with scales are the most often used in the process of schooling; in ranking candidates have to rank the samples on the scale in order of intensity of particular property or liking, respectively, while in rating samples are allocated on an ordinal scale in a similar way, but more than one sample may be allocated to the same scale point.
- Candidates following seminars of more than 30 school hours are introduced also into the methods of *descriptive analysis*. These are the most sophisticated sensory techniques that can be carried out only by trained assessors. Candidates learn about how descriptors are created and sensory properties determined, about principles for setting the criteria for assessment of the properties.

Education in frames of study programmes of Biotechnical Faculty

Extent of courses from sensory analysis depends on the level of study programme, i.e. Bologna first (BSc) or second level (MSc), respectively. The courses vary in hours, in profoundness of theoretical knowledge and in activities performed by students. We have published a textbook *Sensory analysis of food* (Golob et al., 2006) in mother tongue to bring chapters from sensory analysis to students and other trainees.

Students of 2nd year of academic study programme in Food science and nutrition (BSc) are introduced into basics of sensory evaluation of food (8 hours of lectures) and carry out some
