ABSTRACT: Standard wholegrain wheat flour pasta formulation was modified by replacement of wholegrain wheat flour with 20% of light buckwheat flour in order to improve functional properties of pasta. Content of free and bound phenolic compounds in dry and cooked pasta was determined by HPLC/DAD. Sample colour was measured using Minolta Chromameter CR-400. Sensory properties of dry and cooked pasta were evaluated by trained panelists using a 5-point category scale.
The results have demonstrated a decrease of about 44% in total phenolic compounds after cooking in comparison to dry pasta, while 8.37% of the total phenolic compounds from dry pasta were present in cooking water. Light buckwheat flour substitution led to a decrease of lightness (L^*), but did not significantly ($P < 0.05$) affect redness (a^*), yellowness (b^*) and hue angle (h) values. Scores for sensory properties were between 4.00-4.80 for dry, and 2.70-4.60 for cooked pasta, indicating the satisfactory pasta quality.
Key words*: functional properties, sensory properties, pasta, buckwheat flour, colour determination*

INTRODUCTION

Pasta is food product that is mainly produced by mixing durum wheat semolina and water. It is a low price product that is largery consumed all over the world and its consumption tends to increase. Since that common wheat pasta is low in protein and essential amino acids, as well as some vitamins and minerals (Heger and Frydrych, 1987) it is recognised as a good matrix for supplementation with various health beneficial supplements.
Buckwheat (*Fagopyrum esculentum* Moench) possesses a great potential for upgrading the functional properties of foods due to its high content of proteins, starch, and vitamins. Antioxidants in buckwheat, including flavonoids, phenolic acids, tannins, phytosterols and tocopherols play important role as anti-inflammatory and anticarcinogenic agents (Kreft et al., 2006; Lin et al., 2009). Among the other cereals and pseudocereals, buckwheat is the richest source of rutin (Vachirapatama et al., 2011) which is confirmed to reduce the fragility of blood vessels and can improve C vitamin absorption. Buckwheat also contains biologically important quercetin that is very effective in anti-tumour, antioxidant and anti-inflammatory activities in vitro systems (Cui and Wang, 2012). Rutin and quercetin were not found in other cereals and pseudocereals. Another functionality of buckwheat comes from its gluten-free characteristics making buckwheat suitable for the diet for celiac disease patients (Sedej et al., 2011).
In order to produce a functional pasta with nutritional benefits, light buckwheat flour has been used for supplementation of a part of wheat flour in pasta formulation. However, the addition of some functional ingredients could result in changes in the sensory properties which may lead to changes in consumers' acceptance (Glanz et al., 1998).
Apart from the evaluation of the cooking quality and sensory properties versus the control pasta made of wheat flour, the aim of this work was to analyze the content of free, bound and total phenolic compounds in dried and cooked buckwheat enriched pasta, as well as in its cooking water.

MATERIALS AND METHODS

Samples
Two types of pasta (spiral shape) (W - wholegrain wheat pasta and WB - pasta enriched with 20% of light buckwheat flour) were produced by using a pasta extruder (Ital past Mac 60 (Parma, Italy)) and pasta dryer (at 40 ºC for 13 h) (Ital past D200).

Pasta cooking quality
Optimal cooking time (OCT), cooking loss (CL) and volume increase (VI) were determined according to Pravilnik o metodama fizičkih I hemijskih analiza žita, mlinskih I pekarskih proizvoda, testenina I brzo smrznutih testa (Sl. list SFRJ, 74/88; Jambrec et al., 2011).

Colour determination
Colour of dry pasta samples was determined by a Minolta Chromameter (Model CR-400, Minolta Co., Osaka, Japan), with granular attachment CR-A50. Colour values were recorded for five randomly chosen types of pasta per batch and averaged. The results were expressed as lightness (L^*), redness-greenness (a^*), and yellowness-blueness (b^*), according to CIE $L^*a^*b^*$ system. Dry pasta samples were ground in 1095 **Knifetec** sample mill.

Extraction of free and bound phenolic compounds from dried and cooked pasta
Cooked pasta was dried at 45 ºC for 1 day before milling. Prior to analysis, pasta samples were milled using 1095 Knifetec mill. A portion of about 5 g of milled pasta was extracted in an ultrasonic bath at 40 ºC with 12.5 mL of ethanol/water (4:1 v/v) for 10 min. The supernatants were collected and evaporated in a Reacti-Therm I (Thermo Fisher Scientific Bellefonte, PA. U.S.A.) to dryness at 40 ºC.
The isolation of bound phenolic compounds required the residues left after the separation of supernatants to be submitted to alkali hydrolysis. Residues were refluxed with 50 mL methanol and 10 mL 50% KOH (in water) for 20 min. Hydrolizates were filtered and neutralized with hydrochloric acid. The final solutions were extracted three times with 50 mL ethyl acetate. The organic fractions were pooled and evaporated in a rotary evaporator to dryness at 40 ºC.
All extracts were dissolved in 5 mL methanol/1% formic acid (1:1) before analysis and filtered through 0.45 µm pore size PTFE filter (Rotilabo-Spritzenfilter 13 mm, Roth, Karlsruhe, Germany) before injection into the HPLC system. Until then extracts were stored at –18 ºC.

Extraction of phenolic compounds from cooking water
Cooking water was evaporated and dried at 130 ºC from 90 min. After that, dry matter from cooking water was extracted in an ultrasonic bath at 40 ºC with 10 mL ethanol/water (4:1 v/v) for 10 min. The supernatants were collected, evaporated at 40 ºC, and dissolved with 5 mL of methanol/formic acid before analysis. The extracts were stored at –18 ºC until use.

HPLC/DAD analysis
HPLC analysis was performed by using a liquid chromatograph (Agilent 1200 series), equipped with a diode array detector (DAD), on an Agilent, Eclipse XDB-C18, 1.8 µm, 4.6 x 50 mm column, at a flow-rate of 1.000 mL/min. A single rapid resolution, reverse phase HPLC method suitable for the determination of 17 phenolic compounds was developed and validated as previously reported (Mišan et al., 2011).

Sensory evaluation
Sensory evaluation was carried out on dried and cooked pasta samples by a panel of five trained assessors from the Institute of Food Technology, Novi Sad. Sensory properties of dry and cooked pasta samples were evaluated by a 5-point category scale (Jambrec et al., 2011; Pestorić et al., 2010). Sensory profiling was performed using a generic descriptive analysis technique, included the selected representative properties of pasta. Each mark was

described with words, using previously prepared standard cards (Tang, et al., 1999; Pestorić 2007; Pestorić, 2011).
All samples were coded with three random numbers and presented simultaneously among assessors. Dry pasta samples were presented on the plastic plates, while cooked pasta samples were presented in thermal plastic cups and served at room temperature within 15 minutes after cooking. Distilled water was used to clean the mouth and hands between samples.

Statistical analysis

Results reported in this study are the means of three measurements, except for the colour measurements where the results are the means of five repetitions. ANOVA and Duncan's multiple range test were used to compare means at 5% significance level by using statistical data analysis software system STATISTICA (StatSoft, Inc. (2008) data analysis software system, version 10.0. www.statsoft.com).

RESULTS AND DISCUSSION

Cooking quality of pasta

The obtained results of pasta cooking quality are shown in Table 1. Optimal cooking time (OCT) of W was longer than WB. Chillo et al. (2008) and Manthey et al. (2004) explained this phenomenon by physical disruption of the gluten matrix and overall lower density of pasta containing buckwheat flour. The lower density provided a path for water absorption into the structure which resulted in a significantly ($P < 0.05$) shorter cooking time and caused significant increase in cooking loss. The obtained results are in accordance with the findings of Alamprese et al. (2007) and Bilgiçli (2009), who reported that pasta with buckwheat flour had a significantly higher VI during cooking than wheat pasta. The authors explained it by the irregular structure of buckwheat starch granules, which contained more amorphous areas than those of wheat. However, our results showed that the volume increase for WB was not significant**,** probably due to the low substitution level in this pasta formulation.

Table 1. Cooking quality and colour values of pasta samples

	Cooking quality			Colour values			
	OCT (min)	**CL (% d.b.)**	**VI**	***L****	***a****	***b****	***h****
W	9.30 ± 0.30^{b}	7.18 ± 0.30^{a}	2.86 ± 0.40^{a}	75.34 ± 0.38^{b}	2.85 ± 0.15^{a}	14.77 ± 0.07^{a}	79.09 ± 0.54^{a}
WB	8.00 ± 0.20^{a}	10.00 ± 0.40^{b}	3.29 ± 0.10^{a}	73.54 ± 0.59^{a}	2.79 ± 0.16^{a}	14.82 ± 0.37^{a}	79.36 ± 0.33^{a}

Abbreviations used in table: OCT– optimal cooking time; CL – cooking loss; VI – volume increase
Values are means of three measurements of the cooking quality and five measurements of the colour values ± SD
Values with the different superscript within a column are significantly different ($P < 0.05$)

Colour determination

Every modification in pasta formulation results more or less in colour changes of the final product (Švec et al., 2008). The obtained results for the pasta colour indicated that fortification of pasta with light buckwheat flour significantly decreased ($P < 0.05$) lightness that is in accordance with previously published results of the other authors (McWatters et al., 2003; Singh and Mohamed, 2007; Sudha et al., 2007), who found that the incorporation of different composite ingredients may contribute to darker surface product (Table 1). In addition, the level of supplementation of the pasta did not significantly affect the other colour values.

Influence of pasta processing and cooking on the phenolic content

The light buckwheat flour was added into standard wholegrain wheat pasta formulation in order to improve functional properties, first of all to increase the content of phenolic compounds. Polyphenolic compounds are known to be relatively thermally stable, but their content can be significantly reduced in the final product as a result of different processes which occur during the production (Mišan et al., 2011). Thus, as a part of this study, the influence of cooking process on the content of polyphenolic compounds was investigated. Rutin, quercetin, catechin, ferulic and vanilic acid were determined by using HPLC/DAD analysis (Table 2). Buckwheat pasta had a majority of phenolic compounds present in a free form, as previously was stated by Hung and Morita (2008). Results sugested that rutin was mainly presented in free buckwheat fraction and cooking process decreased its content for about 8.50%. Since that recommended doses for rutin are in the range between 10-25 mg/day for adults (Filipčev et al., 2011), the consumption of 100 g of pasta supplemented with buckwheat flour at the tested level, would satisfy about 2-5% of daily dose. During pasta cooking, rutin from its bound form was converted into quercetin, as showed by the increase of quercetin content for about 20%. Ferulic acid, the main phenolic acid in wheat grain (Sedej et al., 2010), was dominantly presented in bound form, which is in accordance to many studies (Inglett et al., 2011; Adom and Liu, 2002; Clifford, 1999).

The results have demonstrated that 56% of total phenolic compounds tolerated the cooking process; 8.37% of the total phenolic compounds were dissolved in cooking water and 35.63% were degraded. Catechin demonstrated minimum tolerance to the cooking process with cooking loss of about 57%.

Table 2. Phenolic content in dry and cooked light buckwheat enriched pasta (c (mg/kg dw))

	Bound		**Free**	
Compound	**Dry**	**Cooked**	**Dry**	**Cooked**
Rutin	1.73 ± 0.26^{a}	1.49 ± 0.43^{a}	4.21 ± 0.35^{b}	3.85 ± 0.03^{a}
Quercetin	1.08 ± 0.08^{a}	1.29 ± 0.08^{b}	1.25 ± 0.70^{a}	1.14 ± 0.18^{a}
Ferulic Acid	46.51 ± 15.05^{a}	40.65 ± 8.39^{a}	5.19 ± 0.39^{b}	3.21 ± 0.14^{a}
Vanilic Acid	0.81 ± 0.22^{a}	0.65 ± 0.21^{a}	1.91 ± 0.18^{b}	1.07 ± 0.02^{a}
Catechin	33.15 ± 6.69^{b}	7.56 ± 0.26^{a}	107.59 ± 9.24^{b}	52.96 ± 1.64^{a}
Sum	83.28	51.64	120.45	62.23

Total (Free + Bound) Phenolic compouns

Compound	**Dry**	**Cooked**	**Cooking water**
Rutin	5.94 ± 0.31	5.34 ± 0.44	2.47 ± 0.83
Quercetin	2.33 ± 0.74	2.43 ± 0.11	1.18 ± 0.60
Ferulic Acid	51.70 ± 15.21	43.89 ± 8.35	2.86 ± 0.71
Vanilic Acid	2.72 ± 0.32	1.72 ± 0.22	2.06 ± 0.47
Catechin	140.74 ± 11.18	60.52 ± 1.78	1.51 ± 0.13
Sum	203.43	113.90	10.08

Values are means of three measurements ± SD
Different latter in the same row indicate significantly different values (P<0.05)

Sensory evaluation

Sensory quality of produced pasta was defined on the basis of evaluation for four properties of dry and seven properties of cooked samples are presented in Figure 1. The obtained scores by sensory evaluation (Figure 1) were between 4.00-4.80 for dry, and 2.70-4.60 for cooked pasta. Buckwheat flour addition in pasta formulation was not significantly ($P < 0.05$) affect the sensory properties, except the elasticity and firmness of cooked pasta which scores were significantly lower. On the whole, the pasta samples with addition of light

buckwheat flour had almost the overall quality scores statistically equal to that of the pasta samples made only of wholegrain wheat. Moreover, from the results, it was observed that the addition of light buckwheat flour determined a good sensory quality due to the presence of resistant starch that is less available and derived from buckwheat flour (Skrabanja et al., 2001). The results of firmness and elasticity are in accordance with the data obtained from Manthey et al. (2004), who found that with the increase from 0% to 30% of buckwheat flour in pasta manufacture there was an enhancement of the firmness and elasticity but when pasta was dried at higher temperature. In general, referring to the results of sensory quality of the pasta, 20% of light buckwheat flour may be used in pasta formulation without producing a negative impact on the sensory properties.

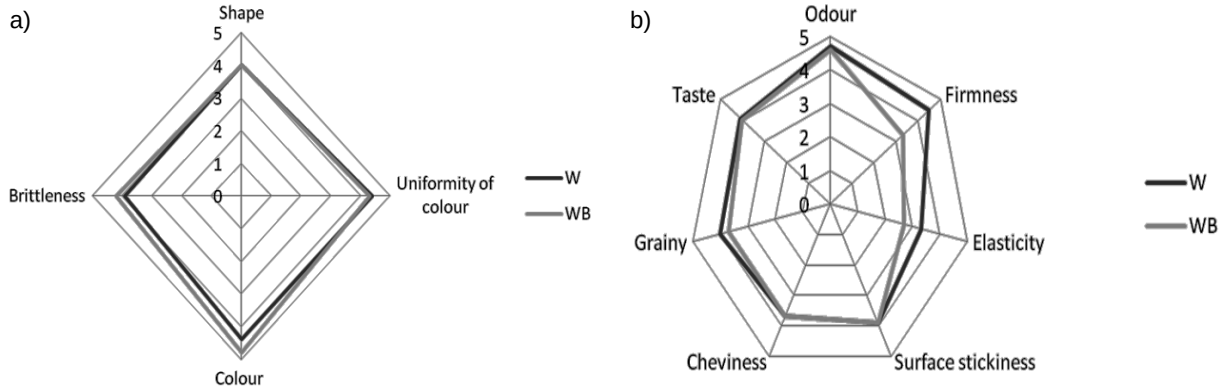

Figure 1. Sensory properties: a) dry pasta; b) cooked pasta

CONCLUSIONS

Supplementation of wholegrain wheat pasta formulation with 20% of light buckwheat flour induced a decrease in some pasta quality properties (significantly lower optimal cooking time and higher cooking loss). Modification of the pasta formulation resulted in darker pasta coloration (lower *L** values). Sensory evaluation showed that dried pasta with addition of light buckwheat flour demonstrated fairly similar sensory properties to the wholegrain wheat pasta. Analisys of the phenolic content showed that the cooking process negatively influenced the phenolic content. In general, in order to enhance functional properties, 20% of light buckwheat flour may be added into the wholegrain wheat pasta formulation without adversely affecting the sensory properties of the final product and may be regarded as health-promoting functional food.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR31029 financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: Following previous research on lemon juice enriched with berries, the aim of this work was to design new blends based on lemon juice mixed with different edible berries from exotic and national origin: maqui (*Aristotelia chilensis* (Molina) Stuntz), açaí (*Euterpe oleracea* Mart.) and blackthorn (*Prunus spinosa* L.). The phytochemical characterization of controls and blends was performed by HPLC-DAD-ESI/MSn, and their antioxidant capacity against DPPH, superoxide and hydroxyl radicals and hypochlorous acid were also assessed. The profiling of the red fruits revealed a wide range of bioactive phenolics: anthocyanins, flavonols, 5-*O*-caffeoylquinic acid and ellagic acid derivatives. The lemon juice displayed flavones, flavanones, flavonols, and hydroxycinnamic acids. In a general way, the novel beverage based on lemon juice and maqui berry (LM) was the most interesting blend in terms of antioxidant capacity. The results suggested that lemon juice enriched with berries, mainly maqui, could be of potential interest in the design of new drinks with a nutritive related function on health for chronic diseases.
Key words: *Aristotelia chilensis, Euterpe oleracea, Prunus spinosa, Citrus limon, antioxidant*

INTRODUCTION

Nowadays, chronic diseases, including cancer, cardiovascular, and neurological disorders, have been taking special relevance in society. For this reason, a continuous flow of information and research results on the positive impact of fruits and vegetables on these diseases has been rising. Previous reports have demonstrated that berries have potential against chronic diseases, and their use in the fresh form or mixed with other juices could act as preventive and improve human´s health status in these disorders (González-Molina et al., 2008; Gironés-Vilaplana et al., 2012). In this sense, the design of new beverages combining lemon (*Citrus limon* (L.) Burm. f.) juice with berries, resulting in effectively increased antioxidant properties of the lemon juice, could offer new possibilities against this actual problem of chronic diseases.

Maqui (*Aristotelia chilensis* (Mol.) Stuntz) is a common edible berry from central and southern Chile that is a source of natural colorants due to the presence of anthocyanins. This fruit has also been recently reported as one of the healthiest berries, due to its bioactive components (Céspedes et al., 2008; Schreckinger et al., 2010). Several reports have linked maqui's phenolics with its high antioxidant capacity (Rubilar et al., 2011), *in vitro* inhibition of adipogenesis and inflammation (Schreckinger et al., 2010), protection against oxidative stress (Miranda-Rottmann et al., 2002), cardioprotection (Céspedes et al., 2008), and *in vitro* and *in vivo* anti-diabetic effects (Rojo et al., 2011; Rubilar et al., 2011). Açaí (*Euterpe oleracea* Mart.) is a berry from palm tree, which is native from Amazon River area in South America. It is commonly used fresh and in the preparation of beverages, and has recently become popular as a functional food due to its antioxidant potential and phytochemical composition (Lichtenthäler et al., 2005). Potential benefits have been attributed to açaí fruits, extracts and juices: antioxidant (Jensen et al., 2008), anti-inflammatory (Jensen et al., 2008), reduction of selected markers of metabolic disease risk (Udani et al., 2011) or atherosclerosis (Schauss et al., 2009), pain reduction improved mobility (Jensen et al.,

2011), and antiproliferative properties (Hogan et al., 2010). Blackthorn (*Prunus spinosa* L.) is a fruit of deciduous shrubs native to Europe, mainly Spain, Portugal and Turkey (Barros et al., 2010). It is commonly used in the preparation of jams or, in northeast Spain, macerated with aniseed liqueur to obtain a digestive alcoholic drink called patxarán. Fruits have also been used as astringent, diuretic and purgative (Barros et al., 2010), and have recently been proved as antioxidants (Ganhão et al., 2010).
The aims of this work were to perform a phytochemical characterization of lemon juice, maqui, açaí and blackthorn berries, to design new blends of lemon juice enriched with these berries (5% w/v), and to determine their antioxidant capacity for future applications in nutrition and health.

MATERIAL AND METHODS

Lyophilized fruits were added separately to lemon juice to obtain final concentration of 5% w/v of the fruit in the beverage. In addition, control solutions using the same proportion in 0.18 M citric acid buffer (pH 2.46) were prepared to study the activities of the different fruits without lemon. Lemon juice alone was also assayed. Samples were labelled as follows: L (lemon juice control), LM 5% (lemon juice plus 5% of maqui berry), M 5% (5% maqui in citric acid buffer), LA 5% (lemon juice plus 5% of açaí berry), A 5% (5% açaí in citric acid buffer), LB 5% (lemon juice plus 5% of blackthorn fruit), B 5% (5% blackthorn in citric acid buffer). All the methods were performed in triplicate.

HPLC-DAD-ESI/MSn

Chromatographic analyses were carried out on a Luna C18 column (250 x 4.6 mm, 5 mm particle size; Phenomenex, Macclesfield, UK). Water:formic acid (99:1, v/v) and acetonitrile were used as mobile phases A and B, respectively, with a flow rate of 1 mL/min. The linear gradient started with 8% of solvent B, reaching 15% solvent B at 25 min, 22% at 55, and 40% at 60 min, which was maintained up to 70 min. The injection volume was 30 µL. Chromatograms were recorded at 280, 320, 360, and 520 nm. The HPLC-DAD-ESI/MS*n* analyses were carried out in an Agilent HPLC 1100 series equipped with a photodiode array detector and a mass detector in series (Agilent Technologies,Waldbronn, Germany). The HPLC system was controlled by ChemStation software (Agilent, version 08.03). The mass detector was an ion trap spectrometer (model G2445A) equipped with an electrospray ionization interface and was controlled by LCMSD software (Agilent, version 4.1). The ionization conditions were adjusted at 350°C and 4 kV for capillary temperature and voltage, respectively. The nebulizer pressure and flow rate of nitrogen were 65.0 psi and 11 L/min, respectively. The full-scan mass covered the range from *m*/*z* 100 up to *m*/*z* 1200. Collision induced fragmentation experiments were performed in the ion trap using helium as the collision gas, with voltage ramping cycles from 0.3 up to 2 V. MS*n* was carried out in the automatic mode on the more abundant fragment ion in MS(*n*-1).Prior to injection, samples were centrifuged (12000 rpm 5 min) and filtered through a PVDF Syringe Filter (0.22 µm). Anthocyanins were quantified as cyanidin 3-*O*-glucoside at 520 nm, flavonols as quercetin 3-*O*-rutinoside (rutin) at 360 nm, hydroxycinnamic acids as 5-*O*-caffeoylquinic acid at 320 nm.

DPPH radical scavening activity

The antiradical capacity was estimated spectrophotometrically in a Multiskan Ascent plate reader (Thermo Electron Corporation), by monitoring the disappearance of $DPPH^{\bullet}$ at 515 nm, according to Oliveira et al. (2010).

Superoxide radical ($O_2^{\bullet-}$) scavenging activity

Antiradical activity was determined spectrophotometrically in a 96-well plate reader by monitoring the effect of controls and blends on the $O_2^{\bullet-}$ induced reduction of NBT at 560 nm. Superoxide radicals were generated by the NADH/PMS system according to a described procedure (Ferreres et al., 2009).

Hypochlorous acid scavenging activity

The inhibition of hypochlorous acid-induced 5-thio-2-nitrobenzoic acid (TNB) oxidation to DTNB was performed according to a described procedure (Valentão et al., 2002), in a double beam spectrophotometer (Heλios α, Unicam, Leeds, UK) at 412 nm.

Hydroxyl radical assay

The deoxyribose method for determining the scavenging effect of samples on hydroxyl radicals was performed as described before (Valentão et al., 2002) in a double beam spectrophotometer (Heλios α, Unicam, Leeds, UK), programmed in photometric function, with the wavelength fixed at 532 nm.

RESULTS AND DISCUSSION

The analysis of the berry fruits revealed the presence of a wide range of polyphenols. Concerning maqui, different glycosides and di-glycosides of delphinidin and cyanidin were found (A1-A6, A9 and A11) (Fig. 1 Table 1), in accordance to previous reports (Gironés-Vilaplana et al., 2012). Flavonols (quercetin and myricetin derivatives, F1-F5, F7-F10), ellagic acid derivatives (E2 and E3), 5-*O*-caffeoylquinic acid (C6) and one ellagitannin (granatin B, E1) were also identified (Fig. 1, Table 1). Only maqui sample presented ellagic acid derivatives. With respect to açaí, three derivatives of cyanidin (A7, A8, and A10) and one of malvidin (A14) were identified (Fig. 1, Table 1). Likewise, quercetin (F5, F7, F9, and F10) and hydroxycinnamic acid derivatives (C3, C6 and C8) were found too (Fig. 1, Table 1). These compounds were previously reported in açaí (Pacheco-Palencia, & Talcott, 2010). Blackthorn presented four anthocyanins (two cyanidin-glycosides (A8, and A10) and two peonidin-glycosides (A12, A13)) (Fig. 1, Table 1), quercetin derivatives (F4, F6 and F8), and hydroxycinnamic acid derivatives (C1-C5, and C7), (Fig. 1, Table 1), in accordance with previous researches (Ganhão et al., 2010). Lemon juice contained flavones, flavanones, flavonols, and hydroxycinnamic acids (Fig. 1, Table 1), as described before (González-Molina et al., 2008).

Concerning the different antioxidant methods, in DPPH$^{\bullet}$ the maqui samples displayed the strongest activity (Table 2). All the samples, controls, and beverages showed a similar strong effect against $O_2^{\bullet -}$, being the blend of maqui berries plus lemon juice (LM) the most interesting (Table 2). Regarding HOCl the activity was of lesser intensity, but again LM was the most active sample (Table 2). LM and the blend of açai berries and lemon juice exerted

the highest capacity against •OH (Table 2). Although samples reacted differently against radical depending on the antioxidant methods employed, it is remarkable that the novel beverage based on lemon juice and maqui berry (LM) was the most active in all the assays tested (Table 4), probably due to the contribution of high content of polyphenols to the blend. Nevertheless, the results suggested that the polyphenol content is not the only reason for the antioxidant potential, but also the quality and the interactions between compounds in the food matrix may be also involved (Sun et al., 2011).

Table 2. Antioxidant activity of control fruits and blends

IC_{50}	DPPH•	$O_2^{\bullet-}$	HOCl	•OH
L	13.27 ± 0.17d	5.24 ± 0.43e	25.71 ± 0.43d	6.93 ± 0.22d

LSD, p<0.05	0.51	0.20	0.29	0.17

Results are expressed in IC_{50} (n=3, mg/ml). L: Lemon juice, M: 5% maqui in citric acid, A: 5% açaí in citric acid, B: 5% blackthorn in citric acid, LM: 5% maqui in lemon juice, LA: 5% açaí in lemon juice, LB: 5% blackthorn in lemon juice. Means (n=3) in the same columns followed by different letters are significantly different at P < 0.05 according to Tukey's test.

CONCLUSIONS

New blends made of lemon juice and different exotic (maqui, açaí) and Iberian (blackthorn) berries with health promoting activities were developed, and their phytochemical profile has been described, revealing a wide range of bioactive phenolics: anthocyanins, flavonols, hydroxycinnamic acid derivatives and ellagic acid derivatives in berries and flavones, flavanones, flavonols, and hydroxycinnamic acids from lemon juice. Results of the different radical-scavenging methods indicated that the lemon-maqui novel beverage (LM) is the most interesting blend in terms of antioxidant activity.

ACKNOWLEDGEMENTS

Authors would like to express their gratitude to the Spanish Ministry of Economy and Competivity for the funding through the project CONSOLIDER-INGENIO 2010 Research Project FUN-C-FOOD (CSD2007-00063) and Fundação para a Ciência e a Tecnologia (FCT) for grant no. PEst-C/EQB/LA0006/2011. Part of this work was also funded by CYTED programme thematic network 112RT0460.

ABSTRACT: Microalgal biomass is a rich source of some nutrients, such as n-3 and n-6 fatty acids, β-carotene, proteins, minerals, and other essential nutrients, which could potentially be used as functional food ingredients. In this work, the fatty acid composition and protein content of *Spirulina Platensis* and several non-toxic strains of *Nostoc spp*. and *Anabaena spp.* originating from Serbia was investigated. Analyses of fatty acid methyl esters (FAMES) were carried out by gas chromatography coupled with flame ionization detection (GC-FID), and the content of crude protein was determined by Dumas combustion method. The results show that 16 carbon (16:0 and 16:1 types) and 18 carbon (18:1, 18:2 and 18:3 types) chain fatty acids represent the most significant constituents of these species. Content of the relatively rare γ-linoleic acid (GLA, 18:3n-6) was highest in the *Spirulina* samples, while it is also shown to be present in the *Nostoc* species, depending on the chemical composition of the growth medium used. All of the investigated species showed very high crude protein content in the dry algal biomass (ranging from 42.8% to 76.5%). It can be concluded that the investigated species of cyanobacteria represent potential rich sources of protein and commercially attractive fatty acids and, since they are shown to be non-toxic, they can be considered as components of various functional food products.
Key words: *cyanobacteria, functional foods, fatty acids, protein*

INTRODUCTION

Cyanobacterial species are among the oldest living organisms known to exist today, and have been known to be used as human food since ancient times (Henrikson, 2009; Ciferri, 1983). In recent years, there has been an increased interest in benefits of using functional foods, that is, foods that are able to provide additional health benefits for human health, other than basic nutritional and energetic requirements (Goldberg, 1996). Microalgal biomass is a rich source of some nutrients, such as n-3 and n-6 fatty acids, β-carotene, proteins, minerals, and other essential nutrients, which could potentially be used as functional food ingredients. A number of papers investigating various potential health benefits of cyanobacteria exist today (Henrikson, 2009; Estrada et al., 2001; Tokusoglu and Unal, 2003). *Spirulina platensis*, which is known for its nutritional properties is a very rich source of biologically valuable proteins and essential fatty acids. Species of cyanobacteria which are especially rich in lipids can also be considered as a potential future source of biofuel and other industrial products (Mata et al., 2010).
In this work, the fatty acid composition and protein content of *Spirulina Platensis* and several non-toxic strains of *Nostoc spp*. and *Anabaena spp.* originating from Serbia was investigated. Preliminary results of the analyses are given in order to assess the potential use of these microorganisms as components of functional foods.

MATERIAL AND METHODS

Samples of *Spirulina Platensis*, *Nostoc spp*. (labeled as 2S7B) and *Anabaena spp*. (labeled as C2 and C5) strains were obtained from the Department of Biology and Ecology at the Faculty of Sciences, University of Novi Sad. All of the investigated strains originated from Vojvodina region of Serbia (Simeunović, 2005). *Nostoc* and *Anabaena* strains were cultivated under laboratory conditions in synthetic mineral broth BG-11, with (+N) and without added nitrogen (-N) (Rippka et al.,1979) while *Spirulina* strains were cultivated in mineral SOT broth (Soong, 1980). All the investigated cyanobacteria were cultivated as steady cultures in Erlenmeyer flasks at temperature of 22-24^{o}C and light intensity of 50 μmol m-2s-1. Daily light regimen was set to 12 hours of light and 12 hours of darkness. After 25 days of cultivation, the strains were lyophilized to obtain the dry algal biomass for analyses and kept well sealed in refrigerator until usage.

Protein and total lipid content

LECO Truspec CHNS analyzer (LECO, St. Joseph, MI, USA) which uses the Dumas combustion method for nitrogen determination was used for analysis of the lyophilized samples. Content of crude protein was calculated from the nitrogen content and expressed as the protein content of the dry algal biomass (Beljkaš et al., 2010).

Total lipid content was determined by extraction of the samples with chloroform-methanol solution (3×3 ml at 2:1 ratio of chloroform to methanol) and weighing the residue after evaporation of the solvents in the stream of nitrogen (Colla et al., 2007).

Fatty acid determination

Fatty acid methyl esters were prepared from the extracted lipids by transesterifitacion using 14% boron(III)-fluoride in methanol (Karlović and Andrić, 1996). The obtained samples were analyzed by a GC Agilent 7890A system with flame-ionization detector (FID), autoinjection module for liquid samples, equipped with fused silica capillary column (DB-WAX 30 m, 0.25 mm, 0.50 um). Helium was used as a carrier gas (purity > 99.9997 vol %, flow rate = 1.26 ml/min). The fatty acids peaks were identified by comparison of retention times with retention times of standards from Supelco 37 component fatty acid methyl ester mix (Sigma-Aldrich, EU) and with data from internal data library, based on previous experiments. Results were expressed as mass of fatty acid or fatty acid group (g) in 100 g of fatty acids.

RESULTS AND DISCUSSION

The results of the total lipid and protein content of the investigated samples are shown in Figure 1. The total lipid content varied from 6.83% (for C5+N *Anabaena spp.* strain) to 26.99% (*Spirulina Platensis*). Addition of nitrogen compounds to the cultivating broth negatively impacted the total lipid content of the investigated *Nostoc* and *Anabaena* strains, which is in accordance with similar findings by other authors (Tedesco and Duerr, 1989). The crude protein content was found to be very high in all the investigated cyanobacterial samples, varying from 42.8% (2S7B-N *Nostoc* spp. strain) to 76.5% (C5+N *Anabaena spp.* strain). In this case, the addition of nitrogen compounds to the cultivating broth positively impacted the protein content of the *Nostoc* and *Anabaena* strains. It should be noted however, that the Dumas combustion method which was used for determination of crude protein content causes all forms of nitrogen in the investigated sample to be converted to molecular nitrogen and therefore even the non-protein nitrogen containing compounds (alkaloids, amino acid derivatives, inorganic nitrogen compounds, etc.) can falsely be measured as total protein content (Beljkaš et al., 2010).

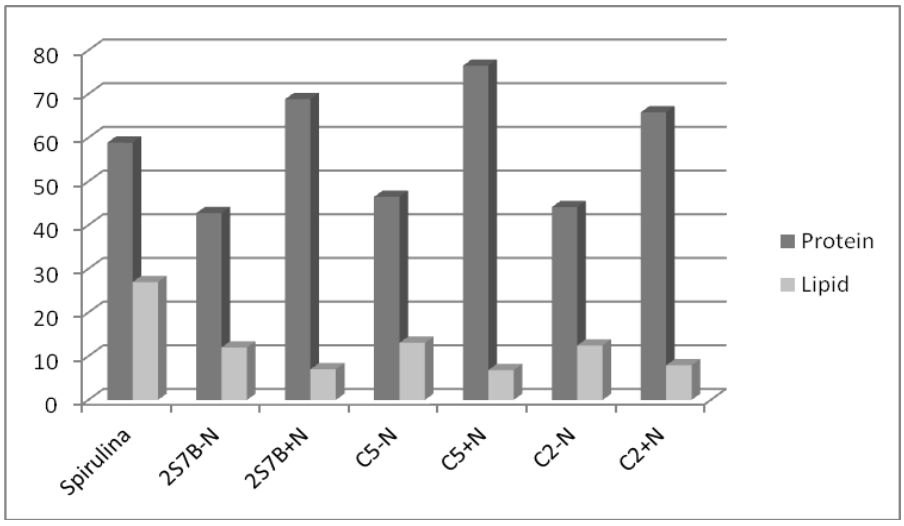

Figure 1. Total lipid and protein content of the investigated cyanobacterial strains

The results of fatty acid analysis by GC-FID are shown in table 1. The results show that 16 carbon (C16:0 and C16:1 types) and 18 carbon (C18:1, C18:2 and C18:3 types) chain fatty acids represent the most significant constituents of these species. Undecanoic acid (C11:0) acid was also determined in all of the investigated samples, ranging in content from 1.96% to 4.65%. Content of the relatively rare γ-linoleic acid (GLA, C18:3n-6) was highest in the *Spirulina* samples, while it is also shown to be present in the *Nostoc* species, although only in trace amounts (not shown in the table). *Spirulina* also showed a presence of significant amount (16.2%) of *cis*-11-eicosenoic (C20:1) acid, which was not present in other investigated species of cyanobacteria. *Nostoc* and *Anabaena* samples had a significant amount of α-linoleic (C18:3n-3) and arachidic (C20:0) acid, which were not present in the investigated *Spirulina* species, as well as much higher content of *cis*-13,16-docosadienoic (C22:2) acid (ranging from 6.80% to 13.07% in these species compared to 0.18% in *Spirulina* sample).

Saturated fatty acids (SFA) have been labeled as a possible cause of cancers and coronary heart disease when present in excessive amounts in human diet. The mean ratio of PUFA/SFA recommended by the British Department of Health is more than 0.45, and WHO/FAO experts have reported guidelines for a “balanced diet” in which suggested ratio of PUFA/SFA is above 0.4 (Wood et al., 2008; HMSO, 1994). All of the investigated species of cyanobacteria showed a favourable PUFA/SFA ratio (from 1.65 to 3.71).

SFA - saturated fatty acid; MUFA - monounsaturated fatty acids; PUFA – polyunsaturated fatty acids; UFA - unsaturated fatty acids (total)

CONCLUSIONS

The investigated species of cyanobacteria in this work have shown to possess very high protein content, but further analysis of the amino acid composition is necessary in order to assess their potential value as a source of proteins in human diet. The fatty acid profile of all the investigated samples showed a favourable PUFA/SFA ratio which indicates a potentially positive health effect of the fats obtained from these species. It can be concluded that the investigated species of cyanobacteria represent potential rich sources of protein and commercially attractive fatty acids and, since they are shown to be non-toxic, they can be considered as components of various functional food products.

ABSTRACT: Thermally treated foods, like bakery products, contain Maillard reaction products some of which are proved as the substances with antioxidant properties. There are many literature data stating that Maillard reaction products together with polyphenols as the potent antioxidants contribute to the overall antioxidant capacity of some bakery products. It was found that pyrazine cation radicals are the precursors in formation of Maillard reaction products. The aim of this work was to investigate the interaction of these radicals with some polyphenols that are frequently contained in ingredients used for bakery production. The formation of relatively stable free radicals in alkaline reaction mixtures (pH 9.0) of the model systems consist of D(+)-glucose (1.0 M) and structural isomers of aminobutanoic acid (1.0 M) heated at the temperature of 98 °C for 20 minutes has been detected by electron spin resonance (ESR) spectrometry. Based on the analyses of hyperfine structure of ESR spectra of reaction mixtures of model systems, the presence of 1,4-disubstituted pyrazine cation radicals formed at the initial stage of Maillard reaction was found. Different polyphenols (gallic, caffeic, ferulic, chlorogenic acid, and tannic acid) were added in model systems to investigate their influence on the generation of pyrazine cation radicals. Decrease of relative intensities (RI) of ESR spectra signals indicated polyphenols' ability to inhibit the generation of the pyrazine cation radicals. It was found that tannic acid was the most efficient of all investigated polyphenols in inhibiting the formation of free radicals at the initial stage of Maillard reaction followed by gallic $>$ caffeic $\geq$ chlorogenic $>$ ferulic acid. These findings indicate a complex relation between antioxidants and the precursor of Maillard reaction products. Further investigation is needed to reveal the overall contribution of both polyphenol(s) and Maillard reaction products to antioxidant capacity of thermally treated product.
Key words: *pyrazine cation radicals, polyphenols, ESR*

INTRODUCTION

Browning reactions, which are some of the most important reactions occurring during food processing and storage represent the phenomenon with significant implications in food technology, nutrition and health. The major groups of reactions resulting in browning are enzymatic and non-enzymatic browning. The latter is favoured by thermal treatment and includes different reactions such as Maillard reaction and caramelisation.
Maillard reaction occurs between the reactive carbonyl group of the sugar and the amino group of the amino acids to produce compounds responsible for a range of odours and flavours in thermally treated foods.
It has been reported that Maillard reaction products possess certain antioxidant activity (Dittrich et al., 2003; Morales and Jimenez-Perez, 2001; Yoshimura et al., 1997). The highest antioxidant activity of Maillard reaction products is generally associated to the formation of melanoidins (Hayase et al., 1989; Yen and Hsieh, 1995; Manzocco et al., 2001). Therefore, increased antioxidant activity of some functional bakery products was addressed not only to the presence of polyphenols present in the functional ingredients but to the antioxidant activity of Maillard reaction products which were formed during baking (Hsu at al., 2004).

From that point of view, Maillard reaction is desirable for increasing overall antioxidant capacity of thermally treated products.
On the other hand, Maillard reaction is known for the formation of relatively stable free radicals in the initial stage of the reaction which were identified as 1,4-disubstituted pyrazine cation radicals (Namiki and Hayashi, 1975; Hayashi et al., 1977; Hayashi and Namiki, 1986; Milić and Piletić, 1984). Kato et al. (1996) found that the reaction mixture of glucose and glycine in the initial stage of Maillard reaction showed characteristic multiline electron spin resonance (ESR) signals due to the presence of 1,4-di(carboxymethyl)pyrazine cation radical.
Pyrazine cation radical may be a key intermediate of imidazoquinoxaline-type mutagens in heated foods (Felton and Knize, 1991; Kikugawa et al., 2000), especially meat (Pearsons et al., 1992).
Food antioxidants, ascorbic acid and erythorbic acid effectively scavenged the pyrazine cation radical generated in the reaction of glucose and glycine (Kikugawa et al., 2000). It could be scavenged by phenolic antioxidants including epigallocatehin gallate (Kato et al., 1996), cysteine and unsaturated fatty acids (Kikugawa et al., 1999). Furthermore, heterocyclic amines as the genotoxic carcinogens that were produced via pyrazine cation radical formation were affected by the addition of black or green tea, and of the tea polyphenols theaflavine gallate and epigallocatechin gallate (Weisburger et al., 1994). Two flavonoids, luteiolin and quercetin, and caffeic acid were found to suppress the formation of heterocyclic amines in cooked foods (Oguri et al., 1998).
Knowing that Maillard reaction may increase overall antioxidant activity of thermally treated foods and also provides pyrazine cation radicals that could deplete antioxidants, the aim of this work was directed to the investigation of the interaction of free radicals characteristic for Maillard rection with some polyphenols frequently contained in ingredients which are used inbakery production.

MATERIAL AND METHODS

Model systems

The formation of relatively stable free radicals in the initial stage of the Maillard reaction was carried out in following model systems:

I D(+)-glucose (1.0 M) - 2-aminobutanoic acid (1.0 M)
II D(+)-glucose (1.0 M) - 3-aminobutanoic acid (1.0 M)
III D(+)-glucose (1.0 M) - 4-aminobutanoic acid (1.0 M)

The pH value of model systems was adjusted to 9.0 using 0.1 M potassium hydroxide and obtained mixtures were heated at the temperature of 98 °C.
The initial stage of the Maillard reaction was detected by measuring the formation of relatively stable free radicals after 20 minutes (blank probe).
The influence of different polyphenols (gallic, caffeic, ferulic, chlorogenic acid, and tannic acid) on the formation of free radicals which are characteristic for the initial stage of the Maillard reaction was investigated by adding each polyphenol at the concentrations of 10^{-3}, $5x10^{-3}$, 10^{-2}, $2.5x10^{-2}$, $5x10^{-2}$ and 10^{-1} mol/dm^3 to the blank probe before heating.
Antiradical activity (AA in %) of poliphenols was calculated according to the following equation:

$$AA=100\cdot(h_o-h_x)/h_o \qquad /1/$$

where h_o and h_x are the heights of the first peak in the ESR spectrum of free radicals of blank probe and probe, respectively.

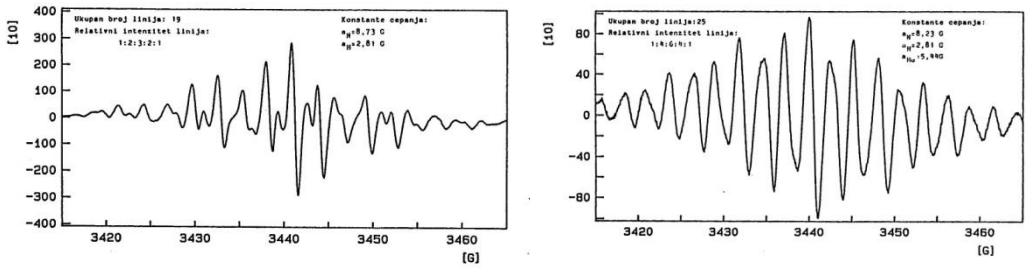
Detection of free radicals

ESR spectra of generated free radicals in investigated Maillard reaction model systems were recorded using Bruker 300E ESR spectrometer (Bruker, Rheinstetten, Germany) under the following conditions: modulation field 100 kHz, modulation amplitude 1.021 G, receiver gain

10^3, time constant 1.28 ms, conversion time 5.234 s, centre field 3440.00 G, sweep width 50.00 G, microwave frequency 9.65 GHz, microwave power 0.632 mW, and temperature (23 ± 1) °C.
A quartz flat cell Bruker ER-160FC was used for detection. Splitting constants were calculated from computer-generated second derivatives of the spectra after optimizing signal-to-noise ratios and were verified by computer simulations. ESR spectral files were imported into the WinSim program (WinSim, Sugar Land, TX, USA) for the analysis of the hyperfine splitting constants (Duling, 1994).

DISCUSSION AND RESULTS

The formation of relatively stable free radicals in alkaline reaction mixtures (pH 9.0) of the model systems consist of D(+)-glucose (1.0 M) and structural isomers of aminobutanoic acid (1.0 M) heated at the temperature of 98 °C for 20 minutes has been detected by electron spin resonance (ESR) spectrometry. The ESR spectra of produced radicals in the initial stage of Maillard reaction are presented in Fig. 1a and b.
The ESR spectrum presents in Fig. 1a consists of 19 lines of the relative intensities of 1:2:3:2:1, characteristic for the presence of 1,4-disubstituted pyrazine cation radicals formed in both systems with the hyperfine coupling constants of a_N = 8.73 G and a_H = 2.81 G. After computer simulation of the ESR spectrum with these hyperfine coupling constants, the obtained simulated spectrum had the same appearance as the experimental spectrum.
In contrast to model systems I and II, ESR spectrum registered in model system III (Fig. 1b) is characterized by hyperfine coupling constants of two pyrazine nitrogens (a_N = 8.23 G), four equivalent pyrazine protons (a_H = 2.81 G) and four equivalent side chain protons (a_H = 5,44 G) confirming the formation of 1,4-disubstituted pyrazine cation radicals in the model system III.
These observations were consistent with the earlier results of Namiki and Hayashi (1975), Milić and Piletić (1984) and Rizzi (2004).
The addition of polyphenols in the concentration range from 10^{-3} to 10^{-1} mol/dm^{-3} in all investigated model systems (blank probes) affected the formation of 1,4-disubstituted pyrazine cation radicals. It was registered by decreasing of intensities of ESR signal.
The influence of gallic, caffeic, ferulic, chlorogenic acid, and tannic acid on the generation of pyrazine cation radicals are presented in Fig 2.



a) b)

Fig. 1. ESR spectra of reaction mixture (a) of model systems I and II (2- or 3-aminobutanoic acid (1.0 M) and D(+)-glucose (1.0 M)) heated at 98 °C for 20 minutes; (b) of model system III (4-aminobutanoic acid (1.0 M) and D(+)-glucose (1.0 M)) heated at 98 °C for 20 minutes

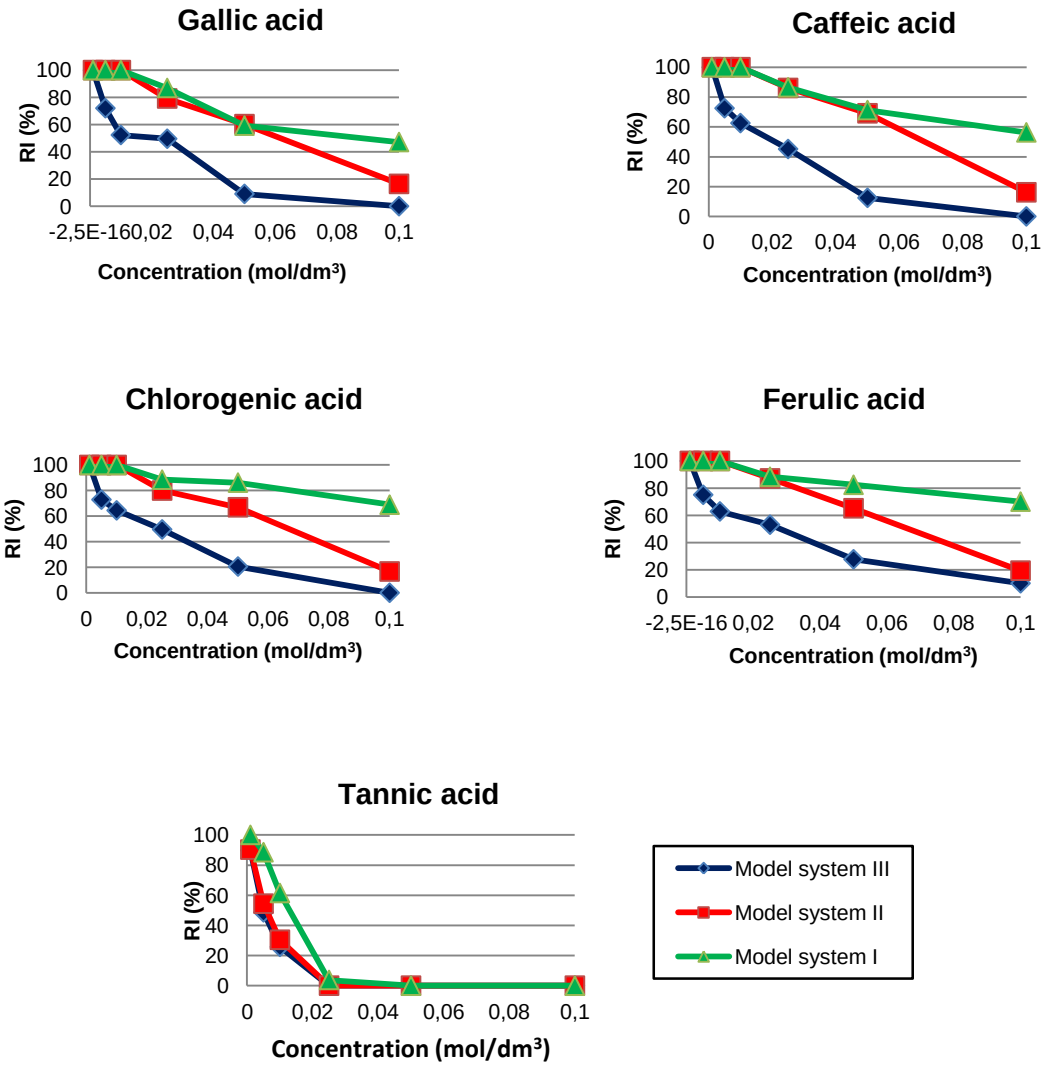


Fig. 2. The influence of (a) gallic, (b) caffeic, (c) ferulic, (d) chlorogenic acid, and (e) tannic acid on the generation of 1,4-disubstituted pyrazine cation radicals formed in the initial stage of the Maillard reaction in model systems I, II and III

Phenolic compounds which are known as powerful antioxidants (Shahidi and Wanasundara, 1992) probably inhibit the generation of pyrazine cation radicals in alkaline media by a single electron transfer followed by conversion of phenolic compounds into phenoxyl radicals. The stabilization of phenoxyl radicals by resonance depends on the structure of antioxidants and influences their effectiveness. The proposed mechanism could be confirmed by the results which were obtained using quinic acid in the defined concentration range (10^{-3}-10^{-1} mol/dm^{-3}) to suppress the formation of pyrazine cation radicals in all model systems. It was found that quinic acid, the moiety of chlorogenic acid, did not inhibit the formation of pyrazine cation radicals under all investigated conditions. That means that chlorogenic acid achieved its antiradical activity towards pyrazine cation radicals through its caffeoyl part via proposed mechanism.

The antiradical activity of polyphenols depends on the model system, as well as the type and concentration of polyphenols (Fig. 2).

The effectiveness of investigated polyphenols to suppress the formation of pyrazine cation radicals in investigated model systems was in the following order: model system III > model system II > model system I. The established order could be explained by steric hindrance between pyrazine cation radical and polyphenol. Namely, pyrazine cation radical formed in the model system III possess four α-protones in contrast to two α-protones bound to the

pyrazine cation radical generated in model systems I and II. Therefore, the interaction between pyrazine cation radical and polyphenol in model system III could be easier and resulted in better suppression of formation of pyrazine cation radicals.
It was found that tannic acid was the most efficient of all investigated polyphenols in inhibiting the formation of free radicals in the initial stage of Maillard reaction followed by gallic $>$ caffeic $\geq$ chlorogenic $>$ ferulic acid. Effectiveness of investigated acids is the result of the abilities of formed phenoxyl radicals to stabilize by resonance. It was previously reported that gallic acid is much potent antioxidant that caffeic and chlorogenic acids due to its chemical features (Brand-Williams et al., 1995). Similar antiradical activities of caffeic and chlorogenic acids were due to their similar structures, i.e. chlorogenic acid reacts using its caffeoyl part as it is mentioned above.
Ferulic acid expressed the lowest antiradical activity towards pyrazine cation radicals among all investigated polyphenols, but was still active (Fig. 3). As this compound represents the major phenolic acid in many cereal products (Liyana-Pathirana and Shahidi, 2007), its activity is very important, especially in bakery products.
Tannic acid was identified as the most potent inhibitor in formation of pyrazine cation radicals (Fig. 3). The ability of tannic acid to act as a potent suppressor was supported by the stability of tannic acid radicals which were detected by ESR (Fujita at al., 1988).
The involvement of polyphenols in the inhibition of formation of pyrazine cation radicals in the initial stage of Maillard reaction leads to the dilemma about contribution of Maillard reaction in overall antioxidant activity of thermally treated bakery products. Nevertheless, it is doubtless that polyphenols could scavenge pyrazine cation radicals and inhibit the formation of imidazoquinoxaline-type mutagens in heated foods.

CONCLUSIONS

It was found that polyphenols inhibit the formation of pyrazine cation radicals that were formed in the initial stage of Maillard reaction in heated alkaline reaction mixtures of model systems consisted of D(+)-glucose and structural isomers of aminobutanoic acid. The effectiveness of investigated polyphenols to suppress the formation of pyrazine cation radicals was in the following order: tannic $>>$ gallic $>$ caffeic $\geq$ chlorogenic $>$ ferulic acid.

ABSTRACT: The aerial parts of *Pterospartum tridentatum*, a wild growing species in Portugal used in traditional medicine and gastronomy, were harvested at different stages (vegetative phase, flowering phase and beginning of dormancy) in two locations in Portugal (Malcata and Gardunha mountains), and the respective aqueous extracts have been studied. The influence of the seasonal variation in the extraction yield, total phenolic content and antioxidant activity was evaluated. The extraction was carried out in boiling water in consecutive steps. After each step, the aqueous extract was separated and fresh water was added maintaining the same plant material. The procedure was repeated seven times, within an overall time period of 180 minutes.
Higher extraction yields were achieved with plant stems collected at the vegetative phases, either from Malcata or Gardunha regions. The total phenolic content of the extracts from Malcata plants ranged from 273 mg to 400 mg gallic acid equivalent/g dry matter, which was quite similar to that determined for extracts from Gardunha (245 to 394 mg gallic acid equivalent/g dry matter). The antioxidant activity was determined by the radical scavenging activity method using 2,2-diphenyl-1-picrylhydrazyl radical (DPPH). The greatest radical scavenging activity was observed in the flowers extracts, even though all extracts produced presented a good antioxidant activity. Furthermore, the antioxidant activity was not affected by the exposure of the plant material at 100ºC for long periods of time (180 min).
The results show that *Pterospartum tridentatum* has a great potential to be used as a new source of natural antioxidants for the food industry.
Key words: *Pterospartum tridentatum; Aqueous extracts; Extraction yield; Antioxidant activity; Phenolic content.*

INTRODUCTION

Researchers are looking for natural antioxidants as alternative to synthetic compounds, such as butylated hydroxytoluene (BHT), butylated hidroxyanisole (BHA) and *ter*-butylhidroxyquinone (TBHQ) that are widely used in the food and pharmaceutical industries. The interest in plant-derived food additives has grown, because the consumption of synthetic antioxidants has been related to the possible health risks.
Some plants synthesize secondary metabolites with biological activity, namely poliphenolic compounds and alkaloids. The amount and type of metabolites produced is dependent on the plant species and environmental factors that affect growth.
Polyphenols participate in plant defense mechanisms to counteract reactive oxygen species in order to avoid oxidative damage. They are often presumed to be safe for human consumption, due to their plant origin, and are used as health promoting ingredients (Moyo *et al*., 2010).
Pterospartum tridentatum L. Willk. [=*Chamaespartium tridentatum* (L.) P. Gibbs.; *Genista tridentata* L. is an European endemic Leguminosae (=Fabaceae) species belonging to the subfamily Papilionoideae and known as *carqueja* or *carqueija* in Portugal. This small shrub,

growing spontaneously up to 100 cm, is very common in the mountains of the north of Portugal and can usually be found in the understory of *Arbutus unedo, Pinus pinaster* and *Eucalyptus* forests. Some authors refer the use of *P. tridentatum* in popular medicine, claiming to possess digestive properties and activity against high blood pressure, cholesterol, diabetes and even obesity (Vitor *et al*., 2004). It is also used in gastronomy as a condiment in rice and rabbit stew to improve flavor. *Carqueja* is an underexploited natural source of compounds with biological activity, which should be fully characterized aiming to its valorization.
In the present study, the aerial parts of *P. tridentatum* were collected in two locations in Portugal (Malcata and Gardunha mountains), at three different vegetative stages. The effect of the harvest period and extraction time on the extract yield, as well as on the total phenolic content and antioxidant activity, was evaluated.

MATERIAL AND METHODS

Samples of the aerial parts of *Pterospartum tridentatum* were collected at different stages: vegetative phase (end of February), flowering period (in May) and beginning of dormancy (end of October). The shrubs were collected in two locations in Portugal: Gardunha and Malcata mountains.
Consecutive aqueous extraction steps were performed by refluxing a mixture of 25 g of plant samples and 100 mL of distilled water in a Clevenger apparatus. They were processed in consecutive time periods in boiling water: 15, 30, 60, 90, and 120, 150 and 180 minutes. After each time period, the aqueous phase was removed and the extraction continued after the addition of an equal amount of fresh water to the same plant material. The recovered aqueous phases were freeze-dried and a solid extract was obtained.
The total phenolic content (TP) of the extracts was evaluated by the method Ribéreau-Gayon (1970), measuring the absorbance at 280 nm. TP values were expressed as mg gallic acid equivalents per gram dry matter. All trials were carried out in duplicate.
The antioxidant activity of the solid extracts was determined by the radical scavenging activity method using 2,2-diphenyl-1-picrylhydrazyl radical (DPPH). The freeze-dried extracts (0.2 mg) were dissolved in water (1 mL), and added to a methanolic DPPH solution (4 mL). After 40 min incubation period at room temperature, in the dark, the absorvance was measured at 517 nm. The radical scavenging activity (RSA) was calculated as follows: RSA (%) = $[(Abs_{control} - Abs_{sample})/ Abs_{control}] \times 100$, where $Abs_{control}$ is the absorvance of DPPH radical in methanol and Abs_{sample} is the absorvance of DPPH radical after reaction with sample extract. Results were expressed as Trolox equivalents (mM Trolox/100 g extract dry mass).

RESULTS AND DISCUSSION

Extraction yield

The cumulative extraction yields presented some differences when comparing different harvesting seasons. Higher extraction yields were achieved from plant steams collected at the vegetative phases, either from Malcata or Gardunha regions (Figure 1). Regarding the extraction from plant parts collected in Malcata, a higher extraction yield was also obtained from the flowers (Figure 1A), when compared to that obtained from stems collected during flowering and in the beginning of dormancy. For all vegetative stages, there was an increase of the cumulative extraction yield over the consecutive batch extraction steps, for all the collected plant parts. This fact means that the plant material still contained unextracted compounds even after seven extraction steps.

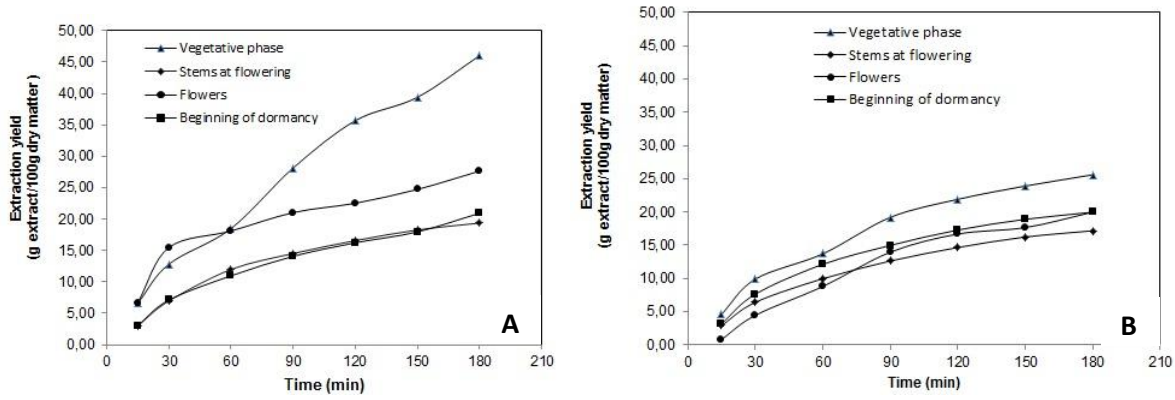

Figure 1. Cumulative curve of the extraction yield of *P. tridentatum* aereal parts collected in Malcata (A) and Gardunha (B) at various stages (stems at the vegetative phase; stems during flowering; flowers; stems in the beginning of dormancy).

The stems from flowering phase and beginning of dormancy showed lower yield values comparing to the plant parts harvested in the other phases. In the beginning of dormancy this fact may be explained by the plant investment in the previous period with fruiting and seed production. The lower extraction yield observed with stems from flowering phase may be due to the channeling of reserves for the floral organ.

In order to determine the most convenient extraction time (which is related with the number of batch extraction steps), the mass of extract recovered in each extraction step was converted as the percentage of the overall mass of extract obtained (Table 1). It was found that the mass of extract recovered after 60 minutes (three extraction steps), for Malcata and Gardunha plants, was between 40 and 65% of the overall mass recovered. After 90 minutes (four extraction steps) the percentage of extract recovered was between 61% to 79%, and after 120 minutes (seven extraction steps) it was on average more than 75%, which may be considered an acceptable value for the extraction time and energy costs involved. In most cases, the addition of an extra hour of extraction leads to a low increase on the cumulative extraction yield. For that reason, the extraction time of 120 minutes (five extraction steps) was considered to be a good compromise between the amount of extract recovered and the time and energy involved in the process.

Table 1. Mass of extract as percentage of the overall mass recovered as a function of extraction time.

	Malcata				**Gardunha**			
Time (min)	**Extract recovered (%)**				**Extract recovered (%)**			
	Vegetative phase	Flowering		Beginning dormancy	Vegetative phase	Flowering		Beginning dormancy
		Stem	Flower			Stem	Flower	
15	14.4	15.6	24.2	14.7	17.9	16.7	4.5	15.9
30	27.9	36.0	55.9	34.0	38.6	37.2	25.1	38.1
60	40.2	61.9	65.5	52.4	53.5	57.9	49.7	60.7
90	61.1	75.0	76.1	67.3	74.9	73.5	79.0	75.0
120	77.5	85.6	81.5	77.6	85.5	85.4	94.5	86.6
150	85.6	94.4	89.5	85.8	93.4	94.6	100.0	94.7
180	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

According to the results obtained by Luis *et al*. (2009) it is verified that the values of extraction yield of aqueous extracts in *Erica* spp. and *Cytisus scoparius* was 4.64 and 4.98% w/w (d.m.) respectively. In another study including *Carissa opaca* species (medicinal product

used in Pakistan) the extraction efficiency was 10.7 ± 0.99% w/w (d.m.) (Sahreen *et al*., 2010). These values are much lower than those observed in this work.

Total phenolic content

The total phenolic content of the extracts recovered from Malcata plants (Figure 2A) ranged from 273 mg to 400 mg gallic acid equivalent/g dry matter, which was quite similar to that determined for extracts from Gardunha (245 to 394 mg gallic acid equivalent/g dry matter) (Figure 2B). For both Malcata and Gardunha plant extracts, the lowest value was observed in flowers extracts after 180 minutes of extraction (eight consecutive extraction steps) and the highest value in vegetative phase after 150 minutes.

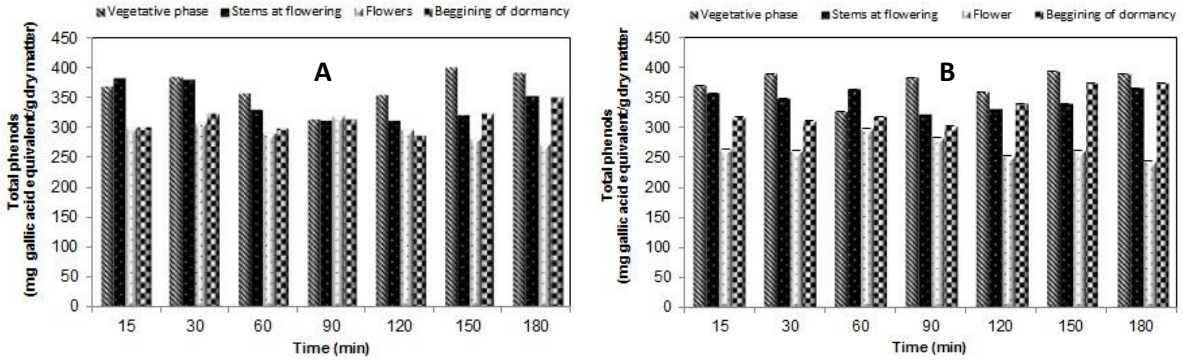

Figure 2 - Total phenols in the aqueous extract of *P. tridentatum* from Malcata (A) and Gardunha (B) (Vegetative phase; Stems at flowering; Flowers; Beginning of dormancy). Measurements were made in duplicate (SD ≤ 0.08).

We can consider that all extracts, from different vegetative phases and different extraction times, presented high levels of phenolic compounds when compared to other species described by Sousa *et al.* (2007). The phenols present in the species *Pterospartum tridentatum* show high levels at any stage of the vegetative cycle and were superior to other studied species such as *Harpephyllum caffrum*, *Sclerocarya birrea* (Ajila *et al*., 2010) and *Carissa opaca* (Saherr *et al*., 2010).

A similar study with five medicinal plants (*Terminalia brasiliensis*, *Terminalia fagifolia*, *Cenostigma macrophyllum*, *Qualea grandiflora*, *Copernicia prunifer)* carried out by Sousa *et al*. (2007) has shown much lower phenolic contents ranging from 11.55 mg gallic acid equivalent/g dry matter in the root extract of *C. prunifera* and 97.6 mg gallic acid equivalent/g dry matter in the leaf extract of *T. fagifolia*. Rockenboch *et al*. (2008) obtained values of total phenolic compounds in aqueous extract of *Physalis peruviana* fruit (47.8 mg gallic acid equivalent/g dry matter).

Antioxidant Activity

All extracts presented antioxidant activity, but higher AA values were obtained for the extracts recovered from plants harvested during the flowering period (Figure 3).

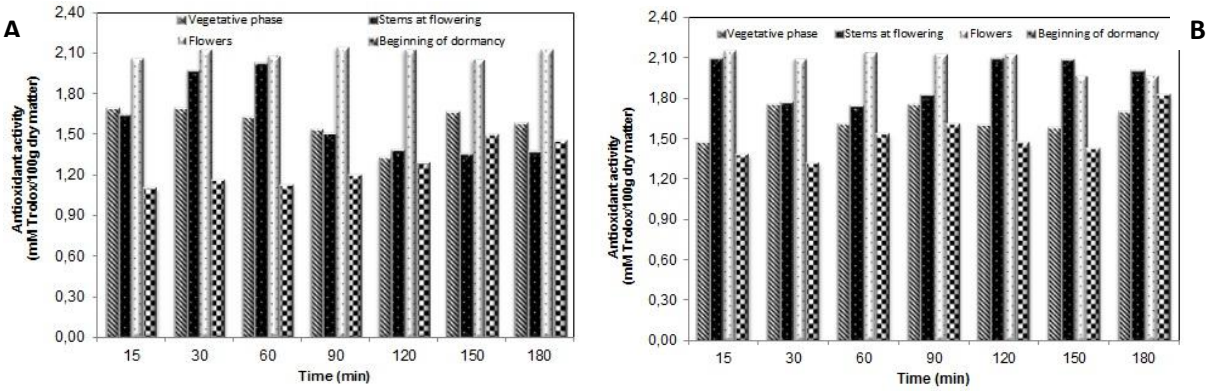

Figure 3 - Antioxidant activity of aqueous extracts of *P. tridentatum* from Malcata (A) and Gardunha (B) (Vegetative phase; Stems at flowering; Flowers; Beginning of dormancy). Measurements were made in triplicate (SD ≤ 0.02).

The values are consistent with the work reported by Luis *et al*. (2009), in which the AA of aqueous extract of *P. tridentatum* was 1.30 mMTrolox/100g dry matter.

CONCLUSIONS

The extraction process of *Pterospartum tridentatum* aerial parts presented a high extraction yield, being the highest yields achieved when processing flowers and plant stems harvested at the vegetative phase. The aqueous extracts presented high contents of total phenolic compounds, which did not change significantly with the harvesting season. In addition, consecutive extracts isolated from the same plant material over time have shown to possess similar total phenolic content and maintained their antioxidant activity. The results show that *Pterospartum tridentatum* has a great potential to be used as a new source of natural antioxidants for the food industry. Future studies will be focused on the identification of the major compounds present in the aqueous extracts and the correlation between the chemical species with the antioxidant activity. Vitor *et al*. (2004) identified some compounds such as isoflavones (namely prunetin, genistin and sissotrin) and the flavonol glycoside isoquercitrin.

ABSTRACT:. In this paper content of phenolic compounds from black radish (*Raphanus sativus* L. var niger) roots of different size were examined. Black radish grown in Serbia, with the same period of development, grouped by size into three groups: (R1) with mass of 350±15 g; (R2): 100±10 g and (R3): 35±5 g, were used. Plant extracts were prepared by using 80% (v/v) ethanol and total phenolic compounds content was determined by spectrometric and the free radical scavenging abilities by DPPH radical method. The phenolic compounds content was in range 42.9 (R1) to 19.7 (R3) μmol chlorogenic acid per g of dried plant material, i.e. 443.7 to 208.6 μmol chlorogenic acid per g of dry extract. The radical scavenging capacity ranged from 88.3 (R1) to 55.6% (R3) and the EC_{50} values were from 1.59 to 2.24 mg/ml. The phenolic compounds content and radical scavenging capacity depended on root size in such a way that bigger root means higher content of phenolic compounds and higher scavenging capacity. By statistical analysis, there was a positive correlation between the phenolic compound content and radical scavenging capacity and Euclidean linkages distances results showed higher similarity between R2 and R3 sample.
Key words: *phenolic compounds, radish, scavenging capacity*

INTRODUCTION

Black radish (*Raphanus sativus* L. var*. niger*) is a plant belonging to *Cruciferae* family. In folk medicine, black radish root has been used since antiquity as a natural drug against the flatulence, formation of gallstones and indigestion (Hänsel, 1985; Pahlow, 1989). Black radish is an effective natural drug for the stimulation of bile function (Böhm, 1959; Ritter, 1984; Weiss, 1985) and significant antiurolithiatic effects of black radish were also reported (Vargas et al.1999). Black radish root contains mixture of various inorganic and organic compounds (minerals, lipids, proteins, carbohydrates, dietary fibres and vitamins).
The biological properties such as anticancer, antimicrobial and antiviral derive from phenolic compounds and sulphur and nitrogen containing organic compounds, such as glucosinolates (Lugasi et. al., 1998). Due to these abilities glucosinolates and phenolic compounds have great attention today. The glucosinolates occur as secondary metabolites of almost all plants of the order Brassicales, derived from glucose and oftenly two amino acids are incorporated. Plants use substances derived from glucosinolates as natural pesticides and as defence against herbivores. These substances are also responsible for bitter or sharp taste of radish (Volder et al., 2009).
Phenolic compounds are product of secondary metabolism of plants which arise biogenetically from the main synthetic pathways: shikimate and the acetate pathway (Bravo, 1998). Phenolic compounds have free radical radical scavenging abilities, which depend on the exposure to stress such as light, temperature, water (Nakamura et al., 2003; Kays et al., 1997), nutritional deficiencies (Dioxin et al., 1995; Robins et al., 1997) type of vegetable tissue (Sonia et al., 2007), mechanical damage such as wounding (Fernando et al., 2007), maturation stages (Ozgen et al., 2009), chemical structure (Lugasi et al., 2003) etc.

With regard to the widespread use of black radish in the diet in this paper the effect of the size of the root on the content of phenolic compounds composition and radical scavenging capacity (SC) were examined. The results could be good indicator for the consumers which size i.e. weight of black radish root for nutritive or healthy benefits is better to consume.

MATERIAL AND METHODS

Plant material

Black radish (*Raphanus sativus* **L**.) var. *niger*) roots, with the same period of development, based on root size i.e. weight, were grouped into R1 (350±15 g), R2 (100±10 g) and R3 (35±5 g) groups. Five samples of roots were collected for each group. The roots were cut in cube shape (1.5x1.5x1.5 cm), dried at 35 ^{o}C during 6 h and left at room temperature for 1 h. Then the five samples were mixed into appropriate group and milled to average particle size of 0.5 mm.Three separate determinations for each group were performed.

Plant material moisture content

The black radish roots moisture content was determined by using the analyzer (Scaltec SMO 01, Scaltec Instruments, Göttingen, Germany). Fresh plant material (3 g) was dried at 110 ^{o}C to a constant weight, and moisture content was read out on the analyzer display.

Extracts preparation

Plant extracts preparation for measurements of the phenolic compounds content were done according to Dokhani et al. (2005) procedure. Dried and milled black radish roots sample (3 g) was measured and 80 mL of 80% (v/v) ethanol was added. The mixture was stirred by MR1 magnetic stirrer (IKA-Werke, Staufen, Germany) for 10 minutes at 200 min^{-1} and vacuum filtered through No. 54 Wathman filter paper (GE Healthcare, Brondby, Denmark). The solids were re-extracted with 60 mL of 80% (v/v) ethanol, the filtrates combined and made to a final volume of 250 mL. For the measurement of phenolic compounds content, 10 mL of each extract was filtered through a 0.45 μm membrane filter (Agilent Technologies, Wilimington, Delaware, USA). For radical scavenging capacity (SC) measurements and HPLC analysis, 200 mL of each extract was evaporated in vacuum at 45 ^{o}C until dry and dissolved in 10 mL of 96% (v/v) ethanol.

Phenolic compounds content

For phenolic compounds content (PCC) measurement, a standard curve for five concentrations of chlorogenic acid (Sigma Chemical, St. Louis, Missouri, USA) concentrations, covering the range from 50 to 1500 μmol, was made. In a test tube, 0.25 mL of 0.1% (w/v) HCl in 95% (v/v) ethanol, 4.50 mL of 2% (w/v) HCl and 0.25 mL of chlorogenic acid standard solutions were added, mixed by vortex and allowed to stand for approximately 15 min. Then the absorbance (*A*) was read at 280 nm using UV 21 000 Sprectrophotometer (Cole Parmer Instruments Company, Vernon Hills, Illinois, USA) as described by Glories (1998). Based on standard curve, the equation for PCC determination was obtained as:

$$\text{PCC} = \frac{A - 0.1083}{4.890 \times 10^{-4}} \quad (1)$$

For measuring phenolic compounds content in black radish extracts, into test tube 0.25 mL of 0.1% HCl in 95% (v/v) ethanol, 4.50 mL of 2% (w/v) HCl and 0.25 mL of filtered extracts were added and further treated as standard solutions of chlorogenic acid. The PCC was obtained based on equation (1) and presented as μmol of chlorogenic acid per g of dry plant material and μmol of chlorogenic acid per g of dry extract.

Radical scavenging capacity

The radical scavenging capacity (SC) of extract diluted by ethanol to concentrations ranging from 0.2 to 6 mg/mL, was determined by the DPPH test (Mensor et al., 2001). Ethanol solution of DPPH radicals, 1 mL of a 0.3 mM, was added to 2.5 mL ethanol solution of given

concentration of investigated extract and allowed to react at room temperature during 30 min. Then the *A* value was measured at 518 nm on UV 21 000 Sprectrophotometer (Cole Parmer Instruments Company), and converted into the percentage of radical SC by using the equation (Mensor et al., 2001):

$$SC = 100 - \frac{(A_{sample} - A_{blank})}{A_{control}} \times 100 \quad (2)$$

where A_{sample} is the absorbance at 518 nm of the ethanol solution of the extract treated with the DPPH radical solution; A_{blank} is absorbance at 518 nm of the ethanol solution of the extract (1 mL of ethanol added to 2.5 mL of extract), and $A_{control}$ is absorbance at 518 nm of ethanol solution of DPPH radical (1 mL of a 0.3 mM/L added to 2.5 mL of ethanol). The final results are presented as EC_{50} value, i.e. concentration of investigated extracts sufficient to decrease the initial DPPH concentration by 50%.

Statistical analysis

Statistica version 5.0 software (StatSoft, Tulsa, Oklahoma, USA) was used to perform the statistical analysis: the mean, standard deviations and the correlation coefficients. The mean and standard deviations were obtained by Descriptive Statistics, marking the Median & Quartiles and Confirm Limits for Means and the correlation coefficients were obtained by correlations matrix analysis with displaying p and N value. The Euclidean distances were obtained by the cluster analysis and the Euclidean method with the complete linkage.

RESULTS AND DISCUSSION

Extract yield, phenolic compounds content and scavenging capacity

The results of moisture content, extract yield, the PCC and radical SC of phenolic extracts from black radish roots are shown in table 1. The results are mean values of three determinations. The dependence of total scavenging capacity on concentration of phenolic compounds content in extract, are presented in figure 1.

The results showed that the PCC varied in range from 42.9 (R1) to 19.7 (R3) μmol chlorogenic acid per g of dried plant material, i.e. 443.7 to 208.6 μmol chlorogenic acid per g of dry extract. Based on results presented on figure 1, the radical scavenging capacity ranged from 88.3 (R1) to 55.6% (R3) and the appropriate EC_{50} values were 1.59 and 2.24 mg/ml, respectively.

Table 1. Moisture content, extract yield, phenolic compounds content and radical scavenging capacity in black radish roots of various weights

Group of parsnip roots	R1 (350±15 g)	R2 (100±10 g)	R3 (35±5 g)
Fresh plant material moisture content (%)	68.2±1.9	71.9±1.3	70.8 ±1.6
Extract yield (g/kg)	48.2±3.5	47.1±3.6	46.4±3.4
Phenolic compounds content (μmol/g of dry plant material)	42.9±2.6	23.1±1.8	19.7±1.6
Phenolic compounds content (μmol/g of dry extract)	443.7±15	241.3±12	208.6±16
EC_{50} (mg/mL)	1.59±0.4	2.98±0.5	3.54±0.5

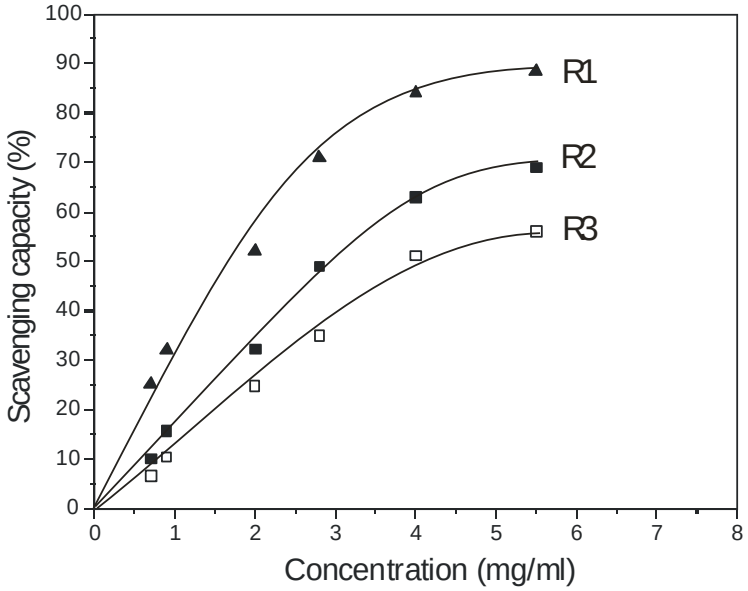

Figure 1. Total scavenging capacity of 80% (v/v) ethanol extract from black radish root of various sizes

Statistical analysis

The correlation coefficients were obtained based on five parameters (1- extract yield, EY; 2- phenolic compounds content as μmol of chlorogenic acid per g of dry plant material, PPC1; 3. phenolic compounds content as μmol of chlorogenic acid per g of dry extract, PPC2; 4- radical scavenging capacity, SC and 5- concentration of investigated extract sufficient to decrease the initial DPPH concentration by 50%, EC_{50}).

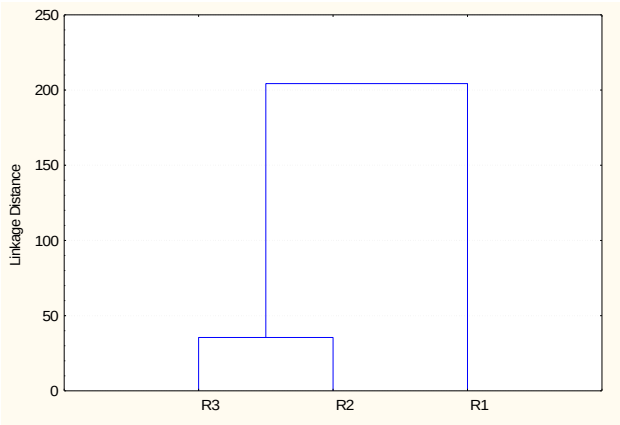

Figure 2. Total scavenging capacity of 80% (v/v) ethanol extract from black radish root of various sizes

The sample size was six (*N* = 6, three groups and their minimum and maximum value of determinations). The results show the high PCC was associated with high (the correlation coefficient was 0.96) and low EC_{50} values (the correlation coefficient was -0.99). As the lower EC_{50} value indicates higher antioxidant capacity, the obtained correlations show that higher phenolic compounds content in black radish root means higher scavenging capacity.

The results of Euclidean linkages distances based on the same parameters as the obtained correlation coefficients, showed higher similarity between R2 and R3 samples than between others (Figure 2), and this is evident from data in Table 1 and figure 1.

CONCLUSIONS

The phenolic compounds content and radical scavenging capacity depended on black radish root size in such a way roots with higher weight had higher content of phenolic compounds and better antioxidant capacity. There was a positive correlation between the phenolic compounds content and total radical scavenging capacity. The black radish root with weight higher than 100 g are recommended for human nutrition for healthy benefits.

ABSTRACT: In the last couple decades inedible polypore fungal species became of great importance as sources of new natural bioactive substances expressing various medical effects: antioxidative, anticancer, antimicrobial, and others. Recently, some edible mushroom species were also detected for their high bioactive potentials which are mostly influenced by the origin of the species. The species *Agrocybe aegerita* (Brig.) Sing., (syn. *Agrocybe cylindracea, syn. Pholiota aegerita)* is an edible, medium-size species broadly distributed in our region, mostly on poplar wood (lignicolous species). It is white-rot fungi containing many bioactive metabolites such as indole derivatives with free radical cavenging activity, cylindan with anticancer activity and agrocybenine with antifungal activity. Aiming to discover antioxidative activity of this indigenous fungal species, crude ethanolic extract from wild-growing species originated from Novi Sad (Serbia) was analyzed for DPPH free radical scavenging capacity (RSC) and total redox potential (FRAP assay)_in relation to total phenol (Folin–Ciocalteu assay) and total flavonoid content. RSC and total redox potential of extracts were in direct positive correlation with total phenol content. *A. aegerita* showed excellent RSC activity reaching EC_{50}≈28.88μg/ml in DPPH assay, the total phenol content (21.58±5.70 mg gallic acid equivalents/g of d.w.) and total flavonoid content (0.84±0.16 mg equivalent of quercetine/g d.w) and the FRAP value (13.47±2.64 mg ascorbic acid eq. mg/gd.w.). The HPLC determination showed that analyzed species contain caffeic, gallic, protocatechic and vanilic acids. Demonstrated results suggest that analyzed fungus contain phenolics that directly contribute to expressed activities and could be valuable sources of natural antioxidants in nutrition.
Key words: *antioxidative activity, extracts, radical scavenging capacity, phenolic acid, Agrocybe aegerita, total redox potential*

INTRODUCTION

Fungi have been used throughout mankind as the primary source of delicacy food called "food of gods" because of their specific aroma and taste. Throughout history they have been also known to possess medicinal effects such as anticancer, antidiabetic or immunomodulating, recognizing them as a great natural source of drugs. Due to their ability to produce a various nutritive and bioactive substances, including antioxidants (Lorenzen and Anke, 1998; Abraham, 2001; Lindequist et al., 2005, Elmastas et al., 2007; Ribeiro et al., 2007; Turkoglu et al., 2007; Dubost et al., 2007; Barros et al., 2007) fungi represent, beside plants, one of the most important sources for the development of new drugs. The scientific interest for fungal biomolecules as sources of antioxidants has grown recently (Mau et al., 2002; Lakshmi et al., 2004; Acharya, et al., 2004). However, the chemical nature of antioxidant compounds is still under investigation world over. Many authors assigned phenol compounds as the major antioxidants of some medicinal fungi (Mau et al., 2002; Cui, Kim, & Park, 2005), despite the fact that there are few data indicating that raw mushrooms represent a poor source of flavonoids and other phenols (USDA Database for the Flavonoid Content of Selected Foods 2003). It is well established that the content of total phenols could contribute to the antioxidant potential of food such as fruits and vegetables. Although fungi are not plants, previous studies that have analyzed the antioxidant properties of mushrooms have

shown a positive correlation between polyphenol content and antioxidant capacity (Kim et al., 2008; Karaman, 2010).
Agrocybe aegerita (V. Brig.) Singer, 1949 (fam. Bolbitiaceae) is known as black poplar or south poplar mushroom (English), like Albarelle, Aloumère (French), Yangimatsutake (Japan) or Zhuzhuang-Tiantougou (Chinese). It is broadly distributed species in South Europe, North America, India and China. It grows from April to October as parasitic or saprtotrophic species on weak or dead wood (poplar, elm, willow, ash). *A. aegerita* is an edible and very tasty species that has a mellow and attractive flavor when young and it is believed that this was the first cultivated mushroom in Europe. It grows in groups, on the smooth white shanks that reach a height of 10 cm. Traditionally it was used against headaches, dizziness, nausea and as a diuretic and antidiuretic in some parts of China (Giovaninni et al., 2006). Two substances showing antioxidant activity were isolated from the methanolic extract inhibiting lipid peroxidation in rat liver microsomes (Giovaninni et al., 2006). Phenolic compounds with low molecular weight and relatively high polarity from *Agrocybe aegerita* were positively correlated with scavenging radical activity and inhibition of LDL oxidation (Lo and Cheung 2005). From this fungus 1,3-βD-glucan has been isolated, showing activity against sarcoma 180 of mice while intraperitoneal administration of polysaccharides isolated from the species *A. cylindracea* has also shown activity in normal and streptomycin-induced diabetic mice (Kiho et al., 1994). A bioactivity-guided investigation detected ceramide, methyl-β-D-glucopyranoside and α-D-glucopyranoside, along with already reported linoleic acid and its methyl ester. Ceramide expressed COX and tumor cell proliferation inhibitory activities (Diyabalanage et al., 2009). According to a broad distribution of this species in our region and its high bioactivity known from the literature, the objective of this work was to investigate the composition and antioxidant activity of ethanolic extract of this indigenous edible fungal species by two biochemical tests in vitro: DPPH free radical scavenging capacity (RSC) and total redox potential. Total phenol and total flavonoid content of extract was measured due to point to the influence of these compounds on the express activities. Moreover, determination of the main components in extract was measured by HPLC chromatography.

MATERIALS AND METHODS

Fungal material and extraction

Wild growing lignicolous fungal species was collected from Sunčani kej location (Novi Sad) near Danube river on dead poplar's log in September, 2005. Samples of mature fruiting bodies were brush cleaned, air dried to constant mass and pulverized in an electrical mill. 10g of each sporocarp powder was extracted by stirring with 350 ml of 80% ethanol at 25ºC on rotary shaker (120 rpm) for 72 h and filtered twice (through absorbent cotton and filter paper). Extract were rotary evaporated at 40ºC to dryness. Dried extract were dissolved in the same solvent to a concentration of 10 %, and stored at 4ºC for further use.

DPPH assay

10 μl of fungal extract (5.0-500 μg/ml) was mixed with 1 ml of methanol solution containing $DPPH^{\bullet}$ (Sigma) to obtain a final concentration of solution of 90 μM $DPPH^{\bullet}$, and filled up with pure MeOH to 4 ml. The mixture was shaken vigorously and left for 60 minutes in the dark and then the absorbance was measured at 515 nm (Soler-Rivas, et al., 2000). The reactions were carried out in triplicate and recorded against tert-butylated hydroxytoluene – BHT (0.25 mol/dm^3) (Fluka AG; Buchs, Switzerland) and butylated hydroxyanisole –BHA (0.32 mol/dm^3) as a positive control. The $DPPH^{\bullet}$ scavenging activity was calculated as a RSC (radical scavenging capacity) by using the following equation:
$RSC\ (\%)=100x\ (A_{blank}-A_{sample}/A_{blank})$.
The concentrations of the extract that express 50 % neutralization of DPPH radical (EC_{50} values), were determined by linear regression analysis from the obtained RSC values in software Origin 2001.

FRAP assay
Assay of ferric reducing ability of the extract is based on comparing the change in absorbance at 600 nm of a sample with the change in absorbance of a known standard ($FeSO_4.7H_2O$) to detect level of antioxidant activity (Griffin and Bhagooli, 2004). This procedure involves the reduction of Fe^{III}-TPTZ to a blue colored Fe^{II}-TPTZ by any biological antioxidant or chemical reductants. Ascorbic acid was used to calculate the standard curve.

Total phenol and flavonoid content
The total phenol content of fungal extract was expressed as gallic acid equivalents (GAE) per g of dry extract (d.w.). It was measured according to slightly modified method using a Folin-Ciocalteu reagent (Fukumoto and Mazza, 2000). After 2h, absorbance was read at 760 nm. Total flavonoid content was measured using a method based on formation of a complex flavonoid-aluminium (Park *et al.*, 1997). The absorbance was determined at 415 nm after incubation (30min, 25ºC). Total flavonoid concentration was calculated using quercetin (Q) as standard, and the results were expressed in mg quercetin equivalents (QE) per g of dry extract (d.w.).

HPLC determination of phenolic acids
Chromatographic analysis of phenolic acids was carried out by HPLC according to the method described previously (Bendini *et al.*, 2003). The HPLC equipment consisted of an integrated system with a pump HP 1100 (Agilent Technologies, Palo Alto, USA) with stationary phase C18 (5 µm particle size, 150 × 4.5 mm I.D. Flow, USA) and UV-DAD detector (280 nm). The mobile phase used was a mixture of two components (95% A + 5% B), where A was a mixture of twice-distilled water and acetic acid (98:2, v/v) and B was a mixture of methanol and acetonitrile (1:1, v/v) at a flow-rate of 0.5 mL/min and elution with linear gradient. Standards of phenolic acids were dissolved in the mobile phase (95% A + 5% B). The compounds in each sample were identified by comparing their retention times and UV-VIS spectra with the standards.

RESULTS AND DISCUSSION

Extraction yield and total phenolic (TP) and flavonoid content (F) in the analyzed extract are presented in Table 1. *A. aegerita* had three times higher average yield (Table 1) than other analyzed species prepared in the same solvent reaching approximatelly 4% (Karaman, 2009). At the same this extract showed the highest solubility. Thus it can be concluded that this edible species is suitable for application in the form of alcoholic tinctures. Obtained results were in accordance with the results established for ethanol extracts of *A. aegerita* species from Istra region in Slovenia (Mujić et al., 2010) when compared both the final yield of extract and total phenol content (15.52%, 23.07 mg/g GAE, respectively). Yield of fungal extract was slightly higher for Slovenian species than for species from Novi Sad what can be explained by the polarity of solvents applied reaching slightly higher yield with 50% EtOH than with 80% EtOH. Moreover, TP/TF ratio was much higher in Slovenian species (21.85%) than the ratio obtained in this work. This can be explained by the fact that different standard equivalent (catechine) was used for calculations of standard curve. However, total phenolic content for Chinese *Agrocybe* species (Ng and Cheung, 2004) contained three times higher content of total phenols than analyzed species.

Table 1. Extraction yield and total phenolic (TP) and flavonoid content (F) in fungal extract

Fungal species	Yield of extract[a] (g/10g) d.w.	Extraction (w/w) %	Total phenols[b] (mg/g)	Flavonoids[c] (mg/g)	F/TP[d] %
A. aegerita	1.19±0.20	**11.93**	21.58±5.70	0.84±0.16	3.9

[a]Extracted from dried fungal sporocarp (10.00g). Each value is the mean of three replicate determinations ± standard deviation (n =3),[b] Total phenolic content is expressed as gallic acid equivalents (GAE; mg/g GAE). Each value is the mean ± SD of triplicate measurements.[c]Total flavonoid content is expressed as mg of quercetin equivalents (QE) per g of dry extract (d.w.)[d]Percent (%) of flavonoid content (F) in total phenol content (TP) (w/w)

Radical scavenging capacity (RSC) assay showed very high ability of extract in neutralization of DPPH· radical reaching EC_{50} value at 28.02±1.79 µg/ml (Table 2). Obtained value was ten times higher then the value for standard synthetic antioxidants (BHT, BHA), indicating lower, but close scavenging activity then pure substances. A lower absorbance at 517 nm indicates a higher RSC activity of the extract. RSC increased in dose dependent manner with the concentration showing strong activity even of 95% at 0.5 mg/ml, 5 times higher than that of other mushroom species (Barros *et al*., 2007). Comparing results for EC_{50} values of RSC activity on DPPH radicals which exhibited almost 2-3 times lower value then the Slovenian species (Mujić et al., 2010), it seems that indigenous species possess much higher RSC activity than the species from Istra and similar to *G. lucidum* methanolic extract obtained recently (Karaman, 2010).

Table 2. Antioxidant activity of examined fungal extracts, expressed as EC_{50} [µg/ml]

RSC EC_{50} [µg/ml][1]	**Antioxidative assays**	
Fungal extract	**DPPH [a] assay** (µg/ml)	**FRAP [b] assay** (mg/g)
A. aegerita	**28,88±1,39**	**13,47±2,64**

*[1]**BHA**- butylated hydroxyanisole (0.32 mol/dm3);[2]**BHT**- tert-butylated hydroxytoluene (0.25 mol/dm3);[3]**PG** - pirogalol;**r^2** - correlation coefficient between concentration and RSC at p<0.05; **RSC-** radical scavenging capacity, **EC_{50}** [µg/ml] – conc. of extracts that coused 50% of activity (neutralisation of DPPH· radicals or inhibition of cell proliferation;[b]Ferric reducing capacity of extract **(FRAP)** is expressed as ascorbic acid equivalents (AAE, mg/g d.w)*

Redox capacity of a compound may serve as a reliable indicator of its antioxidant capacity, and it is known that the effectiveness of certain antioxidants is associated with their redox capacity. Some authors considered that the redox capacity of antioxidants is generally associated with the presence of reductones, such as ascorbic acid (Duh et al., 1999). These compounds exhibit antioxidant activity in several ways, one of which is to react with certain precursors of peroxide, which prevents the formation of peroxides (Haliwell and Gutheridge, 2007).

From the results obtained in this work for *A. aegerita* (Table 2), it is evident that the mushroom extract had lower redox capacity when compared to other mushroom species (Karaman et al, 2009). It seems that this type of antioxidative mechanisms is not dedicated to the manifested activity for this species. Since phenolics are known to have ability to chelate metals, inhibit lipoxygenase and scavenge free radicals (Dubost *et al.*, 2007) we tried to detect some phenolic acids in this sample. The majority of analyzed phenolic acids were identified in *A. aegerita.* The highest content was obtained for gallic and protochatehuic acids while lower content was shown for caffeic and vanillic acid. These results support the healing properties of this edible species (Table 3). Comparing these values to the results obtained recently with other lignicolous species (Karaman et al, 2010), it seems that *A. aegerita* is

similar to *M. giganteus* species in a content of gallic acids, while having twice higher content of protochatehuic acid. It was also similar to *G. applanatum* according to the qualitative presence of all analyzed phenolic acids, containing much higher amount of all of the analyzed species except vanilic acid.

Table 3. Phenolic acid content of *A. aegerita* extract [µg/g]

Fungal species	**Phenolic acid [µg/g]**				
	Galic	Protochatehuic	Caffeic	p-cumaric	Vanilic
A. aegerita	606	696	396	nd	242

nd –not detected

Phenolic acids identified in some commercial fungi were p-hydroxybenzoic acid, p-coumaric acid, vanillic acid, tr-cinammic acid and caffeic acid (Dubost et al., 2007). Comparing these results with data obtained for *A. agrocybe* or other lignicolous fungi (Karaman et al., 2010), it can be said that the chemical composition of commercial mushroom drastically differs from the analyzed lignicolous species growing wild. Result demonstrated in this work is consistent with results obtained by comparison of commercial and wild species, according to which the amount of total phenolics was significantly higher in wild species (Barros et al., 2008). Moreover, these results could also confirm the assumption that the amount of phenolic antioxidants are dependent to a large extent on external environmental factors such as habitat, locality, or exposure to stressful influences, when the metabolic pathways of organisms are changing and moving in the direction of secondary metabolism (Puttaraju et al., 2006).

CONCLUSION

In conclusion, these results indicate that fungal species *A. aegerita* could be used as an excellent natural source of antioxidants in nutrition and as a good replacement for carcinogenic synthetic antioxidants commonly used as additives as well.
Considering the fact that ethanol extract of this species possess high yield and high RSC activity and contains phenolic acids, tinctures made of this species would be a good choice in consuming this fungi as dietary supplement in a daily nutrition, as well as in the future studies of bioactivity of this fungi.

ABSTRACT: According to the preliminary analysis of development indicators, food production in Serbia has been identified as one of top national priorities. The food industry represents one of the leading industries in our country, and it is developed most in Vojvodina, where it participates with 36.3% in the industrial structure (www.vojvodina.gov.rs). Serbia's food industry is comprised mostly of small and medium-sized businesses. As integral parts of all market economies, small and medium-sized businesses are important factors in economic development in all countries. These small and medium-sized businesses produce considerable amounts of food, so it is clear that food safety of their products affects the integrity of the whole food supply chain. One member of this group of businesses is the company "Galus d.o.o.", based in Pancevo, which has a business unit for the production of vegetarian food products "Soya Food", located in the village Lokve. The main activity of "Soya Food" business unit is the production and processing of soybeans and vegetarian food products. In our country, soybean is grown on an average of around 140,000 hectares, with only a slight portion being produced by organic production methods.
Starting with 2011, the company "Galus d.o.o." has introduced the organic production standard in its total production area, thereby establishing the prerequisites for the produced raw materials and subsequent finished products to carry the label "organic soybean products". This has created favourable conditions for reaping financial and ecological benefits from organic production, and added value of the existing and some new soybean products. This paper will examine in more detail the structure of this company, production and processing of organic products, and production methods regulated by law.
Key words: *value-added, soybean products, "Soya Food"*

INTRODUCTION

Small and medium enterprises (SMEs) are very important for the Serbian economy and its development, and since Serbia has become a candidate for the EU membership, European policies are increasingly affecting the operation of Serbian enterprises. Due to their large developmental importance, as well as the desire to make Serbia an equal member of the European Union - Serbia, following the EU model, is creating laws, programmes and support schemes in order to help domestic SMEs reach the European level of development and use their full development potential. In expert and political circles of the EU, SMEs have been identified as a key source of changes, competitiveness, inovation, flexibility, new jobs, and increase in productivity. They are an important factor in economic stability on both national and regional levels, the driving force behind cultural development and sustainable changes in Europe, and the engine of overall economic development. In accordance with the recognized importance, the European Union places SMEs in the center of its development policies and devises various measures and support programmes (Nikolić and Stošković, 2011).
In the Eropean Union, small and medium enterprises constitute 99% of the total number of its twenty-one million enterprises, the majority of them consisting of micro enterprises which employ 1-9 workers. SMEs are the main source of employment and wealth creation, providing for over 80 million jobs. Employees of SMEs make up two thirds of the total number of employees in the private sector, and generate 70% of the total turnover, 600,000 euros

per employee, 65,000 euros of added economic value per worker, and 60% of the EU's gross national product (Grozdanić, 2004).
In the EU these businesses are in the focus of interest of all policy and system creators who, via institutional and strategic mechanisms employed on the level of these micro economic entities, aim to create a favourable economic climate with the ultimate goal of creating an economy with the highest competitive advantage in the world. A key component of the transition process in DCs (developing countries) is the development of small and medium businesses (Babović, 2005). The development of SMEs in transitional economies is determined by initial conditions existing at the beginning of transitional process, SMEs' growth rates seen through the prism of political orientation, and potential support of the international community for the encouragement of SMEs' development.
In the upcoming period, considerable attention will be paid to “greening“, for example, crop diversification or the protection of permanent green areas. The “greening“ component in the Commission's draft, i.e. the measures defined by the term ˝greening˝, are a set of regulations which have been known for years in organic production. These regulations will come into force in 2014 as the best way to stimulate further popularization of both organic production and the practices already adopted by organic farmers. Organic production is framed by law, and compliance with these regulations is controlled according to the established procedures (organic production inspectors), evaluated and certified at the state level by issuing of the official label – “organic product“. Authorized inspection bodies (organizations, institutions) have trained and authorized inspectors for different types of production and processing.
A great demand for soybean in China has led to the increase in price of this oil crop of as much as 38% in the course of the last year. Global demand for soybeans as a favourable raw material and biofuel is on the rise. The countries which are the largest producers of soybeans are the USA, Brasil and Argentina, and they produce GMO soybeans.
For this reason, the demand of foreign buyers and primarily buyers from the EU for domestic organic soybeans is growing significantly every year.

Case study – a small enterprise “GALUS“ doo Pancevo, business unit RJ “SOYA FOOD“ Lokve in organic production

SMEs are usually defined by using various quantitative parameters such as: the number of employees, investment scope, the size of available capacities, etc. In the EU legislature, “small enterprise“ is a term which refers to companies with 50 to 100 employees (Radenković-Jocić, 2002). In our country small and medium enterprises are not defined by law, but the term “small enterprise“ usually refers to companies with under 50 employees (Bešić, 2009). One such company is Pancevo based “GALUS“ doo, which was founded in 1992. This enterprise has 12 employeees, one with a university diploma (education level VII in Serbia) and 11 employees with high-school diplomas (level IV). The company's activity is “Manufacturing of other foods“, and in 2005 this firm opened ˝Soya food˝ plant for the production of vegetarian food in order to expand its business.
“Soya Food“ plant for the production of vegetarian food is located in the village Lokve (San Mihai in Romanian) in Southeast Banat, 60 km from Belgrade and 40 km from Vrsac, in the Municipality of Alibunar. “Soya Food“ is a relatively new company founded by Ilija Stanču and his family in Lokve (soya-food.net, 2012). The production plant and storage area cover 260 m^2. This company submitted the application for the HACCP certification in 2011, thereby gaining competence in addressing HACCP principles which apply to the needs of small enterprises, which have been introduced by the certification body “AQA“ d.o.o. from Belgrade. In the upcoming period, the company's management plans to introduce the ISO 22000:2005 standard, the role of which is to provide food safety management.
Since 2008, the company has been cooperating with ˝Tamiš Institute“. In 2011, the company adopted a new approach to its future policy and development by introducing organic production over its complete area of 36 hectares, under the control of the certification organization ˝Ecocert Balkan˝ from Belgrade.

“Soya food” products

In the Scientific and Technological Development Strategy of the Republic of Serbia 2009-2014, innovation in food production is the area of research with top-priority. In addition, the new EU Common Agricultural Policy Draft for the period from 2014 to 2020 brings to the fore research and innovations, the production of ecological products, ensuring food safety and opening new jobs. Innovations, organic farming and the young, as the three cornerstones of the future EU Common Agricultural Policy will also be the field of activity of Serbian agriculture which has recognized organic production as one of the top priorities in the future strategy for agriculture and rural development (Filipović i sar., 2012).
Innovativeness in the work of ˝Soya food˝ team was evident in the preceding period as well, when it cooperated closely with a number of research organizations, one of which being the Faculty of Agriculture in Novi Sad. The company's product range currently consists of 18 different products, which will in the near future bear the prefix “organic“ and be labelled with organic logo. All of these products are being sold in domestic market and in Bosnia and Herzegovina. “Safe food's“ product range includes: three types of soy milk (natural, cinnamon and vanilla), six kinds of tofu (natural, with cumin, with dill, with paprika, with sesame seeds, and “Dimsi“ silken tofu), two kinds of tofu cream cheese (with horseradish and with dill), two types of vegetarian pates (vegetarian and vegetarian special), four kinds of vegetarian sausages (frankfurter vegetariana, sausage vegetariana, vegetarian roast with paprika – salami and vegetarian bologna), and one kind of mayonnaise (low-calorie). All products can be classified as safe and functional foods, containing no artificial preservatives, artificial dyes, nor arficial aromas.
In a subsequent part of this paper we will examine only one soybean product – soy milk. Soy milk is known to be rich in vitamins and minerals, it doesn't contain lactose or cholesterol, and its saturated fat content is very low. Apart from other vitamins, it is particularly rich in the B-group vitamins and vitamin E, and contains minerals such as phosphorus, magnesium, and iron. It has a delicious taste and refreshing aroma, and it can be used in the preparation of sweet puddings, muesli, sauces, milk shakes, nescafé, etc. It is lactose-free and gluten-free. It is not recommended as a substitute for cow's milk for children under 12 months. Technological process of soy milk production is represented in Figure 1.

Organic production - ˝Soya food˝ Lokve

Our laws and subordinate legislation are to a large extent in compliance with European legislation. They protect organic producers from various forms of fraud and incorrect and false representation in the market, enabling control over manufacturing, storing, transporting and marketing (Filipović, 2005). There is a great interest in marketing our “organic“ products to the European market, however, a lack of activity on our part has opened up this window of opportunity to the countries which, despite their poorer product quality, narrow product range and exessive distance, have managed to break into this picky market (Filipović, 2008).

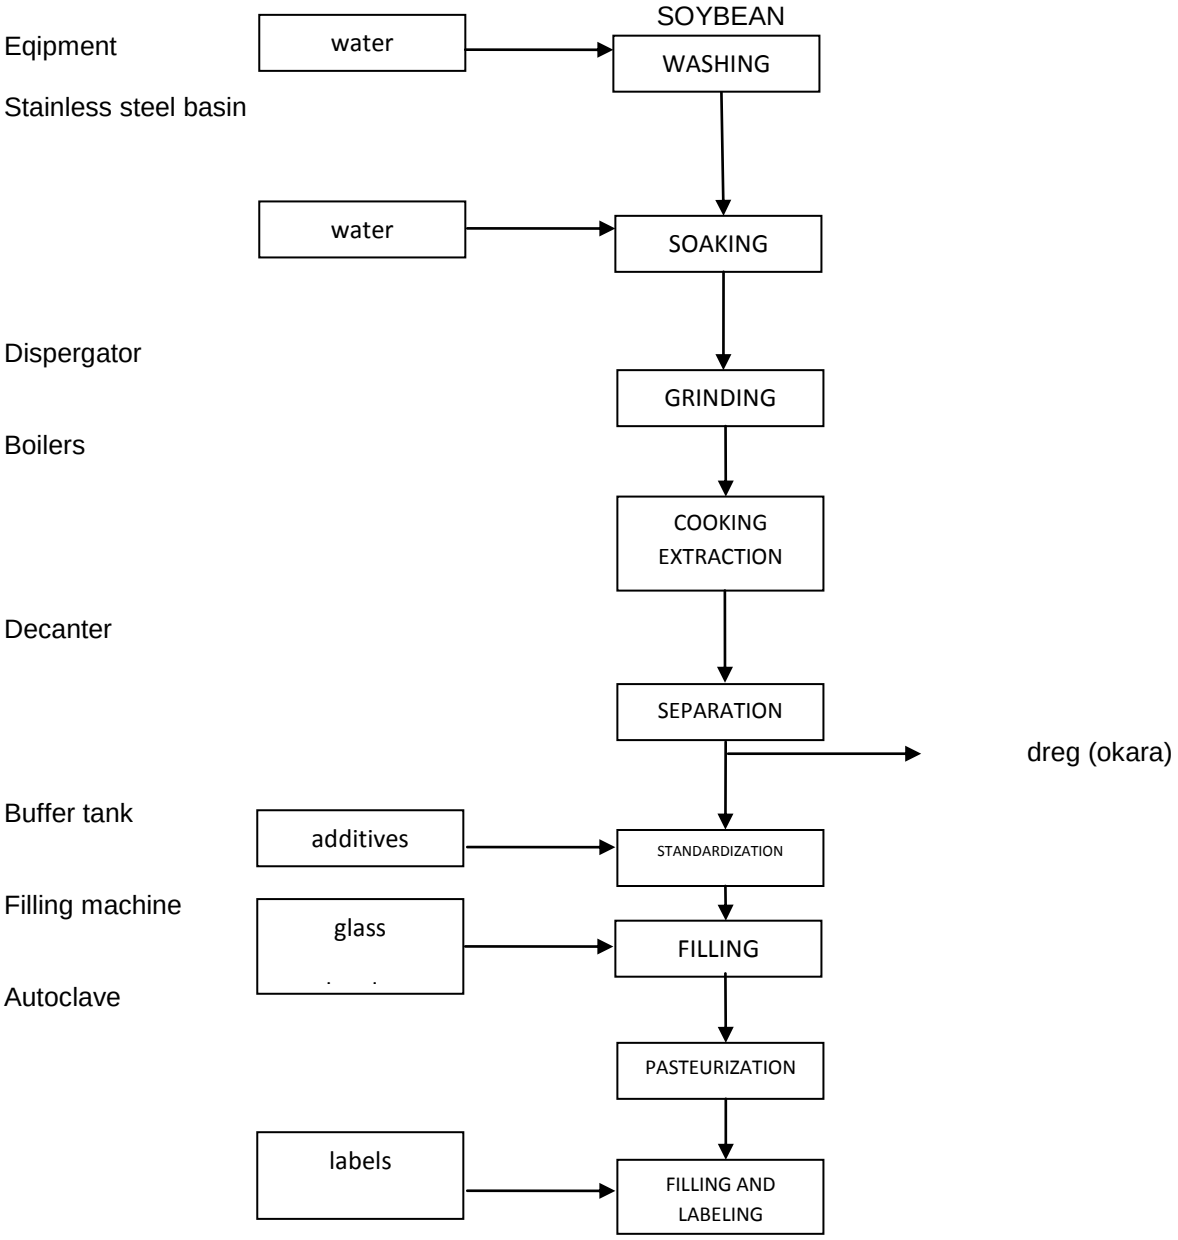

Figure 1. Flowchart representing soy milk production (Popović-Vranješ et al., 2007)

Sustainable development and economical and ecological profits generated in organic production provide opportunity for the improvement of the existing production. In organic production (and processing), standard agronomic knowledge is being built into regulated methods of production, packaging, storing and transport. Organic compliance is controlled by means of established procedures (organic production inspectors), evaluated and certified at the state level by issuing of the official label – “organic product“. All segments of production, control and certification are covered by the law and rulebooks (Organic Law, 2010; Organic rulebook, 2011).

SWOT analysis of organic production in RJ ˝Soya food˝ Lokve

SWOT analysis can serve as an appropriate tool which helps a company develop its business in conditions where there are external opportunities and threats, and internal strengths and weaknesses. SWOT analysis of this company's present and future opportunities, external threats, and internal weaknesses was performed from April 2011 to February 2012. Mr Ilija Stanču, the owner of “Galus”, and Mr George Munćan, ing., the chief technologist in RJ ˝Soya food˝ have given their full support during the analysis. The analysis was conducted in the following stages: 1. Performing of internal analyses [main internal strengths and critical internal weaknesses], 2. Performing of external analyses [opportunities in the environment and main threats in the environment]. After comparing external (threats and opportunities) and internal (strengths and weaknesses) variables, four types of strategy can be identified:

1. Mini-mini strategy (WT) which attempts to find ways to minimize internal weaknesses and avoid external threats.
2. Mini-maxi strategy (WO) which attempts to find ways to minimize internal weaknesses and maximize external opportunities.
3. Maxi-mini strategy (ST) which attempts to find ways to minimize external threats and maximize its strengths.
4. Maxi-maxi strategy (SO) which attempts to find ways to take the maximum advantage of its external opportunities by the maximization of its internal strengths.

Table 1. SWOT analysis – organic production in the case study - RJ ˝SOYA FOOD˝ Lokve

Strengths	**Weaknesses**
- Nearness to raw materials - Tradition in and knowledge of conventional agricultural production of vegetarian food - Membership in associations whose principal activity is organic production - Favourable location of the enterprise - High level of technological competence - Concept of cooperation with scientific research institutions - Existence of HACCP system	- Lack of basic raw materials for the production of some products - Lack of knowledge about foreign organic production regulations - Low interest of local community in organic production - Lack of active cooperation between organic and conventional producers - Nonexistence of a transparent data base of organic food producers and retailers
Opportunities	**Threats**
- Export potential for marketing soybean products - Association within a sector and between sectors (clustering) - Harmonisation of legislature with the EU and international standards - Potential cooperation and partnerships among a large number of "young" producers - Expected growth of organic food consumption per capita - Products protected by a recognizable brand name ˝Soya food organic˝ - Export potential - Widening of the current product range - Easier integration into the EU via organic production - Purely competitive market	- Insufficient political awareness of the vital role of organic farming in the restructuring of agricultural sector in the process of accession to the EU - Marginalization of organic production by various economic entities - Potential negative impact of current bureaucracy on all production stages, from the purchase of repro materials, through incentivising, to export - Foreign threats and the need to 'protect' domestic organic food from the imported - Non-compliance with international organic production regulations - Low purchasing power of the domestic market - Political instability

CONCLUSION

From everything mentioned above it is clearly necessary to encourage the development of small enterprises in the domestic food industry, while at the same time taking care of the public health protection. It is therefore important to devise a strategy for food safety and integration of HACCP standards into SMEs. Although they are not primarily food exporters, SMEs have a large influence on national and regional economies and a potentially strong influence on the health of domestic consumers, and consequently on overall national health. The strategy for further development of "GALUS" doo company from Pancevo, i.e. its branch, RJ ˝SOYA FOOD˝ Lokve, is ongoing work and improvement with the goal of producing safe food. The company's determination to certify its whole production and processing as organic is in alignment with the policies of the EU and our country. Unfortunately, there are some obstacles on this road, which have been presented in this paper through the SWOT analysis.

ACKNOWLEDGEMENTS

This paper is a represents a part of the research results within the Project of Integral and Interdisciplinary Research No. 046006 "Sustainable Agriculture and Rural Development in the Function of the Accomplishment of Strategic Objectives of the Republic of Serbia in the Danube Region", financed by the Ministry of Education and Science of the Republic of Serbia.

ABSTRACT: Beer is one of the oldest beverages. Throughout history, it has been accepted not only as a refreshing drink, but also as a liquid bread, a source of energy, a healing remedy and, lastly, as a safe drink that can promote well being. Nowadays, beer is one of the most popular beverages all over the world and an integral part of diets in most countries. For the last decade, it has been in focus of significant medical research and the numerous results have given the scientific confirmation of the statement known for centuries: beer is far more than a thirst-quenching low-alcohol beverage. Published data have indicated that beer contains a wide range of nutrients with bioactive properties and, if consumed moderately and in a responsible manner, can be a useful part of a healthy diet. Of particular interest are its polyphenol, mineral, trace element and vitamin composition, as well as its antioxidant properties. It seems that we have reliable enough results to claim that beer has a potentially positive influence on low blood pressure, atherosclerosis and cardiovascular diseases, and may help protect against gallstones and kidney stone formation, dementia, osteoporosis etc. However, several facts deserve to be discussed: the latest information considering the beer's beneficial action, the meaning of moderation in each particular case, the significance of beer versus wine in health promotion, the thirst-quenching effect as a low-alcohol beverage, the influence on the energy intake and the problem with obesity, and, finally, the perspective in terms of the new beer types with new sensory and functional properties.
Key words: *beer, bioactivity, antioxidants, minerals, cardiovascular diseases*

INTRODUCTION

Beer has been drunk for more than 8000 years, from the time when it was first made probably unintentionally during mid-ancient times. For centuries, it has played an important part in many cultures, serving as a warming beverage, and safe drink in an age when the purity of water was uncertain. Ever since, it has been accepted not only as a refreshing drink, but also as a liquid bread, a source of energy, and, a drink that can promote well being (Bamforth, 2000). For the last decade, it has been the focus of significant medical research and the numerous results have given the scientific confirmation that beer is far more than a thirst-quenching low-alcohol beverage. Published data have indicated that beer contains a wide range of nutrients with bioactive properties and, if consumed moderately it can be a useful part of a healthy diet, improve well-being, and reduce risk of various types of diseases.

BIOACTIVE COMPONENT IN BEER

Beer is an extremely complex beverage. Apart from water, which normally represents more than 90%, and about 5% v/v of ethanol, beer contains about 800 organic compounds and many of them are biologically active. Potentially beneficial effects on the human body are the consequents of two facts, the small amount of alcohol and the presence of other compounds, such as vitamins, minerals, trace elements, phytoestrogens, and antioxidants. Numerous studies confirmed that beer consumption in moderation could provide a considerable increase of B vitamins in human body (Table 1) (Bamforth, 2002). From the nutritional point of view and the position of beer as a part of the diet, the most important minerals are potassium, magnesium, sodium, and phosphorus. Beer is rich in potassium and magnesium, low in sodium and calcium,

and may be a significant dietary source of phosphorus, and even selenium, and silicon (Table 2) (Buiatti, 2009; Leskošek-Čukalović, 2009).

Table 1. The composition of beer relative to recommended dietary intakes of vitamins

Parameter	*Daily adult (age 25 – 50) requirement*		*Range in beer (per litre)*
	Male	*Female*	
Energy (Kcal)	2550	1940	150-1100
Protein (g)	63	50	3-5
Vitamin C (mg)	60	60	0 -30
Thiamine (mg)	1.5	1.1	0.003 – 0.08
Riboflavine (mg)	1.7	1.3	0.02 – 0.8
Niacin (mg)	19	15	3 - 8
Vitamin B_6	2.0	1.6	0.07- 1.7
Folate (µg)	200	180	40 - 600
Vitamine B12 (µg)	2	2	3 - 30
Biotin (µg)	30 - 100	20 - 100	2 - 15

Table 2. Mineral content of beer

Mineral	*Beer (mg/L)*	*Mineral*	*Beer (mg/L)*
Potassium	200 – 600	Silica	40 - 120
Sodium	10 - 100	Phosphate	260 - 995
Magnesium	60 - 250	Sulphate	60 - 300
Calcium	20 - 160	Chloride	150 - 400
Iron	0.01 – 0.3	Selenium	<0.0004 – 0.0072
Copper	0.02 – 0.4	Lead	< 0.01 – 0.1
Zink	0.02 – 4.5	Fluoride	0.09 – 0.2
Manganese	0.03 – 0.2	Cobalt	0.01 – 0.11

Polyphenols from malt and hops are the major natural antioxidants in beer. There are many references in literature determining their content of beer. Identified are 78 different phenolics compounds including simple phenolics, aromatic carboxylic and phenol carboxylic acids (Gerhäuser, 2005; Gorjanović et al., 2010). The antioxidant capacity of beer depends a lot on beer type. Dark beers seem to be considerably inferior to coffee, red wine and tea, but can be compared to rose and white wine, and orange juice (Table 3) (Lugasi and Hóvári, 2003).

Table 3. Antioxidant capacity of beverages (FRAP and ABTS assays)

Beverage	FRAP (µmol Trolox/100 ml)	ABTS (µmol Trolox/100 ml)
Coffe	2,267 ± 18.9	1,328 ± 5.1
Tea	601 ± 5.5	631 ± 8.0
Red wine	1,214 ± 24.5	1,093 ± 54.2
Rose wine	286 ± 39.2	261 ± 23.7
White wine	154 ± 36.8	181 ± 22.2
Orange juice	515 ± 41.5	249 ± 3.4
Cola	20.7 ± 0.7	≤10
Lager beer	139.6-149.5	220.0-305.6
Dark beer	278.8	259.0-536.5
Alcohol-free beer	75.6-91.2	155.8-175.3

Prenylflavonoids in beer that deserve special attention are xanthohumol (XH), isoxanthohumol (IX) and 8-prenylnaringenin (8-PN). They are present almost exclusively in hops and beer is practically the only foodstuff in which they can be found. Their final content in beer strongly depends on the production process. Although XH is the main prenylflavonoids in the hop cone, their abundance in beer is much lower. During the wort boiling much of the XH is converted by thermal isomerization into IX therefore, IX and 8-PN are the main prenylflavonoids in beers (Table 4) (Possemiers et al., 2009).

Table 4. Prenylflavonoid contents in beer and dietary supplements

Beer (µg/l)	*xanthohumol*	*isoxanthohumol*	*8-prenylnaringenin*	*Total*
Pils	9-34	400-1060	13-21	460-1100
Lager	0.2-28	20-1910	2-175	24-2342
Porter	690	1 330	240	2900
Stout	340	2100	69	2680
Hefeweizen	5	300	8	330
Strong ale	240	3440	110	4000

BEER IN RELATION TO HEALTH

During the past decades, numerous prospective population studies have described the impact of alcohol intake on all-cause mortality as a J-shaped curve, indicating that there is a beneficial effect of light to moderate alcohol intake and a detrimental effect of high alcohol intake. It has been evident that heavy uncontrolled drinking carried major medical risks, and is often considered as one of the leading causes of preventable deaths. The main causes claim to be coronary heart disease (CHD) and other athero-thrombotic diseases. However, there is also substantial evidence now that the intake of light to moderate amounts of alcohol beverages is associated with reduced morbidity and mortality from CHDs. The main beer constituents responsible for beneficial action on the diseases of vasculature system are alcohol, polyphenols, well balanced array of minerals (most important are phosphoric acid, potassium, magnesium and sodium) and vitamins (folate, B12 and B6). Phosphoric acid and magnesium are known to be important for the proper blood vessels functioning, while the high potassium and low sodium content is the right balance for healthy, low blood pressure. Moderate beer drinkers usually have a lower blood pressure than abstainers and heavy drinkers. This effect on blood pressure cannot just be explained by a vasodilatation action of alcohol, because changes also occur in the hormone, water and electrolyte balance (Winkler et al., 2006). Folate and vitamin B12 and B6 are associated with homocysteine as an independent risk factor of cardiovascular disease and its involvement in mechanisms of thrombosis (Tamai et al., 2011).

Beer is intensively analyzed in connection with other diseases as well: carcinogenesis, osteoporosis, kidney stones, dementia, etc.

Concerning malignancy there is convincing evidence that high alcohol intake is related to carcinogenesis. The available evidence indicates that the alcoholic beverage consumption considered to be causally related to cancers of the upper aerodigestive tract (oral cancer and cancers of the oropharynx, hypopharynx, larynx and oesophagus), liver, and probable to colorectal cancer in men, and breast cancer in women (Gerhäuser,2005). Beer drinking is almost invariably related to alcohol consumption. However, in 1996 beer was first reported to possess antimutagenic components (Arimoto-Kobayashi et al., 1999).

Scientific evidence accumulated over the past decade points to the cancer preventing potential of XH and hop bitter acids. The latest studies have proven that XH shows cancer chemopreventive activities, antimutagenic and anticarcinogenic properties with an exceptional broad spectrum of inhibitory mechanisms at all three stages of the carcinogenesis, initiation, promotion, and progression (Gerhäuser, 2005; Ferk et al., 2010). 8-PN is of special interest as the most powerful phyto-oestrogen found in nature (Chadwick et al., 2006) and might exhibit several biological activities (Strathmann et al., 2010). Until recently, possible health effects after moderate beer consumption related to the presence of 8-PN were considered negligible because concentrations in beers are generally very low. The latest study shows that this approach may no longer be valid. Data show that moderate beer consumption can lead to 8-PN exposure values of 1-2 mg/d that might fall within the range of human biological activity (Possemiers et al., 2006; Arimoto-Kobayashi, 2005).

The available knowledge on the relationship between the consumption of alcoholic beverages and a variety of human cancers is based primarily on epidemiological evidence. For moderate consumption (2-3 drinks/day for men and 1-2 drinks/day for women), the risks never increase above twofold and are mostly less than 25% above baseline. The evidence from the epide-

miological literature suggests that 25g/d of alcohol is associated with a relative risk of 1.9 for cancers of the oral cavity and pharynx, 1.4 for cancers of the esophagus and larynx, about 10% for colorectal cancer (mechanisms unclear), and 20% for liver cancer (mechanisms well described). The association between alcohol and breast cancer is not strong and not necessarily causative, at least for moderate consumption (WHO/IARC, 2010).
Silicon impacts bone mineral density in humans and supplementing in the diets of women with osteoporosis increased bone mineral density. Silicon increases type I collagen synthesis and promotes the differentiation of osteoblast-like cells (Jugdaohsingh et al., 2004). Silicon is present in beer in the soluble form of orthosilicic acid which is >50% bioavailabile. Therefore, beer has been claimed to be a major contributor to the overall silicon intake in the Western diet (44% in adult males) (Troy et al., 2010).
The prevalence appears kidney stones have increased in the last quarter of the 20th century for men and women. Nowadays, numerous observational and experimental data obtained confirmed that daily consumption of beer (330ml, 4.5%w/w) may reduces the risk of developing kidney stones by 21-40% (Curhan et al., 1996; 1998). The protective effect of beer could be mediated through water, alcohol and mineral composition, high potassium and magnesium content, and diuretic properties.
Dementia as a serious loss of global cognitive ability is not a single disease, but rather set of signs and symptoms in which affected areas of cognition may be memory, attention, language, and problem solving. Although the adverse effects of excessive alcohol intake are well known results of many studies suggest that in older people, small to moderate amounts of alcohol consumption (beer, wine, or spirit) are associated with reduced incidence of dementia and Alzheimer's disease (Stampfer, 2005). Several mechanisms have been proposed to explain the association of moderate alcohol consumption with better cognition. In the case of beer, very high and significant correlations were found suggesting that moderate beer consumption, due to its alcohol and bioavailable silicon content, possibly affording a protective factor for preventing Alzheimer's disease. Aluminum is a highly neurotoxic element that may be involved in neuronal degeneration in human brains. Silicon and silicic acid may decrease aluminum bioavailability by blocking its uptake through the gastrointestinal tract and by impeding reabsorption (González-Muñoz et al., 2008).

INFLUENCE OF BEER ON THE ENERGY INTAKE

The position of alcohol beverage as part of the diet is defined with their alcohol content and its contribution in energy intake. The influence of alcohol on food consumption and availability is diverse. Alcohol can alter appetite for food modifying hormonal processes that have been implicated in appetite regulation. Moreover, it has influence on metabolic parameters related to obesity and has other effects on many neurochemical systems (Monteiro et al., 2009).
Alcohol is an energy-providing item, with an energy content of 29 kJ/g (7.1 kcal/g). It has no storage capacity, but its consumption can lead to positive fat balance through the sparing effect on fat oxidation, leading to increased fat storage (Yeomans, 2004). Few studies have reported a J-shaped relationship between alcohol consumption and body mass index and waist-to-hip ratio such that light to moderate drinking has beneficial effect in reducing weight whereas non-drinking and heavy or risky drinking having the opposite effect (Lukasiewicz et al., 2005).
Beer as an alcohol beverage is rather specific. Besides alcohol, it contains carbohydrates (more than most other alcohol beverage), and possesses defined calorific value. For a long time it has been blamed as the cause of overweight, waist circumference, particularly in men – a phenomenon popularly referred to as "beer belly".
Beer caloric content depends on the beer type (amount of alcohol and extract contained). For example, beer with a 3.2%w/v extract, 5%v/v alcohol content contains approximately 42 kcal per 100 ml. Assuming that the daily caloric requirements of an adult averages to 2,500 kcal, the caloric content of 1 l of beer represents approximately one-sixth of the daily requirement.
On the other hand, the residual starch-derived carbohydrate in beer (isomaltose and other dextrins) are classified as the less digestible, "slow release" carbohydrate polymers, namely "good carbs". Furthermore, one of the major carbohydrate fraction present in beer are the β-

linked materials derived from the β-glucan and arabinoxylan present in barley. Such molecules are metabolized neither by brewing yeast nor by the human body and they are highly likely to be of value as pre-biotics (Bamforth, 2007).

BEER *versus* WINE IN HEALTH PROMOTION

Now there is a growing body of evidence from studies performed in humans that supports a connection between regular moderate wine drinking and improved health. Red wine is almost overall accepted as unique drink among alcoholic beverages with most efficient health promotion action (phenomenon known as French paradox). Numerous studies that have been carried out in the health-wine field, affirmed that red wine, thanks to its unique polyphenols content and composition, supplementing the regular diet increases the total antioxidant capacity in plasma, HDL lipoprotein, fibrinolytic and antithrombin activity, reduces oxidative damage and platelet aggregation etc. (Yoo et al., 2010; Fernández-Mar et al., 2012). The mechanisms responsible for the health effects of wine are extremely complex. Both the alcohol and the polyphenol components have been extensively studied and there is controversy over which component is more important (Hansen et al., 2005). Some controversy still exists over whether red wine has superior protective effects than other alcoholic beverages as well (Guilford and Pezzuto, 2011). Several review articles have discussed the relation between the types of alcoholic beverage consumed (wine, beer, liquor) and the risk of CVD and they did not find that one type of drink was more cardioprotective than the others (de Lorimier, 2000).
Numerous studies have investigated whether the risk for different kind of cancer depends on the type of alcoholic beverage consumed as well. The results obtained are sometimes contradictory and again misleading. In other words, the strength of the apparent protective effect of different beverages is still disputed (Fillmore et al., 2006; Grønbæk, 2009).
So, what is going on? Is red wine really better than beer in health promotion? Perhaps it is, but few facts deserve to be mentioned.
Antioxidant properties (AO) of both wine and beer are well investigated (Ghiselli et al., 2000; Rivero et al., 2005; Gorjanović et al., 2010). Recent studies suggest that amount of phenolics in beer and wine might be comparable. Results obtained *in vivo* confirm that AO capacity of beer and red wine are similar despite different concentrations of total polyphenols, possibly due to superior absorption of the beer phenolics as compared with those in red wine (Gorinstein et al., 2000; Nardini et al., 2006). Although beer per drink (of equivalent alcohol content) contains more than twice as many of the AOs as white wine and only half the amount in red wine, the red wine AOs may be larger molecules that are not as readily absorbed as the smaller AOs in beer (Ghiselli et al., 2000).

THE THIRST-QUENCHING EFFECT AND REHYDRATION

Beer can be regarded as a valuable rehydration beverage particular after hard physical working and sport training and exercise. Beer is truly a natural drink, more than 90% of water and is a thirst quenching drink, which contains relatively low content of alcohol, contains electrolytes and well digestible carbohydrates for efficient energy recovery. The osmotic pressure of beer is on average 1012 mmol/kg, while in the case of alcohol-free beer it is value of 290 mmol/kg, the same as blood (Mettler et al., 2006). Alcohol-free beer can thus be classified as an isotonic drink and be regarded as a most natural drink for thirst quenching. The sugars, salts, and bubbles of carbon dioxide stimulate fluid absorption and promote rehydrating effect so that alcohol diuretic effect is minimized significantly (Walzl, 2005).
However, beer is an alcohol beverage, and alcohol deserves special attention regarding well-known ethanol diuretic effect. However, results suggest that this effect is negligible when alcohol is consumed in dilute solution as beer is and after a moderate level of hypohydration. There appears to be no difference in recovery from dehydration whether the rehydration beverage is alcohol-free or contains up to 2% alcohol. Drinks containing 4% alcohol tend to delay the recovery process (Maughan, 2000). In other word, alcohol concentrations like

those in beer may not adversely affect long-term rehydration, but should not be relied upon when rapid and complete rehydration is desired. The greatest complaint regarding beer as rehydrating drink is its low potassium content.

NEW BEER TYPES WITH FUNCTIONAL PROPERTIES

According to market statistics, consumers are increasingly interested in the health benefits of foods. This interest combined with a more widespread understanding of how diet affects disease, rising health-care costs and an aging population are driving a growing market for products with functional properties. Beer as a natural drink, which already possesses a lot of functional properties can be an excellent base for developing new products with additional benefits and functionality. Several products like this have been already present on the market.

In 2004, two new beverages were introduced in the German market. Weihenstephan brewery launched, XAN Hefeweissbeer (XAN wheat beer) with elevated levels of XN up to 1.4 mg/L, and XAN Wellness (beermix with 40% of alcohol-free wheat beer and 60% natural multi-fruit juice -apple, acerola, lemon- and, advertised as the first ever soft drink to contain XN) with 4 mg/L of XN. Soon after Žatecký brewery in Czech Republic promoted ZATEC Xantho, dark beer with 0.3 mg/L of XN and 3 mg/L of IXN.

German brewer Karlsberg (not to be confused with Danish Carlsberg) has launched functional beer for women Karla - the mixed drink in two varieties. Both were low in alcohol content (1%v/v) and a blend of beer and fruit juices. *Karla Balance* claimed to provide 'peace and balance' by mixing hops with lemon balm, a herb well-known for its sedative properties. *Karla Well-Be* was enriched with ingredients such as soy-derived lecithin (which may positively affect cholesterol levels), folic acid (recommended for women considering pregnancy), and other vitamins. Emphasis on health, Karlsberg supplied its beer through an unusual distribution channel: pharmacists. However, although singled out by Polish business magazine Handel as Poland's best new FMCG product of 2006, Karla cannot be found any more on Karlsberg's web site (www.karlsberg.de).

There are also several beers with added functional additives or modified content to satisfy defined target group of costumers. One example is *Spirulina beer*. Spirulina is blue-green algae that contains numerous bioactive components and can be consumed as a dietary supplement, as a functional food additive, as well as a whole food. It is supposed to promote health in many ways: protects from oxidant stress and supports the immune system and a healthy inflammatory response. It is cultivated worldwide and is available in tablet, flake and powder form, now as a beer as well. Spirulina beer is claimed to keep the nutritional components and flavor of traditional beer, and increases its nutrient content derived from Spirulina (Liang et al., 2004). Gluten-free beer is another example. A celiac disease or gluten intolerance is a digestive disease that damages the small intestine and interferes with absorption of nutrients from food. People who suffer from this disease cannot tolerate gluten, a protein in wheat, rye, barley, and food containing these cereals, such is beer. Nowadays gluten-free beer is a solution for all those who suffer from such a disease and cannot allowed themselves regular beer. These beers are produced mostly with buckwheat and sorghum as the substitutes for barley molt (Bamforth, 2009).

A variety of plants, medicinal herbs, and mushrooms give a lot of possibilities to create a new beer line with defined functional properties and therapeutic action as well. During the past decades, public interest in natural therapies, namely herbal medicine, has increased dramatically. This fact may be the challenge for brewing industry to make a breakthrough for the growing functional food market. Possibilities are enormously high (Despotović et al., 2007; Leskošek-Čukalović et al., 2010a; Leskošek-Čukalović et al., 2010b; Veljović et al., 2010).

CONCLUSION

Studies focusing on the associations between different health conditions and alcohol consumption confirm the hazards of excess drinking but also indicate the existence of potential windows of alcohol intake that may confer a net beneficial effect of drinking, at least in terms of survival, both in men and in women. However, available epidemiological studies in many cases have provided contradictory results, showing positive, or negative, or non-significant associations between alcohol consumption and prevalence for given diseases, differences between type of alcohol beverage, active constituents and mechanisms of their beneficial action. In many cases, they have yielded no conclusive evidence that alcohol either promotes or prevents diseases. Therefore, the question whether to drink or not is still open. Moderate drinking seems to be beneficial in prevalence of some diseases but to recommend anyone to drink alcohol because of that would be very dangerous. Beer is a drink with numerous constituents important for healthy body functioning and regarding alcohol content is less hazardous than other alcohol beverages, but not an exception in terms of binge drinking. All studies found a negative association between alcohol consumption and health, especially in heavy drinkers and binge drinkers, regardless the type of alcohol.

ABSTRACT: Soybean and full-fat soybean products contain approximately 20% of oil and are susceptible to lipid peroxidation, particularly during the storage and distribution of raw material and thermal treatments used in full-fat soybean production.
Antioxidant properties of soybean isoflavones (genistein and daidzein) have been investigated in soybean oil model systems by measuring the ability of genistein and daidzein to inhibit the formation of radicals which were stabilized in the presence of spin trap N-*tert*-butyl-α-phenylnitrone (PBN) and detected in by electron spin resonance (ESR) spectrometry.
In both thermal and catalytic oxidation of soybean oil, the same hyperfine coupling parameters (a_N=14.75 G and a_H^{β}=2.80 G) confirmed the generation of PBN-OOL/-OL spin adducts (lipid oxyradicals). The antiradical activity of genistein and daidzein, in the 0.005-0.02% concentration range, was tested by measuring their ability to inhibit the formation of lipid oxyradicals during thermal and catalytic oxidation of soybean oil.
The antioxidative nature of genistein and daidzein was also tested by using DPPH test and chelating activity on Fe^{2+} assay.
It has been found that genistein inhibits the thermal oxidation of soybean oil by decreasing the concentration of lipid oxyradicals, while during the inhibition of catalytic oxidation of soybean oil it acts as a chain-breaking antioxidant and a metal chelator. Daidzein acts as a very weak chain-breaking antioxidant which does not demonstrate chelating activity on Fe^{2+} ions.
Key words: *genistein, daidzein, lipidoxyradicals, ESR, DPPH radicals, chelating activity*

INTRODUCTION

Soybean and full-fat soybean products contain approximately 20% of oil and, therefore, they aresusceptible to one of the non-desirable reactions of foods – lipid peroxidation. Thermal treatments which are used during the production of some soybean based foods could cause thermal oxidative degradation of soybean lipids. Also, soybean contains catalytically active metal ions which could act in catalytic oxidative degradation of soybean lipids. Full-fat soybean products could also be prone to lipid peroxidation during storage, as well as during distribution of foods, when susceptibility increases due to exposure to light (photooxidation) or air (high contact surface) (Namiki, 1990).
As lipid peroxidation represents one of the greatest problems during the production, storage and distribution of foods and feeds, it is necessary to reduce or eliminate the acting of the process. The use of antioxidants is one of the best ways for suppression the lipid peroxidation. Synthetic antioxidants such as butylated hydroxyanisole (BHA) and butylated hydroxytoluene (BHT) have limited use in foods, as they are suspected to be carcinogenic (Namiki, 1990). Therefore, the use of natural antioxidants or the implementation of processes that could preserve the natural antioxidant capacity of raw material during food processing has increased tremendously in recent years.

Soybean antioxidants include liposoluble antioxidants – α-tocopherol (Hamilton et al., 1997), soybean phospholipids or lecithin (Reblova et al., 1991), carotenoids (Bast et al., 1998), and non-liposoluble antioxidants, particularly soybean isoflavones (Cassidy et al., 1994; Tyug et al., 2010).
Soybean isoflavones are reported to act as phytoestrogens (Böhm and Franke, 1996), anticancerogens (Adlercreutz, 1995) and they can reduce the risk of cardiovascular diseases (Sacks et al., 2006; Tikkanen et al., 1994) and chronic renal disease (Ranich et al., 2001). The mentioned activities of soybean isoflavones are often related to their antioxitant activity (Yang et al., 2000), especially in the case of genistein (Lee et al., 2005; Record et al., 1995).
The antioxidative properties of soybean isoflavones are important for the medicinal and nutritional purposes (Mateos-Aparicio et al., 2008; Messina and Barnes, 1991; Xiao, 2008), as well as for food preservation (Pinto et al., 2005; Shimoni, 2004; Tyug et al., 2010).
There are many literature data related to the antioxidant capacity of soybean foods and feeds that is attributed to the presence of soybean isoflavones (Murphy et al., 1998; Wang et al., 1999; Hasnah et al., 2009).
Therefore, the aim of this work was to estimate the influence of genistein and daidzein on: a) thermal and catalytic oxidation of soybean oil using electron spin resonance (ESR) spectroscopy and "spin-trapping" technique b) DPPH radicals (scavenging effect) and c) concentration of Fe^{2+} (chelating effect).

MATERIAL AND METHODS

Material

Commercial soybean oil was purchased from the local market for the preparation of model systems intended for testing thermal and catalytic oxidation of soybean oil. Genistein, daidzein, N**-**tert**-**butyl-α**-**phenylnitrone (PBN), 1**,**1-diphenyl-2-picryl-hydrazyl (DPPH) and tetramethyl murexide were supplied by Sigma Chemical Company, St. Louis, MO, USA, and hexamine was obtained from Aldrich, Chemical Company, USA.

Thermal oxidation of soybean oil

The system for investigation of thermal oxidation of soybean oil (model system I) was prepared by mixing 6.0 mL of soybean oil with 21.3 mg (0.12 mmol) of spin trap N-*tert*-butyl-α-phenylnitrone (PBN) (blank probe I). Reaction mixture was heated at 60 °C. Thermal oxidative degradation of soybean oil was detected by measuring the formation of PBN lipid radical spin adducts after 24 h.

The influence of genistein and daidzein on the thermal oxidation of soybean oil was investigated by adding genistein or daidzein at 0.05-2.00% concentrations to blank probe I.

Antiradical activity (AA in %) of isoflavones was calculated according to the following equation:

$$AA=100\cdot(h_o-h_x)/h_o \qquad /1/$$

where h_o and h_x are the heights of the first peak in the ESR spectrum of PBN lipid radical spin adducts of blank probe I and probe I, respectively.

Catalytic oxidation of soybean oil

The system for investigation of catalytic oxidation of HESO (model system II) was prepared by mixing 6.0 mL of soybean oil, 3.0 mL of distilled water, 21.3 mg (0.12 mmol) of spin trap N-*tert*-butyl-α-phenylnitrone (PBN) and 3.9 mg (0.015 mmol) of ferrous sulphate heptahydrate (blank probe II). Reaction mixture was allowed to stay at room temperature (23 ± 1 °C). Catalytic oxidative degradation of soybean oil was detected by measuring the formation of PBN radical spin adducts after 3 h.

The influence of genistein and daidzein on the catalytic oxidation of soybean oil was investigated by adding genistein or daidzein at 0.05-2.00% concentrations to blank probe II.

Antiradical activity (AA in %) of genistein and daidzein was calculated according to Eq. 1, where h_o and h_x are the heights of the first peak in the ESR spectrum of PBN radical spin adducts of blank probe II and probe II, respectively.

Detection of oxygen free radicals

ESR spectra were recorded with spin trapping technique using Bruker 300E ESR spectrometer (Bruker, Rheinstetten, Germany) under the following conditions: modulation field 100 kHz, modulation amplitude 0.204 G, receiver gain 10^3, time constant 327.68 ms, conversion time 1310.72 ms, centre field 3440.00 G, sweep width 100.00 G, microwave frequency 9.64 GHz, microwave power 20.0 mW, and temperature 23 ± 1 °C.

Magnetic field scanning was calibrated using Fremy's salt (peroxylamine disulphonate). A quartz flat cell Bruker ER-160FC was used for detection. Splitting constants were calculated from computer-generated second derivatives of the spectra after optimizing signal-to-noise ratios and were verified by computer simulations. ESR spectral files were imported into the WinSim program (WinSim, Sugar Land, TX, USA) for the analysis of the hyperfine splitting constants (Duling, 1994).

Scavenging activity on DPPH radical

Different concentrations of genistein and daidzein solutions (0.25 mM, 0.50 mM, 1 mM, 2 mM) (80% ethanol, 4 mL) were mixed with a methanolic solution of DPPH radicals (1 mL), and the final concentration was 0.2 mM. The absorbance was measured after 30 minutes at 517 nm (Shimada et al., 1992).

Chelating activity on Fe^{2+}

Chelating effect was determined following the method of Shimada et al. (1992). Different concentrations of genistein and daidzein solutions (0.25 mM, 0.50 mM, 1 mM, 2 mM) (80% ethanol, 2 mL) and tetramethyl murexide (1 mM, 0.2 mL) were added into the mixture (2 mL) of 30 mM hexamine, 30 mM KCl and 9 mM ferrous sulphate ($FeSO_4$ x $7H_2O$). The absorbance was measured after 3 minutes at room temperature (23 ± 1 °C) at 485 nm.

RESULTS AND DISCUSSION

The thermal and catalytic oxidation of soybean oil in the investigated systems (model systems I and II) was registered by recording ESR spectra of PBN spin adducts of formed radicals during the reaction period of 24 h at the thermal oxidation and during 3 h of the catalytic oxidation of soybean oil.

The ESR spectra recorded in both model systems consist of six lines of the same relative intensities, characteristic for the interaction of unpaired electron and ^{14}N-atom (I=1) and ^{1}H-atom (I=1/2), with hyperfine coupling parameters (a_N=14.75 G and a_H^{β}=2.80 G). Radicals trapped in the investigated systems are recognized as lipid oxyradicals, i.e. spin adducts obtained in these systems are marked as PBN-OOL/-OL spin adducts (Sakač et al., 2010).

PBN-OOL/-OL spin adducts were also detected in model systems I and II in which genistein or daidzein was added, but their formation was affected by the addition of genistein in both model systems in the investigated concentration range, while daidzein did not manifest antioxidant activity in model system I, but slightly suppressed the formation of PBN-OOL/-OL spin adducts in model system II (Fig. 1).

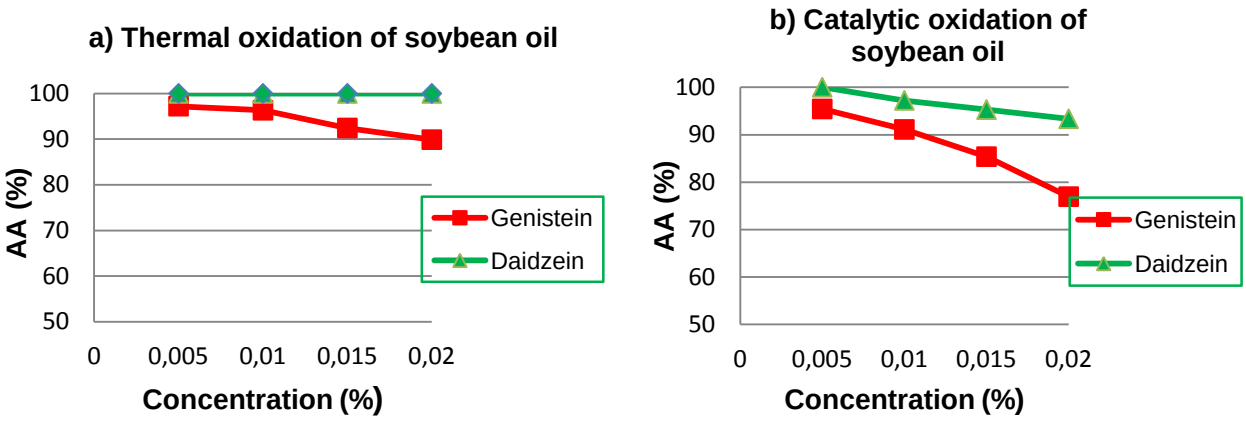

Fig.1. Antioxidative activity of genistein and daidzein on PBN-OOL/-OL spin adducts formed during thermal (a) and catalytic (b) oxidation of soybean oil in model systems I and II

The obtained results (Fig. 1) suggest that genistein acted as a relatively weak chain-breaking antioxidant in the model system I, capable to scavenge free radicals and thus preventing the thermal oxidation of soybean oil. In contrast, it acted in two ways in model system II – as a chain-breaking antioxidant and as a metal-chelator.

The statement that genistein, but also daidzein, although weakly, could act as an antioxidant by donating H-atom was confirmed in DPPH assay (Fig. 2) in which a dose-dependent scavenging activity was observed for both isoflavones.

Chelating properties of genistein were evidenced during measurement of chelating activity on Fe^{2+}, while daidzein expressed extremely weak tendency to chelate Fe^{2+} (Fig. 3).

The antioxidant effectiveness of genistein as a chain-breaking antioxidant, which donates H-atom to DPPH radicals (Fig. 2), was indicated by Record et al. (1995). Yang et al. (2000) reported that the fermented soy drinks, known for their high content of isoflavone aglycones, showed a relatively strong scavenging activity on DPPH radicals. The scavenging activity of genistein and daidzein was also recorded by Mitchell et al. (1998), who used ESR spectroscopy to monitor the scavenging activity of a number of phytoestrogens in the presence of galvinoxyl-radicals. Their results demonstrated that genistein and daidzein did not strongly scavenge DPPH or galvanoxyl radicals. Lee at al. (2005) also found out that genistein and daidzein possess antioxidative capacity, but they were less effective compared with known potent antioxidants, such as epicatechins and α-tocopherol. Our results are in agreement with those of mentioned authors, who established that genistein was much potent that daidzein in FRAP and
DPPH assays.

The ability of genistein, but not of daidzein, to inhibit the formation of PBN-OOL/-OL spin adducts during catalytic oxidation of soybean oil (Fig. 1b) was in agreement with the cited results of chelating capacity of isoflavones (Mitchell et al., 1998) and with the results of chelating activities of isoflavone aglycones reported by Lee and Cheigh (1997).

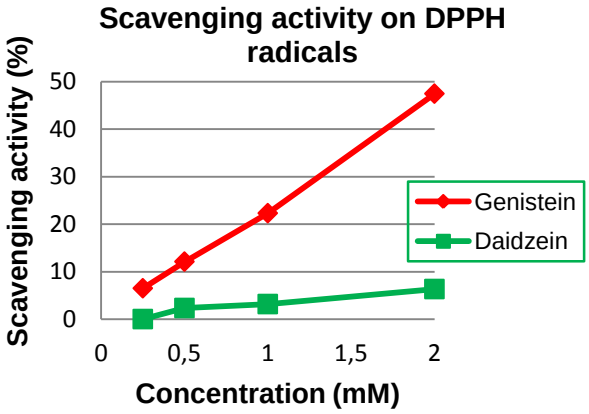

Fig. 2. Scavenging activity of genistein and daidzein on DPPH radicals

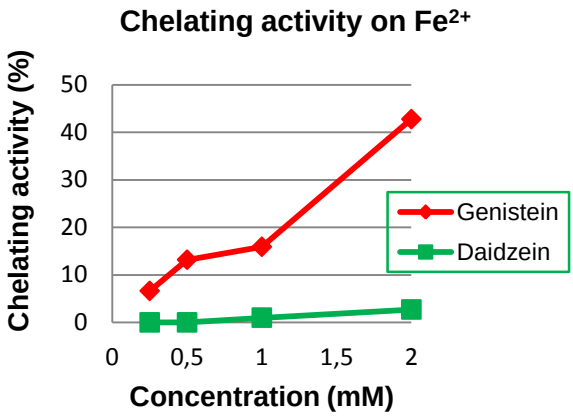

Fig. 3. Chelating activity on Fe^{2+} of genistein and daidzein

The chelating activity of genistein is attributed to the keto group at position 4 and the hydroxyl group at position 5, although these chemical features are not so powerful for chelation as some others (for example, those of quercetin). The structure of daidzein, without the structural predisposition for chelating activity, indicates that it is unable to act as metal-chelator, although it demonstrated extremely weak chelating activity on Fe^{2+} (Fig. 3).

The established antioxidant properties of investigated soybean isoflavones may contribute to the inhibition of lipid peroxidation which occurs during the production, storage and distribution of full-fat soybean foods and feeds.

CONCLUSIONS

Genistein inhibited the thermal oxidation of soybean oil being capable to suppress the formation of PBN-OOL/-OL spin adducts acting as H-donor. In contrast, genistein acted as a chain-breaking antioxidant and a metal-chelator during the catalytic oxidation of soybean oil. It was confirmed that genistein is able to donate H-atom in DDPH test and to chelate Fe^{2+} in chelating activity assay.

Daidzein acted as a very weak chain breaking antioxidant and almost did not exhibit the chelating activity on Fe^{2+}.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR31029 “Funkcionalni proizvodi na bazi žita namenjeni osobama sa metaboličkim poremećajima (Functional Cereal-based Products for People with Metabolic Disorder)” financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: The aim of this study was to compare the antioxidant properties of five *Lamiaceae* plant extracts using eight different antioxidant assays and to investigate the influence of the rosmarinic acid content on the antioxidant properties of investigated plant extracts. The research includes five plant extracts: *Melissa officinalis*, *Mentha piperita*, *Origanum vulgare*, *Salvia officinalis* and *Thymus serpyllum*. The content of rosmarinic acid in extracts was determined using HPLC-RP-DAD. All extracts were extremely rich in phenolic compounds and contained high concentrations of rosmarinic acid. The highest rosmarinic acid content as well as the best antioxidant properties using most of the methods were obtained for *Melissa officinalis*. The significance and role of rosmarinic acid in the antioxidant properties of *Lamiaceae* plant extracts was confirmed and undoubted, but the contribution of other compounds and their possible cumulative or synergistic action also should not be neglected.
Key words: *antioxidants, Lamiaceae, rosmarinic acid*

INTRODUCTION

There is a great demand in the food industry for compounds that effectively inhibit the oxidation of food components, which is the major cause of food deterioration. These processes may be avoided or delayed by antioxidants. The possible toxicity of the conventional synthetic antioxidants, together with consumers' preference for "natural" products have intensified research of different plant extracts which are known to possess the antioxidant activity (Durling et al., 2007; Krishnaiah at al., 2010). There is an increasing interest for spices and aromatic herbs because of their strong antioxidant properties, which exceed many currently used natural and synthetic antioxidants.
Based on the latest literature, the family *Lamiaceae* is a rich source of phenolic acids. The aim of this study was to investigate the influence of the rosmarinic acid content on the antioxidant properties of *Lamiaceae* plant extracts. Rosmarinic acid is known as one of the most dominant phenolic compound in *Lamiaceae* plants and it is often used as chemotaxonomic marker of this plant family (Zgorka and Glowniak, 2001). The results of this investigation should be helpful in order to better explain the complex pharmacological activity of medicinal plants belonging to the *Lamiaceae* family.

MATERIAL AND METHODS

Reagents, solvents and standards

All reagents and solvents used in the experiments were of adequate analytical grade and were obtained from Fluka (Buch, Switzerland), Kemika (Zagreb, Croatia), Merck (Darmstadt, Germany) and Sigma-Aldrich GmbH (Steinheim, Germany).

Instruments

Spectrophotometric measurements were performed on a UV-Vis double beam Specord 200 spectrometer (Analytik Jena GmbH, Germany), Hewlett Packard UV-Vis spectrophotometer model 8453 (Hewlett Packard, Waldbronn, Germany) and Sunrise basic microplate reader (Tecan GmbH, Austria).

The HPLC system used for separation and quantification of rosmarinic acid was composed by a Varian 330 UV/Vis photodiode array (PDA) detector, a ternary gradient liquid Pro Star 230 pump, a model 500 heater, Star 6.0 chromatography workstation and UltraAqueous C 18 column (250x4.6 mm, 5 mm; Restek; maintained at 30°C). The extracts were filtered through 0.45-mm syringe filters, adequately diluted with MeOH, and directly injected through a 20 ml fixed loop into a C 18 guard column.

Plant material and preparation of plant extracts

Plant material, *Melissa officinalis*, *Mentha piperita*, *Origanum vulgare*, *Salvia officinalis* and *Thymus serpyllum* leaves, produced and distributed by Suban (Samobor, Croatia), were purchased from a local herbal pharmacy.

Dried, pulverized plant material (5 g) was extracted with 250 ml of ethanol/water mixture (80/20, v/v) at 60°C for 60 minutes. After the cooling, the sample was filtered and the residual tissues were washed with solvent (3x10 ml). The extractions were performed in triplicate for each sample, and after the filtration, the three sample extracts were combined in a total extract that was evaporated to the volume of 150 ml, centrifuged and used for further analysis.

Antioxidant methods

The antioxidant properties of plant extracts were evaluated by eight different antioxidant assays. All methods were carried out in triplicate, and the presented data are the means of three measurements.

The Folin-Ciocalteu assay has been used for many years as a measure of total phenolics in natural products, but the basic mechanism is an oxidation-reduction reaction and, as such, it can be considered as another antioxidant method (Prior et al., 2005). Total phenolic concentration in *Lamiaceae* plant ethanolic extracts was determined by the Folin-Ciocalteu colorimetric method (Singleton & Rossi, 1965; Amerine & Ough, 1980), calibrated against gallic acid standards and expressing the results as mg of gallic acid equivalents (GAE) per l of plant extract.

Total reducing capacity of the samples, FRAP, was estimated following the procedure originally described by Benzie & Strain (1996). A standard curve was prepared using different concentrations of Vitamin C.

Radical-scavenging activity was determined using stable 2,2-diphenyl-1-picrylhydrazyl (DPPH) free radical according to the procedure reported by Katalinić et al. (2010), and using stable 2,2'-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) radical cation (ABTS) according to the procedure reported by Re et al. (1999). The results were expressed as IC50 values, the concentration of an antioxidant needed to decrease the initial radical concentration by 50%. The IC 50 values were estimated from the graph plotting the inhibition percentage against the extract concentration and were expressed in mg GAE/l of tested sample.

Measurement of superoxide anion scavenging activity of the extracts was based on the method Roback & Gryglewski (1988).

The chelating of ferrous ions by the sample was estimated using the method described by Yen et al. (2000).

The antioxidant activity of sage extracts was determined through the Briggs-Rauscher oscillating reaction (Prenesti et al., 2005; Generalić et al., 2011; 2012). The plant extracts were diluted to a total phenol concentration of 100 mg GAE/l before analysis. The efficiency of the antioxidants was expressed as the inhibition time, in minutes, of the oscillations.

The antioxidant activity of *Lamiaceae* plant extracts in an aqueous emulsion system of linoleic acid and β-carotene was determined according to a method of Moure et al. (2000)

(Terpinc & Abramovič, 2009). The final concentration of plant extract phenolics in the emulsion was 1000 mg GAE/l.

HPLC method

A gradient consisting of solvent A (MeCN), solvent B (H_2O/AcOH 99:1 (v/v)), and solvent C (MeOH) was applied at a flow rate of 1.0 ml/min as follows: from 1% A, 95% B, 4% C at 0 min to 5% A, 85% B, 10% C at 15 min, to 15% A, 35% B, 50% C at 45 min, to 20% A, 5% B, 75% C at 60 min, to 1% A, 95% B, 4% C at 72 min, maintaining 1% A, 95% B, 4% C for 3 min (75 min). The signal was monitored at 280 nm, and rosmarinic acid content was quantified based on the areas of their peaks using external standard calibration curves.

RESULTS AND DISCUSSION

Among the plants reported to have antioxidant activity, *Lamiaceae* plants (mint family) are the most widely used and commercialized. These plants have been used in variety of food preparations since ancient times usually as flavouring agents, but various publications have documented also good antioxidant activity of those extracts or its specific compounds (Petersen & Simmonds, 2003; Generalić et al., 2012).

Good antioxidant properties are result of numerous compounds from diverse chemical groups acting together, including a range of phenolic compounds (Lu & Foo, 2002; Durling et al., 2007; Generalić et al., 2011). The majority of the phenolic acids in mint family plans are exclusively those of caffeic acid derivatives. Although presence of different flavonoids and other phenolics in sage extracts is confirmed, the main antioxidant effect has been reported to relate to the presence of phenolic diterpenes (such as carnosic acid and carnosol), caffeic acid oligomers (known as labiataetannins) and, especially, rosmarinic acid (Fecka and Turek, 2008, Generalić et al., 2011). Flavonoids are widely distributed in *Lamiaceae* plants being mostly present as flavones (apigenin, luteolin and their corresponding 6-hydroxilated derivatives), flavonols (mostly kaempferol and quercetin methyl ethers, narirutin, hesperidin), flavononols (taxifolin) and flavon or flavonol glycosides (Cuvelier et al., 1994; Lu and Foo, 2002, Fecka and Turek, 2008). Among phenolic compounds, the rosmarinic acid (ROA), an ester of caffeic acid and 3,4-dihydroxyphenyllactic acid (Figure 1), is usually a dominant phenolic of many species of the *Lamiaceae* family (Petersen et al., 2009). A multitude of biological activities for ROA have already been described and investigated (Petersen & Simmonds, 2003).

The results of this study confirmed the presence of ROA in all investigated *Lamiaceae* extracts in extremely high concentrations. The highest content of ROA was detected in *Melissa officinalis* extract (2413 ± 8 mg/l), what is more than four times higher content than it was found in *Origanum vulgare* extract (Figure 2).

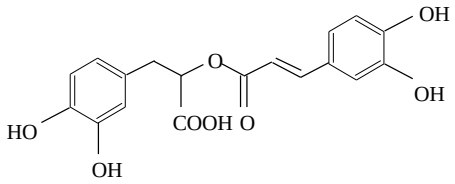

Figure 1. The structure of rosmarinic acid (ROA).

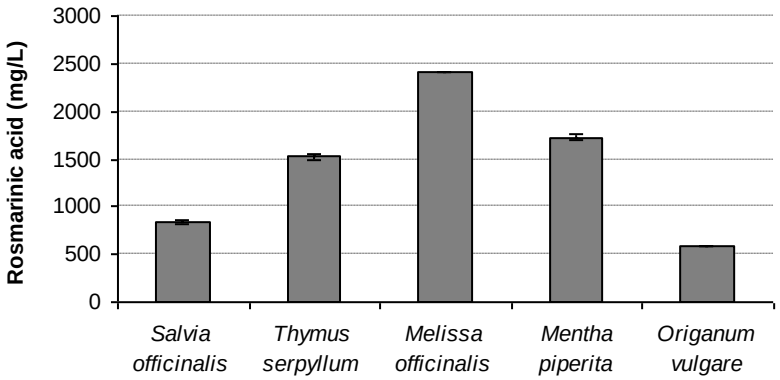

Figure 2. The content of the rosmarinic acid in *Lamiaceae* plant extracts.

The aim of this study was to investigate if there is any connection between the ROA content in plant extracts and its antioxidant properties. The obtained results for all used methods are presented in Figure 3.

As shown in Figure 3a, the total phenolic content in investigated *Lamiaceae* plant extracts was very high and ranged from 4916 to 8998 mg GAE (gallic acid equivalents)/l. The highest content of total phenolic compounds was detected in extracts of *Salvia officinalis* and *Origanum vulgare*. If we compare these results with the results obtained for rosmarinic acid content presented in Figure 2, it can be noticed that the extracts richest with phenolic compounds contain the smallest amounts of ROA. The reason for this could be in the fact that Folin-Ciocalteu reagent is not specific for phenolic compounds only as it can also be reduced by many non-phenolic compounds (Karadag et al., 2009). Compounds like sugars, proteins, aromatic amines, organic acids, inorganic substances, different metal chelators etc. are recognized as interfering substances which can react with FC reagent to give elevated apparent phenolic concentrations (Prior et al., 2005). The reagent therefore measures the reducing capacity of a sample, not just the level of phenolic compounds.

The FRAP values of the investigated plant extracts ranged from 13.2 (*Origanum vulgare*) to 31.8 (*Melissa officinalis*) mM Vitamin C equivalents (VCE) (Figure 3b). It could be noticed that *Melissa officinalis* extract showed the strongest reducing capacity, which was probably related to the presence of high level of ROA in it. Very significant linear correlation was found between the contents of ROA and FRAP values (r = 0.9858). Katalinić et al. (2006) investigated reducing capacity of 70 medicinal plants and also reported best results using FRAP method for *Melissa officinalis* extract, among all tested extracts.

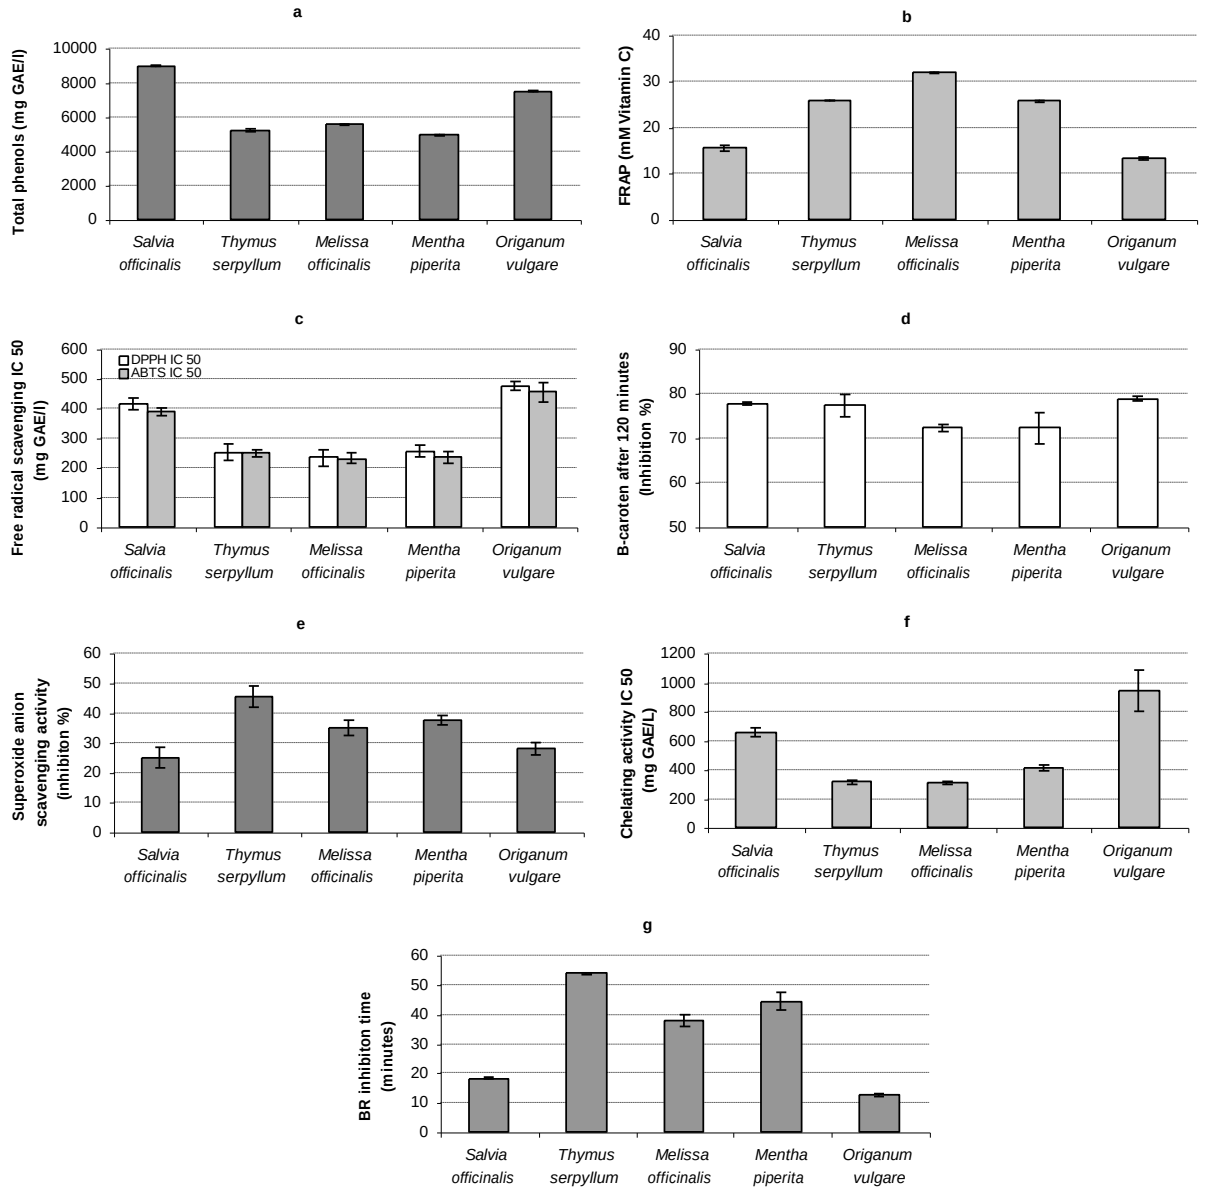

Figure 3. Results for antioxidant properties of *Lamiaceae* plant extracts.
a) Content of total phenols in plant extracts determined using Folin-Ciocalteu assay; b) The ferric-reducing antioxidant power (FRAP) of plant extracts; c) Free radical scavenging activity expressed as values IC 50 (IC 50 is sample concentration needed to decrease the initial free radical concentration by 50%) for DPPH and ABTS (in mg of gallic acid equivalents (GAE)/l of extract); d) Antioxidant activity obtained after 120 min using the B-carotene bleaching assay; e) Superoxide anion scavenging activity of plant extracts expressed as IC 50 value; f) Chelating activity (%) of plant extracts; g) The antioxidant results for the Briggs-Rauscher method, expressed as inhibition time of oscillations

The free radical-scavenging activity of the plant extracts was tested with two synthetic, stable free radicals, $DPPH^{\cdot}$ and $ABTS^{\cdot-}$. The obtained results, expressed as IC 50 values, are presented in Figure 3c. An extremely significant correlation between the IC 50 values of DPPH and ABTS of the extracts was observed (r = 0.9978), and the best results were again obtained for the *Melissa officinalis* extract (DPPH IC 50 = 233 mg GAE/l; ABTS IC 50 = 232 mg GAE/l). Capecka et al. (2005) also investigated free radical scavenging activity of *Lamiaceae* plant extracts. It their study *Melissa officinalis* extract provided the highest antioxidant activity what is in accordance with our results. Negative linear correlation was found between the contents of ROA and IC 50 values obtained by DPPH method (r = -0.9197), as well as by ABTS method (r = -0.9102).

The reactions that occurs in FRAP, DPPH and ABTS methods utilize the same single electron transfer mechanism (ET). This could be reason for good correlation between the ROA content and obtained antioxidant properties (Prior et al., 2005; Badarinath et al., 2010). The position and/or number of OH groups on the benzene ring also affect the extent of direct electron transfer reactions. Rosmarinic acid has four hydroxyl groups and that could be the reason why the extract with the highest share of ROA showed best results.
The best antioxidant activity using superoxide anion assay was obtained for *Thymus serpylum* plant extract (45.49%). This method also provides information on free radical scavenging activity, but it is based on hydrogen atom transfer (HAT) so there is no correlation between obtained results and ROA content.
The antioxidant activity of the *Lamiaceae* plant extracts was also tested as the lipid peroxidation inhibition potential using the B-carotene bleaching method. In the B-carotene/linoleic acid system, the *Origanum vulgare* extract was superior to the other extracts studied. Results of good activity of *Lamiaceae* plants in preventing lipid oxidation were also reported by Su et al. (2007) and Dastalmachi et al. (2008). A negative correlation was found between the contents of ROA and B-carotene inhibition % ($r = -0.8801$).
The results of chelating activity again confirmed that the best antioxidant results were provided for *Melissa officinalis* extracts (KEL IC 50 = 305 mg GAE/l). This is in accordance with results of Dastalmachi et al. (2008). Rosmarinic acid has two *ortho*-dihydroxy groups (catechol structures) (Figure 1), which is the most important structural feature for strong chelating activity of the phenolic compounds (Shan et al., 2005). A negative correlation was found between the contents of ROA and chelating activity ($r = -0.8831$), what confirms this observations.
The results obtained using Briggs-Rauscher oscillating methods are presented in Figure 3g. The inhibition time of the oscillations depends on the free-radical scavenging ability of the added antioxidant compound/mixture (Generalić et al., 2012). The *Thymus serpylum* extract provided the longest inhibition (54 minutes), while the time of inhibition of the *Salvia officinalis* extract as well as *Origanum vulgare* extract was 3-4 times lower.

CONCLUSIONS

The results of this study confirmed that all investigated *Lamiaceae plant* extracts are rich source of rosmarinic acid. The highest content of rosmarinic acid, the best antioxidant properties using FRAP, DPPH and ABTS methods and the best chelating activity were obtained for *Melissa officinalis* plant extract. Single electron transfer mechanism (ET) of these methods and catechol structure of the rosmarinic acid could be reasons for good correlation between the ROA content and antioxidant results. The significance and role of the rosmarinic acid in the antioxidant properties of investigated *Lamiaceae* plant extracts was confirmed and undoubted, but the contribution of other compounds and their possible cumulative or synergistic action should not be neglected.

ACKNOWLEDGEMENTS

ABSTRACT: In recent years there is an increased demand for food enriched with physiologically active components. Quinces were selected as a raw material in this study. They belong to the same family of fruits such as pears and apples. The quinces that have been examined had around 20% dry mass, 1.7 % fibers, more than 6 mg vitamin C per 100 g fruit, pectin, antioxidants, and other components. Because of the astringent, tart flavour, quinces are commonly processed into marmalades and jellies, with addition of sucrose to improve their taste. Therefore the purpose of this investigation was to develop a new quince snack product which besides functional properties, will also have improved taste due to the infusion of the alternative sweetener, stevia. This study was carried out to evaluate selected quality attributes of a quince snack enriched with prebiotic (inulin) and alternative sweetener (stevia) accompanied with an antibrowning agent by the use of vacuum impregnation. The porosity of the quince was 0.35 cm^3/cm^3, confirming that its tissue was highly suitable for vacuum infusion. Texture profile analysis was measured on texture analyzer using the compression test that simulates the mastication process. The L*, a* and b* color values were recorded and used to calculate the browning index in all processing steps, in order to obtain the kinetics of the browning reaction. Due to the quince's susceptibility to intensive browning, the kinetics of the browning reaction was necessary to optimize the concentration of the antibrowning agent.
Key words: *quince, inulin, stevia, functional food, snack*

INTRODUCTION

Quince is the fruit of a deciduous tree of the *Rosaceae* family, *Cydonia oblonga* Miller. When ripe, quince fruits impart an agreeable, long-lasting, and powerful flavor. Quince fruit is too acid, astringent, and tough to be consumed fresh. As they are not edible unprocessed because of their very hard, tough, and fibrous consistency, they are often used for preparing jam (Silva et al., 2005). Nevertheless, the consumer's demand for a broader variety of convenient food products has forced the researchers to also investigate the other possibilities of quince processing besides jam.
Vacuum impregnation (VI), has been used as an effective technique in the food industry for enriching porous matrixes and production of new functional foods, due to its advantages: kinetics of transference of fast masses, higher gain of solutes in short times, better color conservation and color improvement in some products and taste and scent conservation of the fresh product (Chiralt et al., 1999). Another potentially great technique with commercial importance is the application of ultrasound (US). Ultrasound waves are supposed to improve porosity of the fruit tissue and enhance the effect of the vacuum infusion. Ultrasonically treated and vacuum impregnated samples can be dried at lower temperatures than the conventional methodology which reduces the probability of oxidation or degradation in the material and therefore their combination can have beneficial effect on the taste, texture and shelf life (Fernandes and Rodrigues, 2007; Fito et al., 2001).
Stevia and inulin, have not been evaluated yet, as potential ingredients, which could be used in quince processing and development of new products. Among the natural sweeteners, stevioside, a sweet glycoside (about 300 times sweeter than sucrose) from *Stevia*

rebaudiana Bertoni, has derived much attention lately (Goyal 2010), and is considered as safe (GRAS) by the FDA. Steviol glycosides can be particularly beneficial to those suffering from obesity, diabetes mellitus, heart disease and dental caries (Ghanta et al., 2007), consumers that could greatly benefit from natural products with low sugar content. Inulin is found widely distributed in nature as plant storage carbohydrates; it is a functional food ingredient that provides unique combination of technological properties. Furthermore, it provides nutritional benefits, which results in better health and attenuation of the risk of many diseases (Nair et al., 2010). Inulin has neutral taste, is colorless, and thereby only minimally influences the organoleptic characteristics of product. The high solubility of inulin enables it to be fortified in many products.
The objectives of this study were to optimize and investigate the effect of stevia and inulin vacuum infusion in fresh quince in order to develop new quince product that can be consumed as dried quince snacks or as a part of dried energy bar or musli formulation.

MATERIAL AND METHODS

Samples and sample preparation

Quince samples were purchased on the market and stored at 1–4°C until use. A few hours prior to use, the samples were left to equilibrate at room temperature. They were peeled manually and cut into 10x10x5 mm cubes after removing the pericarp. Quince cubes were sprayed with 0.25, 0.5 and 1% ascorbic acid solution to inhibit enzymatic browning.

Ultrasound treatment and vacuum impregnation

The quince cubes were dipped separately in three different concentrations of stevia solutions (NOWfoods, USA), 0.75%, 1% and 2% (w/v), and 20% of inulin solution (inulin from dahlia tubers, Fluka, USA). The quince cubes immersed in 250 ml of one of the solutions were exposed to ultrasound (US) treatment for 5, 10 and 15 minutes at three different temperatures (20, 40 and 60 °C). Afterwards, the quince cubes were subjected to vacuum impregnation (VI) step. The vacuum impregnation was carried out for 14 min, where a gradual increase of the vacuum for 4.5 min, was followed by 5 min holding time at vacuum pressure, 100 mbar, and then the gradual release of the vacuum was 4.5 min.

Drying treatment

After the US+VI treatments quince samples were dried at 45°C in a vacuum dryer until constant mass. After the drying, the quince cubes were cooled down to room temperature for 20 min and packed in multi-layered packaging bags. The packaging material was metalized polypropylene and the cubes were packed under the nitrogen atmosphere to avoid moisture absorption, discoloration and spoilage till further analysis. Three replicates were used for each treatment where a replicate consisted of six randomly selected cubes from two quince samples.

Porosity

The bulk volume of fresh quince was measured using the liquid displacement technique. The bulk density, ρb, (g/cm3) was expressed as the ratio of the sample to its bulk volume, while the solid density, ρs, was determined by dividing the mass of the grinded sample by its solid volume. The test was repeated three times. The porosity, Φ, was then calculated as:

$$\Phi = 1 - \frac{\rho_b}{\rho_s}$$

Texture analysis

Texture measurements were conducted by means of a texture analyzer (TA-XT2i of Stable Micro Systems, Godalming, England). To determine the texture of the fresh quince and quince snacks compression test was. This test was conducted using a cylindrical probe (diameter-5 mm; height-25mm). The probe descended at speed of 10 mm/s and compressed the sample at a speed of 1 mm/s up to a distance making 50% deformation. When the compression stroke was completed, the probe abruptly reversed its direction and started the upward move at 10 mm/s. Then a second down and up cycle was run on the same sample. A force-time curve was recorded by the instrument and three textural attributes including hardness, cohesiveness and springiness were calculated.

Measurement of color

To measure the color of fresh quince as well as the color of the treated quince samples, Dr. Lange spectro-color colorimeter was used. The instrument was calibrated against the black and white tile before use. After collecting the three parameters that is L* (lightness), a* (greenness) and b* (yellowness) they were fitted in three equations to calculate the total color change, *ΔE,* and the browning index, *BI*. The experiments were replicated five times.

$$\Delta E = \sqrt{(L^* - L_0^*)^2 + (a^* - a_0^*)^2 + (b^* - b_0^*)^2}$$

$$BI = \frac{100}{0.17}\left(\frac{a^* + 1.75L^*}{5.645L^* + a^* - 3.012b^*} - 0{,}31\right)$$

RESULTS AND DISCUSSION

Due to the quince's susceptibility to intensive enzymatic browning, the kinetics of the browning reaction of fresh cut quince samples and samples treated with 0.25, 0.5 and 1% ascorbic acid as anti-browning agents, was evaluated to optimize the concentration of the anti-browning agent. The enzymatic browning of the fresh quince followed the 0-order kinetic (Fig 1). As can be seen from the results, the 1% ascorbic acid slowed down the browning process more efficiently than 0.25% and 0.5% ascorbic acid solutions.

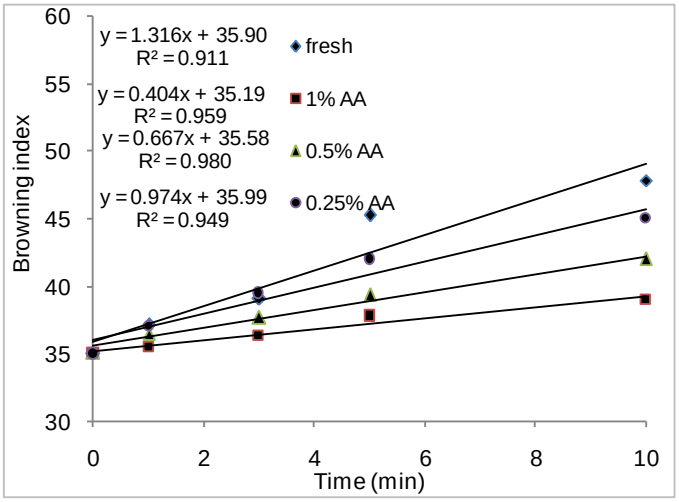

Figure 1. Browning kinetics of fresh and ascorbic acid treated quince

Porosity of the quince samples can be related to the degree of water loss and solute uptake, the fruit's moisture content and the microstructural changes of the tissue during drying. Usually the changes in fruit porosity result in changes of its texture, especially its firmness (Mandala et al. 2005). Therefore, variation in porosity due to the US treatment at temperatures of 20, 40 and 60°C in duration of 5, 10 and 15 minutes was examined (Fig. 2a). Texture profile analysis were also performed (Fig. 2b). The textural changes of the quince

tissue with the change of porosity were compared in order to optimize the US treatment. The US treatment of 10 minutes at temperature of 20°C was chosen as the best condition for pre-treatment of the quince samples. The porosity of those samples was 0.484 cm^3/cm^3, which is 1.4 times higher than fresh untreated quince sample. Even though the porosity of the quince increased with the higher temperature, from the texture profile it was evident that higher temperature led to tissue hardening and loss of springiness and cohesiveness. Furthermore, treatment at this temperature brought development of cooked flavor, which might have negative effect on the sensorial properties of the processed quince cubes.

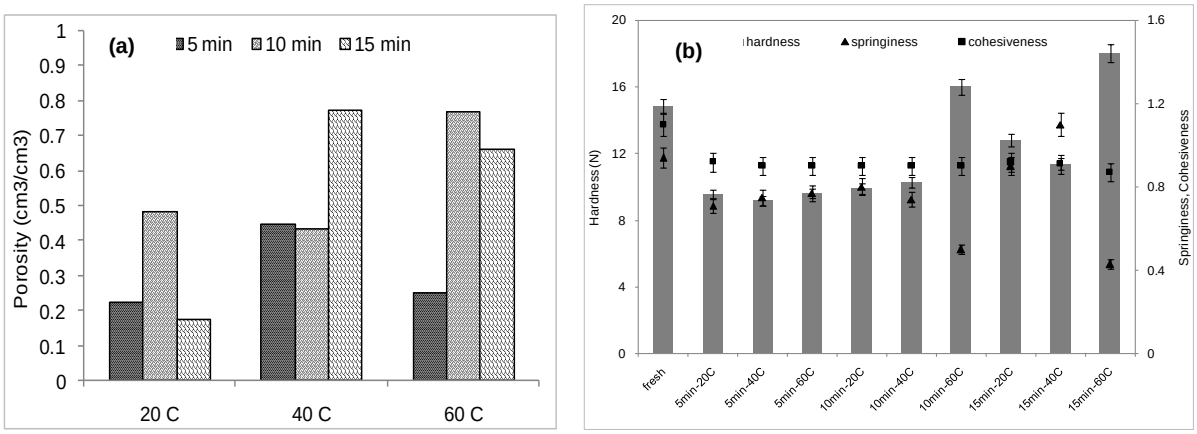

Figure 2. Porosity (a) and textural changes (b) of the quince samples treated with ultrasound

After the optimization of the US treatment, the quince samples were vacuum infused with stevia (1%) and inulin (20%) to investigate the weight gain of the different combination of the pre-treatments (Tab. 1). From the presented results it was noticeable that the combination of the US followed by VI step gave the highest weight gain of the samples. Only VI exhibited slightly lower solute gain, while the application of US after the VI led to loss of the infused solute. Therefore, the further experiments were a comparison between VI and US+VI quince samples.

Table 1. Weight gain of the vacuum infused inulin and stevia in quince tissue

treatment	**weight gain (%)**	
	inulin	**stevia**
Vacuum infusion	9,7	0,85
Ultrasound+Vacuum infusion	10,3	0,98
Vacuum infusion+Ultrasound	6,08	0,56

The textural changes of the quince samples after pre-treatment and after drying are given in Fig.3. The results showed that the pre-treatment did not cause significant change of the tissue firmness. The springiness after the pre-treatment was slightly more pronounced confirming the higher elasticity of the tissue when compared to fresh quince sample. In general, the addition of the US step to the VI treatment increased the springiness of the samples, probably due to cellular restructuring under the ultrasonication. The textural profile of the pre-treated dried samples (Fig. 3b) exhibited tissue hardening after the drying, as expected. The US+VI samples were 2 to 3 times harder when compared to just VI samples. The differences in the firmness between inulin and stevia infused samples were not significant. The springiness of the treated samples after drying followed the same behaviour as after vacuum infusion, meaning that US+VI samples maintained the higher elasticity when compared to just VI samples.

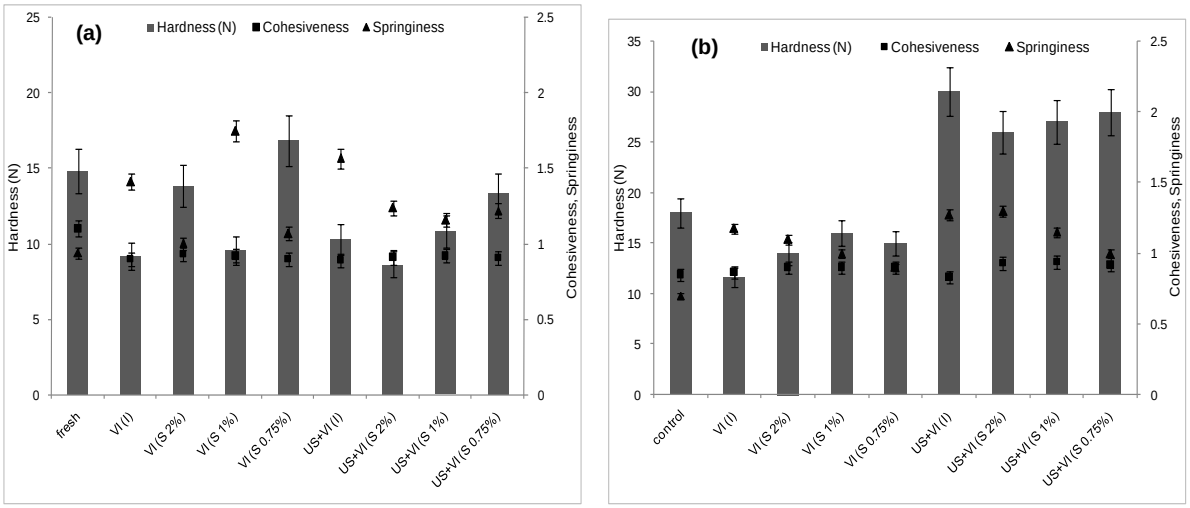

Figure 3. Changes in texture properties of quince samples after pre-treatment (a) and drying (b)

Figure 4 shows the total color change and browning index of the fresh and processed quince samples. As can be seen from Figure 4, the quince enriched with inulin, both VI and US+VI processed, showed similar total color change values as fresh quince, but increased browning index. The stevia infused samples had higher total color change values than the fresh samples and lower degree of browning. These lower values were associated with transparency gained due to air loss, an effect that is produced by the total or partial substitution of the air present in the pores by the impregnation solution (Moreno et al., 2000). The US+VI samples treated with stevia maintained the same browning degree and only inulin treated quince showed significantly higher browning degree when compared to the rest of the samples.

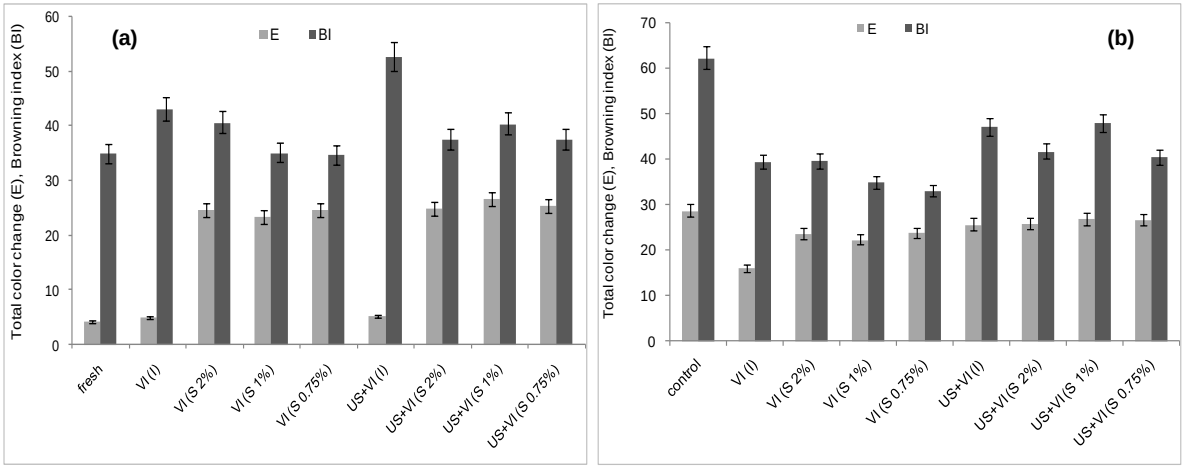

Figure 4. Changes in the surface color of quince samples after pre-treatment (a) and drying (b)

After the drying the pre-treated quince cubes were compared to the color of fresh quince used as positive control and the color of the dried non-treated quince as negative control. It was evident that the pre-treatment led to significantly lower color changes and browning index when compared to the non-treated dried quince. The comparison between the VI and US+VI samples showed that longer processing time (US+VI) ended in higher changes, but still in the acceptable region as proposed by the use of these pre-treating techniques in fruit processing.

CONCLUSIONS

From the above results it was concluded that the combination of ultrasound and vacuum impregnation is a good method for development of functional food and to obtain high quality products. When comparing the results from the experiments, it was evident that the US and VI treatment gave the highest weight gain and maintained the higher springiness. Pre-treatment led to significantly lower color changes and browning index when compared to the non-treated dried quince.

ABSTRACT: Olive oil is a prominent source of monounsaturated fatty acids (MUFAs) due to its high oleic content, as well it's a rich source of natural antioxidants (vitamin E, polyphenols such is oleuropein and tyrosol). Its antioxidant content depends on different factors, such is cultivar, fruit ripening stage, climate conditions and olive growing techniques. Oxidative stability of olive oils is related to the ratio of monounsaturated and polyunsaturated fatty acids, and is also influenced by phenolic fraction. The aim of the study presented in this paper was to determine the fatty acid composition, total phenol content and composition of single phenol compounds and their correlation with oxidative stability of examined oils. Fatty acid content was determined by GC technique. Total phenol content was measured colorimetrically, while the single phenol composition was determined using HPLC-DAD/MSD system. Oxidative stability of oils was evaluated by OSI instrument. In this study, in all samples, very good total phenol content was detected, up to 384.33 mg/kg. Among single phenolics, the most representative was hydroxsityrosol and oleuropein aglycon. Oxidative stability data showed very good storage capacity, depending on fatty acid and phenol composition. Oxidative stability of two cultivars was correlated with their oleic/linoleic ratio, while in others it depends also on phenol composition.
Keywords: *olive oil, oxidative stability, phenols, fatty acid composition*

INTRODUCTION

As a central part of Mediterranean diet, virgin olive oil (VOO) is considered to have significant biological and nutritional characteristics. It is obtained directly from the fruit of the olive tree solely by mechanical or other physical means. It is only vegetable oil that can be consumed directly in its raw state, without refinement, and thus contains important nutritional elements (vitamins, antioxidants etc.) It is composed of triacylglycerols (97-98%), minor compounds – partially glycerides, phospholipids and oxidized triacylglycerols- and around 1% of unsaponifiable constituents of varied structure and polarity (Boskou, 1996).
The oxidative stability, sensory quality and health properties of VOO stem from a prominent and well-balanced chemical composition (Bendini et al., 2007). VOO is unique among other vegetable oils due to its high levels of monounsaturated fatty acids (mainly oleic acid) and to the presence of minor components, such as phenolic compounds among others (Cerretani et al., 2004; Deiana et al., 2002; Esti et al., 2004). The content of phenolic compounds is an important factor that influences the quality of VOO (Servilli et al., 2004) particularly because of their potent antioxidant activity and significant contribution to stability of VOOs against oxidation (Tura et al., 2007). The concentration and composition of phenolic compounds VOO are strongly affected by agronomical (Pinelli et al., 2003) and technological factors (Angerosa et al., 1996), such as olive cultivar (Baccouri et al., 2008; Tura et al., 2007), place of cultivation (Cerretani et al., 2006; Blekas et al., 2002), climate, ripening degree (Bonoli et al., 2004), crop season and production process (Oliveras-López et al., 2007). The oxidative stability of VOO depends primarily on the characteristic fatty acid composition (mainly

monounsaturated) (Aparicio and Luna, 2002; Velasco and Dobargenes, 2002) and on the presence of minor components (Baldioli et al., 1996; Oliveras-López et al., 2007) having a marked antioxidant activity, phenolic compounds, improperly referred as polyphenols (Gallina Toschi et al., 2005). These compounds are typical for unrefined oils and thus they posses valuable functional, biological (Visioli et al., 2002) and nutritional function (Del Carlo et al., 2004).

Croatia has a great number (about 40) of autochthonous olive varieties (Bakarić et al., 2007). Among them the main variety is Oblica, which is present in about 70% olive orchards, mostly in Dalmatia region. Variety Oblica has dual character; it's used for oil production and as a table olive. Others important cultivars are: Lastovka, Levantinka, Drobnica, Istarska Bjelica, Buža etc. Certain cultivars have local importance, while others are very difficult to find in productive orchards. The aim of the present study was to evaluate the fatty acid composition and the minor polar compounds of 5 monocultivar VOOs in order to characterized autochtonous VOOs and investigate the oxidative stability in relation to analyzed parameters.

MATERIALS AND METHODS

Five VOO samples, obtained from five olive cultivars, have been chemically characterized. The olive fruit samples were all picked up at the same ripening degree and processed in oil by laboratory plant. Besides basic quality parameters, fatty acid content was determined by GC technique. Determination of fatty acid composition was performed according to the standard method (ISO 5508, 1990). Fatty acid methyl esters (FAME) from the oil samples were obtained by alkaline treatment with 1M KOH in methanol.

The analyses of minor components (phenolic fraction) were also carried out. Liquid–liquid extraction of phenolic compounds from olive oils was performed following the protocol described by Pirisi et al. (1997), modified according to Rotondi et al. (2004). Unless otherwise stated, extractions were performed in three replicates (n=3). Extracts were stored at -18°C before use. Total phenol content was measured colorimetrically according modified method of Gutfinger (1981), while the single phenol composition was determined using HPLC-DAD/MSD system, according to Rotondi et al., (2004). Oxidative stability of oils was evaluated by OSI instrument (Oxidative Stability Instrument), Omnium, Decatur, Il USA. Eight channel OSI instrument was adjusted to 110^{o}C. With air flow of 120 mL/min. Oil stability index (OSI) was measured according to Bendini et al., (2007) in triplicate.

RESULTS AND DISCUSSION

The results for free acidity, peroxide value and UV absorbance show that all analyzed oils were in the category of extra virgin olive oil, according to EC regulations. The fatty acid composition of the analyzed oils obtained from different cultivars showed some differences between them (as showed in table 1), but in all cases met the limits reported in the EC Regulations for olive oils. Fatty acid composition in all samples showed oleic content above 70%. In all samples a stable ratio of oleic and linoleic acid (18:1/18:2) was detected (figure 1), with values close to or higher than 7, with an exception for variety Lastovka that had value 6.38, due to a particularly high content of linoleic acid (11.42%). The monounsaturated fatty acids have great importance because of their nutritional implication and effect on oxidative stability of oils. All analyzed oil samples had content of oleic acid (C18:1) higher than 70%. The highest level of oleic acid was detected in oils from Levantinka variety (over 76%), while the lowest value was found in Lastovka oil. Further, in all oil samples a satisfactory content of palmitic acid (C16:0), the major saturated fatty acid in olive oil, has been detected with media of 12.57%. The content of another important saturated fatty acid, stearic acid (C18:0) had the values within the range 1.26% for Mastrinka oil to 2.19% for oil from Lastovka cultivar.

Table 1. Fatty acid composition (% of total FA) of analyzed olive oils from different cultivars

Fatty acid composition (% of total FA)	**Oil samples**				
	Oblica	Lastovka	Levantinka	Drobnica	Mastrinka
16:0	12. 26 ± 0. 38	12. 32 ± 0. 59	11. 72 ± 0. 13	13. 51 ± 0. 93	13. 02 ± 0. 00

Results are given as mean ± standard deviation (n = 3)

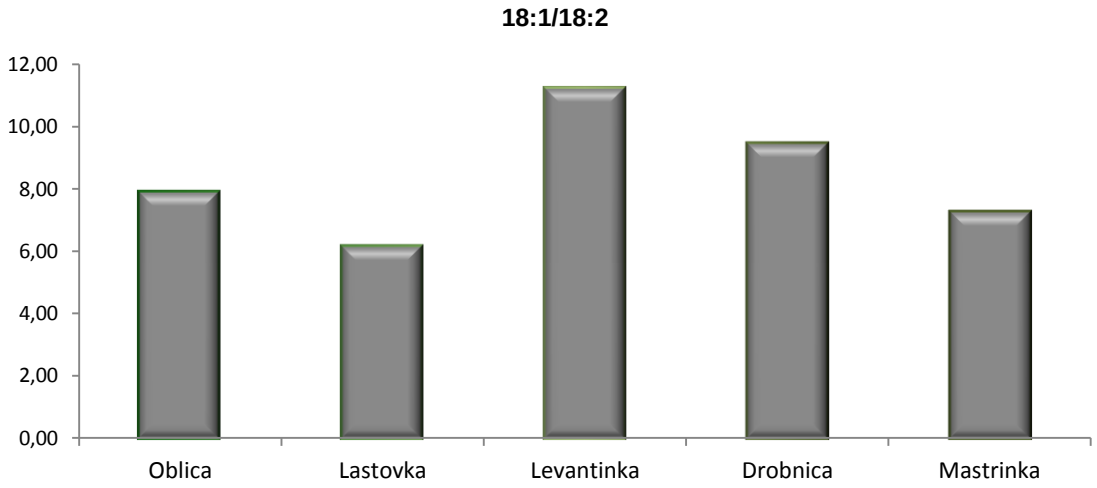

Figure 1. 18:1/18:2 ratios in examined oil samples

The amount and composition of the polyphenols in olive oil was already shown to depend on olive cultivar (besides the agricultural practice and the degree of ripening, too) (Montedoro et al., (1992); Carrasco-Pancorbo et al., 2005). It is shown that in monovarietal oils from Croatian cultivars total polyphenols content have mostly satisfied values, reaching much high content in samples grown in north Adriatic regions (Koprivnjak et al., 1998).
All analyzed VOOs in this study had a total phenol content between 134.4 and 394.40 mg/kg, as well as different composition of individual phenolic compounds, depending on the olive cultivar (Table 2). Among single phenolic compounds, the most representative was hydroxsityrosol and oleuropein aglycone.

Table 2. Total phenols and phenolic composition and proportion of compounds (mg/kg)

		Oil samples				
		Oblica	Lastovka	Levantinka	Drobnica	Mastrinka
Total phenolic content* (mg/kg)		315.57 ± 28.58	286.55 ± 42.86	195.36 ± 56.88	354.72 ± 39.98	254.13 ± 34.68

***(1) HYTY – hidroxytyrosol; (2) TY – tyrosol; (3) DOA – decarboxy methil oleuropein aglycone; (4) PIN – pinoresionl; (5) DLA +AcPin – decarboxy methil ligstroside aglycone + acetoxypinoresinol; (6) OA – oleuropein aglycone; (7) LA – ligstroside aglycone; (8) LU – luteoline; (9) AP - apygenine*

Oxidative stability data (figure 2) showed very good storage capacity, depending on fatty acid and phenol composition. Low OSI level for Oblica oil seems to be correlated with 18:1/18:2 ratio, and OSI value for Lastovka to its total phenol content. The highest OSI value was detected for oils from Drobnica and Mastrinka.

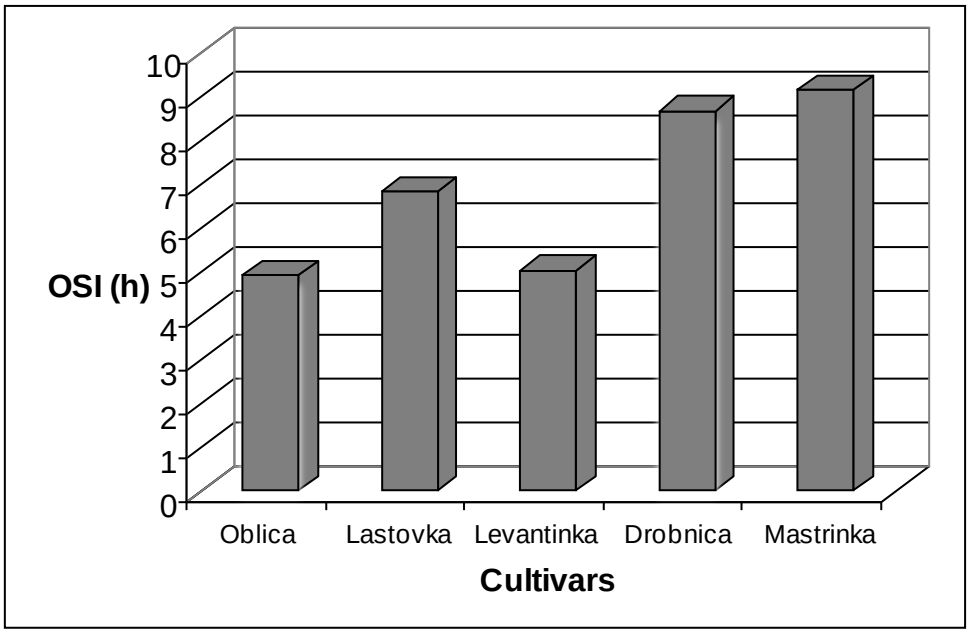

Figure 2. Oil stability index (OSI) for some analyzed olive oils

CONCLUSIONS

In all samples in this study very good total phenol content was detected. Oil from Drobnica variety had the highest level of total phenols, same as the pretty high level of 18:1/18:2 ratio. Thus it can be concluded that this oil has good oxidative stability according to those parameters. Oxidative stability of two cultivars Lastovka and Drobnica was correlated with their oleic/linoleic ratio, while in others it depends also on phenol composition. The best oil stability was attested in VOOs with higher level of total phenols and also higher 18:1/18:2 ratios. Based on the obtained results, further investigations will be focused on determination the correlation between single phenols and oxidative stability of autochthonous VOOs.

ABSTRACT The aim of this paper was to study the effect of growth regulators in connection with diversified fertilization (concerning the form, the doses and kind of fertilizer) on the nutrients content (Vitamin C and protein) in Allium cepa (*onion)* culture, in different stages of morphogenesis. Field trials were conducted during the early seasons of 2011, on a black Chernozem soil. The experiment was a randomized complete block design with four replications. The experimental site was prepared in 28 beds of 1 x 1 m^2 each in size and the variants used were: $N_0P_0K_0$, $N_{60}P_{45}K_{45,}$ $N_{90}P_{60}K_{60,}$ $N_{120}P_{60}K_{60}$, $N_{60}P_{60}K_{60}$ + Aqzyme 1 l/ha, $N_{60}P_{60}K_{60}$ + 2 x Pervaide 1 l/ha, Manure 20 t/ha.
The protein content analyses were performed in the Laboratory of Soil Science and Plant Nutrition, Faculty of Agriculture, USAMVB Timisoara.
The protein content % was determined with the help of Kjeldahl unit (Velp Scientific 127) and Vitamin C (mg/100 g) content was done according to STAS 6182/15-87.
NPK fertilizers dose not influence the Vitamin C accumulation with highest value being registered in variant v2 – $N_{60}P_{45}K_{45}$, in all morphogenesis stages, 13 mg/100 g (1st stage), 14 mg/100g (2nd stage) and 18 mg/ 100g (3rd stage). Growth regulators and manure does not influence the vitamin C accumulation**.**

INTRODUCTION

Vegetables are a great source of essential vitamins and minerals in the everyday diet. Quality can be characterized by functional values that can be measured or analyzed. The chemical composition and content of nutrients are important for the human diet and determine the nutritional quality of a product (Hauffman, S. and Bruce, A, 2002).
Best quality onion can be produced through application of well balanced fertilizers. Research work has been done on the base of NPK in different soil types and in various climatic conditions, but very limited work has been reported on various sources of fertilizes for a certain nutrient (Ghulam N. et al., 2010).
Onions start bulb formation when the day length is of the proper duration. Different varieties of onions require different day lengths to initiate bulbing. Onions have a high demand for micronutrients such as copper, manganese, molybdenum and zinc.
Fertilization is the most important and controllable factor affecting nutritional value of vegetables. The type and value of fertilizer and the level of application directly influence the level of plant available nutrients and indirectly influence plant physiology and chemical content (Griepentrog H. and Porter J., 2002).
A lot of studies were carried about the differences in vegetables nutrient levels, grown at various levels of nitrogen fertilizer. These studies compare various levels of artificial, organic and mixed fertilizer. However, very few studies compare the effect of fertilizer on nutritional quality of vegetables in organic and conventional production.
Of the major nutrients, nitrogen (N) is often required in the greatest quantity by crops, primarily for vigor and yield. Nitrogen plays a key role in chlorophyll production and protein synthesis (Moigradean Diana et al., 2007).
Proteins are nitrogenous organic substances, composed of substances with plastic role for forming tissue and regeneration. Proteins as macromolecular substances are substances made of amino acids. Proteins have a very wide variety of compounds and they are

practically very difficult to classify and determine as entity substances. It therefore appeals to the determination of total protein (the amount of protein). These substances contain carbon, hydrogen, oxygen and nitrogen always (at a rate of 16%) (Dima D et al., 1991).
Vitamin C is required for the synthesis of collagen, an important structural component of tendons, bones, teeth, blood vessels and muscles. The vitamin also synthesizes a neurotransmitter called norepinephrine. It also plays a role in the fat transport system of cells and cholesterol metabolism (prevention of gallstones). Vitamin C is a powerful antioxidant that assists the body in contesting viral infection, bacterial infections and toxicity (http://www.lenntech.com/vitamins/vitamin-c.htm). A deficiency leads to scurvy, which was the leading cause of death among sailors on ocean vessels from ancient times up until the 18th century. Scurvy is still widespread today in developing countries. In France there does not appear to be major problems in Vitamin C intake among children and adolescents. However, nearly 20% of adults (and especially men) have an intake level of less than two thirds the recommended allowance of Vitamin C. There is no real risk of excess Vitamin C. Only exceptionally high doses that are not possible with a regular diet are potentially toxic (http://www.fondation-louisbonduelle.org/france/en/know-your-vegetables/health-and-nutrients/vitamine-c.html#axzz1sHlTNpRV).
The aim of this research was to determine the effect of growth regulators in connection with diversified fertilization (concerning the form, the doses and kind of fertilizer) on the content of nutrients (Vitamin C and protein) compositions of onion culture, in different stages of morphogenesis.

MATERIALS AND METHODS

Field trials were conducted during the early seasons of 2011, on a black Chernozem soil. The experiment was a randomized complete block design with four replications.
The experimental site was prepared in 28 beds of 1 x 1 m^2 each in size and the variants used were: $N_0P_0K_0$, $N_{60}P_{45}K_{45}$, $N_{90}P_{60}K_{60}$, $N_{120}P_{60}K_{60}$, $N_{60}P_{60}K_{60}$ + Aqzyme 1 l/ha, $N_{60}P_{60}K_{60}$ + 2 x Pervaide 1 l/ha, Manure 20 t/ha. The fertilizers used were NPK complex type 16:16:16, and NH_4NO_3. De Stuttgart variety was used as onion test crop. Weeds were controlled by hoeing and herbicide Dual Gold application.
Aqzyme growth regulator contains Fungi enzymes (99%), copper (0.05%), iron (0.10%), manganese (0.05%), zinc (0.05 %). The state of macro and micronutrients of soil supply was proper, for phosphorus (P) registered 121 mg/kg, the range for vegetables grown in the field, is between 108.1 – 144.0 according to studies of literature [8]. Nt % soil supply state was medium 0.185 %, framing in range 0.141 – 0.270 %, quoted in other studies (Budoi, Gh., 2004).
The onion samples were collected in 3 major stages of culture development: green onion stage *(1st stage of morphogenesis),* beginning of bulb formation *(2nd stage of morphogenesis) and* full maturity *of plant* (*3rd stage of morphogenesis).*
The protein content analyses were performed in the Laboratory of Soil Science and Plant Nutrition, Faculty of Agriculture, USAMVB Timisoara.
The Nt % was determined with the help of Kjeldahl mineralization - distillation unit (Velp Scientific 127) digested in H2SO4 distilled and titrated with 0.1M NaOH. The amount of protein is calculated by the following relationship: *Total Protein content (%) = 6.25 x Nt (%),* where: 6.25 namely 100/16 is the coefficient of conversion into protein. For vitamin C (mg/100 g) determination in onion samples was used 2,6-diclorfenolindofenol, method, according with STAS 6182/15-87. Ascorbic acid content was estimated titrimetrically by 2,6-Dichlorphenolindophenol sodium. 5 mL of vegetable extracts was diluted with 10 mL water, ad 1 mL HCl 1N and was titrated with 1 mM solution 2,6- Dichlorphenolindophenol sodium to pink color (Gergen I., 2004).

RESULTS AND DISCUSSIONS

The influence of mineral and organic fertilizers and growth regulators on crude protein content and vitamin C accumulation is presented in tables 1-2.

Table 1. Vitamin C (mg/100g) content in onion samples in all stages of plant development

Experimental variants	Vitamin C [mg vit.C/100g]		
	1st stage of morphogenesis	*2nd stage of morphogenesis*	*3rd stage of morphogenesis*
v_1 - $N_0P_0K_0$	8±*0.45*	9 ±*2.65*	11±*1.87*
v_2 – $N_{60}P_{45}K_{45}$	**13±*1.37***	**14±*0.45***	**18±*2.13***
v_3 – $N_{90}P_{60}K_{60}$	12 ±*2.41*	13 ±*3.19*	15 ±*0.92*
v_4 – $N_{120}P_{60}K_{60}$	11 ±*1.65*	12 ±*2.67*	14 ±*1.44*
v_5-$N_{60}P_{60}K_{60}$ + Aqzyme 1 l/ha	9 ±*0.45*	13 ±*1.22*	15 ±*2.01*
v_6-$N_{60}P_{60}K_{60}$ + 2 x Pervaide 1 l/ha	10 ±*2.40*	11 ±*1.33*	14 ±*1.15*
v_7 – Manure 20 t/ha	11 ±*2.88*	13±*3.14*	16 ±*0.72*
Cv%	0.162	0.138	0.145

Results for Vitamin C (%) (1st; 2nd; 3rd morphogenesis stages) are given as mean of 4 determinations.

Experimental variants ordered from lowest to highest fertilizers doses showed wide differences between culture morphogenesis stages. The Vitamin C content of onions increases as the culture forward in vegetation towards full maturity. Vitamin C content, for onion, ranged from 8.0-13.0 mg/100g fresh matter, in green onion, in the young plants, highest content was found in $N_{60}P_{45}K_{45}$ fertilization rates and lowest in control samples.
NPK fertilizers dose not influence the Vitamin C accumulation highest value being registered in variant v_2 – $N_{60}P_{45}K_{45}$, in all morphogenesis stages, 13 mg/100 g (1st stage), 14 mg/100g (2nd stage) and 18 mg/ 100g (3rd stage) (table 2). Growth regulators and manure does not influents the vitamin C accumulation. The results are in accordance with other studies that show a content of Vitamin C in onions of 10 mg /100g. (http://www.lenntech.com/vitamins/vitamin-c.htm)
In Romania were done similar studies in tomatoes culture *Lycopersicum esculentum.* Moigradean D. et al., in 2007, studied Vitamin C content in tomatoes samples fertilized with different NPK doses. The results showed that the highest content in Vitamin C was determined in variant with moderated fertilizer dose ($N_{45}P_{45}K_{45}$) and not in variant with highest NPK dose ($N_{120}P_{60}K_{60}$).

Table 2. Protein content (%) in onion culture samples in different morphogenesis stages

Experimental variants	Protein (%)		
	1st stage of morphogenesis	*2nd stage of morphogenesis*	*3rd stage of morphogenesis*
v_1 - $N_0P_0K_0$	2.44±*0.76*	2.84±*1.05*	2.87±*1.13*
v_2 – $N_{60}P_{45}K_{45}$	2.56±*0.67*	3.06±*0.98*	3.24±*1.54*
v_3 – $N_{90}P_{60}K_{60}$	3.22±*1.21*	3.25±*1.53*	3.83±*2.16*
v_4 – $N_{120}P_{60}K_{60}$	**4.75±*1.75***	**4.88±*2.33***	**5.07±*0.99***
v_5-$N_{60}P_{60}K_{60}$ + Aqzyme 1 l/ha	3.06±*2.05*	3.30±*2.12*	3.44±*1.41*
v_6-$N_{60}P_{60}K_{60}$ + 2 x Pervaide 1 l/ha	3.14 ±*1.80*	3.24±*1.75*	3.35±*2.35*
v_7 – Manure 20 t/ha	3.58 ±*1.65*	3.65±*0.78*	3.86±*2.09*
Cv%	0.236	0.194	0.192

Results for crude protein content % (1st; 2nd; 3rd morphogenesis stages) are given as mean of 4 determinations.

Protein content (%) in the early stages of vegetation, for *Allium cepa* culture, in all experimental variants, showed a lower content ranging between 2.44 - 4.75%, values that increase with plant maturity (2.84 - 4.88 % - beginning of bulb formation) or 2.87 - 5.07% at physiological maturity of onions (Table 1).
This is explained by the fact that once plant completes phases of plant growth the maturity, nitrogen needs increase and thus protein content, indispensable for the development of onion culture.
For 2nd morphogenesis stages (beginning of bulb formation of onion culture) the variation limits of protein content are frame between 2.84 – 4.88% (Table 2).
The quality attributes increased as the N rates increased with the highest contents recorded at 120 kg N/ha of fertilizer application. Total crude protein content (%) in green onion, in the 1st morphogenesis stage, ranged from 2.44% to unfertilized control variant to 4.75% to variant 4 fertilized with 120 kg N (Table 2).
Nitrogen is an essential element for healthy plant growth, being a constituent of proteins and chlorophyll. In all morphogenesis stages, the highest protein content was determined at the application of fertilizers in a dose of $N_{120}P_{90}K_{90}$. There is a proportional increase of the protein content of onions with the increasing dose of nitrogen fertilizer applied. Similar results were found by Westerveld et al., in 2006. Onions absorb nitrogen throughout the vegetation period. The amount of nitrogen absorbed is reduced to seeds germination, but grows in phenophases were the main vegetative organs are formed. Presence of phosphorus and potassium applied as fertilizer favors nitrogen accumulation. High nitrogen content stimulates leaf growth at the expense of root development and yield, and also delays harvesting. Very lush leaf growth may also promote the development of diseases, such as Sclerotinia white mould (Alexa E., 2088).
The limits of variation of crude protein content (%) at full maturity of plants, frame between 2.87% (v1) – 5.07 % (v4) (Table 2).

CONCLUSIONS

- During the early morphogenesis stages of vegetable species studied, the values of Vitamin C (mg/100g) and protein (%) were lower, but during culture development the content increases.
- NPK fertilizers dose not influence the Vitamin C accumulation, with highest value being registered in variant v_2 – $N_{60}P_{45}K_{45}$, in all morphogenesis stages, 13 mg/100 g (1st stage), 14 mg/100g (2nd stage) and 18 mg/ 100g (3rd stage).
- Growth regulators and manure does not influence the vitamin C accumulation.
- Protein content (%) in the early stages of vegetation, for *Allium cepa* culture, in all experimental variants, showed a lower content ranging between 2.44 - 4.75%, values increase with plant maturity (2.84 - 4.88 % - beginning of bulb formation) or 2.87 - 5.07% in physiological mature onions.

ABSTRACT: There is an evident problem with withdrawn bread in Serbia, in terms of quantity, environmental and health aspects. There is no organized way for withdrawn bread collecting and distributing for further processing. The absence of these actions contributes to the increasingly polluted environment, and creates problems in the food chain. This paper contributes to solving problem with withdrawn bread using extrusion of the mixtures of corn meal and withdrawn bread (50:50 and 60:40) moisturized up to 18% prior to extrusion. Extrusion of these mixtures was carried out in a single screw extruder (Metal-matic Beočin, Serbia) at temperature of 95-105°C. The results confirm that the obtained products are safe concerning microbiology and mycotoxicology. The total count of molds and microorganisms is below the maximum allowable concentration indicating that the produced extrudates could be used as safe feeds.
Key words: *withdrawn bread, corn meal, extrusion, health and safe food*

INTRODUCTION

In a survey conducted in 45 municipalities in Vojvodina, an analysis of the current situation regarding the type and quantity of withdrawn bread was carried out with the aim to define the sources of its formation and suggets solutions to overcome the existing problem. Withdrawn bread that satisfies, hygienic and microbiological criteria for use in food animals may be raw material quality .

Based on surveys of the Institute of Food Technology in Novi Sad (FINS) made in the period January - March of 2010., the quantity of withdrawn bread varies between 5-10% (Nježić et al., 2010).

It was concluded that approximately 50,000 loaves (500 g) from one million loaves produced in Vojvodina per day are not used. Depending on the health safety withdrawn bread can be considered either a very attractive raw material or a major problem (Nježić et al., 2010).

The solution to increased food production for humans and animals is the application and use of new technologies in biotechnology and bio-industry. New technological procedures aimed at increasing the nutritional value of food intended for human consumption and animals, as well as evaluation of secondary food products and primary agricultural production. Today, thermal processing of oilseeds and cereal grains like toasting, extrusion, micronization, microwave treatment and dielectric heat treatment (Marsman et al., 1998; Sakač et al., 2001) are in use, but in Serbia extrusion process is the most experienced (Filipović et al.; 2008, Sakač et al., 2006).

Thermal treatments have to be optimized to decrease the content of thermolabile antinutrients to acceptable level and to increase the digestibility of some nutrients (oils and carbohydrates) as well as to improve the sensory properties and microbiological characteristics of the final product. (Filipović et al., 2007; Zhou and Erdman, 1995).

Corn extrusion in the feed production contributes to a better valorization of food in animal nutrition (Filipović et al., 2008).

Along with the reduction of the antinutrients, it is necessary to preserve thermolabile nutritionally valuable components and the process requires a compromise between these two efforts (Jensen et al., 1995).

Extrusion leads to changes in the carbohydrate complex of corn meal and bread crumbs, or a decrease in starch content due to its degradation to dextrins. Such changes contribute to *in vitro* and *in vivo* digestibility of starch, since starch gelatinization provides increased availability of enzymes that break down or to inactivation of amylase inhibitors (Douglas et al., 1990).
The aim of this study was to determine the effect of extrusion on the quality of the mixture of corn meal and bread crumbs.

MATERIALS AND METHODS

Starch content, as well as total and reducing sugars were determined by the Regulation on the physical and chemical methods of analysis for quality control of grain, milling and bakery products, pasta and deep frozen dough (Službeni list SFRJ, 1988). Bulk density was determined by the Regulations on methods of sampling and methods of performing physical, chemical and microbiological analysis of animal feed (Službeni list SFRJ, 1987). The basic chemical composition (moisture, crude protein, crude fat and ash) of corn meal and bread crumbs mixture is determined by AOAC methods
Prior to extrusion moisture of corn meal (moisture 12%) and bread crumbs (50:50 and 60:40) was adjusted to of 18% in a premixer. Extrusion was carried out in a extruder which capacity is 900 kg/h. The installed electric power of extruder and the screw dispenser was 100 kW and 1.1 kW, respectively. Extrusion temperature was 90 and 95 °C, and die diameter was 7.5 mm.
Total count, the number of yeasts and molds and isolation and identification of *Salmonella* and Sulphite-reducing *Clostridia* were determined by the Regulation on the method of the microbiological analysis of food and super analysis of animal feed (Službeni list SFRJ, 1980).
For determination of the presence of coagulase positive *Staphylococci*, Proteus species and *Escherichia coli* modified method of sample preparation. 50 g of sample was weight in the test flask and poured Erlenmajer to 450 ml of sterile nutrient broth prepared. Prepared sample is gently homogenized and incubated for 24 h at 37 °C. Isolation and identification is carried out, according to the method of the microbiological analysis and superanaysis of food (Službeni list SFRJ, 1980).

RESULTS AND DISCUSSION

Chemical composition and particle size distribution of corn meal, are presented in Table 1 indicating that the feed is characterized with 75.23% of starch, protein 6.88% and 1.14% fat, and with energetic value of 1544 kJ/100 g. The particle size distribution shows that only 9.8% of particles were greater than 550 microns and 81% of particles possesed the diameter greater than 250 microns. Bulk density of investigated corn meal was 654 kg/m^3. Table 2 shows the content of microorganisms and mycotoxins in corn meal.

Table 1. Chemical composition, particle size distribution and bulk density of corn meal

Quality parameters	Content (%)
Moisture	13.36
Ash	0.24
Crude protein	6.88
Total sugar	2.23
Reducing sugars	0.49
Starch	75.23
Fat	1.14
Energetic value	**kJ/100 g**
Calorimetric determinated eneregetic value	1544
Particle size distribution	**Content (%)**
Sieve fractions over 550 µm	9.8
Sieve fractions over 250 µm	81
Sieve fractions under 63 µm	9.2
Bulk density	654 kg/m^3

Table 2. Microorganisms and mycotoxins content in corn meal

Microorganism	**dilution**	**number**
Salmonella spp	in 50 g	not detected
Coagulase positive *Staphylococci*	in 50 g	not detected
Sulphate-reducing *Clostridia*	in 1 g	not detected
Proteus varieties	in 50 g	not detected
Escherichia coli	in 50 g	not detected
Total number of yeasts	in 1 g	not detected
Total number of fungi	in 1 g	80
Total number of microorganisms	in 1 g	500
Mycotoxin content	**µg/kg**	
Aflatoxins B1+G1+B2+G2	<3	
Ochratoxin A	<10	
Zearalenon	<25	

From the data shown in Table 2 it is evident that *Salmonella spp.*, Coagulase positive *Staphylococci*, sulphate-reducing *Clostridia*, *Proteus* species, *Escherichia coli* and yeasts were not found in investigated corn meal. Total number of fungi and microorganisms in 1 g was 80 and 500, respectively. Mycotoxicology shows that the aflatoxin, ochratoxin A and zearelenon content was less than 3 µg/kg, 10 µg/kg, and 25 µg/kg, respectively indicating that this is according to the Regulation (Pravilnik o metodama vršenja mikrobioloških analiza i superanaliza životnih namirnica, 1980). Table 3 shows the chemical composition and particle size of the bread crumbs.

Table 3. Chemical composition, particle size distribution and bulk density of bread crumbs

Quality parameters	**Content (%)**
Moisture	12.87
Ash	2.24
Crude protein	11.44
Total sugar	2.72
Reducing sugars	2.08
Starch	63.34
Fat	3.18
Energetic value	**kJ/100 g**
Calorimetric determinated eneregetic value	1589

Sieve fractions over 550 µm	45.6
Sieve fractions over 250 µm	40.2
Sieve fractions under 63 µm	14.2
Bulk density	415 kg/m^3

Bread crumbs are a food product obtained by subsequent treatment of withdrawn bread.This product contains 63.34% starch, 11.44% protein and 3.18% fat, with the energy value of 1589 kJ/100 g, thus it is high quality energy feed. The content of microorganisms and mycotoxins in bread crumbs is shown in table 4.

Table 4. Microorganisms and mycotoxins content in bread crumbs

Microorganism	**dilution**	**number**
Salmonella spp	in 50 g	not detected
Coagulase positive *Staphylococci*	in 50 g	not detected
Sulphate-reducing *Clostridia*	in 1 g	not detected
Proteus varieties	in 50 g	not detected
Escherichia coli	in 50 g	not detected
Total number of yeasts	in 1 g	not detected
Total number of fungi	in 1 g	30
Total number of microorganisms	in 1 g	30

Aflatoxins B1+G1+B2+G2	<3	
Ochratoxin A	<10	
Zearalenon	<25	

Microbiological and toxicological tests show that bread crumbs are hygienically safe, Table 4. The total number of fungi and microorganisms are 30 per 1g, while aflatoxins, ochratoxin A and zearalenone were less than 3 µg/kg, 10 µg/kg, and 25 µg/kg, respectively. Table 5 shows the chemical composition and particle size distribution of the extruded mixture of bread crumbs and corn meal.

Table 5. Chemical composition, particle size distribution and bulk density of extruded mixtures of corn meal and bread crumbs

Quality parameters	**Content (%)**	
	Extruded mixture of corn meal:bread crumbs, 50:50	Extruded mixture of corn meal:bread crumbs, 60:40
Moisture	8.40	8.53
Ash	9.25	9.81
Crude	1.25	1.03
Total	5.20	5.93
Reducing sugars	3.46	3.40
Starch	69.8	65.36
Fat	2.64	2.12
Energetic value	**kJ/100 g**	
Calorimetric determinated eneregetic value	1635	1642
Particle size distribution	**Content (%)**	
Bulk density	119 kg/m^3	92 kg/m^3

From the obtained results a reduced moisture content compared to the starting raw materials reduction in starch, and increased total and reducing sugars is evident, as a result of thermal decomposition of starch, resulting in increased digestibility and improved utilization of starch (Douglas et al., 1990; Zhou and Erdman, 1995). Increased sweetness, i.e. change the sensory properties is a consequence of chemical changes in starch. Change is evident in the decreased bulk density of extrudates tha are in the range 92 - 119 kg/m3.
The content of microorganisms in extruded corn meal and bread crumbs mixtures is shown in Table 6.

Table 6. Microorganisms in mixtures extruded corn meal and bread crumbs

Microorganism	dilution	number	number
		Extruded mixture of corn meal:bread crumbs, 50:50	Extruded mixture of corn meal:bread crumbs, 60:40

Total number of fungi	in 1 g	not detected	not detected
Total number of microorganisms	in 1 g	40	20

Obtained results indicate that the extrusion process has contributed to a complete reduction of microorganisms despite the relatively low extrusion temperatures (95-105 °C) and a very short extrusion time (6-10 s), but very high extrusion pressure, which ranges from 30 to 40 bar (Kormanjoš et al., 2007). In the extruded mixtures *Salmonella spp*., Coagulase positive *Staphylococci*, Sulphate-reducing *Clostridia*, *Proteus* species, *Escherichia coli*, were not detected and the total number of microorganisms is meeting the Regulations on the maximum quantities of hazardous substances and ingredients in animal feed (Službeni list SFRJ, 1990).

CONCLUSION

It was found that the main causes of high percentage of non used and withdrawn bread are:

1. bread is still a social category of food,
2. a relatively low price of bread,
3. a relatively low level of quality,
4. the habits of consumers to buy more bread than they consume,
5. food culture in which the stale bread is rarely used.

Extrusion process leads to improving the nutritive value of extruded corn meal mixture and bread crumbs due to increased content of total and reducing sugars, as well as, positive changes in the complex starch extrudates therefore increasing the digestibility of food, thereby increasing the performance efficiency. Heat treatment (temperature over 90 °C) along the extruder and the high pressure that occurs due to friction, contribute to reducing the total number of microorganisms in the product. Reduction of microorganisms provides a hygienic nutrient obtained. Extrusin of corn meal with bread crumbs may positively contribute to solving the problem of withdrawn bread in the bakery industry. The resulting extruded feeds are recommended in the nutrition of young animals, above all in feed production for fish and pets.

ABSTRACT: Natural phenols are synthetized by large group of plants where they play an important role in plant metabolism and protection against pests. These compounds, in addition to being indispensable in plant metabolism, also exhibit complex biological activity in humans for what they are constantly in the focus of scientific interest. The aim of this study was to modify standard spectrophotometric method for polyphenols determination. Modification included application and optimization of microwave-assisted extraction which significantly reduced sample preparation time and improved extraction yields. Furthermore the goal of this study was to improve determination sensitivity by applying differential spectrophotometric measurement. Optimized analytical method was implied to determine anthocyanins, neutral and total polyphenols in different fruit and vegetable samples, as well as in cakes remaining after oil extraction of several oilseeds. Purification of extracts and fractionation of polyphenols to different classes was performed by using solid phase extraction. Individual acidic and neutral polyphenolic compounds were identified in plant extracts by thin layer chromatography.
Key words: *Natural phenols, microwave-assisted extraction, differential spectrophotometry, thin layer chromatography*

INTRODUCTION

Since ancient times it has been known that consumption of fruits and vegetables contributes to health and well being. Scientific development and improvement of analytical instruments enabled the identification of bioactive compounds responsible for positive health effects. Great number of published work describes antioxidant, anticarcinogenic and anti-inflammatory effects of polyphenols, as well as their positive effects on cardiovascular system (Higdon and Frei, 2003; Lazarou et al., 2007). For these reasons characterization of natural products in respect to the content of polyphenolic compounds and their identification, as well as improvement of existing analytical methodologies is of high scientific interest. In the analysis of natural phenols predominantly two techniques are used, spectrophotometric (Gonzalez et al, 2003) and chromatographic (Vinas et al., 2000), with chromatographic having advantages in respect to sensitivity, selectivity and reliability of determination, but, on the other hand, requiring much more expensive and sophisticated instrumentation and exploitation costs. Spectrophotometric methods allow determination without utilization of expensive and sophisticated analytical instrumentation that is often unavailable to some laboratories. The analyst should be aware that the application of these optical methods is limited by their sensitivity and that sample components interfere with spectrophotometric measurement. Determination of natural phenols in foodstuffs has been the subject of extensive research and many papers have been published. The aim of this work was to modify standard spectrophotometric method for phenol determination in natural products in order to reduce total analysis time and to improve sensitivity of determination.

MATERIALS AND METHODS

Instrumentation

Fruit, vegetable and oilseed cake samples were extracted by using modified domestic microwave oven (LG Electronics). Obtained extracts were evaporated to dryness by using vacuum evaporator (Roravapor R, Switzerland) and were fractioned on Baker Octadecyl SPE cartridges. Spectrophotometric measurements were made on a single-beam "Spekol" spectrophotometer.

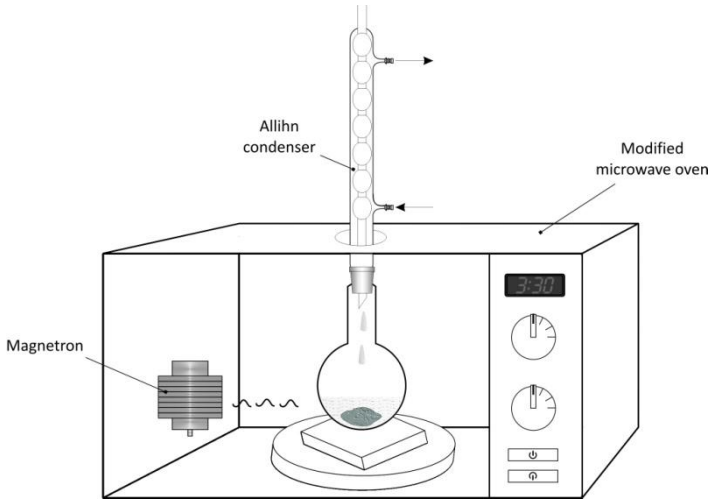

Figure 1. A modified domestic microwave oven used for microwave-assisted extraction.

Chemicals and Reagents

Solvents used for the extraction were prepared by mixing methanol, distilled water and acetic acid in ratio 14:5:1. Reagent of $AlCl_3$ for spectrophotometric measurement was obtained by dissolving 13.3 mg of $AlCl_3 \cdot 6H_2O$ and 40 mg of sodium acetate in distilled water and diluting to 100 ml. Standard rutin solution (1.02 mg/ml) was prepared by dissolving the glycoside in distilled water. For preparing acetate buffer (pH = 4.5) 60 g of acetic acid and 20 g of sodium hydroxide were dissolved in distilled water and diluted to 1000 ml.

All used chemicals were of p.a. purity grade and were supplied by following producers: Centrohem (methanol, ethanol, hydrochloric acid, sodium-carbonate, ethyl-acetate, formic acid), Zorka (acetic acid, sodium acetate), Lachner (sodium hydroxide), Kemika (alumina-chloride hexahydrate, buffer pH 1, benzene), Fluka (catechin, chlorogenic acid), Biochemica (Folin-Ciocalteau reagent, rutin three hydrate) and Macherey-Nagel (Silica gel G).

Sample Preparation

The content of different classes of polyphenols was determined in samples of pear, kohlrabi, cauliflower, aubergine and cakes of pumpkin seed and walnuts left after mechanical oil removal. Samples of fruits and vegetables were purchased at the local market and were prior extraction chopped and air dried at the room temperature. Oilseed cake samples were obtained from the Department of Food Technology, Faculty of Technology, University of Novi Sad. After drying all samples were grinded.

Samples (5 g) were transferred to the extraction cuvettes and 30 ml of extraction solvent was added. Microwave extraction followed the program: 1 minute heating at 160 W; 1 minute heating at 320 W; 2x5 minutes heating at 480W. Between all heating steps a short breaks (45 s) were made in order to avoid overheating. Obtained extracts were filtered and evaporated to dryness at 50°C applying a rotary vacuum evaporator. Dry residue was dissolved in 10 ml of 0.5 mol/l H_2SO_4 with ultrasound assistance. The extracts were further filtrated through HPLC 0.45 μm filters in order to prevent the channeling and pore blocking in subsequently applied SPE.

In order to remove sugars, aminoacids, proteins and other interfering substances, as well as to separate extracted compounds to different phenol classes, C18 SPE cartridges were used.

Fraction of Total Phenols
Cartridges were conditioned with 2 ml of methanol and 5 ml of 5 mmol/l H_2SO_4. The samples (2 ml) were passed through the column under the vacuum. After eluting the impurities with 2 ml of 5 mmol/l H_2SO_4 phenols were eluted with 2 ml of methanol and 5 ml of water.

Fraction of Neutral and Acidic Phenols
Neutral and acidic phenols were separated from the fraction of total phenols in which the pH was adjusted to 7 by adding 0.5 mol/l of NaOH and 0.05 mol/l of NaOH. For collecting the fraction the cartridges were previously conditioned with 8 ml of methanol and 4 ml of double distilled water. Previously obtained fraction of total phenols was passed through the column. Fraction of acidic phenolics was eluted with 10 ml of double distilled water and required further purification. Neutral polyphenols were stripped from the cartridge with 12 ml of methanol.

Fraction of Acidic Phenols
Eluted fraction of acidic phenols was further purified by SPE. Prior fraction introduction on SPE cartridge pH was adjusted to 2 with 2 mol/HCl. The cartridge was conditioned with 8 ml of methanol and 4 ml of 0.01 mol/l of HCl. Impurities were eluted by 5 ml of 0.01 mol/l HCl and acidic fraction was collected in 12 ml of methanol.

Determination of Total Polyphenols
Purified fraction of total phenols (3 ml) was mixed with 500 μl of Folin-Ciocalteau reagent, 2 ml of 20% of Na_2CO_3 and was diluted to 10 ml by distilled water. The blank and the standard solutions of chlorogenic acid were prepared in the same fashion. Absorbances were measured at 750 nm after allowing the reaction to proceed for 2h. By using calibration curve defined with standard solutions of chlorogenic acid the content of total phenols in the samples was expressed as chlorogenic acid equivalents (mg chlorogenic acid/g).

Determination of Neutral Polyphenols (Flavonoids)
Purified fraction of neutral polyphenols was evaporated to dryness and the dry residue was dissolved in 10 ml of 70% methanol. Dilute solution (5 ml) was mixed with 4 ml of $AlCl_3$ reagent. For defining calibration curve standard solutions of rutin were mixed with $AlCl_3$ reagent. Measured absorbances at 446 nm were very low due to low flavonoids content for what a differential spectrophotometry – the method for low absorbances was applied. In applied method 100% of transmission was set with pure solvent while 0% transmission was adjusted with the highest concentration of rutin standard solution. Flavonoid content was expressed as rutin equivalent (mg rutin/g).

Determination of Anthocyanins
Two probes of 1.5 ml of purified fractions of total phenols were transferred to volumetric flasks of 10 ml which were filled up to a mark with buffers of pH = 1 and pH = 4.5 for each probe. After allowing 15 minutes standstill the absorbances at 515 nm and 700 nm were measured. The concentration of total anthocyanins was expressed as cyanine-3-glucoside equivalent and was calculated according to:

$$C_{tot} = \frac{A_{tot} \cdot M}{\varepsilon \cdot l}$$

$$A_{tot} = (A_{515nm} - A_{700nm})_{pH1}$$

where:

A_{tot} was the total solution absorbance
$A_{515\,nm}$ was the solution absorbance at pH = 1 and 515 nm
$A_{700\,nm}$ was the solution absorbance at pH = 1 and 700 nm
M was the molecular mass of cyanine-3-glucoside (449.2 g/mol)
ε was the molar absorption coefficient of cyanine-3-glucoside
l was the optical path (10 mm)

The concentration of (C_{mon}) monomeric anthocyanins was expressed as cyanine-3-glucoside equivalent and was calculated according to:

$$C_{mon} = \frac{A_{mon} \cdot M}{\varepsilon \cdot l}$$

$$A_{mon} = (A_{515nm} - A_{700nm})_{pH1} - (A_{515nm} - A_{700nm})_{pH\,4.5}$$

where:
A_{mon} was the absorbance of total monomeric anthocyanins
$A_{515\,nm}$ was the solution absorbance at pH = 4.5 and 515 nm
$A_{700\,nm}$ as the solution absorbance at pH = 4.5 and 700 nm

The concentrations of total and monomeric anthocyanins were expressed as cyanine-3-glucoside equivalent (mg cyanine-3-glucoside/g) whereas the concentration of condensed anthocyanins was calculated from the difference of total and monomeric anthocyanins.

Thin Layer Chromatography
Plates for thin layer chromatography were prepared by applying a suspension of silica gel G on clean glass plates in 0.25 mm layer. Prior use plates were air-dried overnight and activated by drying in oven at 105°C for 1h.
All polyphenolic fractions together with available standards were simultaneously analyzed. The mixture of benzene:ethyl acetate:formic acid = 3:3:1 was used as a mobile phase. After chromatographic separation obtained chromatogram was visualized with the Folin-Ciocalteau reagent allowing 2h color to develop.

RESULTS AND DISCUSSION

The contents of flavonoids, anthocyanins (total, monomeric and condensed) and total phenolics, calculated by described methods are presented in Table 1 and are expressed as $x_{mean} \pm 2SD$, based on three separate sample analyses. Calibration curve defined with chlorogenic acid yielded a good linearity (y = 51.6x – 0.015; r = 0.9889) whereas, as expected on the basis of theoretical considerations of spectrophotometry, calibration curve for flavonoids, defined with rutin, produced non-linear dependence best approximated with logarithmic function (y = 0.123ln(x) – 0.284; r = 0. 9910).

Table 1. The contents of flavonoids, anthocyanins (total, monomeric and condensed) and total phenolics

Determined content					
Sample	Flavonoids[a]	Anthocyanins[b]			Total phenolics[c]
		Total	Monomeric	Condensed	
Pear	185.1[d]±0.9	4.2±0.2	2.1±0.3	2.1±0.2	431.8±0.9
Kohlrabi	185.9±0.8	33.8±0.4	nd	33.8±0.4	916.0±1.2
Cauliflower	202.6±0.8	15.1±0.2	5.0±0.4	10.1±0.3	1463.8±2.9

[c]*mg equivalent of chlorogenic acid/100g dry weight*
nd – not detected
[d]*mean value±2SD*

The sample of aubergine demonstrated to be the richest source of total phenols, flavonoids and anthocyanins, as known from the literature (Apak et al., 2007), and served as a reference sample. Available data on phenol content in other analysed samples were not so abundant in the literature.
Research conducted within this assay showed that flavonoids reacted with iron ions in alkaline media forming a dark blue product that produced very sensitive spectrophotometric response. On the basis of these observations it is anticipated to investigate more thoroughly this reaction and to compare the analytical performance with that of standard Markham method, in which the colored product is formed with Al(III).

Identification of Phenolic Compounds

Due to limited number of available standards and great diversity of natural phenolic compounds, only several compounds were reliable identified in natural extract (Table 2). Available standards that were analyzed simultaneously with prepared extract included as little as three standard compounds, more specifically rutin, catechin and chlorogenic acid. Even for fractions rich in phenolics, as determined by spectrophotometry, the assay demonstrated that applied chromatographic conditions were not adequate for separation and visualization of different phenolic classes requiring further optimization. For more reliable identification of natural phenols the use of more powerful instrumental analysis, such as HPLC MS is required.

Table 2. Qualitative analysis of different phenolic fractions of natural extracts by TLC

	Chromatogram	
Sample	Flavonoid fraction	Total phenolics fraction
Pear	-	One unidentified compound
Kohlrabi	One unidentified compound	One unidentified compound
Cauliflower	-	Catechin
Aubergine	-	Catechin Chlorogenic acid Two unidentified compounds
Walnuts cake	-	Catechin Two unidentified compounds
Pumpkin seed cake	-	Chlorogenic acid

By applying thin layer chromatography catechin was detected in samples of cauliflower, aubergine and walnuts cake, while chlorogenic acid was identified in aubergine extracts and pumpkin seed cake.

CONCLUSIONS

The content of total phenolics, total anthocyanins, monomeric and condensed anthocyanins, as well as flavonoid contents, were determined in different samples of fruit and vegetables as well as in two samples of oilseed cakes by applying differential spectrophotometric method and fractionation to different phenol classes by SPE. The extraction of all samples was performed in microwave field in open system. According to obtained results the highest content of total phenols and individual classes was observed in the sample of aubergine. Catechin was detected in samples of cauliflower, aubergine and walnuts cake, while chlorogenic acid was identified in aubergine extracts and pumpkin seed cake.

ABSTRACT: Chocolate liqueurs are attractive beverages because of their desirable sensory properties, but they could also be presented as a good source of bioactive compounds, derived from cocoa. Cocoa and cocoa products have received increased scientific attention due to their health benefits attributable to interesting phytochemical composition, especially high content of polyphenols and methylxanthines. Since the processing parameters and different recipes, in chocolate liqueur production, can influence the content of bioactive compounds in the final product, the purpose of this study was to determine the best combination of the type of chocolate (regarding cocoa solid content) and ethanol content aimed to produce functional chocolate liqueurs. UV/VIS spectrophotometric methods were applied in order to compare the composition of polyphenols between dark chocolate liqueurs and milk chocolate liqueurs. Antioxidant capacity of prepared liqueurs was evaluated using DPPH (2,2-diphenyl-1-picrylhydrazyl) and ABTS (2,2-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid) assays. Among the studied samples, dark chocolate liqueur containing 20% of ethanol and milk chocolate liqueur containing 30% of ethanol were presented as the richest sources of bioactive compounds with strong antioxidant properties.
Key words: *bioactive compounds, chocolate liqueur, cocoa, ethanol*

INTRODUCTION

Alcoholic beverages comprise a large group of products that contain varying amounts of alcohol (ethanol) which, produced on an industrial scale, include beer, wine and distilled spirits such as brandy, whisky, rum, gin, cognac, vodka, tequila and liqueurs (Cacho and Lopez, 2005). Liqueurs are popular alcoholic beverages made by direct extraction of fruits, nuts or herbs with spirits (Wende and Beta, 2010). Chocolate liqueurs are made of liqueur base, chocolate and alcohol (with minimum volume of 15%), without distilling process. In the last few years, cocoa products have received much attention due to the natural composition of cocoa, which contains a mixture of bioactive compounds, with polyphenols as predominant. Regarding their significant content, which enables them to exhibit different levels of antioxidant activities, it is possible to postulate that there may be direct or indirect synergysm between bioactive compounds in cocoa in delivering their health benefitial properties due to their significant polyphenol content from which they may possess different levels of antioxidant activity (Jalil and Ismail, 2008). Besides polyphenols, cocoa contains substantial content of minerals, fats, proteins and caffeine that can provide significant contribution to consumers' nutrient intake, as well as to unique sensory characteristics of cocoa based products (Wilson and Temple, 2004). Antioxidants in alcoholic beverages, such as whisky, liqueurs, beer and red wine, are considered to have protective effects on ethanol-induced health damage (Wende and Beta, 2010). In a study by Blanco-Colio et al. (2007) it was demonstrated that consumption of some alcoholic beverages can be associated with a reduction of cardiovascular mortality, an effect partly attributed to their antioxidant properties. Since there is no distilling process, which can significantly reduce antioxidant content, chocolate liqueurs are characterized with higher content of native bioactive compounds. Favorable and stable aroma plays an important role in consumer's acceptance and contributes to the enjoyment of chocolate alcoholic beverages (Wende and Beta, 2010).

Sensory properties of liqueurs are strongly associated with their phenolic content (Montoro et al., 2006), which contribute to their astringent but pleasant taste (Stampar et al., 2006). The presence of other nutrients like proteins, carbohydrates and fat in chocolate liqueurs, and the interaction between them, may directly or indirectly affect the bioavailability of polyphenols (Jalil and Ismail, 2008). Type of chocolate used for chocolate liqueur production, as well as the content of alcohol, are important factors that influence antioxidant properties of the final liqueur product. Therefore, this study was conducted to investigate the effect of two main ingredients (chocolate and alcohol) and their combination in order to develop functional chocolate liqueur.

MATERIAL AND METHODS

Preparation of samples

Two types of chocolate (dark chocolate with 50% of cocoa solids (DC) and milk chocolate with 32% of cocoa solids (MC)) were combined with 3,3% cream liqueur base and spirits containing 20%, 25% and 30% (v/v) of ethanol in order to prepare chocolate liqueurs. Chocolate was added in a content of 10% at temperature of 30 ^{0}C. Samples were well homogenized and left to stand for one week.

Chemicals

Folin–Ciocalteu, sodium carbonate, formaldehyde, methanol, n-butanol, acetone and hydrochloric acid were supplied by Kemika (Zagreb, Croatia). DPPH (2,2-diphenyl-1-picrylhydrazyl) was supplied by Fluka (Buchs, Switzerland) . Vanillin, 4-dimethylaminocinnamaldehyde, Trolox (6-hydroxy-2,5,7,8-tetramethylchromane-2-carboxylic acid), ABTS (2,20-azino-bis (3-ethylbenzthiazoline-6-sulphonic acid) diammonium salt) and gallic acid (GA) were obtained from Sigma–Aldrich (Steinheim, Germany).

Determination of total phenol (TPC) and flavonoid content (TFC)

Total phenol and flavonoid content of the samples were determined spectrophotometrically according to a modified method of Lachman et al. (1998). Flavonoid content was calculated as subtraction of total phenol and non-flavonoid content. Gallic acid was used as the standard and the results were expressed as mg gallic acid equivalents (GAE) per litre of liqueur sample (Kramling & Singleton, 1969). All measurments were performed in duplicate.

Determination of flavan-3-ol content

Vanillin assay

Samples were analyzed using a method described by Di Stefano et al. (1989). The content of flavan-3-ols was calculated according to the formula: (+)-catechin = 290.8 ×ΔE, and the results were expressed as mg (+)-catechin/L of liqueur sample.

Reaction of 4-dimethylaminocinnamaldehyde (p-DAC)

A standard procedure reported by Di Stefano et al. (1989) was used. The content of flavan-3-ols was calculated according to the formula: (+)-catechin = 32.1 ×ΔE, where ΔE is the subtraction of absorbances between the tested liqueur sample and appropriate blanks. The results were expressed as mg (+)-catechin/L of the liqueur sample.

Quantative determination of proanthocyanidins

Proanthocyanidins were analyzed by the procedure described by Porter et al. (1986), with some modifications. The quantity of proanthocyanidins was determined from a standard curve of cyanidin chloride treated with BuOH–HCl–Fe^{III} mixture, and expressed as mg cyanidin chloride equivalents (CyCl)/L of liqueur sample.

Determination of antioxidant activity

DPPH radical scavenging assay
Antioxidant capacity of the liqueur samples was determined using the DPPH radical scavenging assay described by Brand-Williams et al. (1995). Antioxidant capacity was expressed as mmol/L Trolox equivalents.

ABTS radical scavenging assay
The Trolox equivalent antioxidant capacity (TEAC) of liqueur samples was also estimated by the ABTS radical cation decolorization assay (Re et al., 1999). The results, obtained from duplicate analyses, were expressed as Trolox equivalents and derived from calibration curve determined for this standard (100-100 µM).

RESULTS AND DISCUSSION

Figure 1 shows total phenol content (TPC) of the liqueur samples expressed as mg GAE/L. TPC of dark chocolate liqueurs (DC) ranged from 613,63 mg GAE/L to 704,54 mg GAE/L, while in milk chocolate liqueurs (MC) ranged from 372,72 mg GAE/L to 418,18 mg GAE/L.

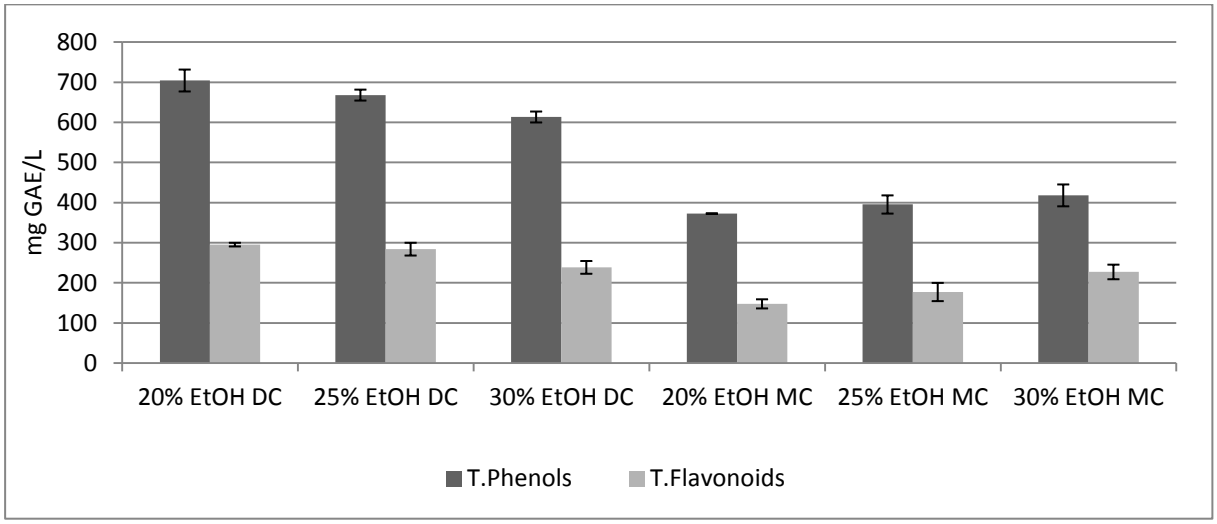

Fig.1. The content of total phenols (TPC) and flavonoids (TFC) in chocolate liqueurs

These results are consistent with the previously published results of Arts et al. (1999) who concluded that polyphenol content of chocolate was increased proportionally to the content of cocoa solids. The highest value of TPC among dark chocolate liqueurs was obtained in the sample containing 20% of ethanol, while the sample with 30% of ethanol was characterized with the lowest TPC which indicates that higher percent of ethanol exhibited lower content of phenol compounds originally present in the chocolate. In opposite to dark chocolate liqueurs, extractability of phenolic compounds in milk chocolate liqueurs was increased with higher ethanol content in the samples. Total flavonoid content (TFC) followed the same pattern of results as total phenol content (Figure 1). The highest TFC value (295,45 mg GAE/L) was obtained in dark chocolate liqueur containing 20% of ethanol, while among milk chocolate liqueurs the highest TFC value (227,27 mg GAE/L) was determined in the liqueur with 30% of ethanol.

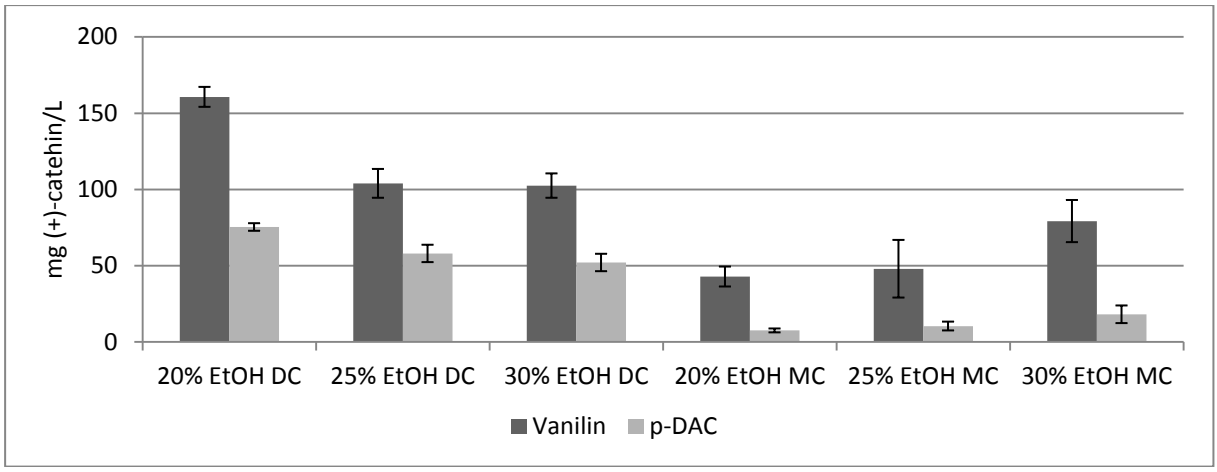

Fig. 2. The content of flavan-3-ols in chocolate liqueurs determined by vanillin and *p*-DAC assays

Flavan-3-ol content of the samples was determined by two assays, in reaction with vanillin reagent and with *p*-dimethiylaminocinnamaldehyde (*p*-DAC), which is shown in Figure 2. Regarding the type of chocolate, content of flavan-3-ols was higher in dark chocolate liqueurs than in samples with milk chocolate. Considering the ethanol percentage, the highest value of flavan-3-ols was expressed in samples with 20% of ethanol, in dark chocolate liqueurs, and in samples with 30% of ethanol, in milk chocolate liqueurs. Since the principle of these two assays is based on the reaction of *p*-DAC reagent with hydroxyl groups in specific C-atom positions in the flavan-3-ol molecules, the reaction of *p*-DAC reagent usually exhibits lower numeric values for the content of flavan-3-ols in comparison with the vanillin assay.

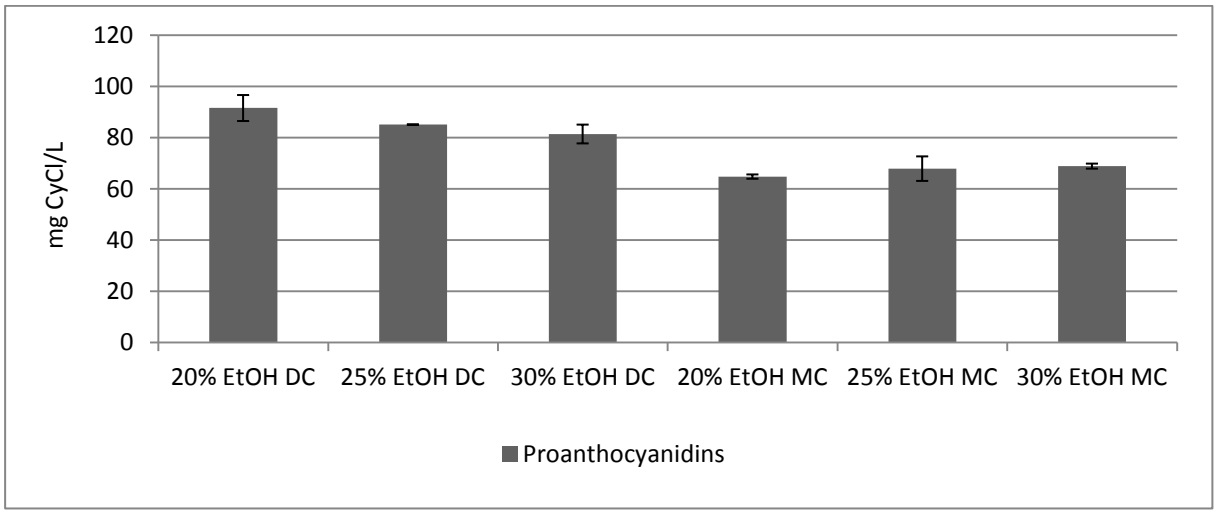

Fig. 3. The content of proanthocyanidins in chocolate liqueurs

The content of proanthocyanidins in chocolate liqueurs exhibited the same trend as polyphenols, observed as an increase of extracted compounds as the content of ethanol was also increasing, in the milk chocolate liqueurs, and decreasing in the case of dark chocolate liqueurs. It is well established that oligomeric cocoa proanthocyanidins exhibit higher antioxidant capacity than monomeric catechins, which is attributed to higher polymerization degree of proanthocyanidin molecules. Therefore, the content of proanthocyanidins should be regarded as an important paremeter for optimization of processing parameters in the production of raw materials for chocolate liqueur preparation, implying that their production should be performed in a way to preserve as highest content of proanthocyanidins as possible. According to the obtained results (Figure 3), the highest proanthocyanidin content

was determined in dark chocolate liqueur with 20% of ethanol (91,54 mg CyCl/L) and among milk chocolate liqueurs, the highest content of proanthocyanidins was observed in liqueur containing 30% of ethanol (68,87 mg CyCl/L). It has been known that proanthocyanidins form complexes with proteins and carbohydrates (Davis & Hoseney, 1979; Leinmuller et al., 1991) so it's likely that proteins in milk chocolate are the reason for the lower content of proanthocyanidins in milk chocolate liqueurs in comparison with dark chocolate liqueurs.

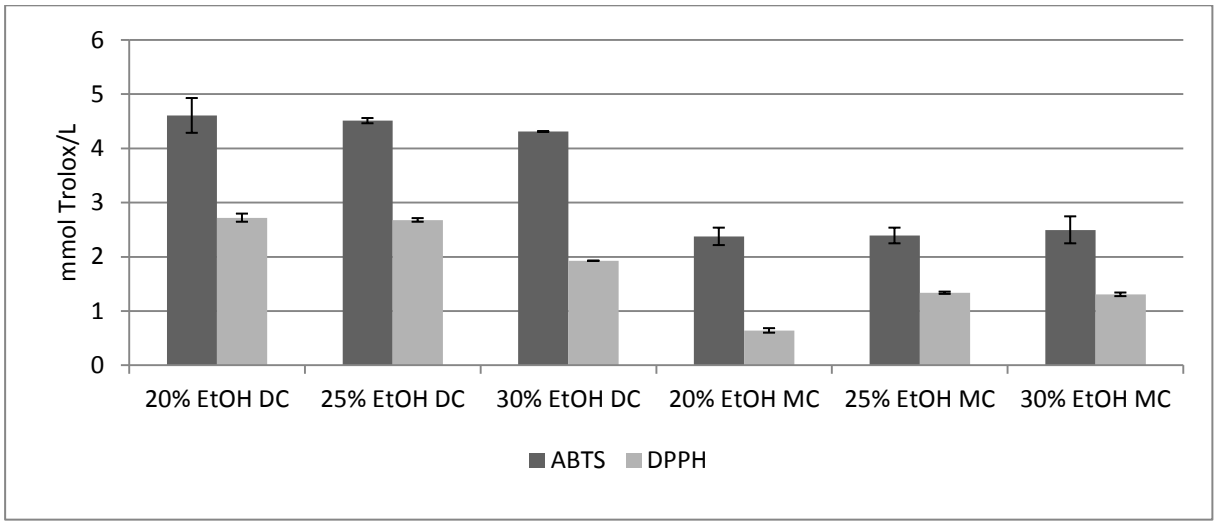

Fig. 4. Antioxidant activity of chocolate liqueurs determined by ABTS and DPPH assays

Previous studies have shown that phenols and flavonoids have antioxidant or antiradical activities (Montoro et al., 2006). As shown in Figure 4., antioxidant activity determined by ABTS and DPPH assays correlated with the result pattern from polyphenol analysis. Antioxidant activity of dark chocolate liqueurs was reduced with higher ethanol content while in milk chocolate liqueurs the influence of ethanol was opposite. Some studies indicate that antioxidant properties of alcoholic beverages are influenced by many factors, such as their phenolic content, time and method of ageing and addition of flavour and colour additives. (Bartoszek and Polak, 2011). Additionally, Tabernero et al. (2006) pointed out that antioxidant capacity of milk containing products could be modified by the presence of proteins from the milk, which was also observed in the present study. This effect could be explained by the formation of milk protein-polyphenol complexes which finally reduce antioxidant capacity but the mechanism of these interactions is still unclear and requests further investigations.

CONCLUSIONS

Among chocolates containing different percentage of cocoa solids and spirits containing different percentage of ethanol, used in production of cocoa based alcoholic beverages, dark chocolate liqueurs containing 20% of ethanol and milk chocolate liqueurs containing 30% of ethanol have the best potential to be considered as functional beverages, which may have positive effect on human health. To determine other positive effects of these products as well as stability of their bioactive composition further studies are required.

ABSTRACT: Properties of chocolate depend on raw chocolate composition, manufacturing process and properly guided phase of precrystallization. In this paper chocolate was produced in a non-conventional way, in the ball mill. Milk powder, as most commonly used raw material for milk chocolate production, was replaced with soy milk powder. In Western countries, soya milk is used in a diet of people who are intolerant to lactose, or who do not consume foods of animal origin. Three types of chocolate have been produced: R1 chocolate mass with 20% cow milk powder, chocolate mass R2 with 15% soy milk powder and R3 chocolate mass with 20% soy milk powder in laboratory ball mill.
The aim of this research was to examine the influence of the milk powder and soya milk powder (15% and 20%) on the total phenolic content. The total phenolic content (TPC) increased with the increase of soya milk content in chocolate samples. Antiradical scavenging activity was in a direct relationship with the total phenolics content. The lowest IC_{50} showed the sample of chocolate with 20% of soya milk.
Key words: *chocolate, soya milk, ball mill, solid fat content, hardness, total phenolics, antioxidant activity*

INTRODUCTION

The production of chocolate in the ball mill has been studied in the last ten years (Lucisano et al., 2006; Alamprese et al., 2007). The ball mill replaces the standard two stage process of chocolate manufacturing: refining and conching occur at the same time. Depending on the time of grinding, ball size and weight of balls, we get the optimal particle size distribution as it is obtained by standard procedure of production. By grinding chocolate in the ball mill or the five-roll refiner, we get the optimal particle size distribution (Afoakwa et al. 2007, Afoakwa et al. 2008). By grinding and continuous recirculation of chocolate mass at a particular temperature we get a stable suspension of solid particles in cocoa butter (Prawira & Barringer, 2009). Melted chocolate is a complex rheological system where the solid particles are dispersed in the fat phase. The fat phase consists of both cocoa butter and milky fat (or soya oil from soya milk). The solid phase is not uniformly dispersed phase, because the particles are with different distributions in size, shape and properties on the surface. The influence of grinding on chocolate mass is reflected in the gradual reduction of the shear stress due to which it gets the appearance of a homological suspension that starts to flow. The stable chocolate mass is tempered before moulding with the aim of creating crystallizing centers in the stable crystal form V cocoa butter (Pajin & Jovanovic 2005, Garti & Sato 1988, Timms 2003). So formed crystals allow moulding and solidification of chocolate i.e. the best possible physical of chocolate.
The chocolates are produced with cow milk in powder and soya milk in powder. Soy flour has great potential for replacing milk powder in chocolate due to its high protein content (Akinwale 2000). Unlike the cow milk, soya milk has a reduced content of polyunsaturated fatty acids and does not contain lactose and cholesteroll. The energetic value of 100 g of whole milk is 64 Kcal, while the soya milk has 49 calories.

Health benefits of various cocoa products arise from cocoa polyphenols and their antioxidant capacity. Recent studies show that soya contains a wide range of bioactive components which are proved to be very effective in preventing heart disease, blood vessels and cancer, which successfully classifies this raw material among functional foods, or food with positive effect on human health (Kurzer 2003, Sacks et al. 2006).
Soya contains flavonoids, isoflavonoids, isoflavones and other polyphenols. These compounds may be important in reducing risk of atherosclerosis, as they have been shown to have favorably effect on plasma lipids and inhibit platelet aggregation (Sacks et al. 2006).
Epidemiologic data support the idea that health benefits are linked to the consumption of certain flavonoids. Flavanol-rich, plant derived foods and beverages include various fruits, wine, tea, as well as cocoa and cocoa products – chocolate (Keen 2001). A recent study suggested that milk proteins reduce the antioxidant activity of milk chocolate, compared with dark chocolate (Serafini et al. 2003).
This paper reports the development of soya-enriched chocolate and characterization of these products. Analyzed is improvement in terms of a total polyphenols and antioxidant activity caused by substituting milk powder with soya milk.

MATERIALS AND METHODS

Materials

The raw materials used for making milk chocolate with soya milk are: cocoa butter (Theobroma, Amsterdam), cocoa liquor (Cargill), medium-grain sugar (Crvenka AD, Serbia), whole cow milk powder (total fat 25%, proteins 28% and carbohydrates 37%) - Imlek, Serbia, skimmed milk powder (total fat 1%, proteins 35% and carbohydrates 51 %) - Imlek, Serbia, soya milk powder (total fat 26%, proteins 44% and carbohydrates 18.5 %) - Olvebra Provesol PSA, Brazil, hazelnut paste (total fat 25%, proteins 28% and carbohydrates 37%) - Arslanturk, Turska, Ethylvanilin (FCC, Norway), Soy lecithin with a minimum insoluble content of 65% in acetone (Soyaprotein AD, Serbia), Polyglycerol polyricinoleate or PGPR (Danisco, Malaysia).

Methods

The description of experiment:
The chocolate was manufactured in a laboratory ball mill with a homogenizer (capacity 5kg), domestic manufacturer. All raw materials were added to homogenizer exept for the 10% cacao butter. The mixing time was 20 minutes. After mixing the mass was transfered to the ball mill. The milling time was 90 minutes and the remaining quantity of the cacao butter was added in the 80th minute.The diametar of the balls in the mill is 9.1mm and the rotation speed of mixer is 50rpm.The ball mill is equipped with the mass-circulation system, the speed of which is 10 kg/hour. The internal diameter of ball mill is 0.250 m, and the height is 0.31 m. The volume of space provided for balls and 5 kg of chocolate mass is 0.0152 m^3.
Three types of chocolate mass were produced (Table1): R1(the chocolate mass with 20% cow milk powder), R2 (chocolate mass with 15 % of soya milk powder), R3 (chocolate mass with 20% of soya milk powder).

Table 1. Composition of chocolate mass

Ingredients	R1	R2	R3
		Content (%)	
Cocoa liquor	10.3	10.3	10.3
Sugar	41.5	50.3	47.2
Cocoa butter	19.8	19.8	19.8
Whole cow milk powder	20.0	0.0	0.0
Skimmed cow milk powder	5.7	0.0	0.0
Soya milk powder	0.0	15.0	20.0
Hazelnut paste	2.1	4.0	2.1
Soya lecithin	0.3	0.3	0.3
PGPR	0.2	0.2	0.2

The precrystallization of chocolate masses was performed in laboratory-modified Brabender precrystallization pharinograph. The temperature of precrystallization was 26, 28^{0}C and 30^{0}C. The flow od precrystallization is monitored indirectly through changes in internal resistance on the occasion of mixing, which is registered on force/time diagram. Precrystallized chocolate masses are cast in moulds and cooled at a temperature of 10-14°C (Pajin 2009). Symbols of used chocolate masses are given in the Table 2 .

Table 2. Symbols of chocolate mass

Symbol	Types of chocolate mass	Refinig time (min)	Temperature of precrystallization (°C)
R1-90-26	R1	90	26
R1-90-28	R1	90	28
R1-90-30	R1	90	30
R2-90-26	R2	90	26
R2-90-28	R2	90	28
R2-90-30	R2	90	30
R3-90-26	R3	90	26
R3-90-28	R3	90	28
R3-90-30	R3	90	30

Sample preparation for determination of total phenolic content and antioxidant activity:
In order to eliminate lipids from samples of chocolates 2.0 g of each sample was extracted three times with 10 ml hexane. The defatted solids were air-dried during 24h to remove the residual organic solvent. The phenolic compounds were extracted twice from 2 g of defatted chocolate products with 5 ml of aqueous methanol (70%) for 30 min in an ultrasonic bath (Model USK 28, power 600W, frequency 40 kHz, EI Nis, Serbia). After each extraction, the mixture was centrifuged for 10 min at 3000 rpm and supernatant was decanted.
Determination of total phenolics content:
The content of total phenolics in chocolate was determined by modified Folin/Ciocalteu method (*Singleton & Rossi 1965*) 100µl of extract was shaken for 1 min with 500 µl of Folin/Ciocalteu reagent and 6 ml of distilled water. After the mixture was shaken 2 ml of 15% Na_2CO_3 were added and the mixture was shaken once again for 5 min. The solution was brought up to 10 ml by adding distilling water. After 2h, the absorbance was measured on the UV/visible spectrophotometer (Ultraspec 3300 pro, Amersham Bioscience, Sweden) at 750 nm. The TPC was assessed by plotting the gallic acid calibration curve and expressed as milligrams of GAE per gram of dried sample. All tests were carried out in triplicates.
Determination of DPPH radical scavenging activity:
Antioxidant activity of three chocolate samples was measured on the basis of scavenging activities of the stable 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical (Cavin *et al.* 1998). In 50 µl of samples of chocolate of various concentrations were added 3.95 ml of methanol and 1 ml 0.2 mM of DPPH methanol solution. After 30 min of incubation in the dark at room

temperature, the absorbance was measured against a blank at 517nm using UV/visible spectrophotometer (Ultraspec 3300 pro, Amersham Bioscience, Sweden). Inhibition of DDPH radical was calculated as a percentage (%) using formula:
Percentage inhibition (%) = [(A control –A sample) /A control] x 100
where A control is the absorbance of control reaction and A sample is absorbance of test compounds. IC50 values were calculated from the regression equation, prepared from the concentration of the samples and percentage inhibition of free radical formation. All tests were carried out in triplicates.

DISCUSSION AND RESULTS

The antioxidant activities and total phenolics of three samples of chocolate are shown in Table 3.
The results of this study imply that chocolate (as cocoa product) is important source of dietary antioxidants. According to the literature data, total phenolic content varies greatly depending on the solvent and procedure for the extraction of polyphenols. The results presented in this study are in accordance with Waterhouse, Shirley and Donovan (1996).

Table 3. The antioxidant activities and total phenols in samples of chocolates

Sample	**R1**	**R2**	**R3**
TPC (mg GAE /g sample)	$6.45 \pm 0{,}06$	$7.77 \pm 0{,}04$	$8.26 \pm 0{,}07$
DPPH (IC_{50}) (µg/ml)	57.7	56.4	52.5

They have found 5.0 mg polyphenols/g milk chocolate using the colorimetric Folin/Ciocalteu method. The results show that by replacing the cow milk with soya milk the total content of polyphenols rises (20.5 and 28.1% respectively) and these chocolates can be relevant source of phenolic antioxidants. Also, our study indicated that satisfactory scavenging ability on DPPH radicals could be the result of phenolic compounds in sample of chocolate with higher content of soya milk. IC50 were lower for sample R2 and than R3 for 2.3% and 9% respectively.

CONCLUSION

Changes in the composition of raw material i.e. replacement of cow milk powder by soya milk powder result in the increasing content of polyphenols. The increase of total polyphenols in the chocolate mass R3 was by 28.1 % comparing to the R1, and in the chocolate mass R2 by 20.5% comparing to R1.

ABSTRACT: Cocoa and their products contain methylxanthines, peptides, biogenic amines and micronutrients which can influence the beneficial health effects of cocoa products, by either enhancing or reducing their biological activity. In this study the relation of polyphenols, methylxanthines and minor and major elements of several cocoa products with their cytotoxic activity and reactive oxygen species formation on one human carcinoma cell line was determined. Non-fat cocoa solids (NFCS), total polyphenol content (TPC) and methylxanthines content of cocoa product extracts were determined using UV/Vis spectrophotometric methods and HPLC analysis. Inductively coupled plasma atomic emission spectrometry (ICP-AES) was used for the determination of major and minor elements present in different cocoa products. Cytotoxic and anti-oxidative/prooxidative effects of cocoa product extracts in the presence of hydrogen peroxide were determined on human laryngeal carcinoma cell line (HEp2). The cocoa products containing higher NFCS exhibited higher TPC and methylxanthines content, while the content of major and minor elements was characterized by higher variability depending on the cocoa product. Experiments revealed a strong relationship between the type of product/concentration/time of exposure and antioxidant/prooxidant character of cocoa products. The observed prooxidant activity of dark chocolate and cocoa liquor may be attributed to higher contents of methylxanthines and transition metals present in these products.
Key words: *antioxidant activity, cocoa, cytotoxicity, non-fat cocoa solids, polyphenols, methylxanthines, minerals*

INTRODUCTION

Considerable experimental evidence has supported a key role of reactive oxygen species (ROS) as an important factor in the development of numerous diseases caused by oxidative damage (Yokozawa et al., 2007). The intake of naturally occurring nutritional sources of antioxidants, such as fruits, vegetables, tea, cocoa or wine, may attenuate the damage caused by oxidative challenges. Polyphenolic compounds, abundant in these nutritional sources, could play a major role in enhancing the antioxidant system, since they behave as ROS scavengers, metal chelators and enzyme modulators (Pietta et al., 1998). Cocoa products are studied for the most part because of the *in vitro* antioxidant and antiradical properties of their bioactive constituents on different cellular models of oxidative stress. The content of cocoa polyphenols is especially important, due to a great number of studies which have reported the health benefits of these bioactive compounds. It has been previously established that cocoa extracts containing polyphenolic compounds have the ability to scavenge ROS and protect human HepG2 liver cells (Martìn et al., 2008), colonic cancer cells (Caco-2 cells) (Carnésecchi et al., 2002) and rat adrenal pheochromocytoma cells (PC12 cells) (Cho et al., 2008) against oxidative stress. However, these effects cannot be attributed solely to polyphenols, given that cocoa and their products also contain methylxanthines, peptides, biogenic amines and micronutrients which can influence the

observed beneficial health effects of cocoa products, by either enhancing or reducing their biological activity (Visioli et al., 2009; Abbe Maleyki and Amin, 2008).
Cocoa derived products are the favourite food items of consumers of all age, among which children are the most susceptible age group to nutrients intake from such type of food items. In view of the complex matrixes of cocoa products having high sugar and organic contents, it is of great importance to precisely determine the bioactive content of this group of food products and to reveal their biological activity in different stress subjected conditions. Literature data regarding the effect of bioactive compounds in commercial types of cocoa products and their biological activity on cell lines are lacking, which indicates the necessity for analysis of these frequently consumed products. Moreover, the biological activities of various cocoa products have been determined mainly using individual polyphenolic compounds, such as procyanindin fractions or cocoa powder extracts, while studies using cocoa extracts of usually consumed cocoa products, especially chocolates are scarce. Therefore the present study reports the concentrations of polyphenols, methylxanthines and minor and major elements of several cocoa products and relates them with their cytotoxic activity and ROS formation on one human carcinoma cell line.

MATERIAL AND METHODS

Four different cocoa products (cocoa liquor, dark, semisweet and milk chocolate) were supplied by the leading Croatian chocolate manufacturer (Zvečevo food industry, Požega Croatia). The NFCS content of cocoa products was determined using a well established procedure within the confectionery industry (Balimann et al., 1999), based on the use of theobromine as a marker of NFCS.

Determination of polyphenols and methylxanthines content

The cocoa samples were prepared, extracted and analyzed for phenolic compounds and methylxanthines according to the procedures described by Belščak et al. (2009). Total phenol content (TPC) was determined spectrophotometrically according to a modified method of Lachman et al. (1998), and the results were expressed as mg gallic acid equivalents (GAE)/g of cocoa product. The content of methylxanthines, theobromine and caffeine was determined using a high performance liquid chromatography method developed by Belščak-Cvitanović et al. (2011).

Mineral analysis of cocoa products

Approximately 0.15 g of cocoa product was weighted into Teflon reaction vessels (in triplicate), and 5 mL of nitric acid (50:50 v/v) with 2 mL H_2O_2 was added to each sample. For the microwave assisted digestion a MWS-2 Microwave System Speedware BERGHOF was used, and the digestion procedure was conducted in three steps for 15 minutes each, at T(°C) and total power (W): 1.–110°C/60W, 2.–170°C/75W and 3.–140°C/50W. The resulting clear solutions of digestion procedure were then brought to 10 mL with ultrapure water. Mineral content of cocoa products was determined with a Prodigy High Dispersive ICP spectrometer (Teledyne Leeman, Hudson, NH, USA) working in a simultaneous mode. The instrument operated with optimal parameters: a radiofrequency power of 1.1 kW; plasma gas flow rate (Ar) of 18 L/min and auxillary gas flow rate (Ar) of 0.8 L/min. All standard deviations were based on measurements in triplicate and amounted to less than 10%.

Determination of biological activity *in vitro*

In order to determine the biological effects of cocoa product extracts, the previously prepared extract was evaporated to dryness and re-dissolved in sterile water. The cocoa products extracts were prepared with different concentrations (ranging from 0.5 x to 2.5x) in growth medium (DMEM). Cytotoxicity of cocoa products was determined by neutral red (NR) assay, while reactive oxygen species formation in the cells after the treatment with cocoa product extracts was determined by dichlorohydrofluorescein assay using microplate reader as described by Durgo et al. (2011). Also, antioxidative potential of cocoa product extracts was

determined prior to treatment with cocoa product extracts, on cells treated with 250 μM hydrogen peroxide for half an hour. Decrease of ROS formation in the cells pre-treated with cocoa extracts in comparison to positive control (250 μM hydrogen peroxide only) would indicate its antioxidative nature.

RESULTS AND DISCUSSION

Quantitative analysis of bioactive compounds of cocoa products (table 1) revealed a correspondence between the increase of NFCS and polyphenolic compounds, as well as methylxanthines of each cocoa product. Based on these results, the higher amount of NFCS indicates the higher phenolic and methylxanthines content of a cocoa product, which has been previously established (Miller et al., 2009; Belščak et al., 2009). However this does not apply to mineral content of cocoa products. The contents of potassium, calcium, sodium and aluminium are not affected by the NFCS content, which indicates that other ingredients of cocoa products may be the source of these major elements. As it can be seen from the results, magnesium and potassium are the prevalent minerals of cocoa products, while the contents of Cd, Co, and Pb are below the limits of detection (1.39, 1.19, and 1.13 μg/g, respectively). Nickel is found in a concentration range 0.10-0.60 μg/g. Similar concentrations are previously reported by Dahiya et al. (2005) in 69 different brands of chocolates and candies mainly made from cocoa, milk solids, dry fruits, fruit flavours and sugar.

Table 1. Polyphenolic and methylxanthines content of water extracts of cocoa products and the content of major and minor elements of cocoa products

	Milk chocolate	**Semisweet chocolate**	**Dark chocolate**	**Cocoa liquor**

*TPC – total phenol content, *- Σ theobromine and caffeine*

None of the examined extracts caused 50% of cell death (figure 1). Cocoa liquor caused dose-response decrease in cell survival during 1 hour of incubation and prolonged incubation (2h). Dark chocolate decreased the cell survival in dependence of concentration and time of exposure, while semisweet chocolate showed its cytotoxic effect after prolonged exposure of HEp2 cells (2h). Carnésecchi et al. (2002) observed that the flavanol and procyanidin contents of the cocoa samples are directly related to their anti-proliferative effect on the human colon cancer cell line Caco-2. According to their results, cocoa powder extract caused only 25% of growth inhibition, whereas procyanidin enriched cocoa extract caused a

75% growth inhibition of Caco-2 cells. Since the results of our study revealed that milk chocolate containing the lowest NFCS had no effect on HEp2 cells survival, while the highest growth inhibition (27%) of cells was induced by cocoa liquor, after 2 hours of treatment, a correlation between the cytotoxic activity and NFCS content of cocoa products has been confirmed.

Since reactive oxygen species are formed continuously in cells as a consequence of both, oxidative biochemical reactions and external factors, the cells were also treated with 250 μM hydrogen peroxide for 30 min, prior to treatment with cocoa product extract. According to our results, noncytotoxic concentrations of milk chocolate extract slightly increased ROS formation after 1 hour of incubation, and this effect was more obvious in the case of 2 hours of incubation. Similarly, lower concentrations (0.1 and 0.5x) of semisweet and dark chocolate, as well as cocoa liquor extracts induced an increase in ROS formation, while the higher concentrations resulted with a significant decrease in ROS formation when compared to control. In cells treated with hydrogen peroxide, it can be observed that the final, highest concentrations of milk and semisweet chocolates, as well as cocoa liquor caused a decrease of ROS formation when compared to the control, as opossed to dark chocolate which increased the levels of ROS and indicated a prooxidant effect exerted by this extract. This might be due to the composition of dark chocolate and cocoa liquor, which contain the highest NFCS content, and consequently the highest polyphenol and methylxanthines content. The effect of this mixture of strong bioactives may be attributed for the observed prooxidant activity of dark chocolate and cocoa liquor extracts.

It has frequently been suggested that metal impurities can contribute to cell toxicity, by triggering ROS production by Fenton's reaction. Dietz et al. (1999) and Sahw et al. (2004) have reported that heavy metals, especially transition metals (Fe, Cu, Mn, etc.) induce oxidative stress in cells and tissues by transfering electrons directly in single-electron reactions, which generate free radicals. In our study, a high variability of toxic metal impurities in cocoa products was found using ICP-AES assays. As can be seen in table 1, dark chocolate and cocoa liquor contain higher contents of transition elements, which would imply on a potential for elevating and inducing ROS formation in HEp2 cells after the treatment with the cocoa extracts. Since dark chocolate and cocoa liquor which were characterized with the highest NFCS (and consequently the highest polyphenol, methylxanthines and mineral contents) also exhibited the highest growth inhibition (the lowest cell viability) and prooxidant activity of HEp2 cells, the results indicate a possible connection between the biological activity and bioactive content of cocoa products.

CONCLUSIONS

The results of this study revealed a strong relationship between the type of product/concentration/time of exposure and cytotoxic and antioxidant/prooxidant character of cocoa product extracts on HEp2 cells. Products containing the highest NFCS (cocoa liquor, dark chocolate) exhibited the most potent cytotoxic effect, as well as antioxidant properties (decrease of ROS formation). The highest concentrations of dark chocolate exhibited a prooxidant effect, which may imply on the effect of other bioactives present in cocoa products, especially methylxanthines and minerals whose effect on human cell lines subjected to oxidative conditions has not yet been clarified.

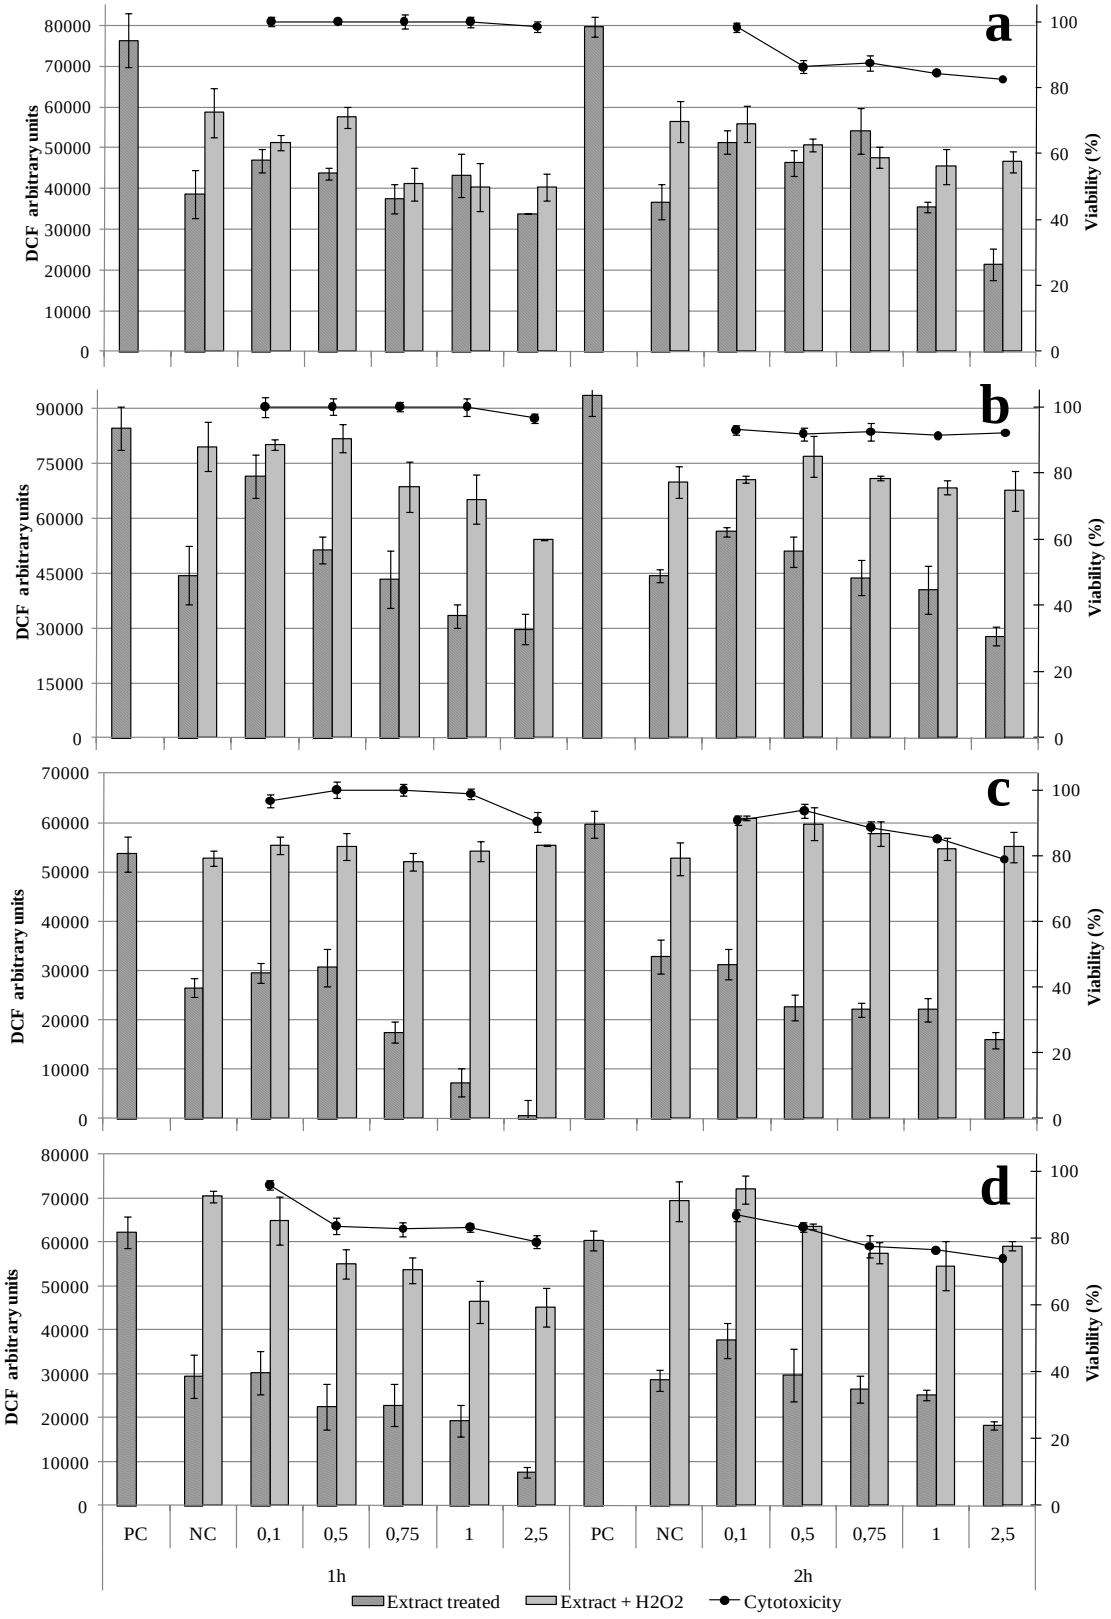

Figure 1. Survival and comparison of reactive oxygen species formation in HEp2 cells following 1h and 2h treatment with a) milk chocolate, b) semisweet chocolate, c) dark chocolate and d) cocoa liquor extracts with and without previous treatment with 250 μM hydrogen peroxide. Pooled data obtained from three experiments (the mean at the point +SD).

ACKNOWLEDGEMENTS

This work was supported by the Ministry of Science, Education and Sports, Republic of Croatia projects Nr. 058-0000000-3470 and 058-0582261-2246. The authors are grateful to Croatian food industry Zvečevo d.d. for supplying the cocoa product samples used in the study.

ABSTRACT: This paper presents the results reflected on obtaining the milk enriched with omega-3 fatty acids. As source of omega-3 fatty acids, product of French company Vitalac called "TradiLin", was used. Trial was carried out on 20 trials (T) and 20 control (C) cows of Simmental breed and it lasted 80 days. Average content of omega-3 in trial and control group was 0.586 and 0.284 g/100g of extracted fat (P≤0.01), whereas content of omega-6 in same order of treatments was 3.141 and 3.011 g/100g of extracted fat (P≤0.05). Ratio omega-6/omega-3 fatty acids of 10.602 (control) was declined to 5.360 (trial), which is considered to be desirable from the aspect of nutrition with milk as functional food. Also, in other milk final product called "mladi kajmak", obtained by taking off milk fat from the surface of heat treated and cooled milk, content of omega-3 in trial and control group showed the same trend, 0.76 and 0.41 g/100g of extracted fat (P≤0.01), whereas content of omega-6 were 3.90 and 3.79 g/100g of extracted fat (P≤0.05). Ratio omega-6/omega-3 in control group was reduced of 9.24 to 5.10, which are considered to be extremely favourable. Chemical constituents of milk, somatic cell count as well as total plate count showed no differences between groups (P>0.05). Also, investigated treatment had no effect on changes in biochemical blood parameters.
Key words*: milk, omega-3 fatty acids, functional food*

INTRODUCTION

The term "functional food" includes those food stuffs which beside their main nutritive value contain such substances which have impact on improvement of general health condition, i.e. they have preventive and therapy effect (Sretenović, 2005).
In this trial as a source of omega-3 fatty acid, product known under the trade name "TradiLin", is used. The varieties of flax are specially selected for their richness in ALA omega- 3 fatty acids. "TradiLin" is produced from a fully patented extrusion technology which liberates the oils without denaturing them, so they can be digested more rapidly in such a way that it is available to the animal at the right time and at the right dose, inactivates the anti-nutritional factors (cyanogens) and preserves the fatty acid profile.
Typically 60% of fat intake for an average human comes from animal products (meat, milk, eggs, etc).These animal products have changed because the feeds that the animals now eat have changed. In the pass times 40 – 50 years ago, animals used to eat mainly forage (high omega -3, lower omega -6) but now typically eat less forage but consume more cereals and soya (high omega- 6, low omega -3) and as a result of that animal products (meat, milk, eggs etc) are much higher in omega -6 and lower in omega -3. So now the human diet, because of what animals are fed, is higher in omega -6 and lower in omega -3 i.e. traditional diets gave an omega -6: omega -3 ratio of 1:1, current human diets show a ratio of 20:1 and in animal diets up to 40:1.
Scientific studies suggest that this imbalance of omega- 6:omega -3 ratios is the cause of numerous physiological disorders and that better-balanced ratios could result in significant health improvements (Association Bleu-Blanc-Coeur, 2004).
In order to overcome numerous health problems, the food stuffs which aren't traditional sources of omega-3 fatty acids such as dairy products and pastry, meat, baby foods, etc. are enriching with moderate quantities of these fatty acids and there is increased demand for such products because of their well known positive effect on human health *(Sretenović et al., 2007a)*.

Since human organism has no enzymatic system necessary for synthesis of omega-3 fatty acids, they must be introduced through diet (they are called “essential fatty acids”).
Modern biotechnologies offer different ways for enriching of products with omega-3 *(Sretenović et al., 2007, Sretenović et al., 2009, Sretenović et al., 2009a)*. Products of animal origin such as milk, meat and eggs, enriched with omega-3 fatty acids are obtained by inclusion of sources of these acids into animal diets. Also, increase of the content of omega-3 fatty acids is achieved by application of modern biotechnological procedures in selection and plant breeding, by growing of varieties which synthesize higher quantity of ALA, i.e. fatty acids similar to EPA and DHA.
In connection with the above mentioned, goal of this research was to get milk and dairy products enriched with omega-3 fatty acids through the introduction of the “TradiLin” preparation in diets of lactating cows.

MATERIAL AND METHODS

Trial was carried out on 40 cows of Simmental breed, divided into two groups with 20 cows in each one. Both groups were made uniform according to relevant criteria, i.e. they were in the second lactation and with similar quantity of milk in previous lactation.
Source of omega-3 fatty acids was product “TradiLin” representing special type of flax processed using specific patented technological procedure.
In the laboratory of the Institute for Animal Husbandry the chemical composition of the product “TradiLin” was analyzed: 18.61% of total proteins, 9.78% of crude fibre, 5.68% of ash, 25.48% of crude fat with iodine number -172.29, g J/100g of fat; acid number -2.07, mg KOH/g of fat and peroxide number -2.66, mmol H_2O_2/kg of fat.
Trial lasted 80 days, i.e. administration of the preparation started in dry period 20 days before calving and lasted 2 months during lactation. Both groups of cows received identical diets and trial group received in the diet flax preparation in the quantity of 0.7 kg in dry period and 1,2 kg during lactation. Diets for cows in dry period consisted of: meadow hay 8 kg, silage of entire maize plant 15kg, concentrate for dry cows (14%UP) – 4.5kg. Fresh cows were fed diets of following composition: alfalfa hay 6 kg, silage of entire maize plant 10 kg, sunflower meal 1,5 kg and concentrate mixture (18%UP)-5.0 kg. Cows in lactation were fed diet consisting of alfalfa hay – 5,0 kg; silage of entire maize plant - 25 kg, maize ear silage – 5.5kg, sunflower meal – 3.5 kg kg and 2 kg of concentrate mixture (18%TP) for production of 30 kg of milk. Nutrition parameters of the diet for lactating cows were following: dry matter – 20.6 kg; 140.00 MJ (NEL); 3210 g total protein and 4302.2 g of crude fibre.
In the laboratory of the Institute for Animal Husbandry, Belgrade-Zemun, chemical composition of livestock feeds and preparation “TradiLin” was established, content of macro and micro elements, as well as content of organic acids in the silage. Following methods were used: total protein - SRPS ISO 5983:2001; moisture SRPS ISO 6496:2001; crude fat SRPS ISO 6492:2001; crude fibre SRPS ISO 6865:2004; ash SRPS ISO 5984:2002; calcium in livestock feeds AAS IS-LDM-14; calcium in premix - IS-LDM-7; phosphorus in premix IS-LDM-5; total phosphorus in feeds -IS-LDM-4; micro elements- AAS IS-LDM-14; sodium - Rulebook[A)] method 22; content of organic acids in the silage-IS-LDM-10; iodine number- SRPS ISO 3961:2001; peroxide number - SRPS ISO 3960:2001; acid number - SRPS ISO660:2000; level of acidity-volumetric method according by Soxhlet-Henkel.
Content of omega-6 and omega-3 fatty acids was done in the SP laboratory AD Bečej, using method MET 358 GC/MS SP.
Milk composition was measured by milkoscan apparatus. Somatic cell count was recorded according microscoping method (EN ISO 13366-1: 1997). The blood was withdrawn from jugular vein of lactating cows and biochemical parameters (glucose, protein, total bilirubin, aspartate aminotransferase-AST, alanine aminotransferase-ALT, total cholesterol, HDL and LDL cholesterol, calcium and phosphorus) were investigated from blood serum by automatic biochemical analyzer model Konelab 20.

The data from the experiment were developed statistically by using the computer program Statistica (Stat Soft Inc., Ver.6. 2003). Significance of mean differences was estimated by Student's t- test.

RESULTS AND DISCUSSION

Chemical composition of feeds and mineral content are presented in the Tab.1.

Tab. 1. Chemical composition of feeds

Parameter	**Feeds**						
	Alfalfa hay	Meadow hay	Maize silage	Maize ear silage	Concentrate (18%)	Sunflower meal	Premix
Total protein, %	15.01	6.61	2.07	5.25	18.88	36.44	-
Moisture, %	9.30	7.90	70.39	34.27	11.77	10.23	-
Crude fat, %	1.83	1.85	2.49	2.09	2.02	1.98	-
Crude fibre, %	32.96	33.02	6.77	4.90	7.60	15.45	-
Ash,%	7.11	10.65	1.47	1.00	6.36	6.78	-
Ca,%	1.20	0.29	1.5	0.28	1.02	2.92	-
P,%	0.29	0.42	0.6	1.43	0.73	9.95	-

Tab.2. Content of organic acids and reviewing maize silage according by Flieg

	Content	**Share%**	**Points**	**Assessment**
Butyric acid	0	0	50	VERY GOOD
Acetic acid	0.8351	19.45	18	
Lactic acid	3.4577	80.55	98	
Total:	4.2928	100.00	98	

From presented results it is obvious that all quality parameters varied within limits characteristic for specific feed.

In Tab 3. the contents of omega-6 and omega-3 in milk were presented and it is noticeable that the content of omega-6 fatty acids in trial group compared to the control one increased by 0.13g/100 g of fat, which was statistically significant at the level of (P≤0.05), whereas the content of omega-3 fatty acids in the same order increased by 0.302g/100 g fat which resulted in statistical significance at the level of P≤0.01. Ratio between omega-6 and omega-3 in milk in the trial group was 5.360, and was much more favorable than in the control one which amounted to 10.602 .

S similar situation regarding the content of fatty acids in the dairy product called "mladi kajmak". So, content of omega-6 fatty acids in trial group had increased by 0.11 g/100 g of fats (P≤0.05), whereas the content of omega-3 had increased by 0.350g/100g of fats, expressed through statistical significance it was P≤0.01.

Tab.3. Content of omega fatty acids and their ratio in milk and »mladi kajmak«

Milk	**Trial group**	**Control group**
Omega-6 fatty acids, g/100g of fat	3.141^{a}±0.1103	3.011^{b}±0.024
Omega-3 fatty acids, g/100g of fat	0.586^{A}±0.1632	0.284^{B}±0.1933
Ratio omega-6/omega-3 fatty acids	5.360	10.602
"Mladi kajmak"		
Omega-6 fatty acids, g/100g of fat	3.90^{a}±0.122	3.79^{b}±0.061
Omega-3 fatty acids, g/100g of fat	0.76^{A}±0.1123	0.41^{B}±0.421
Ratio omega-6/omega-3	5.10	9.24

All value expressed as mean ± Sd
a,b-values in rows with different letters differ significantly (P≤0.05)
A, B-values in rows with different letters differ significantly (P≤0.01

In Tab.4. durability of "mladi kajmak" is presented. Namely, "mladi kajmak" is declared as product with durability and taste which are maintained during 10 days in sale, and later the product undergoes fermentation and acquires characteristics of "stari kajmak". "Mladi kajmak" is characteristic and popular product on the territory of Serbia. In this product, in refrigerator's conditions the change in parameters of unsaturated fatty acids was monitored, i.e. inclination towards oxidation. Obtained results unambiguously indicate that "mladi kajmak" of the trial group enriched with omega-3 fatty acids, beside increased content of omega fatty acids has better durability compared to standard quality, since changes during the time occur slower, which was confirmed by lower values of peroxide number and level of acidity. In this way, nationally recognizable product which has been avoided by consumers due to health reasons and high content of saturated fats becomes foodstuff of high value with properties of functional food.

Tab.4. Durability of „mladi kajmak"

Parameter	**Sampling period, days**									
	Trial group					**Control group**				
	1	6	10	15	18	1	6	10	15	18
Iodine number,g J /100g fat	37.34					29.12				
Acid number, mg KOH/g fat	0.06					0.06				
Peroxide number,mmol H_2O_2/kg fat	1.08	1.14	1.44	1.46	1.58	1.12	1.23	1.54	1.56	4.88
Level of acidity, SH°	6.29	6.38	6.91	8.61	12.23	7.75	9.70	11.88	13.19	16.21

In Tab.5. chemical composition and quality of milk obtained from control and trial group are presented. Even though increased values of milk fat and proteins in trial group compared to control one were established, no statistical significance was exhibited because of high variations within groups. In both groups the somatic cell count, as well as total plate count, were at satisfactory level considering farm's conditions i.e. it is result of good managing system.

Tab.5. The chemical composition and bacteriological quality of milk

	Parameter/Parametar					
	Milk fat ,%	Protein,, %	Lactose,%	Dry matter without fat,%	Somatic cell count in 1ml	Total plate count in 1 ml

C	3.80^{a}±0.3000	3.39^{a}±0.2449	4.74^{a}±0.2646	8.94^{a}±0.3464	208880^{a}±326.46	<78000

**Values in rows with same letters not differ significantly P>0.05*

In the beginning and in the end of trial, the blood was taken from v. jugularis and the most important blood parameters were recorded. At the beginning of trial there were no differences in biochemical blood parameters, and at the end of trial period, as it can be seen from Tab. 6, all of them were in physiologically optimal limits (regardless of the fact that in

trial group levels of bilirubin and ALT, which resulted in statistical significance) which indicated stable health condition of heads of cattle and also that the stress occurring in this most productive physiological stage has been overcome. Physiologically optimal values were compared according by Kaneko (1989).

Tab. 6. Biochemical parameters of the blood

Parameter	Groups		Reference range
	Trial	Control	
Glucose, mmol/l	2.74±0.3606	2.91±0.2646	2.5-4.2

Feeding dairy cows a ration containing whole flax seeds (linseed), flax (linseed) oil or milled, extruded or micronized linseed has five beneficial effects on the fat profile of cow's milk: (1) increasing the content of alpha-linolenic acid (ALA); (2) increasing the content of conjugated linoleic acid (CLA); (3) decreasing the omega-6/omega-3 ratio; (4) decreasing the overall saturated fat content; and (5) increasing the proportion of stearic acid relative to other saturated fatty acids. These enhancements to the fat profile of milk give consumers value-added foods with good sensory qualities and a healthier fat profile (Morris, 2009).

When results obtained in this study are compared with results obtained by other authors it can be said that they are in correspondence with them. *Oba et al. (2009).* obtained very important results by comparing the effects of α-linolenic acid in milk fat from Holstein cows which were fed diets supplemented by whole unprocessed, ground flax seed in the amount of 100g per kg of dry matter of diet. Problem occurs because of the specificity of digestion in ruminants where bio-dehydrogenization of unsaturated omega-3 fatty acids occurs, and in this way their digestibility is decreased unless they are made available, by processing procedure, to micro-organisms of rumen. Hypothesis that both feeding treatments influence the increase of concentration of α-linolenic acid in milk fat (8.3 and 8.6g/kg^{-1}) was confirmed and its concentration was three times higher in comparison to the one before the treatment, where instead of flax seed sunflower seed was used (2.6 g/kg^{-1}). Both treatments with whole unprocessed flax seed and ground seed indicate similar degree of absorption of α-linolenic acid in spite of lower digestibility of the whole unprocessed seed, which is noticeable by its content in faeces (259 vs. 129 g day^{-1}; $P < 0.001$). Ground flax seed doesn't increase significantly the absorption of α-linolenic acid in milk fat, since by increasing of its digestibility also the level of bio-dehydrogenization in rumen is increased.

Also, in research of *Petit (2002)* the effects of whole unprocessed flax seed as source of omega-3 fatty acids in diets for high yielding cows were studied and compared to other energy sources such as Megalac and micronized soy bean as energy source. It was concluded that inclusion of whole flax seed into diets for cows influenced not only the increase of quantity of milk (35.7kg/day compared to other two energy sources - 33.5 and 34.4kg/day), but also the protein content in milk as well as decrease of ratio of omega-6 and omega-3 fatty acids, which made it product of high quality from the aspect of human nutrition. Human diets rich in omega-6 fats result in a high omega-6/ omega-3 ratio. A high dietary omega-6/omega-3 ratio is linked with low-grade chronic inflammation that contributes to diseases such as Alzheimer disease, cancer, coronary heart disease, metabolic syndrome, obesity, type 2 diabetes, osteoporosis and even dry eye syndrome (Morris, 2007) Reducing

the omega-6/omega-3 ratio helps decrease inflammatory reactions and lowers the risk of chronic disease. A dietary ratio between 4:1 and 10:1 is recommended (Gebauer, 2006). Improving the ratio can be achieved by eating less omega-6 fats, eating more omega-3 fats or doing both. Buying milk and meat products with a low omega-6/omega-3 ratio helps improve the dietary mix of fatty acids in the human diet (Morris, 2009).

CONCLUSION

Including the whole flaxseed (patented procedure of special flax cultivar) into dairy cows diet has the beneficial effects on the fat profile of cow's milk. This is a good and simply way of obtaining milk with functional food properties. Having in mind that milk enriched with omega-3 fatty acids has a favorable effects on human and animal health, inclusion of flaxseed through product called "TradiLin" has a full justification.

ABSTRACT: Light buckwheat flour (LBF) was used to substitute 20% of wholegrain wheat flour (WWF) in the formulation of wholegrain wheat pasta. Wholegrain wheat pasta (WWP) and buckwheat enriched wholegrain wheat pasta (BWWP) were produced on an industrial scale in the form of tagliatella.
Rheological test of control WWF dough and dough supplemented with LBF was used to predict the behaviour of dough using Mixolab. Results indicated that substitution of WWF with LBF in the formulation of pasta resulted in minor changes that did not influence the quality of enriched pasta.
Proximate composition, cooking quality and mineral content of BWWP were analysed and compared with those of WWP.
The substitution of WWF with LBF in the pasta formulation at the level of 20% resulted in significantly increased ($P < 0.05$) contents of P, Mg, K and Zn compared to WWP in dry pasta.
The reduction in mineral content of BWWP during cooking was significantly higher ($P < 0.05$) compared to WWP. The content of P, Mg and K were at same level in both type of pasta after cooking.
The obtained results suggest that enrichment of WWP with LBF at the level of 20% did not improve the mineral content of cooked pasta, although increase in minerals was observed in dry pasta.
Key words: *pasta, light buckwheat flour, dough rheology, Mixolab, mineral content*

INTRODUCTION

Pasta products are largely consumed all over the world and they are frequently manufactured from wheat flour, which is known to be the best raw material suitable for its production. The best properties of wheat flour for pasta production result from protein structure of wheat that enables to form a matrix with encapsulated starch granules. On the other hand, wheat flour is characterized with relatively low lysine, methionine and treonine content, as well as some minerals and vitamins (Heger and Frydrych, 1987). Fortification of wheat pasta in order to improve its nutritional quality and to produce functional pasta product is described in literature (Bahnassey et al., 1986; Rayas-Duarte et al., 1996; Shogren et al., 2006).
Buckwheat (Fagopyrum esculentum Moench) is an important pseudocereal known as a dietary source of protein containing high levels of essential amino acids (Bonafaccia et al., 2003b), starch and dietary fibres (Skrabanja et al., 2004), essential minerals (Steadman et al., 2001) and trace elements (Bonafaccia et al., 2003a). This crop also contains antioxidant compounds (Dietrych-Szostak and Oleszek 1999), first of all rutin (Holasava et al., 2002), being responsible for benefitial effect on health. Regular consumption of buckwheat containing products reduces the risk of high blood pressure, prevents oedema and hemorrhagic diseases, prevents diabetes and reduces the risk of arteriosclerosis (Ihme et al., 1996; Kim et al., 2004).
Buckwheat flour has been used for supplementation of wheat pasta in order to produce functional pasta with nutritional benefits (Bilgiçli, 2009a; 2009b; Bonafaccia and Kreft, 1994; Chillo et al., 2008; Hung et al., 2007). Furthermore, buckwheat bran has been incorporated into spaghetti formulation to improve its quality (Manthey et al., 2004; Manthey and Hall, 2007).

The majority of research of buckwheat enriched pasta was focused on its mechanical strength and cooking quality related to decreased gluten matrix (Hung et al., 2007; Rayas-Duarte et al., 1996), and sensory properties (Chillo et al., 2008; Rayas-Duarte et al., 1996).
The production and cooking of pasta influence its nutritional quality. Therefore, the supplementation of pasta with functional ingredient(s) has to be followed by availability of added compounds that contribute to desirable nutritional benefits. The loss of amino acids, i.e. lysine, during processing (Dexter et al., 1984), as well as some minerals (Manthey and Hall, 2007) and polyphenols (Verardo et al., 2011) during cooking of pasta has been reported.
Knowing that production and cooking influence the mineral content of pasta, the aim of this work was to investigate if there is a possibility to produce buckwheat enriched wholegrain wheat pasta with acceptable properties from the rheological point of view, and to determine the effect of processing and cooking on mineral content of pasta. The obtained information would be useful for optimization of process parameters that would provide the stability of nutritional components at the time of pasta consumption.

MATERIAL AND METHODS

Raw materials

Light buckwheat flour (LBF) was obtained from Hemija Commerce, Novi Sad, Serbia, and wholegrain wheat flour (WWF) was purchased from Žitko, Bačka Topola, Srbija.

Pasta dough formulation

Wholegrain wheat pasta (WWP) was produced using WWF and buckwheat enriched wholegrain wheat pasta (BWWP) was obtained by substitution of WWF with LBF at the level of 20%. WWF or WWF-LBF mixture was hydrated with deionised water to 320 g kg^{-1} absorption in order to achieve proper dough consistency (Manthey et al., 2004).

Rheological characteristics of pasta dough

The rheological behaviour of both prepared dough formulations was examined using Mixolab (Chopin, Tripette et Renaud, Paris, France). All measurements were performed using the modified Mixolab “Chopin +” protocol (ICC, 2006). Modification of “Chopin +” protocol is due to dough mass increase from 75 g to 90 g because of the specific nature of the buckwheat flour. Instrumental settings were: initial mixing at 30 °C for 8 min, heating to 90 °C during 15 min at a heating rate 4 °C/min, holding at 90 °C for 7 min, cooling to 50 °C at a 4 °C/min cooling rate and holding for 5 min at 50 °C. Mixing speed was kept constant during the measurement at 80 rpm.

Industrial pasta production

Two types of pasta (WWP and BWWP) were produced on an industrial scale by using Ital past Mac 60 (Parma, Italy). WWF or WWF-LBF mixture was hydrated and mixed in pre-mixer for 12 min. After that, the entire quantity was transferred to a mixer and mixed for 6 minutes. The obtained dough was extruded at the extrusion speed of 42 rpm as tagliatella for 42 min. The extruded tagliatella was dried in a dryer (Ital past D200) for 13.5 h at the temperature of 41.3 °C.

Proximate composition

Proximate composition of WWF, LBF, WWP and BWWP was analyzed using AOAC methods (1984) for determination of moisture, crude protein, ash, crude cellulose, crude fat and starch content.

Mineral composition

Mineral composition (P, Mg, K, Zn, Fe and Mn) of WWF, LBF, WWP and BWWP (uncooked and cooked) was determined using a Varian Spectra AA 10 (Varian Techtron Pty Limited, Mulgvare Victoria, Australia, 1989) atomic absorption spectrophotometer equipped with a

background correction (D2-lamp). The sample preparation consisted of a dry ashing procedure at 450 °C as described by Pavlović et al. (2001).

Pasta cooking quality

Optimal cooking time, cooking loss and volume increase of WWP and BWWP were determined according to AACC methods (1995).

Statistical analysis

All analyses were performed in triplicate, and the mean values with the standard deviations (S.D.) are reported. Analysis of variance and Duncan's multiple range test were used. Statistical data analysis software system STATISTICA (StatSoft, Inc. 2008). *P* values < 0.05 were regarded as significant.

DISCUSSION AND RESULTS

Proximate composition of flours

Proximate composition of the commercially available WWF and LBF are presented in Table 1.

The protein content was significantly higher (*P* < 0.05) for LBF compared with WWF, followed by higher ash and fat content. The results obtained in the present study are comparable with the published data (Alvarez-Jubete et al., 2009; Bonafaccia et al., 2003b; Steadman et al., 2001).

Also, content of P, Mg, and K in LBF was found to be much higher compared to WWF (Table 1). The obtained mineral contents of WWF and LBF are within the ranges reported by Ikeda et al. (1995), Steadman at al. (2001) and Bonafaccia et al. (2003a).

Table 1. Proximate composition (%, dry basis) and minerals (mg/100 g) of wholegrain wheat flour (WWF) and light buckwheat flour (LBF)

Proximate composition	WWF	LBF
Moisture	11.7 ± 0.02[a]	12.1 ± 0.02[b]
Crude protein (Nxfactor)[a]	13.6 ± 0.12[a]	15.8 ± 0.19[b]
Ash	1.46 ± 0.01[a]	2.00 ± 0.0[b]
Crude cellulose	1.55 ± 0.03[b]	0.87 ± 0.01[a]
Crude fat	1.52 ± 0.02[a]	2.49 ± 0.11[b]
Starch	66.6 ± 0.18[b]	58.5 ± 0.01[a]
Minerals		
P	253 ± 4.26[a]	447 ± 18.15[b]
Mg	81.9 ± 1.38[a]	177 ± 1.77[b]
K	272 ± 5.38[a]	535 ± 4.68[b]
Zn	2.09 ± 0.11[a]	2.38 ± 0.02[b]
Fe	3.51 ± 0.09[a]	4.20 ± 0.08[b]
Mn	2.79 ± 0.11[b]	1.72 ± 0.02[a]

[a] *– Nitrogen-to-protein conversion factors are: 5.7 for WWF and 6.25 for LBF.*

Values are means of three determinations ± standard deviation.

Values of the same row with the same superscript are not statistically different (P < 0.05).

Rheological characteristics of pasta dough

Physical and chemical changes take place at micro structural levels in dough when some part of wheat flour in the formulation is replaced with another type of flour. It has already been concluded that rheological tests on dough can predict its behaviour during production on an industrial scale (Torbica et al., 2010). Therefore, the rheological properties of wholegrain wheat dough and dough enriched with LBF were investigated using the Mixolab (Table 2).

Table 2. Mixolab properties of dough systems made by using wholegrain wheat flour (WWF) and mixture of 80% wholegrain wheat flour and 20% light buckwheat flour (80WWF-20LBF)

Dough type	Development time (min)	Stability time (min)	C2 torque (Nm)	C3 torque (Nm)	C3-C4 torque (Nm)	C5-C4 torque (Nm)	Water absorption (%)
100WWF	8.39[a]	7.91[a]	0.51[a]	2.20[a]	0.51[b]	0.78[a]	62.6[a]
80WWF-20LBF	8.50[a]	8.05[a]	0.53[a]	2.15[a]	0.29[a]	0.77[a]	63.6[a]

Values are means of three determinations ± standard deviation.
Values of the same column with the same superscript are not statistically different (P < 0.05).

Based on the results presented in Table 2 it can be concluded that rheological behavior of two investigated systems is quite similar. This enabled the production of buckwheat enriched wholegrain wheat pasta (BWWP) in industrial conditions without modifying equipment and process parameters of traditional pasta production.

Proximate composition of pasta

Proximate composition of WWP and BWWP are presented in Table 3. The pasta containing LBF is superior in protein, ash and fat content than WWP due to higher content of these nutrients in LBF compared to WWF (Table 1).

Table 3. Proximate composition (% dry basis) of wholegrain wheat pasta (WWP) and buckwheat enriched wholegrain wheat pasta (BWWP)

Pasta sample	Moisture	Crude protein	Ash	Crude cellulose	Crude fat	Starch
WWP	11.3 ± 0.03[b]	13.1 ± 0.11[a]	1.30 ± 0.03[a]	1.46 ± 0.01[b]	1.30 ± 0.01[a]	65.9 ± 0.18[b]
BWWP	11.1 ± 0.01[a]	14.1 ± 0.08[b]	1.59 ±0.02[b]	1.36 ± 0.02[a]	1.58 ± 0.08[b]	64.1 ± 0.01[a]

Values are means of three determinations ± standard deviation.
Values of the same column with the same superscript are not statistically different (P < 0.05).

Pasta cooking quality

Optimal cooking time was shorter for BWWP when compared to WWP (Table 4). This may be due to the physical disruption of gluten matrix which provided water absorption into BWWP. Similar observations were reported by Manthey et al. (2004) and Chillo et al. (2008). The weakening of gluten matrix in BWWP caused the significant increase in cooking loss of enriched pasta (Table 4). Alamprese et al. (2007) and Bilgiçli (2009b) also found that matter loss in cooking water was higher in pasta containing buckwheat.

Moreover, Alamprese et al. (2007) detected that buckwheat containing pasta had a significantly higher weight increase during cooking than wheat pasta. The authors explained this observation underlining the high non-starch polysaccharide content of buckwheat with high water absorption capacity and the structure of buckwheat starch granules with irregular structure containing more amorphous areas than those of wheat. The disruption of gluten matrix in buckwheat containing pasta could also promote greater water absorption in comparison with wheat pasta (Manthey et al. 2004). However, the volume increase for BWWP is not significant probably due to the low substitution level in this pasta formulation.

Table 4. Cooking quality of wholegrain wheat pasta (WWP) and buckwheat enriched wholegrain wheat pasta (BWWP)

Pasta sample	Optimal cooking time (min)	Cooking loss (%)	Volume increase
WWP	9.10 ± 0.32[b]	7.83 ± 0.65[a]	2.86 ± 0.24[a]
BWWP	8.05 ± 0.12[a]	9.33 ± 0.40[b]	3.07 ± 0.46[a]

Values are means of three determinations ± standard deviation.
Values of the same column with the same superscript are not statistically different (P < 0.05).

Mineral content of pasta

Mineral contents of WWP and BWWP are presented in Table 5. The substitution of WWF with LBF in the pasta formulation at the level of 20% resulted in significantly increased ($P < 0.05$) contents of P, Mg, K and Zn, which were expected considering the mineral content of WWF and LBF (Table 1). The high K, Mg and P contents of buckwheat flour increased the mineral content of tarhana (Bilgiçli, 2009a), gluten-free tarhana (Bilgiçli, 2009c) and eriste (Bilgiçli, 2009b) which were produced following the modified formulations that included buckwheat flour instead of a part of wheat flour.

Table 5. Effect of cooking on mineral content (mg/100 g dry basis) of wholegrain wheat pasta (WWP) and buckwheat enriched wholegrain wheat pasta (BWWP)

Pasta sample	P	Mg	K	Zn	Fe	Mn
Uncooked						
WWP	268 ± 0.83[a]	94.5 ± 2.81[a]	277 ± 0.32[c]	2.03 ± 0.01[a]	3.92 ± 0.12[a]	3.53 ± 0.14[a]
BWWP	345 ± 16.5[b]	125 ± 5.20[b]	402 ± 8.48[d]	2.32 ± 0.01[b]	4.09 ± 0.28[a]	2.82 ± 0.07[b]
Cooked						
WWP	253 ± 12.1[a]	96.8 ± 2.62[a]	47.7 ± 0.02[a]	2.06 ± 0.10[a]	3.92 ± 0.10[a]	3.58 ± 0.08[a]
BWWP	268 ± 7.39[a]	96.0 ± 1.09[a]	68.6 ± 1.87[b]	2.43 ± 0.16[b]	4.08 ± 0.07[a]	2.87 ± 0.09[b]

Values are means of three determinations ± standard deviation.
Values of the same column with the same superscript are not statistically different ($P < 0.05$).

Processing of dough into both types of pasta (WWP and BWWP) had little or no effect on mineral content (Table 1 and 5). This finding was in accordance with observation of Yaseen (1993) and Manthey and Hall (2007), who reported that pasta processing did not influence the mineral composition of pasta.

During cooking some amount of material is released into the cooking water. The loss of materials for nontraditional pasta is greater than for wheat pasta due to weak gluten matrix of nontraditional pasta that permits a greater leaching of nutrients into the cooking water (Duarte et al., 1996; Resmini and Pagani, 1983). The reduction in mineral content of BWWP during cooking was significantly higher ($P < 0.05$) compared to WWP (Table 5). The reduction in P, Mg and K in BWWP was of 22%, 23%, and 88%, respectively. Contrary, there were no significant reduction in P and Mg for WWP, but the reduction in K was 83%. These results are in agreement with average reduction in minerals of about 28% in spaghetti containing 25% buckwheat bran flour published by Manthey and Hall (2007). These authors reported that the major reduction was detected for K (62%). Other literature data suggest that the decline of 10-30% in minerals during cooking of traditional pasta was typical, with the exception of K that leached out by 67% (Ranhotra et al., 1985; Yaseen et al., 1993).

In contrast, the contents of Zn and Fe in both types of pasta were unaffected by cooking (Table 5). In general, the increased contents of P, Mg and K in enriched dry pasta that had been achieved by substitution of WWF with LBF were decreased and reached the same levels as in WWP after cooking. That implies that enrichment of WWP with LBF at the level of 20% did not improve the mineral content of cooked pasta, although increase in minerals was observed in dry pasta.

CONCLUSIONS

The substitution of WWF with LBF in the pasta formulation at the level of 20% resulted in significantly increased ($P < 0.05$) contents of P, Mg, K and Zn compared to the control pasta (WWP). The increased contents of these minerals in buckwheat enriched wholegrain wheat pasta (BWWP) declined and reached the same levels as in WWP after cooking.

The obtained results suggest that enrichment of WWP with LBF did not result in significant improvement in mineral content of cooked pasta, although increase in minerals was observed in dry pasta.

ABSTRACT: Consumer acceptance of healthy food is subordinated to quality and sensory properties. Nevertheless, red fruit juices can display unpleasant and unacceptable brown colour because of thermal treatments. As an attempt to solve these browning problems in pomegranate juices, the effect of two different heat treatments on the phytochemical composition and colour parameters of pure and blended juices was assessed through storage. *Mollar de Elche* varietal juice was mixed with lemon juice in order to assess the effect of blending on *Mollar de Elche* preservation. Juices were heat treated at 65ºC for 30 s (LTLT pasteurization) or 90ºC for 5 s (HTST pasteurization). Colour parameters and bioactive phytochemicals (individual anthocyanins and vitamin C) were monitored. Blended juices showed a protective effect on colour even though high falls in anthocyanins were recorded. Vitamin C was kept in those juices containing lemon but not in pure pomegranate juices. Heat processing had a remarkable effect on the blend of pomegranate with lemon as LTLT-treatment preserved the bioactive composition much better than HTST. Overall, blended juices protected juice characteristics in a greater extent than *Mollar de Elche* juice.
Key words: *Pasteurization, anthocyanins, ascorbic acid, colour,* Punica granatum *L.*

INTRODUCTION

Pomegranate (*Punica granatum* L.) has been asserted as a natural source rich in bioactive phenolics, such as anthocyanins and ellagitannins, with a myriad of health promotion features (Mena et al., 2011a). Pomegranate fruits are usually earmarked for direct fresh consumption and are also processed by food industry for the elaboration of juices, wines, and jams, among other products. Nevertheless, pomegranate industrialization may display complications since processing stages alter the phytochemical composition and quality parameters of juices (Ferrari et al., 2010; Mikkelsen and Poll, 2002; Yildiz et al., 2009). Likewise, although pasteurization treatments are usually used to preserve pomegranate juices and extend their shelf-life, heat processing varies the aroma profile and result in colour degradation (Maskan, 2006). Consequently, this decline of important marketable quality attributes leads to consumer's disapproval and falls in product sales. Actually, browning and colour alteration are the main problems of some slightly coloured pomegranate varieties as *Mollar de Elche*, cultivar widely grown in Spain (Mena et al., 2011b). Therefore, solving colours alterations of pomegranate juices during storage is the major sticking point for pomegranate juice processing.

Different technological approaches are being developed and could be regarded as promising ways of pomegranate quality preservation (Ferrari et al., 2010; Yildiz et al., 2009); nonetheless, thermal pasteurization is still regarded as the most rentable preservation process for being inexpensive, efficient, and environmentally friendly (Silva and Gibbs, 2010). Then, attending to the widespread use of thermal pasteurization and the industrialization problems for some pomegranate varieties aforementioned, novel and combined solutions should be performed. In this sense, blends of pomegranate with other fruit juices have been emphasized as successful ways to improve and preserve the phytochemical quality of pomegranate juices through storage (González-Molina et al., 2009;

Waskar, 2011). However, the effects of heat treatments in these promising blended juices have not been assayed yet despite they could remarkably alter juice quality.
The aim of the present work was to solve browning problems in slightly coloured pomegranate juices at thermal processing. For that, the effect of two different heat treatments (high temperature-short time and low temperature-long time) on the phytochemical composition and colour parameters of different juices made from cultivar *Mollar de Elche* were assessed for along juices shelf-life. In this way, a pure *Mollar de Elche* varietal juice and a blend of *Mollar de Elche* (75%) plus lemon juice (25%) were compared, after pasteurization, during storage. Likewise, these assays provided basic information on how thermal treatments affect browning developing according to juice composition and storage conditions.

MATERIAL AND METHODS

Mollar de Elche varietal juice was mixed with lemon juice (75%M+25%L, labelled as ML). Likewise, *Mollar de Elche* 100% (labelled as M100) was kept also as control juice. Juices were heat treated at 65 ºC for 30 s (LTLT, low temperature-long time pasteurization) or 90 ºC for 5 s (HTST, high temperature-short time pasteurization) in a semi-tubular pasteurizer 25 L/h (Mipaser Prototype). Later, juices were aseptically placed in screw capped plastic vials (15 mL) and stored in darkness at 25 ºC for 42 days. Triplicate solutions were prepared for each juice.

Colour measurement

Colour measurement was determined after centrifugation as in Mena et al. (2012). Data (CIEL*, *Chroma*, and *Hue* angle) were recorded and processed using the Minolta Software Chromacontrol S, PC-based colorimetric data system.

Identification and quantification of main bioactive phytochemicals

Chromatographic analyses were carried out on Merck-Hitachi liquid chromatograph equipped with a DAD UV–vis L-7455 (Tokyo, Japan). Chromatograms were recorded and processed on a Merck-Hitachi D-7000 HSM PC based chromatography data system. A 20 µL sample was analysed on a Luna C18 column (25 cm x 0.46 cm, 5 µm particle size; Phenomenex, Macclesfield, UK). Chromatographic conditions are described in Pérez-Vicente et al. (2004). UV chromatograms were recorded at 520 nm and chromatographic comparison was used to identify anthocyanins previously reported (González-Molina et al., 2009). Anthocyanins were quantified as cyanidin 3-glucoside by the absorbance of their corresponding peaks.
Ascorbic acid (AA) and dehydroascorbic acid (DHAA) contents were determined by HPLC-UV as described elsewhere and fully detailed in González-Molina et al. (2008). The vitamin C content was calculated as the sum of AA and DHAA.

RESULTS AND DISCUSSION

Characteristic colour parameters of M100 were improved by the addition of lemon juice to *Mollar de Elche* varietal juice (blend ML) (Table 1) (González-Molina et al., 2009). Regarding the influence of thermal treatments on colour parameters during storage (Figure 1), slight increases were displayed in lightness (CIE*L*) for all juices as it has been already reported for untreated juices (González-Molina et al., 2009; Pérez-Vicente et al., 2004). Likewise, M100, both LTLT- and HTST-treated, changed significantly its colour parameters during storage (Figure 1), rendering juices highly browned (higher *Hue* angle) and with a lesser colour intensity (lower *Chroma*). Similar colour alterations were also recorded for unpasteurized pomegranate juice by Martí et al. (2002). On the contrary, blended juices displayed superior colour stability rather than pure *Mollar de Elche* juice. Actually, although variations in *Chroma* and *Hue* angle of ML juices were registered, these changes resulted in minor losses of colour purity and hue when compared to M100. Therefore, blended juices were found to

possess an appealing colour along storage with reduced browning and chromatic characteristics close to the effective juice colour of pomegranate juices (Yildiz et al., 2009). With regard to the treatment effect along storage, pure pomegranate juices (M100) did not reveal significant variations between both heat processing (LTLT and HTST). However, ML-LTLT preserved the colour properties of ML juices much better than ML-HTST by reducing *Hue* increases through storage and, hence, pointing out the importance of heat treatment. In fact, ML-LTLT tendency was quite similar to that recorded for unpasteurized lemon-pomegranate juices where browning occurrence was attenuated because of mixes (González-Molina et al., 2009). Polymerization, anthocyanins degradation, and non-enzymatic browning may be the responsible reactions behind the colour deterioration of red juices (Maskan, 2006).

Table 1. Colour parameters and bioactive phytochemicals of the raw juices

Raw juice	Colour parameters			Bioactive phytochemicals (mg/100mL)	
	CIE*L*	*Chroma*	*Hue* angle	Antocyanins	Vitamin C
M100	75,49 ± 0,14 [a]	28,37 ± 0,72	-4,11 ± 0,08	16,61 ± 0,41	8,86 ± 0,73
ML	68,28 ± 0,22	46,50 ± 0,42	-1,19 ± 0,03	13,37 ± 0,42	8,50 ± 0,75
p-value	* * * [b]	* * *	* * *	* * *	n.s.

Statistical treatment notes: [a] Values are expressed as means of triplicate determinations ± standard deviation [b] Significant differences ($p < 0.001$) between raw juices parameters were determined by Student's t-test.

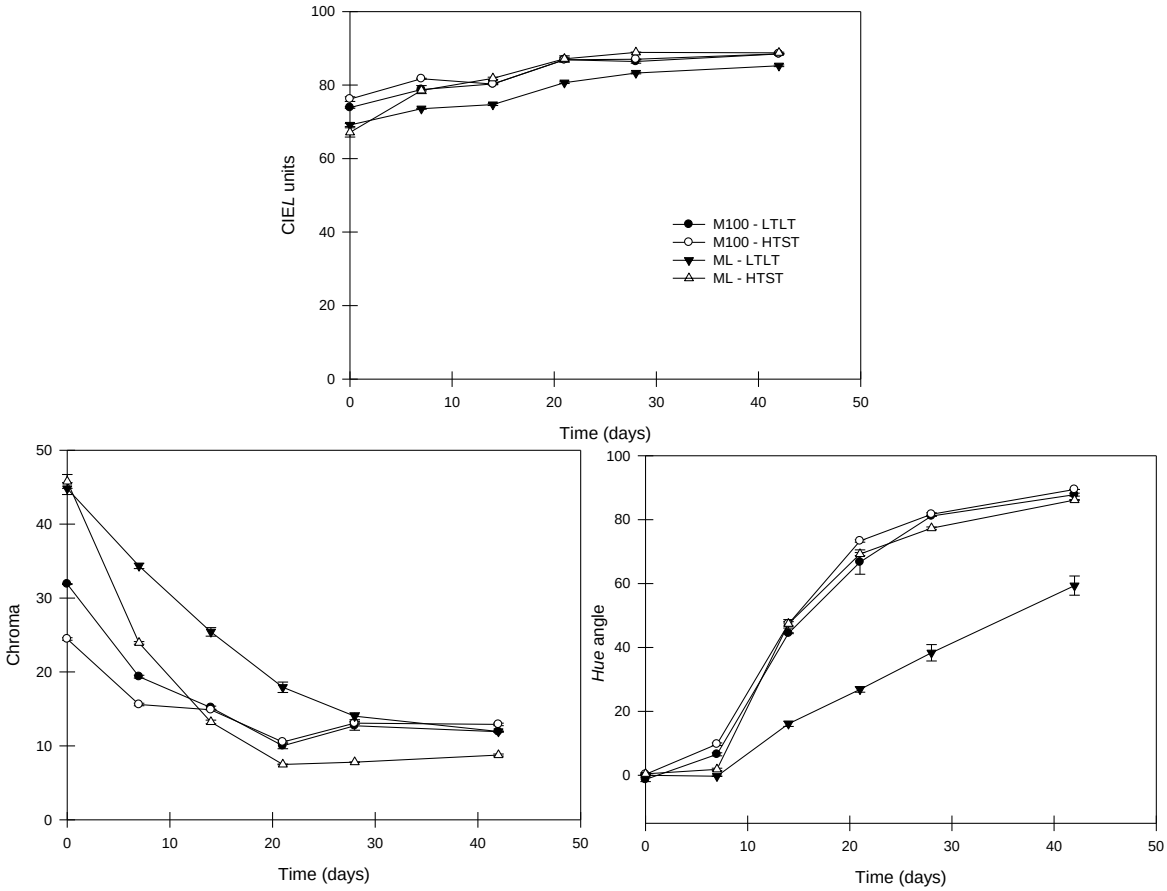

Figure 1. Evolution of colour parameters through storage of pasteurized pomegranate juices

With regard to anthocyanins, the phenolic pigments responsible for the red colour of pomegranate juices, decreases in their concentration during storage are displayed in Figure 2. Drops in anthocyanins were marked by the kind of pasteurization used. Likewise, Mikkelsen and Poll (2002) emphasized how the extent of thermal treatment may affect anthocyanins stability owing to enzymes inactivation. In fact, HTST-treatment resulted in two-folds more pigment destruction than LTST-treatment in ML juice, justifying the severe colour alterations of ML-HTST aforementioned. Decreases in anthocyanins of pure pomegranate juices (M100-LTLT and M100-HTST) did not undergo important differences with respect to the thermal treatment used. Likewise, anthocyanins decreases were well correlated to *Chroma* variations ($r = 0.79$, $p < 0.001$) but not to *Hue* angle (no strong correlation was established) (Alighourchi and Barzegar, 2009; Fischer et al., 2011). Consequently, reductions in anthocyanin content would be responsible for the *Chroma* variations showcased herein for all the juices.

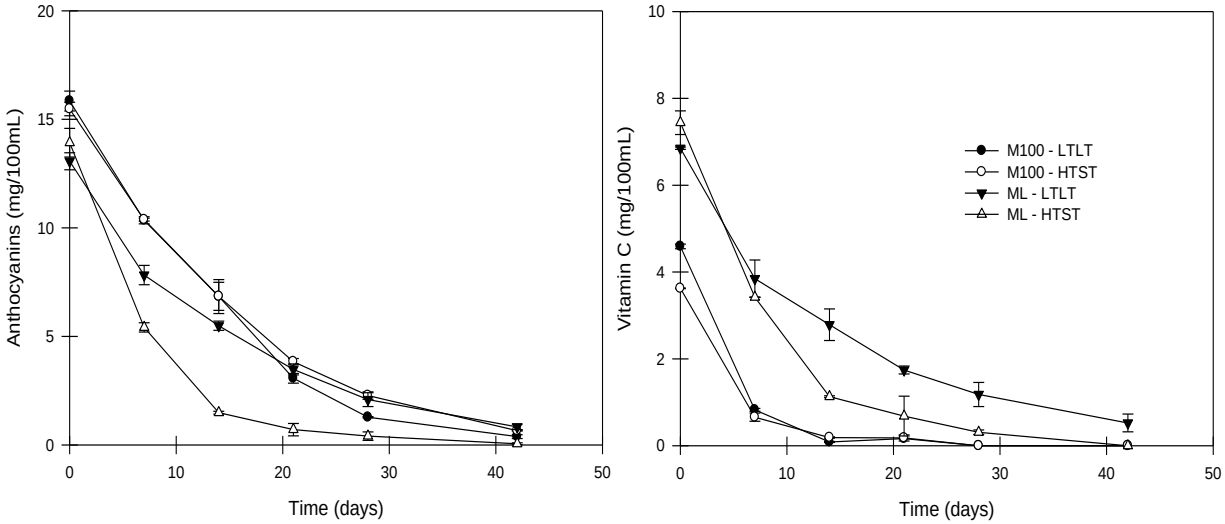

Figure 2. Evolution of anthocyanins and vitamin C through storage of pasteurized pomegranate juices

Concerning vitamin C evolution through storage, the full degradation of this vitamin was registered for M100 at the beginning of the storage (Figure 2). ML juices presented always the lowest degradation rates and, thus, vitamin C in pomegranate-lemon blends (ML-LTLT and ML-HTST) was more stable than in pure pomegranate juices (M100), as expected (Martí et al., 2002). González-Molina et al. (2009) pointed out that vitamin C of lemon juice was preserved when mixed with pomegranate juice and a similar protective effect of vitamin C by combining juices was here noticed. Regarding the thermal treatment influence, LTLT protected the vitamin C content of juices in a greater extent than HTST. Likewise, it should be mentioned that ML-HTST juice had remarkably variations in anthocyanins and colour parameters besides the strong vitamin C decreases. Consequently, the protective role of anthocyanins in vitamin C preservation (González-Molina et al., 2009) was not observed for this treatment although the concomitant degradation of vitamin C and anthocyanins could account for this result (García-Viguera and Bridle, 1999). Actually, the mutual degradation of both phytochemicals may explain how higher vitamin C degradation rates are correlated well with higher anthocyanins degradation rates ($r = 0.81$, $p < 0.01$). Moreover, the degradation of both phytochemicals may boost browning process (Maskan, 2006) as colour parameters reflected for ML-HTST. On the contrary, lower losses of both vitamin C and anthocyanins in ML-LTLT juice as well as minor colour variations would assert the role of phytochemicals degradation in browning.

CONCLUSIONS

Pasteurization of pomegranate juice mixed with lemon showed to protect the juice characteristics of pasteurized *Mollar de Elche* juices. In fact, blended juices preserved the chromatic composition of slightly coloured *Mollar de Elche* juices as well as enhanced and/or retained their bioactives. Moreover, a specific pasteurization treatment should be applied for each juice in order to achieve the highest quality of rich-in-phytochemicals pomegranate juices.

ABSTRACT: The study is based on the investigation of total phenol contents and antioxidant potential of blackberry and sour cherry juices blended with apple juice. The objective was to determine the effect of apple juice added in different amount on total polyphenols and antioxidant activity of blended mixtures. Blackberry, sour cherry and apple juices were made from concentrated fruit juices. Apple juice was used for the correction of acidity. The content of the total polyphenols in fruit juices was determined using the Folin-Ciocalteu reagent while the antioxidant activity was investigated using FRAP method. The total polyphenols content as well as antioxidative activity were gradually decreased in all tested mixture with the increasing amount of apple juice. However, it was concluded that the mixture of blackberry or sour cherry juice with apple juice was sensory more acceptable than the juices obtained from only one type of small fruit.
Key words: *blackberry, sour cherry, apple, juice, total polyphenol, antioxidative capacity*

INTRODUCTION

Berries such as blackberry and sour cherry are the fruits which can be eaten either as a fresh fruit or as processed food in juices, jams, dried fruit, ice cream, etc (Amakura et al., 2000). These fruits are among the most important sources of polyphenol compounds in our diets, especially hydroxybenzoic and hydroxycinnamic acid derivatives, anthocyanins, flavonols, catechins, and tannins (Manach et al., 2004), which continue to be present in their processed products (Heinonen et al., 1998). The significance of the antioxidant properties of foods in the maintenance of health and in protection from degenerative diseases is of growing interest among scientists, food manufacturers, consumers, and health organizations (Müller et al., 2010; Obón et al., 2011; Bermudez-Soto &Tomas-Barberan, 2004). The Food Standards Agency (FSA) has established that increasing consumption of fruits and vegetables to 5 or more daily servings provides a desirable intake of antioxidants and improves human health (FSA, 2010). For this reason, there is a trend in the food industry toward functional foods, with health promoting effects based on their antioxidant properties (Mazza et al., 2002; Wootton-Beard & Ryan, 2011). In addition, the results of *in vivo* experiments have shown that the consumption of small fruit juices contributes to maintaining of human health (Netzel et al., 2002;García-Alonso et al., 2006).
Fruit juice concentrate is the result of an industrial process of evaporation of excess water by heat treatment in order to obtain the product with better conditions for storage, transport, and preservation. According to some authors processing of food can increase flavonol levels in the food (Stewart et al., 2000). Fruit juice processing can increase the flavonoid content because extraction processes can release flavonoids from the peel, and these flavonoids might be better absorbed than those from the fresh fruits. Therefore, small fruit juice concentrates could be very suitable for the production of functional foods.
In this study blackberry and sour cherry juices were made from the concentrate fruit juices. However, juices of small fruits cannot be consumed in large quantities due to their sensory properties, especially acidity. In order to improve their sensory properties they are mixed with

other juices. The most common juice used for this purpose is an apple juice. Considering the lower antioxidative potential of apple juice, the main objective of this work was to investigate the influence of apple juice added in different amount in blackberry and sour cherry juices on their total polyphenols content and antioxidative capacity. The other objective was to evaluate the sensory acceptable amount of small fruit juice in the mixture with apple juice that would still have a significant level of total polyphenols and high antioxidative effect.

MATERIAL AND METHODS

Preparation of juices

Blackberry, sour cherry and apple juices were obtained from concentrated fruit juice, diluted to a dry matter prescribed by regulation (Službeni Glasnik, Republike Srbije, 2011). Blackberry and sour cherry juices were mixture with 0, 20, 40, 60 or 80 % of apple juice.

Total polyphenol content

The total polyphenols content was determined by using the Folin-Ciocalteu method as described in the work of Fu et al., (2011). Two hundred microliters of sample solution diluted in appropriate solvent was mixed with 1000 µl of 1:10 diluted Folin-Ciocalteu reagent. After 6 min, 800 µl of sodium carbonate (75 g/l) was added. The sample stood for 120 min at room temperature before the absorbance was measured at 760 nm. As a control, the solvent was used instead of the diluted sample. Gallic acid was used as a standard, and a total polyphenol content was expressed as a mg gallic acid equivalent (mg GAE)/l of juices. Triplicate measurements were taken and mean values were calculated.

Ferric-reducing antioxidant power (FRAP) assay

The FRAP test is based on the reducing potential of antioxidant substances. This method was used to determine the antioxidant activity of juices. FRAP method was done according to the procedure described in the work of Fu et al. (2011). Briefly, FRAP reagent was made of acetate buffer (300 mM, pH 3.6), TPTZ solution (10 mM TPTZ in 40 mM HCl) and $FeCl_3$ solution (20 mM in water) in a volume ratio of 10:1:1, respectively. A sample containing 3 ml of freshly prepared FRAP and 100 µl of the diluted sample was incubated at 37 °C for 4 min and the absorbance was measured at 593 nm. The standard curve was constructed using $FeSO_4$ solution, and the results were expressed as µmol Fe (II)/ l of juices. All test analyses were run in triplicate.

Statistical analysis

All measurements were done in triplicate and results were expressed as mean ± standard deviation. The results of total polyphenol content and antioxidant capacity (FRAP method) were analysed using ANOVA and Tuckey's HSD test.

RESULTS AND DISCUSSION

Small fruit juices such as blackberry and sour cherry juices, could not be consumed in large quantities because of its high acidity. In order to reduce their acidity the apple juice at different proportion was added. The aim of this study was to evaluate how the addition of apple juice (0, 20, 40, 60 and 80 %) in these acidic juices affected their total phenolics content and antioxidant capacity.

The Folin-Ciocalteu method measures the reduction of the reagent by phenolic compounds with the formation of a blue complex that can be measured at 760 nm against gallic acid as a standard (Imeh & Khokhar, 2002). As it could be expected, the values for total polyphenols gradually decreased in both small fruit juice mixtures, with increasing the proportion of apple juice. The content of total polyphenols in the studied juice samples is shown in Fig. 1. In addition, in 100 % apple juice the total polyphenol content was 522.35 ± 14.73 mg GAE/l of juice. The lowest amount of total phenols in blended juices was determined for a sample with

20 % of sour cherry juice (773,11 mg GAE/l of juice), while the highest amount was in 100 % of sour cherry juice (2485,57 mg GAE/l of juice) (Fig.1).

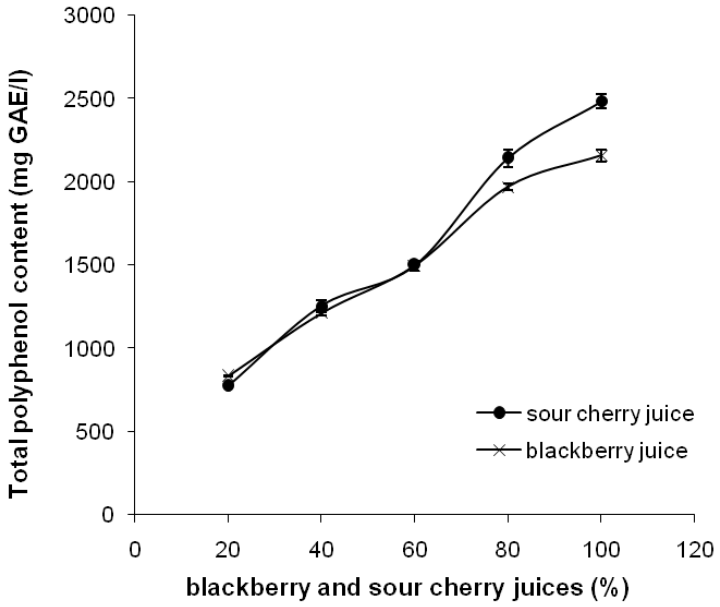

Fig.1. The total phenols content of small fruit juices blended with apple juice

The values obtained for the antioxidant activity with FRAP method also decreased with the addition of apple juices in small fruit juices. The values obtained for antioxidative activity of tested juices by FRAP assay are shown in Fig. 2. In addition, the FRAP value for 100 % apple juice was 4776.43 ± 72.49 µmol Fe (II)/l of juice. The lowest FRAP value of the blended juices was obtained for a sample with 20 % of sour cherry juice (7188.95 µmol Fe (II)/l of juice), while the highest antioxidative activity was performed for 100 % of blackberry juice (30907.14 µmol Fe (II)/l of juice) (Fig. 2).

Generally, the values of antioxidative activity were higher in sour cherry mixtures than in blackberry mixtures, while the value of total polyphenols were similar in both studied juice mixtures until the 60 % of small fruit juice content. Further increase in the proportion of small fruit juices to 80 and 100 % resulted in higher phenolic contents in mixtures with sour cherry juices in relation to blackberry juices. Also, comparing these results with literature, similar values were reported for these two methods in a work of Fu et al., (2011); Piljac-Žegarac & Šamec, (2011); Müller et al., (2010); Piljac-Žegarac et al., (2009); Bermudez-Soto & Tomas-Barberan, (2004); and Deighton et al., (2000).

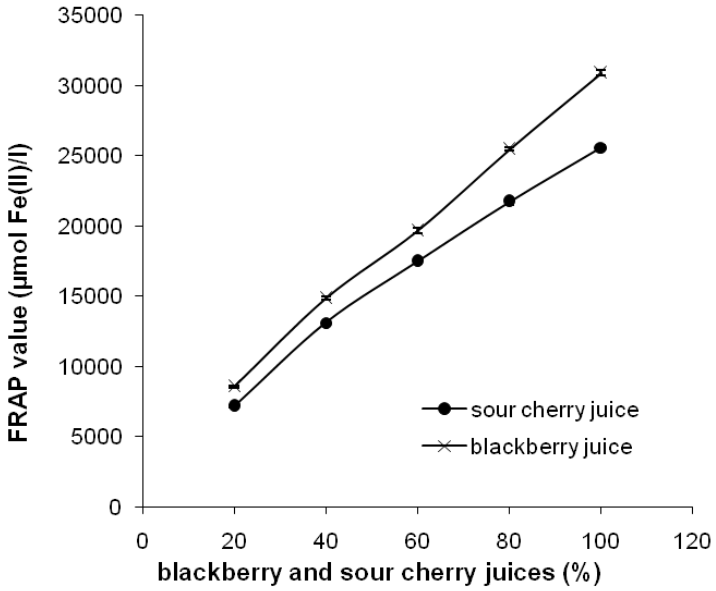

Fig. 2. The antioxidative activity of blackberry and sour cherry fruit juices blended with apple juice

The correlation between total polyphenol content and antioxidant activity is presented in Fig. 3.

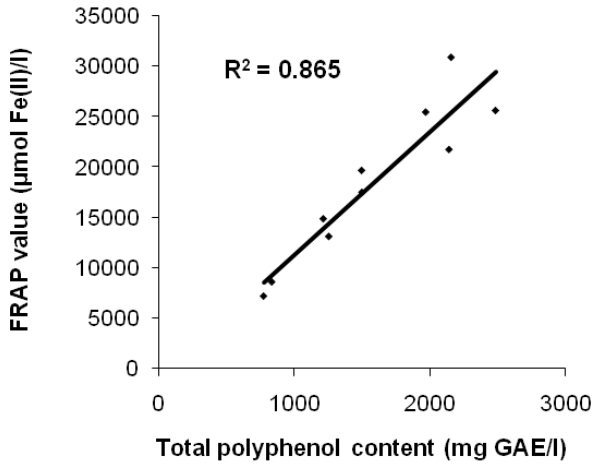

Fig. 3. Correlation between the antioxidant capacities and total phenol content

A highly positive correlation (R^2= 0.864) between the FRAP value and total phenolic content indicated that phenolic compounds could be one of the main components responsible for antioxidative capacity of these juices. A similar value for the correlation coefficient between these two methods was obtained in the work of Fu et al. (2011). However, the better correlation coefficient was performed in the work of Deighton et al. (2000).

Preliminary sensory analysis showed that the addition of apple juice in blackberry and sour cherry juices was necessary in a certain amount. The best evaluated samples were equally the mixture with 40 and 60 % of either blackberry or sour cherry juices (data not shown). This means that the reduction of total polyphenol content and antioxidant capacity was approximately 50 % with the addition of apple juice in best-rated samples. However, these results suggest that in the production of small fruit juices the amount of small fruit juice in the mixture with the apple juice could be even 60 %. The juices with such a high proportion of small fruit would certainly represent important sources of polyphenols in our diet and could be regarded as functional food.

CONCLUSIONS

Blackberries and sour cherries are widespread in our country and present a rich sources of flavonoid and other polyphenols. It should be emphasized that the consumption of small fruit juices is highly desirable due to its strong antioxidative capacity.The results obtained in this study showed that even though the addition of apple juice reduced the antioxidant potential in blackberry and sour cherry juices, the best sensory evaluated samples still had a high level of total polyphenols and high antioxidant capacity. Also, these results support the previous findings that small fruits and their products possess potent antioxidant effects and make foundation for further research in order to enhance health benefits of small fruit.

ABSTRACT: Tomato (*Solanum lycopersicum*) is the world's second largest vegetable crop after the potato and a major source of lycopene. Lycopene is a red carotenoid and an efficient free radical scavenger, which presence in the diet positively correlates with reduced risk of chronic diseases. Although tomatoes are usually used as a salad vegetable, more than 80 % of tomatoes consumption comes from processed products such as ketchup, tomato juice, pickled tomatoes, sauces etc. Jam is another possibility of tomato processing. Tomato jam was produced in an open 120 liters oil jacketed stainless steel kettle. The proportion of sugar to fruit was 1:2.5, while the final concentration was 65°Brix (Bx). Lycopene content was estimated spectophotometrically at 503 nm and concentration was calculated using molar extinction coefficient of 17.2 x 10^4 $M^{-1}cm^{-1}$. An examination of the antioxidant capacity of samples was performed using DPPH assay. Obtained results indicate that lycopene content of tomato jam was slightly lower compared to fresh ones (79.66 mg/kg in fresh tomatoes and 75.54 mg/kg in tomato jam), while antioxidant capacity has increased during processing (0.335 and 1.195 mM Trolox equivalents per kilogram of samples for fresh tomatoes and tomato jam, respectively). Moreover, heat processing of tomatoes could result in increased bioavailability of lycopene. Based on the results, it may be concluded that tomato jam can be a high-quality product which can be a desirable component of healthy diet.
Key words: *tomato jam, lycopene, antioxidant capacity*

INTRODUCTION

Tomato (*Solanum lycopersicum*) is the world's second largest vegetable crop after potato, with more than 152 million tons produced in 2010 (http://faostat.fao.org). It is native to the Andes of South America and evolved from the cherry tomato (Jy et al., 2004). The world consumption of tomato is increasing, but varies greatly between countries and regions (Slimestad and Verheul, 2009). Although tomatoes are usually used as a salad vegetable, more than 80 % of tomatoes consumption comes from processed products such as ketchup, tomato juice, pickled tomatoes, sauces, paste, purée, etc. (Gould, 1992). Tomato is a very important component of healthy diet and rich source of natural bioactive compounds. Numerous studies have shown that increased consumption of tomato and tomato products has been linked with decreased risk of various chronic diseases, such as cardiovascular and cancer diseases (Heber and Lu, 2002). Compound which may be responsible for such effects of tomato is lycopene. However, many other compounds (polyphenols, vitamins, minerals) can contribute to beneficial effects of tomato consumption. The nutritional value of tomatoes varies with the stage of maturity, with the highest concentration of bioactive compounds in fully ripe tomatoes (Motamedzadegan and Shahiri Tabarestani, 2011).
Lycopene is a red colored acyclic carotenoid without provitamin A activity, which contains 11 conjugated double bonds arranged linearly in the all-*trans* form (Stahl and Sies, 1996). In addition to conjugated, lycopene contain and 2 unconjugated double bonds, but do not have the terminal β-ionic ring. The main dietary sources of lycopene are tomato and tomato-based products (more than 80 %), but it is also found in moderate to high concentrations in some other fruits and vegetables, such as watermelon, red grapefruit, apricots, guava and papaya (Clinton, 1998). The lycopene content of tomato varies significantly with ripening and the variety of tomatoes and is linked with the content of insoluble solids (Sharma and Le Maguer, 1996; Thompson et al., 2000).

The first investigations on bioactive effects of lycopene were shown that intraperitoneally injected lycopene increases the survival rate of X-irradiated mice and the resistance of mice toward bacterial infections (Forssberg et al., 1959; Lingen et al., 1959). After these first studies, numerous of epidemiological and clinical researches indicate protective effects of lycopene on various diseases, e.g., cardiovascular diseases, prostate, gastrointestinal and epithelial cell cancer, osteoporosis, cataract etc. (Rao and Rao, 2007). Biological activities of lycopene include antioxidant activities (singlet oxygen quenching, scavenging of peroxyl radicals), induction of cell-cell communication and growth control (Martinez-Valverde et al., 2002). Lycopene is one of the most efficient natural antioxidants, probably due to the presence of a long chain of conjugated double bonds. However, the increased reactivity of lycopene compared to other carotenoids is related to the presence of the two nonconjugated double bonds (Conn et al., 1991). All-*trans* isomeric form of lycopene is primarily present in nature, but it can undergo mono or poly isomerization during tomato processing and storage by light, thermal energy and chemical reactions to its *cis*-isomeric form. The formation of *cis* isomers may decrease biological activity of lycopene (Lee and Chen, 2002). Lycopene is a relatively stable under the conditions of thermal processing, but its stability varies in different food systems due to the complex nature of food components (Agarwal et al., 2001). Some studies indicate that uptake of lycopene is greater from heat processed tomato products than from raw tomato (Rao and Agarwal, 1998).

In addition to lycopene, tomatoes contain many other valuable components which can contribute to a healthy diet. These compounds include flavonoids and phenolic acids, ascorbic acid, vitamin E and carotenoids. Polyphenols are very efficient natural antioxidants and are associated with reduced risk of cardiovascular diseases and some type of cancer. The main phenolic compounds of tomato are quercetin, naringenin, rutin and chlorogenic acid (Slimestad and Verheul, 2009).

The main objective of this study was to determine the lycopene content and antioxidant properties of tomato jam and raw tomato used in jam production.

MATERIAL AND METHODS

Tomato used in jam production was obtained from experimental school estate “Radmilovac” of Faculty of Agriculture, Belgrade. Hexane, butylated hydroxytoluene, sodium acetate, glacial acetic acid, 2,2-diphenyl-1-picrylhydrazyl (DPPH), and 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid (Trolox®) were purchased from Sigma-Aldrich (Steinheim, Germany). Acetone was obtained from Fisher Scientific (Loughborough, United Kingdom).

Jam production

Tomato jam was produced in an open 120 liters oil jacketed stainless steel kettle. After sorting, the tomatoes were washed in cold water and clean and sound tomatoes were crushed. The obtained tomato pulp (50 liters) with 4 % w/w of soluble dry matter was blended with ascorbic acid (prevents oxidation) and one-half of the total sugar to be added (10 kg). The mixture was heated to 90°C with mechanical stirring (40 rpm) to evaporate part of the water. When the mixture was well homogenized and soluble solids content (Brix) was significantly increased, the rest of the sugar was added to reach the total sugar level of 65°Brix. At the same time, the pH was adjusted to 3.3 ± 0.1 with a citric acid solution (10 % w/v) and required amount of pectin solution (5 % w/v solution of high methoxyl pectin HM 64020 in water) was then added. Afterwards, the temperature was raised to 95°C in order to achieve final soluble solids content and enable the filling of hot jam without subsequent sterilization. When the finished point at 65°Brix and the appropriate consistency was reached, the hot jam was poured into clean transparent glass jars. The samples were stored in dark place at room temperature. Dry matter of samples was determined using an Abbe refractometer (Bellinghan & Stanley Ltd., United Kingdom).

Lycopene determination

Total lycopene content was determined spectrophotometrically according to method described by Perkins-Veazie *et al*. (2001). A 1 g of samples (tomato jam or fresh tomato) was added to a mixture consisting of 25 ml of hexane, 12.5 ml of acetone, 12.5 ml of ethanol and 0.05 % (w/v) butylated hydroxytoluene. The mixture was stoppered and placed on an orbital shaker to mix at 180 rpm for 15 minutes (temperature of mixing was 5°C). After shaking, 7.5 ml of cold deionized water was added and the mixture was agitated for another 5 min. The suspension was left at room temperature for 10 minutes to allow separation of polar and non-polar layers. The absorbance of non-polar (upper) layer was measured in a 1 cm path length glass cuvette at 503 nm versus a blank of hexane solvent using Jenway 6105 UV/Vis spectrophotometer (Jenway, United Kingdom). The lycopene content was calculated using following equation:

$$\text{Lycopene content (mg/kg)} = \frac{}{}$$

where the molar extinction coefficient of 17.2 x 10^4/Mcm is that reported by Zechmeister et al. (1943).

Determination of antioxidant capacity - DPPH assay

The total antioxidant capacity of samples was determined by DPPH assay using the modified procedure described by Kaneda et al. (1995). For analysis of antioxidants, approximately 10 g of samples was homogenized and dissolved in 30 ml of ethanol solution (70 % v/v). The samples were mixed for 10 minutes at 5°C and then centrifuged at 9000 rpm for 10 minutes. The supernatant was poured off and pellet was re-extracted with 15 ml of ethanol solution by the same procedure. The obtained supernatants were combined and the total volume was adjusted to 50 ml with 70 % v/v ethanol solution.

The extracts of samples (0.2 mL) were added to the DPPH solution (2.8 mL) (mixture of 1.86 x 10^{-4} mol/L DPPH in ethanol and 0.1 M acetate buffer (pH 4.3) in ratio 2:1) and mixed vigorously. After 60 minutes of incubation in a dark place, the absorbance was measured at 525 nm. The standard curve was constructed using 1 mM Trolox solution and the results were expressed as mM Trolox equivalents (TE) per kilogram of sample (tomato or tomato jam).

Statistical analysis

All measurements were conducted in triplicate and data were expressed as mean ± standard deviation. The significance of differences among means was tested using t-test for independent samples.

RESULTS AND DISCUSSION

Tomato and tomato based products are the main dietary source of lycopene, one of the strongest natural antioxidants. Dry matter, lycopene content and antioxidant activity of tomato jam and raw tomato used in its production are presented in table 1. Lycopene content of fresh tomato used in this study are slightly higher than those reported by Martinez *et al.* (18.6-63.37 mg/kg fresh weight) and Clinton (8.8-42.0 mg/kg fresh weight), but similar to those of Nguyen and Schwartz (31-77 mg/kg fresh weight).

Table 1. Dry matter, lycopene content and antioxidant capacity of raw tomato and tomato jam

Samples	Dry matter (%)	Lycopene (mg/kg fresh weight)	Lycopene (mg/kg dry matter)	DPPH (mM TE/kg sample)
Raw tomato	4.0	79.66 ± 1.14	1991.50 ± 28.56	0.335 ± 0.008
Tomato jam	65.0	75.54 ± 1.38	908.91 ± 16.59	1.195 ± 0.059

Values of lycopene content and antioxidant activity are means of three determinations ± standard deviation

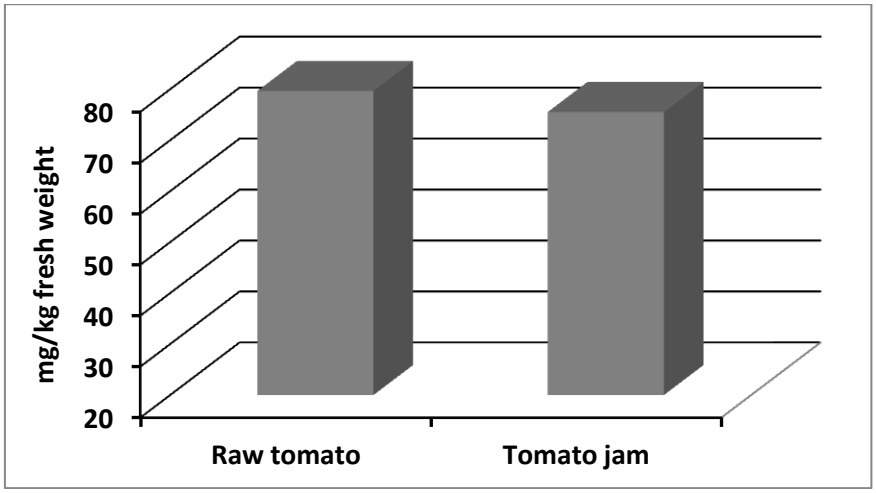

Figure 1. Lycopene content of raw tomato and tomato jam

Tomato jam has statistically significantly lower content of lycopene ($p = 0.018$; $p<0.05$) compared to fresh tomato used in its production. However, the lycopene content of tomato jam was lower by only 4.12 mg/kg in comparison with fresh tomato. The lycopene content expressed as mg/kg dry matter was more than twice lower than in fresh tomato. Given that 8.31 % of tomato jam dry matter was originating from tomato, the absolute content of lycopene was reduced by 54.34 % during the jam production.

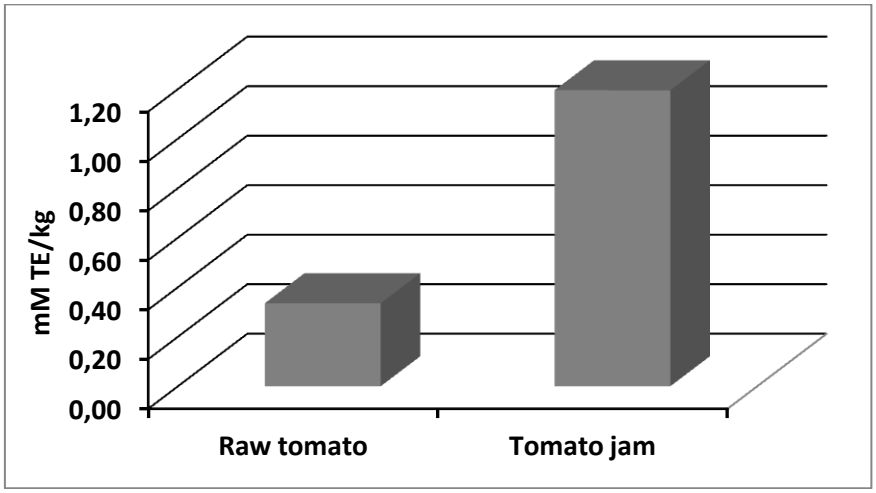

Figure 2. Antioxidant capacity of raw tomato and tomato jam

Antioxidant capacity of tomato jam was very significantly higher compared to raw tomato (more than 3.5 times). This result is in accordance with those found in literature where Wang *et al.* (1996) and Takeoka *et al.* (2001) have reported that heat-processed tomato juice and

tomato paste had a much higher antioxidant capacity than fresh tomato. Such increases in antioxidant capacity as a result of heat processing are still not completely explained.
In addition, tomato jam was characterized by typical red-brown color with low granulous texture and shiny surface, enjoyable fruit taste and intense pleasant fragrance (internal laboratory sensory evaluation).

CONCLUSIONS

Results showed that the lycopene content of tomato jam was slightly, but significantly lower than in fresh tomato. In the other hand, the absolute lycopene content was reduced more than 50 % during thermal processing of tomatoes into jam. However, many studies have shown that uptake of lycopene is greater from heated-processed tomato products than from unprocessed tomato. The reason for this occurrence is probably enhanced bioavailability due to breaking down of sturdy cell walls, thus making lycopene more accessible. Antioxidant capacity of tomato jam was more than 3.5 times greater in comparison with raw tomato. In addition, tomato jam had pleasant sensory profile with retained distinctive tomato aroma. Obtained results suggest that tomato jam can be a high-quality product which can be a desirable component of healthy diet.

ABSTRACT: Fruiting bodies of some wild and cultivatable mushrooms contain medicinal compounds which are being used in traditional medicines and cosmetics. Champignon mushroom (*Agaricus bisporus*) is the most widely cultivated species of edible mushroom worldwide. This paper focuses on antioxidant and antimicrobial importance of *A. bisporus*. Water-soluble polysaccharide-enriched fraction was isolated from the dry carpophores of *Agaricus bisporus*. Antioxidant activities were investigated using *in vitro* assay systems: 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging and chelating ability on ferrous ions. Antimicrobial activity was tested against Gram positive and Gram negative bacteria *in vitro* by disk diffusion method in order to determine the zones of inhibition. At concentrations of 0.1-10 mg/ml, the scavenging abilities of *A. bisporus* ranged between 12.3-75.5 %. The radical scavenging ability of the positive controls -tocopherol and ascorbic acid, at the concentrations of 0.1-20 mg/ml, were between 79.9-80.8 and 80.6-91.1 %, respectively. Polysaccharide extract from *A. bisporus* showed steadily increasing chelating ability as concentrations increased to 88.2 % at 20 mg/ml. The chelating ability of the citric acid was between 7.2-10.7 %, at the concentrations of 0.1-20 mg/ml. The study of antimicrobial potential of polysaccharide extract showed more potent activity against Gram-positive *Enterococcus faecalis* ATCC 49532 (26.7 ± 0.2 mm), *Bacillus cereus* 10876 (27.5 ± 0.4 mm), *Geobacillus stearothermophylus* ATCC 7953 (22.8 ± 0.3 mm) than Gram-negative bacteria *Pseudomonas aeruginosa* ATCC 35032 (10.4 ± 0.6 mm), *Proteus hauseri* ATCC 13315 (12.1 ± 0.1 mm) *Escherichia coli* (0157:H7) 35150 (12.7 ± 0.4 mm) with exception of *Klebsiella pneumoniae* ATCC 27736 (22.3 ± 0.2 mm).
Key words: *Agaricus bisporus, antioxidant, antimicrobial, polysaccharide extract*

INTRODUCTION

Agaricus bisporus (J. Lge) Imbach also called champignon, white mushroom, common mushroom or button mushroom is one of the most well-known, most cultivated and most used edible mushrooms. Human beings have been consuming champignons since Ancient times. Ancient Egyptians believed that the *Agaricus bisporus* held the key to immortality, while Ancient Romans revered the mushroom as one of the foods of the gods. During the 1600s, the French began to cultivate *Agaricus bisporus*, using dark underground tunnels beneath Paris that are still used for mushroom growing today (Spencer, 1985). *Agaricus bisporus* is now cultivated in at least 70 countries around the world (Cappelli, 1984). Global production in the early 1990s was reported to be more than 1.5 billion kg, worth more than US$ 2 billion (Chang, 1993).

In addition to its own unique flavor, eating this mushroom may provide important health and nutrition benefits when made a regular part of the diet. *Agaricus bisporus* is a source of excellent nutrition, providing a range of vitamins, minerals, carbohydrates, protein and phytochemicals that are important for human health. It provide the minerals selenium, copper, potassium, iron and zinc, as well as a range of vitamins including thiamin, riboflavin, pantothenic acid, niacin and vitamins C and D (Chang, 1993; Spencer, 1985).

In addition to the nutritional benefits of this mushroom, it may have useful medicinal properties that support health and well-being. *Agaricus bisporus* significantly stimulated

immune activity, specifically cytokines and enzymes that are responsible for inflammation (Kozarski et al., 2011; Ren et al., 2008; Wu et al., 2007). *Agaricus bisporus* may prevent breast cancer through an aromatase-inhibiting action that reduces enzymes that increase estrogen levels and drive breast cancer growth, making the mushroom both hormone-balancing and chemo-preventative (Chen et al., 2006; Grube et al., 2001).
Recently, there has been growing interest for polysaccharides of mushrooms, since there has been reported a great influence of these components on human health. Polysaccharides are potentially useful biologically active ingredients for pharmaceutical use, such as for immune regulation, for anti-radiation, anti-blood coagulation, anti-cancer, anti-HIV and hypoglycemic activities (Klaus et al., 2009; Kozarski et al., 2009; Yang et al., 2005; Yoon et al., 2003; Lee et al., 2002). The mushroom-derived polysaccharides lentinan, schizophyllan, and krestin have been accepted as immunoceuticals in Japan, Korea and China (Zheng et al., 2005). The activity of polysaccharides is determined by their conformation, composition and size (Bohn and BeMiller, 1995).
In the present study, we have determined the antioxidant activity of polysaccharide enriched water soluble extract from *Agaricus bisporus* using assays pertaining to different ways of antioxidant action. Antimicrobial potential of polysaccharide extract was observed on several microorganisms of medicinal importance.

MATERIAL AND METHODS

A. bisporus Horst U1 fruiting bodies were obtained from the Mushroom Experimental station (Horst, The Netherlands). Crude polysaccharide extracts were prepared by hot water extraction as described before (Klaus et al., 2011). Polysaccharides were semi-purified by precipitation in 65% ethanol and repeated washing to remove the excess mannitol and ethanol-soluble phenolic compounds. The preciptitate was dried at 42 °C, in vacuum and stored for further use. The yield of extract was 3.7 ± 0.2 g/100g express on a dry weight basis of fruiting body.

Antioxidant activity assays

Antioxidant activities were investigated using *in vitro* assay systems: 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging capability and chelating ability on ferrous ions.

Scavenging capability for DPPH radicals

The assay was done according to the modified method of Ekanayake et al, (2005). In the first series the 2 ml of extract dissolved in dimethyl sulfoxide (DMSO) was mixed with 1 ml freshly prepared DMSO solution of 0.2 mM DPPH. In the second series, extract (2 ml) was mixed with 1 ml DMSO solution. Both series were placed in the dark at room temperature for 1 hour. The radical-scavenging activity was calculated as a percentage of DPPH discoloration using the equation: $[1-(A_i-A_j)/A_c]$ x100, where A_i was the absorbance of 2 ml extract mixed with 1 ml DPPH solution, A_j was the absorbance of 2 ml extract mixed with 1 ml DMSO solution and A_c was the absorbance of blank-2 ml of DMSO mixed with 1 ml of DPPH solution. Ascorbic acid, butylated hydroxytoluene (BHT) and α-tocopherol dissolved in DMSO were used as the positive control. The EC_{50} value (mg extract/ml) is the effective concentration at which DPPH radicals were scavenged by 50% and was obtained by interpolation from linear regression analysis**.** EC_{50} was calculated concerning concentration of 5 mg/ml at which extract reached maximum in DPPH radical scavenging activity.

Chelating ability on ferrous ions

Polysaccharide powder (0.1 to 20 mg/ml, 1 ml) in Milli-Q water was mixed with 3.7 ml of methanol and tested for Fe^{2+} chelating ability according to the method of Dinis et al., (1994). The Fe^{2+} was monitored by measuring the formation of ferrous iron-ferrozine complex at 562 nm. The lower the absorbance of the reaction mixture, the higher the Fe^{2+}-chelating ability. The EC_{50} value (mg extract/ml) is the effective concentration at which ferrous ions were chelated by 50%. Citric acid and ethylenediaminetetraacetic acid (EDTA) were used for comparison.

Antimicrobial activity

Microorganisms
Antimicrobial activities of the crude polysaccharide extract of *A. bisporus* on Gram-positive *Enterococcus faecalis* ATCC 49532, *Bacillus cereus* 10876, *Geobacillus stearothermophylus* ATCC 7953 and Gram-negative bacteria *Pseudomonas aeruginosa* ATCC 35032, *Proteus hauseri* ATCC 13315, *Escherichia coli* (0157:H7) 35150 and *Klebsiella pneumoniae* ATCC 27736 were investigated in this study. The bacteria were obtained from the culture collection of the Department for Industrial Microbiology, University of Belgrade - Faculty of Agriculture. All bacterial strains were stored at +4^{o}C on appropriate agar slants, subcultured every two weeks and checked for purity.

Screening of antimicrobial activity of extract by disc-diffusion test
The disk-diffusion method was applied for the evaluation of the antibacterial activities of the polysaccharide extract. The bacterial cells were washed from the surface of agar and suspended in sterile saline to a concentration of 1.0x10^{5} CFU/ml. Appropriate agar in Petri dish was seeded with 100 µl of bacterial suspension. The crude polysaccharide extract was dissolved in DMSO to a final concentration of 30 mg/ml and filter-sterilized through a 0.22 µm membrane filter. On the surface of the agar, the 6 mm filter discs were placed (three discs per agar plate). Ten microliters of the tested crude polysaccharide extract were added to the disc. Reference discs used for control contained penicillin and tetracycline. The plates with bacterial cultures were incubated overnight at 37^{o}C and the diameter of the resulting zone of inhibition was measured and compared with those of reference discs. Inhibitory activity of DMSO was also tested.

RESULTS AND DISCUSSION

The results of scavenging ability and chelating ability on ferrous ions of polysaccharide extract from of *A. bisporus* are shown on figure 1 and 2. As it can be seen, at concentrations of 0.1-10 mg/ml, the scavenging abilities of *A. bisporus* polisaccharide enriched extract on DPPH radicals were between 12.3-75.5% (Figure 1). At 0.1-20 mg/ml, the radical scavenging ability of the positive controls BHT, ascorbic acid and α-tocopherol were between 1.1-69.1, 80.6-91.1 and 79.9-80.8 %, respectively. The radical scavenging ability at of the extracts and positive controls, at 5 mg/ml decreased in the following order: ascorbic acid > α-tocopherol ≈ *A. bisporus* > BHT. EC_{50} values of the DPPH scavenging activity of the polysaccharides from champignon mushroom was 2.0 ± 0.18 mg/ml.

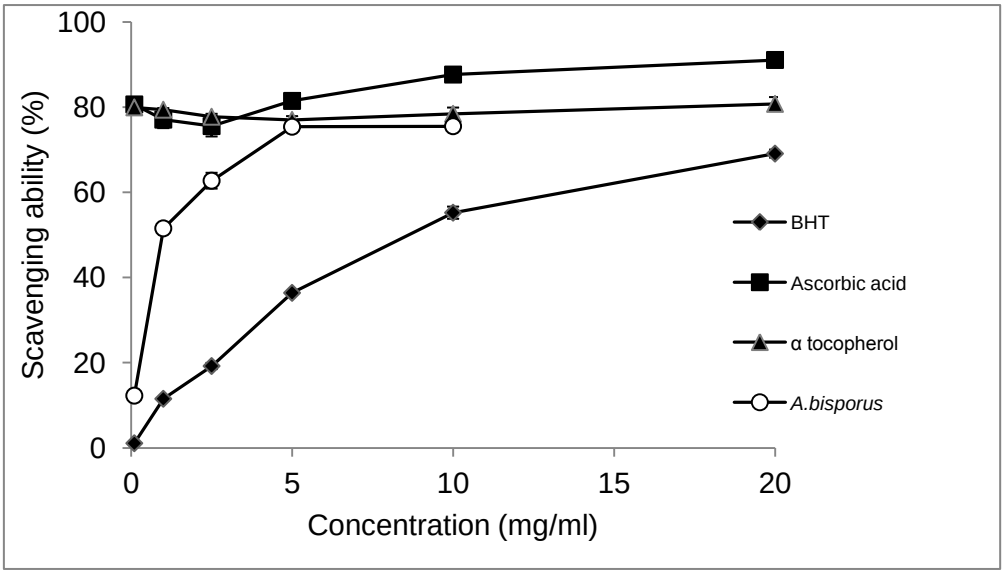

Figure 1. Scavenging ability on 1,1-diphenyl-2-picrylhydrazyl radicals of polysaccharide- enriched extract from of *A. bisporus*. Each value is expressed as mean ± standard deviation (*n* = 3).

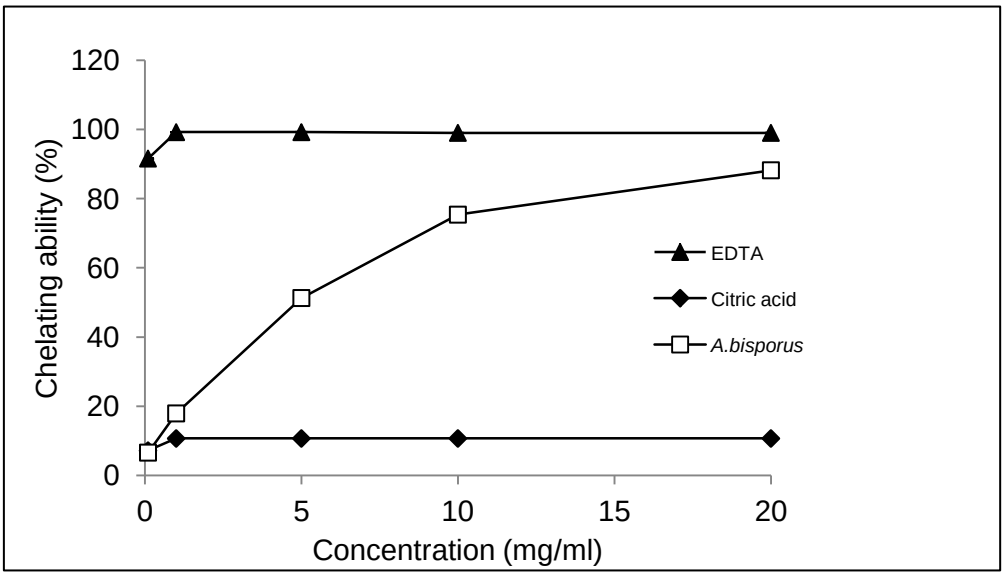

Figure 2. Chelating ability on ferrous ions of polysaccharide-enriched extract from of *A. bisporus*. Each value is expressed as mean ± standard deviation (*n* = 3).

Chelating effects of the polysaccharide extract from *A. bisporus* on ferrous ion increased with the increased concentrations (Figure 2). At 0.1-20 mg/ml, the chelating ability of *A. bisporus* polysaccharide extract was between 6.6-88.2%. The chelating effect of the synthetic metal chelator EDTA was between 91.6-99% at 0.1-20 mg/ml, while citric acid was not as good chelating agent for ferrous ions in this assay and its chelating ability was 10.7% at 20 mg/ml. EC_{50} values of the chelating ability of ferrous ions for *A.bisporus* extract was 7.80 ± 0.21 mg/ml.

The main mechanism of ferrous ion chelating activity is the ability of chelators to deactivate and/or chelate Fe^{2+} which can promote the Fenton reaction and hydroperoxide decomposition. Iron toxicity (high organ storage of iron) and/or high blood levels of iron are associated with an increased risk of free radical damage and cancer. The capability of iron to generate free radicals from peroxides by Fenton reactions has been implicated in

cardiovascular disease. Free radicals formed as a result of high iron can attack low-density lipoproteins (LDL) and subsequently lead to fatty plaque buildup, damage to the walls of arteries, as well as to heart muscle tissue. Chelation therapy may possibly reduce iron-related free radical damage and increase overall survival in cardiovascular disease (Halliwell and Gutteridge, 1990).
Factors affecting and/or attributing to chelating effects of polysaccharide-enriched extract from *A. bisporus* need to be further studied.

Antimicrobial activity of extract
As summarized in Table 1. tested Gram positive bacteria seemed to be more sensitive than Gram negative bacterial strains to the examined polysaccharide extract of *A. bisporus*. The most susceptible bacterium was *Enterococcus faecalis* ATCC 49532 (26.7 ± 0.2). Regarding the fact that all examined bacteria are serious pathogens, their sensitivity to the mushroom extract is of particular interest.

Table 1. Antibacterial acivity (inhibition zone measured in mm, including 6 mm filter discs) of the polysaccharide extract of *A. bisporus*

bacterial strain	***A. bisporus***	**P**	**T**
Enterococcus faecalis ATCC 49532	26.7 ± 0.2	12.6 ± 0.5	24.3 ± 0.6
Bacillus cereus ATCC 10876	27.5 ± 0.4	-	12.4 ± 0.6
Geobacillus stearothermophylus ATCC 7953	22.8 ± 0.3	-	17.6 ± 0.5
Pseudomonas aeruginosa ATCC 35032	10.4 ± 0.6	-	-
Proteus hauseri ATCC 13315	12.1 ± 0.1	19.8 ± 0.2	24.8 ± 0.7

Klebsiella pneumoniae ATCC 27736	22.3 ± 0.2	15.4 ± 0.3	16.7 ± 0.1

P, penicillin; T, tetracycline; (–) no inhibition.
Each value is expressed as mean ± standard deviation (n = 3).

CONCLUSIONS

Measurements of antioxidant and antimicrobial properties of hot water polysaccharide extract of fruiting bodies of *A. bisporus* showed moderate antioxidant and strong antimicrobial activities. The antioxidant and antimicrobial compounds of the polysaccharide extract were resistant to high temperatures, even to a period of 45 min of boiling at 120ºC during the extraction process.
Champignon mushroom polysaccharides act as natural antioxidant. As oxidative stress appears to be an important part of many human diseases, the use of antioxidants in pharmacology is intensively studied.
In recent decades microorganisms are becoming resistant to antibiotics due to their excessive use in medicine, but in food industry, too. On the other hand, it is known that antibiotics can have adverse effects on the health. This study has shown that commonly used mushroom *A. bisporus* could be suitable as food preservative against food spoilage microorganisms, i.e. as antimicrobial agent in the food industry. Further investigations are necessary to verify these activities *in vivo.*

ACKNOWLEDGEMENTS

This paper is a result of the research within the projects III 46001, III 46010 and III 43004, financed by the Ministry of Science and Technological Development, Republic of Serbia. *A. bisporus* fruiting bodies were kindly provided by prof. dr Leo van Griensven, University of Wageningen.

ABSTRACT: Fig has been a typical fruit component of the health-promoting in the Middle East for a very long time. Phenolics are an important constituent of fruit quality because of their contribution to the taste, color and nutritional properties of fruit. In this study, the phenolics of fig (*Ficus carica* cv. Sabz) pulp from Iran, stahban region-southern part of Shiraz-were extracted by three different solvents (boiling water, ethanol/water (v:v, 50:50) and methanol/water (v:v,50:50)) in different concentration by ultrasound-assisted method. The total fig phenolics extract (TFPE) was expressed on a fresh weight (FW) basis as mg of gallic acid equivalence (GAE) per 1 kg of fresh weight(FW) .With the HPLC system. The following phenolics were determined: gallic acid, chlorogenic acid, catechin and rutin. Results showed that the highest content among phenolics was 4768.46 (mg GAE/kg FW) related to extracted solution by boiling water solvent with 40%(w:v).The fig pulp is rich in gallic acid, chlorogenic acid, catechin and rutin with maximum amounts of 644,1449.3,621.3 and 978 (mg/kg FW).It is a clear relation between concentration of fig pulp and phenolics content. This special cultivar contains highest level of phenolics, compared with common figs from Mediterranean region.
Key words: *fig (*Ficus carica cv. *Sabz), ultrasound-assisted method, total fig phenolics extract, HPLC*

INTRODUCTION

Fig (*Ficus carica*) is one of the earliest cultivated fruit trees (Solomon et al.,2006).They are a widespread species commonly grown, especially in warm, dry climates. The world production of figs is about one million tons, and it is mostly concentrated in the Mediterranean (Veberic, 2008).*Ficus carica* cv. Sabz is generally produced in Stahban region –southern part of Shiraz- from Iran. Nowadays over than 20000 tons of this cultivar produced in Stahban and Iran become the biggest producer of this specific cultivar. The diameter of *Ficus carica* cv. Sabz is between 33-37 millimetres, its colour is yellow-greenish and dried from the top of fruit before harvested (Faghih, Sabet Sarvestani, 2002).Dried figs contain one of the highest concentrations of phenolics among the commonly consumed fruits and beverages (Vinson et al., 2005).Figs are also an excellent source of minerals, vitamins and dietary fibre; they are fat and cholesterol free and contain a high number of amino acids (Slavin, 2006).

The interest in phenolic compounds has increased over the last few decades, as these agents have become popular among the public, who attribute them several medicinal properties, mostly related to their antioxidant activity (Aviram et al., 2004). Phenolic compounds may serve this purpose by reducing or donating hydrogen to other compounds, scavenging free radicals, and quenching singlet oxygen (Merken and Beecher, 2000; Fattouch et al., 2007; Costa et al., 2009). The content level of phenolics is usually influenced by cultivar (Veberic et al., 2005).Although figs are an important fresh fruit variety in many countries. There are only a few reports dealing with the phenolic contents of these fruit (Solomon and Vaya, 2010; Caliskan and Polat, 2011; Del Caro and Piga, 2008).

The main objective in this study was to report phenolic extraction from *Ficus carica* cv. Sabz grown in Stahban region, southern part of Shiraz. To our knowledge there is no report in this regard. Thus, the aim of this study was to extract polyphenols in different concentrations (w/v,g/ml) of these cultivar using ultrasound assisted method with three different solvents (boiling water, methanol/water (50:50,v:v) and ethanol/water(50:50,v:v)) and give information on the amounts of total phenolic contents by Folin Ciocalteau method as well as some of

phenolic important classes:Gallic acid,Chlorogenic acid,Rutin hydrate and Catechin analyze with HPLC.

MATERIAL AND METHODS

Chemicals

Figs (*Ficus carica* cv. Sabz) at commercial stage of maturity with homogeneous size were packaged in cardboard boxes (in monolayer) and transported to the laboratory for further analyses. Methanol, ethanol and Folin Ciocalteau reagent were purchased from MERCK. Phosphoric acid, gallic acid, chlorogenic acid, rutin and catechin were purchased from Fluka.Sodium carbonate was purchased from Sharlue.

Extraction method

The pulp of 10-15 fig fruits were homogenized using a woring-blender.Four concentrations was determined: 3.3%, 10%, 25% and 40% (w/v, g/ml).Boling water, methanol/water (50:50, v: v) and ethanol/water (50:50, v: v) were three different solvents for the primary extracion.Incubation was done in static mode in different times. For boiling water the incubation times were 15, 30 and 45 minutes and for two others were 5, 15 and 24 hours. The secondary extraction was done by ultrasound probe (SONOPULS ultrasonic homogenizers, BANDELIN Company) for 5 minutes. The mixture of extracted solution with solid pulp of fig was separated by centrifugation in 3000 rpm (Figure 1).

Total phenolics (TP)

TP of each sample were measured according to the Folin Ciocalteau method and results were expressed as mg gallic acid equivalents (GAE) per 1 kg of fresh weight (GAE/1kg FW).1ml of the fig extract was dissolved in 7.75 ml distilled water and mixed with 0.25 ml of Folin Ciocalteau reagent. After 5 min, 1ml of saturated solution of sodium carbonate was added. The mixture had been allowed to stand for 25 min at room temperature and the absorbance was measured at 765 nm using spectrophotometer.

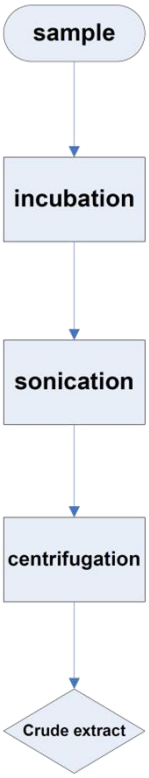

Figure 1.Schematic protocol of ultrasound assisted extraction method

HPLC analysis

The samples were analyzed on the Agilent 1200 series HPLC system with a diode array detector at 280 nm.The elution solvents were aqueous 0.01 M phosphoric acid (A) and 100% methanol (B).The samples were eluted according to the linear gradient described by Escarpa and Gonzalez (1998).The injection amount was 20 µl, and the flow rate was 1 ml/min.The following phenolic compounds were identified: gallic acid, chlorogenic acid, catechin and rutin. Identification of compounds was achieved by comparing the retention times and the spectra as well as by the addition of standards. The concentrations of phenolic compounds were calculated with the help of a corresponding external standard.

RESULTS AND DISCUSSION

Results showed that there is a straight relationship between concentration and total fig phenolics extract (TFPE) (Table 1).As shown, among three solvents, boiling water is the best one for extracting phenolics. In comparison of different samples, concentration of 40% (w/v, g/ml) with 15 min incubation time of boiling water solvent has been the highest amount as a matter of TFPE.

Table 1. Total fig phenolic extracted (TFPE) by (A) Boiling water, (B) ethanol/water (50:50, v: v) and (C) methanol/water (50:50, v: v) in different concentration and incubation time

The maximum amounts of various phenolics for gallic acid is 644 mg/1 kg FW refer to boiling water solvent,40% concentration and 45 min incubation time (Table 2).Other results showed that the highest amount is not just related to specific solvent, but in greater concentration (40% (w/v,g/ml)).

CONCLUSIONS

To our knowledge, this is the first study extracting and determination total phenolics from *Ficus carica* cv. Sabz. This study showed that considerable amount of antioxidant exist in these especial cultivar. The best solvent for extracting antioxidant is boiling water according to results from Folin Ciocalteau method. With notice to previous research on phenolic capture from different cultivars of fig especially from Mediterranean region, it can be showed that this cultivar is one of the finest cultivars regard to phenolic component. Phenolics extracted from natural sources like figs can be use not only as a medicine application but also for preventing food products from oxidation with low cost level.

ACKNOWLEDGEMENTS

We greatly acknowledge Dr. Mahnaz Ghanbariane for cooperation in HPLC tests.We are grateful for supporting by biological laboratory of chemical engineering faculty of Amirkabir University of Technology.

ABSTRACT: Albania is one country with geography on both the Mediterranean moderate climate, hence the possibilities to enlarge the area of nuts cultivation is evident. Scientific study of the hazelnut grown in Albania is important due to the scientific background to the national scheme under implementation for the enlargement of the cultivated area with nuts. Scientific studies on the hazelnut have revealed the nutritional and healthy benefits. Beyond the energetically sources the hazelnut fruit is very important for the nature of the fatty acids which are rich in unsaturated FA.
Preliminary studies on the main constituents from the samples were conducted in two selected sites. The chemical analysis was carried out according to the AOAC (2000) methods. These results are part of an ongoing study started in 2010 and will last for three years. Evidences indicate, that the main constituent in the dried hazelnuts result the triglycerides of 69.1- 70.5 g/100 g dry weight. The carbohydrates vary on 16.2-17.0 g/100 g dry weight hazelnut, and the protein content varies 14.7-15.1 g/100g.
Key words: *Hazelnut,* Corylus Avellana *L., Carbohydrates, Triglycerides, Protein*

INTRODUCTION

Hazelnut (*Corylus avellana L*) has been consumed as fruit for a long time throughout the world, since prehistoric civilization. In the modern times it is used as processed ingredient in the chocolates and other sweets. Main constituents of hazelnuts are fatty acids (FA). The profile is mainly constituted of unsaturated FA, 50 – 73% (Garcia *et al*. 1994). Chemical analyses show that other secondary constituents are phytosterols (Amaral *et al*. 2006a), phenolic compounds and other antioxidants. This compound is supposed to intervene in the controlling other cardiovascular diseases, such as blood hypertension (Alasalvar *et al*. 2006), or in the control of cholesterol level in the blood (Plat and Mensink 2001). Other secondary constituents are vitamins, α-tocopherols (Amaral *et al*. 2006), organic acids and fibers (Botta *et al*. 1994; Alasalvar *et al*. 2006). Recently is reported that hazelnut extracts show antimicrobial activity to the gram-positive bacteria (Oliviera *et al*. 2008).
A number of scientific studies have presented results on the mineral content and vitamins may have indicated by geographical factors (Dunar and Altundag 2004a; Amaral *et al*. 2006 b, c). Studies have confirmed that mineral content in hazelnut is influenced by geography, climate, irrigation and fertilization practices, and the harvesting period in accordance with ripening stage.
Until 1990, the annual domestic production was calculated to reach 100 ton hazelnut and concentrated to the Visoka, Mallakastra region. Recent statistics show that the production have reached 184 ton, in 2011. Mainly it is consumed as unprocessed fruit and in minor part to the confection industry (Rama *et al*. 2011). Actually the consumption is in minimal scale, 0.08 kg/person. The imports are calculated to be 18 ton (DSA, 2007). Compared to the EU countries where the consumption on that assortment is >1kg/person, this value is very low and is a good possibility to ensure a sustainable development to the agriculture to add the cultivation of the *Corylus avellana* L. in the hilly regions of the country.
A very limited data on the chemical composition do exist in the *Corylus avellana L* cultivated in Albania (Osmani-Lataj, Vorpsi and Topi, 2011). Biochemical composition, nutritive values has been the aim of this study. Different regions have been selected for that study and compared to other studies (Koksal *et al*. 2006).

MATERIAL AND METHODS

Plant Material

Seeds of two hazelnut cultivars were harvested during their ripening period 2010-2011, from Visoka plantations, Mallakastra District. The plantation in study was 0.5 ha area, altitude 150m above sea level and Geographic Latitude 40' 36". The samples were stored with husk until conduction of the chemical analysis.

Analytical Methods

Total fat were extracted by Soxhlet at 60^0C per 6 hours and n-hexane was employed as solvent. The hazelnut oil produced was kept in 4^0C in dark place, until GC analysis. The fatty acids were analyzed as Fatty Acid Methyl Esters (FAME) and the equipment employed was GC-FID (Thermo Quest, 2000) with capillary column (23.3m x 0.25mm x 25 μm) according to the AOCS methods (AOCS, 1990). The total ash was calculated according to Koksal *et al*. (2006).

Minerals were analyzed by Spectrophotometer of Atomic Absorption (Varian Spectra AA – 400 Plus). The phosphor was analyzed as phosphomolibdat vanadium according to James (1995) by Spectrophotometer. The chemical analyses were conducted in a four week period after harvesting of the samples.

Statistical analysis

The studied samples was taken during the harvesting period (2010- 2011). Chemical analyses were conducted in three parallel samples from both cultivars. Each sample was of 100 seeds. Data were presented as mean value ±STDEV. Statistical analysis was conducted by Minitab Statistical software (MINITAB INC. 814-238-3280) and standard error $P \leq 0.05$.

RESULTS AND DISCUSSION

Fatty acid composition and total fat

The total fat content was analyzed in both cultivars resulted over 50%, where the *Visoka* cultivar resulted by 61.02% not too much different from *Tonta romana* 60.89%, where identified a number of fatty acids were most important were six of them. Oleic acid was the most abundant by 83.36 %, and others respectively presented in the Table 1. The results on the both cultivars present significant differences for five of FA, except the palmitoleic acid ($P \leq 0.05$) (Table 1). The palmitic acid vary from 4.56% (*Visoka*) to 0.33% (*Tonta romana*), palmitoleic acid 0.33% (*Visoka*) to 0.37% (*Tonto romana*). The oleic acid mean values for both cultivars varied to 83.00%. The linoleic acid content resulted higher to "*Tonta romana*" by 0.42%.

Analysis of minerals

Ash content was significantly high respectively 1.91% (*Visoka*) and 1.97% (*Tonta romana*) a mean value of 1.94% ($P \leq 0.02$) (Table 2). The minerals in higher values resulted potassium by 620.25 mg $100g^{-1}$, phosphor by 251.2 mg $100g^{-1}$ and calcium (113.32 mg $100g^{-1}$). Higher value to the phosphor resulted to *Visoka cultivar by* 290.1 mg $100g^{-1}$ while *Tonta romana* resulted by 212.3 mg $100g^{-1}$. The potassium varied from 112.2 mg $100g^{-1}$ (*Tonta romana*) to 114.44 mg $100g^{-1}$ (*Visoka*). Higher content to the manganese resulted to *Tonta romana by* 63.92 mg $100g^{-1}$. The *Visoka* cultivar resulted with higher content of copper by 1.82 mg $100g^{-1}$, while the *Tonta romana* by 1.14 mg $100g^{-1}$. The iron measured to *Visoka* resulted *to* 3.71 mg $100g^{-1}$ and *Tonta romana* by 2.36 mg $100g^{-1}$. Zinc resulted to 2.09 mg $100g^{-1}$ (*Tonta romana*), and the minimum value 2.05 mg $100g^{-1}$ (*Visoka*).

Table 1: Total fat (g/100g); fatty acids (% FAME) as mean ± STDEV

Fatty acid	Hazelnut cultivars		Mean
	Visoka	Tonta Romana	
Total fat	61.02± 0.27	60.89± 0.29	60.46± 0.28
Palmitic	4.56± 0.15	0.33± 0.15	2.45± 0.15
Palmitoleic	0.33± 0.04	0.37± 0.08	0.35± 0.06
Stearic	1.82± 0.05	1.87± 0.04	1.85± 0.04
Oleic	81.51± 0.11	85.21± 0.46	83.36± 0.28
Linoleic	7.89± 0.23	8.31± 0.02	8.10± 0.12
Linolenic	0.15± 0.04	0.11± 0.02	0.13± 0.03
SFA	6.44± 0.18	7.04± 0.06	6.74± 0.06
PUFA	93.56± 0.32	92.96± 0.1	93.26± 0.16
SFA/PUFA	13.56± 0.44	13.2± 0.12	13.38± 0.26

Comparison of the results with data from the literature indicates similarity in the mineral content with cultivars of Eastern Mediterranean Sea (Alasalvar. et al, 2003; Koksal et al, 2006; USDA, 2007). A recent publication, in the Balkan region, has published that palmitic acid values were higher levels compared to the cultivars of eastern region of Black Sea 4.72 – 5.87% (Köksal et al. 2006).

Table 2: Ash content (g $100g^{-1}$), minerals (mg $100g^{-1}$) expressed as mean value ± STDEV (P≤0.05)

Mineral	Hazelnut cultivars		Mean
	Visoka	Tonta Romana	
Ash	1.91± 0.01	1.97± 0.03	1.94± 0.02
Potassium	680.20± 10.60	560.30± 8.40	620.25±9.50
Phosphor	290.10± 11.3	212.30± 13.5	251.2± 24.4
Calcium	114.44±0.26	112.20± 0.10	113.32± 0.18
Magnesium	61.04± 0.26	63.92± 0.40	62.48± 0.33
Sodium	9.90± 0.40	6.81± 0.47	8.355± 0.43
Manganese	11.04± 0.28	9.68± 0.34	10.36± 0.30
Copper	1.82± 0.08	1.14± 0.04	1.48± 0.06
Iron	3.71± 0.06	2.36± 0.08	3.68± 0.07
Zinc	2.05± 0.02	2.09± 0.04	2.07± 0.03

While the palmitoleic and Stearic acids were in similar values to that of eastern region of Black Sea (Köksal et al. 2006), Stearic acid (2.01%) content resulted higher that our results (1.90%). Oliviera et al. (2008) has reported the mean values of Stearic acid, 1.80% for these cultivars. In our study mean values of the Stearic acid was 1.85% in both cultivars. Oleic acid content 83.36% higher than these of Köksal *et al*., (2006) for cultivars of Black Sea (79.58%). Our results on oleic acid for cultivars *Visoka* and *Tonta romana* differ slightly to these of (Köksal et al. 2006). Mean value of Linoleic acid (8.81%) were lower than those reported in the study (13.0%) of Köksal et al. (2006). Based on the data, the results of FA may attribute mainly to the geography, but the differences on the FA profiles are not so different, significantly. The ash content was significantly different between two cultivars 1.91% (*Visoka*) and 1.97% (*Tonta romana*) ($P \leq 0.02$) (Table 2).

CONCLUSIONS

This study analyses the chemical composition of two hazelnut cultivars in the Mallakastra region. The fat content of the cultivars resulted over 50%, in accordance with results from

other publications (Özdemir et al. 2006). The fatty acid profiles (Table 1) were similar with cultivars of other publications (Garcia et al. 1994.).
Mineral in higher values resulted potassium by 620.25 mg$100g^{-1}$, phosphor by 251.2 mg $100g^{-1}$ and calcium 113.32 mg $100g^{-1}$. Maximum phosphor content was found to *Visoka* by 290.1 mg $100g^{-1}$ and minimum to *Tonta romana* (212.3 mg $100g^{-1}$). The *Visoka* cultivar resulted by maximum iron content (3.71 mg $100g^{-1}$). The maximum zinc content resulted to "*Tonta romana*" cultivar by 2.09 mg $100g^{-1}$. Both cultivars in the study are a good source of bioactive fatty lipids and essential minerals. The essential minerals for both cultivars resulted cooper (1.48%), manganese (10.36%), iron (3.68%), magnesium (62.48%), phosphor (25.12%), zinc (2.07%). These data are comparable to the publications on the literature review. That bring to the result that cultivation of these cultivars in Visoka plantations has significant interest. Further studies are important to the comparison of the results and to have a database that will give a broad panorama related to the other climatic and human factors in the hazelnut cultivation.

ACKNOWLEDGEMENTS

ABSTRACT: Inadequate calcium intake may result in weak bones, especially for women who have a greater risk of osteoporosis later in life. This point should be emphasized for young people who need to maximize their peak bone mass, so an ideal time for prevention of osteoporosis may be during the college years. Adequate folate intake in women of childbearing age can reduce the risk of serious birth defects, including neural tube defects. The aim of this study was to determine the average dietary folate and calcium intake among young people from mountain region, taking into account the importance of these two micronutrients in health. In the mountain region, milk and dairy products are traditionally present in a daily diet, which is not the case for the consumption of fruits and vegetables. The study included 321 university students both gender (50.2% females and 49.8% males), 19-25 years old, from Croatian mountain region. Validated food frequency questionnaires were used to assess an average folate and calcium intake. The average dietary folate intake was 239.8 μg DFE i.e. 60.0% DRI. The average dietary calcium intake was 1062.0 mg i.e. 106.2% DRI. The average dietary folate and calcium intake was not significantly different ($p<0.05$) according to gender. As was expected, the average daily calcium intake was in accordance with the recommended value, while the average daily folate intake was below recommended value. Higher intake of folate-rich foods should be advised to university students in Croatian mountain region.
Key words: *folate, calcium, food frequency questionnaire, student population*

INTRODUCTION

The role of folate in normal cell division makes it particularly important in embryogenesis, thus adequate folate intake is important for women of childbearing age because in period before conception can reduce the risk of serious birth defects, including neural tube defects (Lee Gallagher, 2008). To reduce the risk for neural tube defects, it was recommended that women capable of becoming pregnant consume 400 μg of folic acid daily from fortified foods, supplements, or both, in addition to food folate from a varied diet (Picciano et al., 2009). The current Dietary Reference Intakes (DRIs) express folate requirements in terms of Dietary Folate Equivalent (DFEs) to take into account this difference in bioavailability between food folate and synthetic folic acid (Institute of Medicine, 1998). Bioavailability estimates for folate range from approximately 50% for naturally occurring food folate to 100% for synthetic folic acid consumed on an empty stomach (Gregory, 1997). Many folate-rich foods are fruits and vegetables, adequate intakes of which have been strongly associated with decreased risk for chronic disease (Steinmetz and Potter, 1996).

Inadequate calcium intake may result in weak bones, especially for women who have a greater risk of osteoporosis later in life. This point should be emphasized for young people who need to maximize their peak bone mass (Ueno et al., 2005), so an ideal time for prevention of osteoporosis may be during the college years. Female college students are suggested to be at high risk of insufficient calcium intake. They have lifestyles that are often characterized by eating out, irregular food intake patterns, skipping meals, and dieting (Wong and Huang, 1999).

In Croatian mountain region, milk and dairy products are traditionally present in a daily diet, which is not the case for the consumption of fruits and vegetables. The study with girls and boys at the age of 14-18 years examines milk and dairy products presence in boarding

school meals in Croatia. Mountain regions Lika and Gorski Kotar show the highest values of dairy products consumption (Gajdoš Kljusurić, 2003).
The aim of this study was to determine the average dietary folate and calcium intake among young people from mountain region, taking into account the importance of these two micronutrients in health.

SUBJECTS AND METHODS

Subjects

The study included a representative sample of people, gender and age considered, 321 university students both genders (50.2% females and 49.8% males), 19-25 years old, randomly selected. The subjects were students of Faculty of Teacher Education and University of Applied Sciences "Nikola Tesla" in Gospić, Lika-Senj County, Croatia. Participation was voluntary. Survey was in a classroom setting.

Food frequency questionnaires

To estimate the average folate intake a validated food frequency questionnaire (FFQ) was used (Colić Barić et al., 2009). The FFQ was designed to measure DFE. The DFE express all forms of dietary folates, including synthetic folic acid used in fortified foods and dietary supplements, as an amount that is equivalent to naturally occurring food folate. To calculate the DFE, the folate content of foods fortified with folate was multiplied by 1.7. The FFQ is a 39-item questionnaire that uses the previous month as a reference period with the following consumption frequencies: never, 1/month, 2-3/month, 1/week, 2-3/week, 4-6/week and every day. The subjects received the FFQ in the form of a booklet with incorporated food photographs (Senta et al., 2004). Each photograph showed small, medium, and large portion sizes. Folate intake was calculated using national food composition tables (Kaić-Rak and Antonić, 1990).
To estimate the average calcium intake a validated FFQ was used (Šatalić et al., 2007). The reference period for the FFQ was the previous year, and subjects were asked to recall how often they consumed certain foods. Options were never, 1/month, 2-3/month, 1/week, 2-3/week, 4-6/week, 1/day, and ≥ 2/day. The FFQ is a 27-item questionnaire. Portion size was defined using life-sized food photographs where for each food a small, medium, and large portion was shown (Hess, 1997), or portion size was described with a kitchen utensils. A Croatian food composition database was used for calculating calcium intake (Kaić-Rak and Antonić, 1990).

Results and Discussion

Subjects' mean age was 21.7 years. There was significant difference between women and men in mean age (22.1 vs. 21.3 years). Men had, as expected, a significantly higher mean BMI (25.0 kg/m^2) compared to women (22.1 kg/m^2) ($p<0.001$), and women had a significantly higher mean percent of body fat (27.8%) compared to men (15.0%) ($p<0.001$) (Table 1).

Table 1. Age and anthropometric characteristics of subjects (mean ± SD)

Parameters	Males	Females	Students	p
Number	160	161	321	
Age (years)	21.3 ± 2.2	22.1 ± 1.7	21.7 ± 2.0	<0.001 *
BMI (kg/m^2)	25.0 ± 6.2	22.1 ± 3.4	23.5 ± 5.2	<0.001 *
% of body fat	15.0 ± 5.7	27.8 ± 8.5	21.5 ± 9.7	<0.001 *

* Significant difference at $p<0.05$ according to t-test

The mean daily dietary folate intake was 239.8 ± 133.8 µg DFE, while the mean daily total folate intake, including folic acid from supplements, was 247.3 ± 144.4 µg DFE. The mean total folate intake was below recommendation (400 µg DFE) in both genders, 265.6 µg DFE

and 228.8 μg DFE in males and females, respectively. There was no significant difference in mean folate intake according to gender (p=0.205) (Table 2).

Table 2. Average daily folate intake according to gender (mean ± SD) (n=321)

Parameters	Males	Females	Students	p
Food folate (μg DFE)	261.4 ± 157.5	218.2 ± 100.6	239.8 ± 133.8	0.179
Food folate (% DRI)	65.3 ± 39.4	54.6 ± 25.1	60.0 ± 33.4	0.179
Supplements (μg DFE)	4.2 ± 37.8	10.6 ± 70.5	7.4 ± 56.5	0.482
Total folate (μg DFE)	265.6 ± 158.4	228.8 ± 126.6	247.3 ± 144.4	0.205
Total folate (% DRI)	66.4 ± 39.6	57.2 ± 31.7	61.8 ± 36.1	0.205

** Significant difference at p<0.05 according to t-test*

In a study with 100 women of childbearing-age (range 20–30 years) from Zagreb, Croatia, mean intake of naturally occurring food folate and folic acid from fortified cereals is 156.6 ± 72.2 μg/day assessed by 24-h recalls (Pucarin-Cvetković et al., 2006), which is lower than the intake found in this study. That survey proved that the values of folate and folic acid intake in a whole day meal were less than 180 μg, which does not meet the criteria for anaemia prevention and particularly not recommendations for prevention of neural tube defects in newborns. In a study of Šatalić et al. with students from all five Croatian University Centers (Zagreb, Split, Osijek, Rijeka and Zadar) mean folate intake is 442.9 μg i.e. 111% DRI in males and 373.4 μg i.e. 93% DRI in females, and it is significantly different according to gender (Šatalić et al., 2007). The mean folate intake in the Spanish students is 301.8 μg in males and 240.3 μg in females, and there is no significant difference between women and men in mean folate intake (Soriano et al., 2000). In a study of Van Diepen et al. participants also failed to consume adequate amounts of folate, 244.6 μg in Dutch and 263.0 μg in Greek university students (Van Diepen et al., 2011).

In this study the mean folate intake less than 100% DRI had 90.0% of females, and 81.3% had folate intake less than 75% DRI. The mean folate intake less than 100% DRI was determined in 85.7% of males, and 70.8% had intake less than 75% DRI (Figure 1). In a study with Croatian university students lower number of subjects have folate intake less than 100% DRI, 62% of females and 49% of males (Šatalić et al., 2007). Lewis et al. state that 68–87% of childbearing-age women population consume folate from foodstuffs in the amount less than 400 μg per day (Lewis et al., 1999).

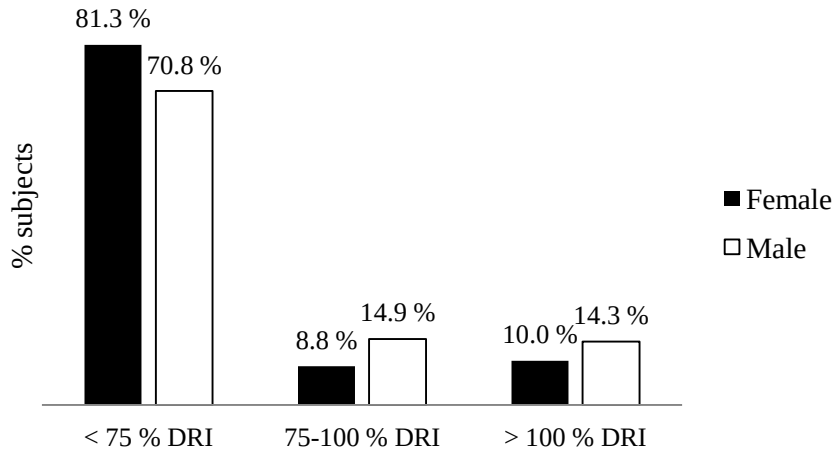

Figure 1. Average daily folate intake presented as a percentage of the DRI according to gender (% subjects)

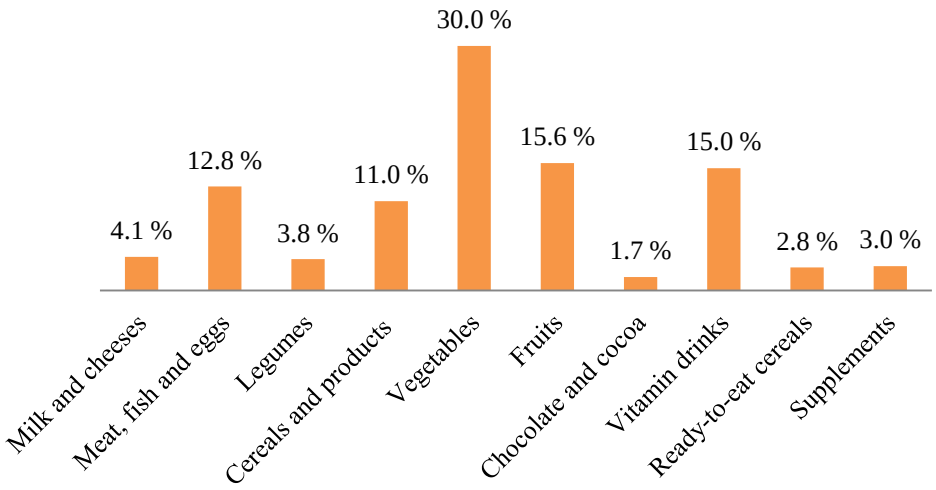

Figure 2. Food groups as main sources of folate in a daily diet

The main sources of folate in a daily diet were vegetables (30.0%), fruits (15.6%) and vitamin drinks (15.0%) (Figure 2). The highest correlation was determined between folate intake and intake of vegetables ($r=0.678$; $p<0.001$) and fruits ($r=0.572$; $p<0.001$). Fruit and vegetable intake was also favorably related to intake of dietary folate in Greek medical students (Bertsias et al., 2005).

The mean daily dietary calcium intake was 1062.0 ± 801.8 mg. No significant difference was determined for mean calcium intake between genders ($p=0.275$), 1110.8 mg (111.1% DRI) in males and 1012.9 mg (101.3% DRI) in females. The mean calcium intake was in accordance with recommendation in both genders (Table 3).

Table 3. Average daily calcium intake according to gender (mean ± SD) (n=321)

Parameters	Males	Females	Students	p
Food calcium (mg)	1110.8 ± 821.5	1012.9 ± 780.9	1062.0 ± 801.8	0.275
Food calcium (% DRI)	111.1 ± 82.2	101.3 ± 78.1	106.2 ± 80.2	0.275

** Significant difference at p<0.05 according to t-test*

The study with 161 healthy adults from the eastern part of Croatia shows that a mean calcium intake is 965 mg/day according to three FFQs, 909 mg for women and 1105 mg for men (Mandić-Puljek et al., 2005). There is a statistically significant difference between genders for daily calcium intake ($p=0.009$). Higher mean calcium intake, than in this study, is determined in a study with Croatian university students (1518.0 mg). Men have significantly higher mean calcium intake than women (1711.1 vs. 1444.4 mg) (Šatalić et al., 2007). Average calcium intake in a study with Spanish university students is 915.3 mg and 815.4 mg in males and females, respectively. There is no significant difference between women and men in mean calcium intake (Soriano et al., 2000), which is also determined in this study.

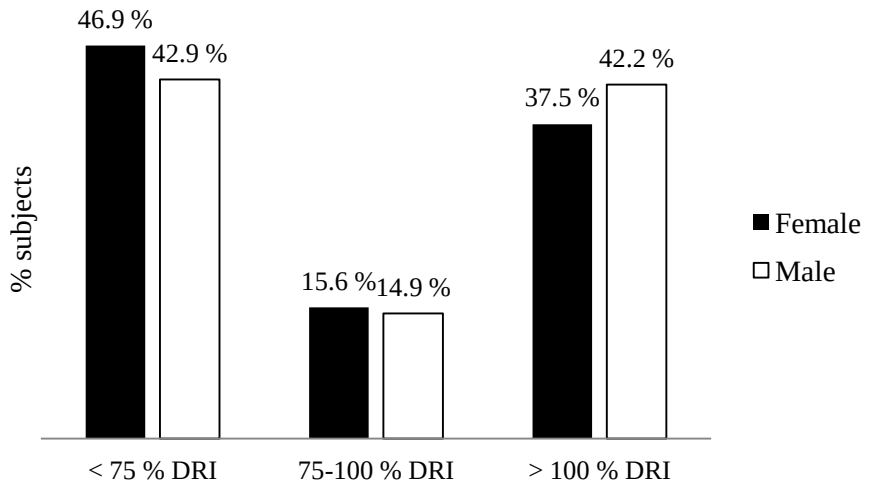

Figure 3. Average daily calcium intake presented as a percentage of the DRI according to gender (% subjects)

Mean calcium intake less than 100% DRI had 62.5% of females and 57.8% of males (Figure 3). Lower number of university students in a study of Šatalić et al. have calcium intake less than 100% DRI, 31% of females and 24% of males (Šatalić et al., 2007).

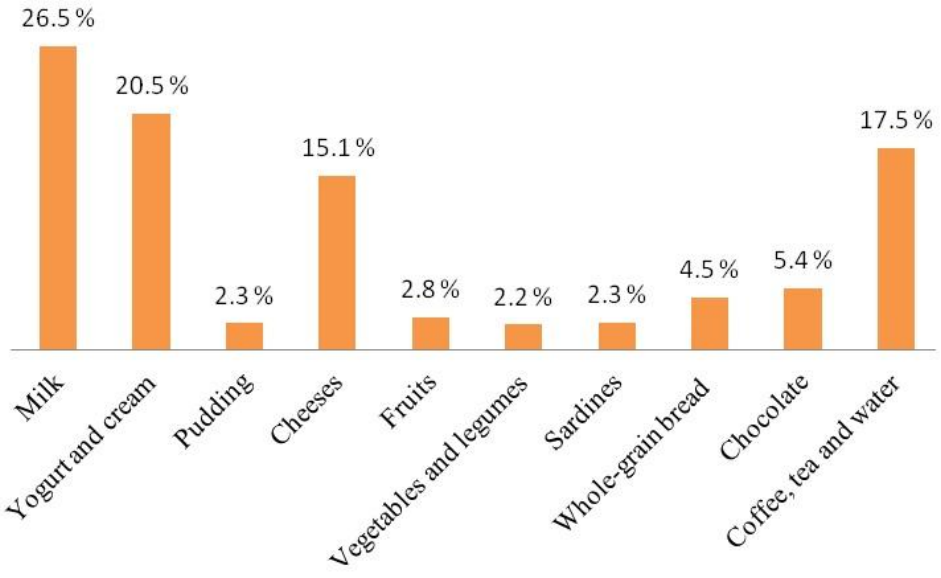

Figure 4. Food groups as main sources of calcium in a daily diet

Milk and dairy products (milk, yogurt, cream, cheeses and pudding) were the main source of calcium in a daily diet (64.4%) (Figure 4). Similar result is found in a study with healthy adults in eastern Croatia (61.3%) (Mandić-Puljek et al., 2005).

CONCLUSIONS

While milk and dairy products are traditionally present in their daily diet it was noticed that the average daily calcium intake was in accordance with the recommended value but the average daily folate intake was below recommended value because of the low consumption of fruits and vegetables. It is important to know the nutritional needs of population for assuring food security. Also, according the study the nutritional recommendations and some changes in daily dietary pattern are needed.

ACKNOWLEDGEMENT

This study is a part of Scientific Project “Diet, Homocysteine and Bone Health”, funded by the Ministry of Science, Education and Sport, Republic of Croatia.

ABSTRACT: Individually quick frozen (IQF) fruits of the most abundant raspberry cultivars (Meeker and Willamette) in Western Serbia were randomly taken from the commercial cold storage in Arilje growing area, and analyzed for main phenolics and antioxidative capacity. All samples for freezing were harvested in the full ripening stage in the orchards in close proximity to the commercial cold storage, frozen by conventional freezing, and stored at -18°C, prior to use. Using high-performance liquid chromatography, high content of ellagic acid (from 13,99 to 27,01 mg/100 g fw for Meeker; from 26,15 to 35,22 mg/100 g fw for Willamette) and cyanidin (from 20,75 to 29,97 mg/100 g fw for Meeker; from 32,97 to 64,68 mg/100 g fw for Willamette) were determined. Significant amounts of pelargonidin (up to 7,08 mg/100 g fw), gallic acid (up to 4,42 mg/100 g fw), quercetin (up to 1,56 mg/100 g fw), and apigenin (up to 0,42 mg/100 g fw) were also detected in all samples. Although the raspberries cv. Willamette contain higher concentration of detected phenolics than raspberries cv. Meeker, nevertheless antioxidative capacity is nearly equal for both cultivars examined.
Key words: *commercial cold storage, Arilje growing area, Meeker, Willamette, IQF, anthocyanins, phenolics, antioxidative capacity, HPLC-DAD, ellagic acid, cyanidin*

INTRODUCTION

Red raspberries (*Rubus idaeus* L.) are soft, juicy fruits with a distinct aroma. It is an economically important berry crop that contains numerous bioactive compounds and natural antioxidants with a high free radical scavenging capacity. Berry fruits are extremely perishable and have a short market life. Therefore processing, in particular freezing, is necessary in order to provide raspberries to the market and consumers over the entire year.
In addition to vitamins and minerals, raspberries are also rich in anthocyanins, phenolic acids, and other flavonoids. Anthocyanins are the major contributors to the red colour pigment in berry fruits and are also used by consumers to judge the quality of a fruit. Mullen et al. (2002) have identified as many as 11 anthocyanins in raspberries. Flavonols (kaempferol, quercetin and myricetin) and phenolic acids (*p*-coumaric, gallic, ferulic and ellagic acids) have been also detected in berry fruits, with proposed beneficial effects on human health (Hertog et al., 1992; Horbowicz et al., 2008; Bobinaitė et al., 2012).
According to the International Raspberry Organization, the world's raspberry production in the period 2000-2010. is between 450.000 and 500.000 t (including Russia). In Serbia, the raspberries are being produced on 13.500 ha, and production is varying between 60.000 and 94.366 t. Arilje growing area is the main production center, with one quarter of the total raspberry production in Serbia (Leposavić et al., 2004).
The object of our study was to determine the chemical composition and antioxidative capacity in a commercial cold-storage frozen fruits of the most abundant raspberry cultivars (Meeker (5%) and Willamette (95%)) in Arilje growing area of Western Serbia (Petrović and Leposavić, 2011).

MATERIAL AND METHODS

Collecting samples

All samples for freezing were harvested in the full ripening stage in the orchards approximately 1 km away from the commercial cold storage, frozen the same day using the conventional freezing (classic) tunnel, and stored at -18°C (Petrović and Leposavić, 2011). Individually quick frozen (IQF) raspberry commercial packs of 2.5 kg were randomly taken from the cold storage from Arilje growing area of Western Serbia, as follows: three packs of cv. Meeker with harvesting dates: (*i*) 20.06.2010., (*ii*) 09.07.2010., (*iii*) 12.07.2010., and five packs of cv. Willamette with harvesting dates: (*i*) 24.06.2010., (*ii*) 14.07.2010., (*iii*) 17.07.2010., (*iv*) 19.07.2010., (*v*), 22.07.2010. Above-mentioned disproportion in number of packs is due to the different abundance of analyzed cultivars in Arilje growing area. Upon receipt at the Department for Fruit Processing Technology, the raspberries were stored at -18 °C until the analysis.

Soluble solid content (SSC), dry matter content (DM), sugar content, and titratable acidity (TA)

The SSC of the fruit was determined on a manual refractometer (3828, Carl Zeiss, Germany). The dry matter content was determined by drying at 105 ºC until constant mass. Titratable acidity (TA) was determined by neutralization of fruit extract with 0.1 N NaOH to pH 8.2, using phenolphthalein as indicator. Acidity was expressed as mg malic acid/100 g fresh weight. Sucrose, inverted sugars, and total sugars content were determined by Luff-Schoorl method (Tanner and Brunner, 1979).

Determination of anthocyanin content

The monomeric anthocyanin pigment content of the aqueous extracts was determined using the pH-differential method described previously (Torre and Barritt, 1977; Prior et al., 1998; Liu et al., 2002). Pigment content was calculated as micrograms of cyanidin-3-glucoside equivalents/100 g fresh weight (mg cyn-3-glu/100 g fw), using an extinction coefficient of 26.900 L/cm/mol and molecular weight of 449,2 g/mol.

Determination of flavonoid contents and total phenolics

Total flavonoid content was determined by a colorimetric method described previously (Zhishen et al., 1999; Liu et al., 2002). The results are expressed as micrograms of catechin equivalents/100 g fresh weight (mg CE/100 g fw).

The total phenolic content was determined using a modified Folin-Ciocalteu colorimetric method (Singleton et al., 1999; Liu et al., 2002), with results expressed as micrograms of gallic acid equivalents/100 g fresh weight (mg GAE/100 g fw).

Antioxidant activity

Antioxidant properties were determined by the ABTS and DPPH assays. $ABTS^{\bullet+}$ radical cation scavenging activity was determined according to the method described by Re et al. (1999). Antioxidant activity was determined using the DPPH method reported by Brand-Williams et al. with modifications (Sanchez-Moreno et al., 1998). Results were expressed as Trolox equivalent antioxidant capacity (mM TE/100 g fw).

Extraction and HPLC-DAD analysis

Samples were prepared according to the method of Hertog et al. (1992). Samples were analyzed using an Agilent 1260 series HPLC (Agilent Technologies, Santa Clara, CA, USA) linked to a ChemStation data handling system, using a ZORBAX Eclipse Plus C18 column (4.6 x 150 mm, 3.5 µm particles). Injection volume was 5 µL and the temperature was set at 30 ºC. Solvent A was 1% formic acid and solvent B was acetonitrile. The gradient used was as follows: 0–10 min, 10% of B in A; 10–25 min, 15–50% of B in A; 25–30 min, 50-80% of B in A; 30–32 min, 10% of B in A. By using this gradient (flow rate 0.5 ml/min), a good purity and separation was achieved in raspberry samples. The HPLC equipment was used with a

diode array detector (DAD). Ellagic acid (EA) and gallic acid (GA) were detected at 260 and 280 nm, respectively; apigenin and quercetin were detected at 329 and 360 nm, respectively; anthocyanins (cyanidin (CYA) and pelargonidin (PEL)) were detected at 520 nm. Phenolic compounds were identified according to peak retention time and UV/Vis spectra by comparing them with those of the standards. The quantities of the different phenolic compounds were based on peak areas, and expressed as mg/100 g fw.

Statistical analysis

For all the experiments, three samples were analyzed and all the assays were carried out in triplicate. The results are expressed as mean values and standard deviation (SD). Data were analyzed by one-way analysis of variance (ANOVA) to examine differences among the cultivars, using Statistica 7 (StatSoft, Inc., Tulsa, OK, USA). The pairwise comparisons between different parameters were performed out using Duncan's test ($p < 0.05$).

RESULTS AND DISCUSSION

Raspberry samples

Raspberries cvs. Meeker and Willamette were analyzed after four months of storage at -18°C. Given that the raspberry fruits ripen successively, the harvest is conducted on several occasions. The raspberry harvest season for the cvs. Meeker and Willamette lasts from 21 to 40 days, depending on the way of growing and agro-ecological condition of the raspberry growing area (Petrović and Leposavić, 2011). Taking this into account, randomly taken IQF raspberry packs of cvs. Meeker (from 20.06.2010. till 12.07.2010.) and Willamette (from 24.06.2010. till 22.07.2010.) from the commercial cold storage completely cover the entire harvesting periods.

Every single IQF raspberry pack was divided in three subsamples, in order to provide three replicate experiments. All results in this study are presented as mean value of all cultivar subsamples ± standard deviation (9 and 15 subsamples for Meeker and Willamette, respectively).

Chemical properties

Chemical properties of berry fruits contribute to fruit flavour. High sugars and high acids are required for good berry flavour.

Table 1. Chemical properties of frozen raspberries from commercial cold storage in Arilje growing area

	ANOVA	Meeker	Willamette
dry matter content - DM (%)	ns	14,17 ± 1,04 a	14,47 ± 0,95 a
soluble solid content - SSC (%)	ns	9,09 ± 1,26 a	9,95 ± 1,37 a
total sugars (%)	ns	5,54 ± 1,07 a	5,83 ± 0,90 a
inverted sugars (%)	ns	4,72 ± 0,96 a	4,92 ± 0,85 a
sucrose (%)	ns	0,79 ± 0,11 a	0,86 ± 0,09 a
titratable acidity (%)	***	1,73 ± 0,21 b	2,15 ± 0,13 a
pH	**	2,86 ± 0,06 a	2,78 ± 0,06 b
sugar/acid ratio	ns	3,30 ± 0,97 a	2,71 ± 0,41 a

Values with a different letters denote statistically significant differences (Duncan's test, $p < 0.05$).
ns,,**,***: non significant or significant at $p < 0.05, 0.01, 0.001$, respectively.*

For instance, high acid and low sugar level result in a tart berry, while high sugar and low acid level result in a bland taste. Moreover, low levels of acid and sugar result in tasteless berries (Wang et al., 2009). Chemical properties of Meeker and Willamette commercially available frozen samples are presented in Table 1. As can be noticed, there are no statistically significant differences between the cultivars examined. As for the titratable

acidity, cv. Willamette has a higher total acids content compared to cv. Meeker, that is already reported (Finn and Lawrence, 2001).
In comparison, the results of chemical properties in our study are in excellent agreement with reports by other researchers (Finn and Lawrence, 2001; Stanisavljević et al., 2002; Kafkas et al., 2008).

Contents of bioactive compounds and antioxidative capacity
The total anthocyanins, total flavonoids, and total phenolics were measured for all the samples. The results are given in Table 2.
The total anthocyanin and total flavonoid contents showed great variation in different raspberry cultivars (Willamette had higher anthocyanin and flavonoid contents, followed by Meeker). On the other hand, regarding the total phenolic content there is no statistically significant difference between the cultivars examined. These results are in great agreement with results by other researchers (Anttonen and Karjalainen, 2005; Wang et al., 2009; Sariburun et al., 2010). Anttonen and Karjalainen (2005) reported that the total anthocyanin and total phenolic contents ranged from 0 to 51 mg/100 g fw and from 192 to 359 mg/100 g fw, respectively, for seventeen raspberry cultivars grown at two different farms in Finland. Bobinaitė et al. (2012) found in raspberry cv. Meeker that the total anthocyanins and total phenolics were 44,3 and 388,8 mg/100 g fw, respectively. However, it is known that the contents of bioactive compounds in fruits and vegetables depend on various factors, such as genotypic differences, pre-harvest climactic conditions and post-harvest handling procedures.

Table 2. Total anthocyanin, total flavonoid and total phenolic contents (mg/100 g fw), and free radical scavenging parameters (mM TE/100 g fw) of frozen raspberries from commercial cold storage in Arilje growing area

	ANOVA	Meeker	Willamette
total anthocyanins	***	44,04 ± 4,05 b	87,04 ± 10,09 a
total flavonoids	***	43,17 ± 4,82 b	69,41 ± 9,78 a
total phenolics	ns	358,77 ± 39,81 a	346,99 ± 42,37 a
ABTS	ns	278,71 ± 18,96 a	255,93 ± 37,08 a
DPPH	ns	27,15 ± 1,83 a	27,34 ± 1,54 a

Values with a different letters denote statistically significant differences (Duncan's test, $p < 0.05$). ns,,**,***: non significant or significant at $p < 0.05$, 0.01, 0.001, respectively.*

The results for the antioxidant capacity (ABTS and DPPH assays) are also given in Table 2. As can be noticed, no statistically significant differences were found amongst these two raspberry cultivars. Since there are a large number of different types of antioxidant compounds that might contribute to the total antioxidant capacity, it is not clear which components are responsible for the observed antioxidative capacity. The antioxidant capacity of raspberry fruits appears to be largely influenced by the polyphenolics, rather than anthocyanins and flavonoids. These data are in agreement with other reports in the literature (Sariburun et al., 2010; Novaković et al., 2011).
Analyzing HPLC-DAD chromatograms of aqueous methanol extracts of frozen raspberries cvs. Meeker and Willamette, six peaks were clearly identified. Some of the peaks are presented in Figure 1. Identified compounds were quantified and summarized in Table 3.

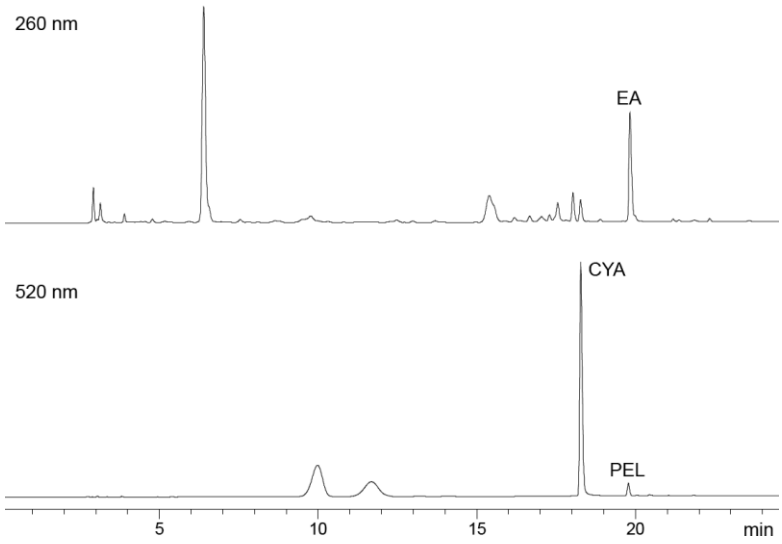

Figure 1. HPLC chromatogram for the quantification of ellagic acid (EA) monitored at 260 nm (top), and cyanidin (CYA) and pelargonidin (PEL) monitored at 520 nm (bottom)

It was found that the amount of quercetin in Meeker is five times lower than that in Willamette. Surprisingly, certain amount of apigenin is found in both cultivars. Kaempferol and myricetin were not detected in any of the samples. Relatively high content of free ellagic acid was found (19,59 and 28,90 mg/100 g fw for Meeker and Willamette, respectively). These results are comparable with the findings previously reported (Anttonen and Karjalainen, 2005; Bobinaitė et al., 2012). The main anthocyanin found in raspberry is cyanidin (23,99 and 53,42 mg/100 g fw for Meeker and Willamette, respectively), followed by pelargonidin. Comparable results are reported in the literature (Horbowicz et al., 2008; Wang et al., 2009).

Table 3. Contents of main phenolics (mg/100 g fw) in frozen raspberries from commercial cold storage in Arilje growing area

	ANOVA	Meeker	Willamette

CONCLUSIONS

In conclusion, commercially available frozen raspberries cvs. Meeker and Willamette were randomly taken from the commercial cold storage in Arilje growing area of Western Serbia, and analyzed by high performance liquid chromatography. Numerous bioactive compounds, such as apigenin, quercetin, ellagic acid, gallic acid, cyanidin, and pelargonidin were identified and quantified, in both cultivars examined. Furthermore, free radical scavenging capacity assays were performed and it was found that antioxidative capacity is nearly equal for both cultivars examined, although the raspberries cvs. Meeker and Willamette contain different concentrations of detected phenolics.

ABSTRACT: *Fagopyri herba*, a herbal drug derived from common buckwheat (*Fagopyrum esculentum* Moench) is a very rich source of various phenolic compounds which are known as potential antioxidants. The main active compound is a flavonol glycoside rutin. The aim of this study was to investigate antihemolytic activity of the *Fagopyri herba* extracts as a parameter which indicates their antioxidant potential in biological systems. Antihemolytic activity assay measures the ability of a tested extract to inhibit hemolysis of erythrocytes in buffer solution caused by oxidative damage of their cell membrane. Since this test is highly dependent on various parameters (cell suspension concentration, species from which the blood was taken, concentration of reagents, type of extract), they were optimized for testing the investigated water and ethanol *Fagopyri herba* extracts. Optimal concentration of hydrogen peroxide solution was found to be 0.0625% (v/v) while 2 μM of sodium azide was added to the erythrocyte suspension to inhibit catalase enzyme. Ethanolic extract showed lower IC_{50} value (3.46±0.185 mg/mL) in comparison to water extract (42.2±7.27 mg/mL), which is in accordance with their rutin content determined by high performance liquid chromatography.
Key words: *Fagopyri herba, antihemolytic assay, method optimisation*

INTRODUCTION

The pathology of numerous chronic diseases involves oxidative damage of cellular components. (Ebrahimzadeh et al., 2010). Carcinogenesis, coronary heart disease, and many other health problems are related to activity of reactive oxygen species (ROS) which affect lipids in cell membranes, proteins in tissues, enzymes, carbohydrates and DNA. Antioxidants prevent tissue damage by preventing the formation of free radicals, scavenging them, or by promoting their decomposition. Antioxidant system in humans includes antioxidants produced in the body (endogenous) and antioxidants obtained from the diet (exogenous) (Pier-Giorgio, P., 2000). The most important exogenous antioxidants are phenolic compounds from different grains, fruit and vegetables.

Common buckwheat (*Fagopyrum esculentum* Moench) is important part of human diet. This pseudocereal is known as a very rich source of antioxidants. Since buckwheat seeds have been extensively investigated (Oomah et al., 1996; Watanabe et al., 1997; Watanabe et al., 1998; Sedej et al., 2010; Sedej et al., 2011) it was interesting to examine its herbal drug as a source of valuable phenolic compounds. Recent studies reported rutin as the main antioxidant compound in *Fagopyri herba* (Baumgertel, et al., 2010).

Over the last decades, numerous tests were developed for determination of antioxidant capacity in various test systems (Miller H. E., 1971; Brand-Williams et al., 2005; Magalhaes et al, 2008), but many of these tests performed in *in vitro* conditions fail to properly assess the biological activity of the investigated compound. Antihemolytic activity assay measures the ability of a tested extract to inhibit hemolysis of erythrocytes in buffer solution caused by oxidative damage of their cell membrane, and therefore, may indicate the potential biological activity of the investigated compound or extract.

Since this test is highly dependent on various parameters (cell suspension concentration, species from which the blood was taken, concentration of reagents, type of extract), the aim

of this work was to optimize these parameters for testing the investigated water and ethanol *Fagopyri herba* extracts.

MATERIAL AND METHODS

Materials

Herbal drug (*Fagopyri herba)* was obtained from the Institute for Medicinal Plants Research "Dr Josif Pančić" from Belgrade.
Crude plant extracts were obtained by maceration (24 h, room temperature) with water and ethanol/water mixture (50:50, v/v), with the ratio of raw materials to solvent of 1:25.
Blood samples were obtained from healthy volunteers by venipuncture, after obtaining informed consent.

Reagents and chemicals

Phosphated buffer solution (PBS, pH=7.4) was made by dissolving 8 g of NaCl, 0.2 g of KCl, 1.44 g of Na_2HPO_4 and 0.24 g of KH_2PO_4 in deionised water to a total volume of 1L in a volumetric flask. Hydrogen-peroxide solution was made by diluting 2.5 ml of 30% H_2O_2 with PBS solution to a total volume of 50 ml in a volumetric flask and subsequently diluting the obtained solution eight times to a final concentration of 0.19% (which corresponds to 0.063%, or 32.5 µM, of H_2O_2 when added to reaction mixture). Sodium-azide solution (0.002 M) was made by dissolving 0.013 g of sodium-azide in PBS solution to a total volume of 100 ml in a volumetric flask.
Methanol (HPLC grade) and formic acid were supplied by Merck KGaA (Darmstadt, Germany). Water used for HPLC analysis was purified using a Millipore, Elix UV and Simplicity Water Purification System (Milford, MA, USA).

Antihemolytic assay-optimized method

Antihemolytic activity of the extracts was determined using a modification of method by *Ko et al* (1997). Blood (4-6 ml) was drawn into heparinated vacuum tubes and centrifuged at 1000×g for 10 minutes, after which the plasma and buffy coat were removed. Remaining erythrocytes were washed three times with PBS and centrifuged to remove the buffer. The remaining cell cake was gently resuspended in sodium-azide solution in PBS (to achieve inhibition of catalase enzyme) to obtain approximately 10% hematocryte. 0.5 ml of the erythrocyte suspension was added to the test tube, after which 0.5 ml of the buckwheat extract dissolved in PBS was added, and the same procedure was followed for all examined concentrations of each extract. Hydrogen-peroxide solution (0.5 ml; 0.0625%) was added to the test tubes, after which they were gently shaken and incubated in water bath at 37^oC during two hours, being periodically gently shaken by hand to facilitate the hemolysis process. For every investigated extract, a "zero hemolysis" sample was also prepared by adding the erythrocyte suspension and PBS extract solution to a test tube, without the addition of hydrogen-peroxide (0.5 ml of PBS solution was added instead). Also, another sample ("uninhibited hemolysis") was prepared by adding hydrogen-peroxide solution to erythrocyte suspension, without adding the investigated extract (0.5 ml PBS solution was added instead of extract). After incubation period, 200 µl of every sample was transferred to an empty test tube and diluted with 3.8 ml of PBS solution. After centrifuging at 1000×g for 10 minutes to eliminate the unhemolyzed erythrocytes, absorbance of the supernatant (marked as A) was measured at 540 nm using a spectrophotometer. Also, 200 µl of every sample was diluted with 3.8 ml of cold distilled water to achieve a total hemolysis, and after centrifuging the absorbance of the supernatant was also measured spectrophotometrically at 540 nm (marked as B). The extent of the hemolysis in every sample was calculated as:

A/B×100 = % of hemolysis

Since the percentage of hemolysis was calculated for all sample concentrations, these values were plotted against sample concentrations and, using linear regression, IC_{50} values of every investigated extract were calculated.

HPLC analysis

Rutin content of the examined extracts was determined according to method reported by Mišan et al. (2011) using a liquid chromatograph (Agilent 1200 series), equipped with Eclipse XDB-C18, 1.8 µm, 4.6×50 mm column (Agilent).

RESULTS AND DISCUSSION

In order to optimize the antihemolytic test conditions, two concentrations of hydrogen-peroxyde of 0.375% and 0.190% (corresponding to final concentrations of 0.125% and 0.063% in the reaction suspension, respectively) were selected for testing. The initial tests showed excessive foam formation after addition of hydrogen peroxyde to the erythrocyte suspension due to rapid scavenging of hydrogen peroxyde by catalase enzyme, which proved problematic and could lead to inconsistent analytical results. To overcome this effect, erythrocyte suspension was subsequently made with PBS solution in which 0.002 mol×dm^{-3} of sodium azide was added to inhibit the catalase enzyme. Concentration of hydrogen peroxyde of 0.375% caused very rapid onset of hemolysis (95.5% hemolysis after first hour) which was unsuitable for further testing. The addition of lower peroxyde concentration of 0.19% to the reaction suspension yielded favorable results of hemolysis (62.7% after 1h, 84.4% after 2h and 89.9% after 3h of incubation) in hemolysis conditions without added antioxidants. Therefore, this concentration of hydrogen peroxyde was chosen for further tests.

Optimal incubation time was determined using water extract of *Fagopyri herba* in the above chosen hemolysis system. Its antihemolytic activity was monitored during three hour period (Fig 1). As it can be seen from the obtained results, *Fagopyri herba* water extracts inhibited the hemolysis of erythrocytes in the presence of 0.063% hydrogen-peroxyde in a concentration dependant manner. Incubation time of two hours was chosen as optimal since, by that time, the suspension not containing hydrogen peroxyde reached more than 80% hemolysis.

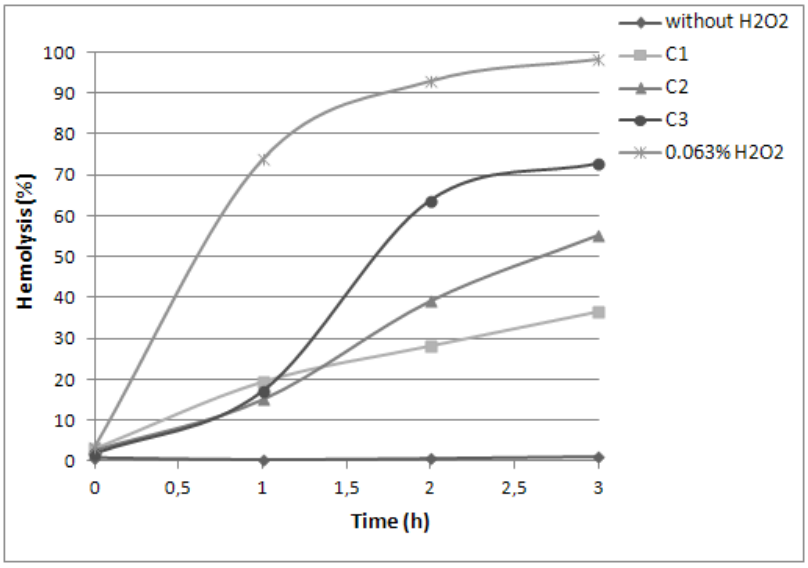

Fig 1. Antihemolytic activity of three different concentrations of *Fagopyri herba* water extract

After optimization of all necessary parameters, optimized antihemolytic assay was performed on water and ethanol/water *Fagopyri herba* extracts in order to test its applicability on different extract types.

The effectiveness of the tested extracts regarding antihemolytic activity could be expressed by IC_{50} value which is defined as a concentration of the investigated extract at which 50% of hemolysis inhibition is achieved. The obtained value of hemolysis (%) was corrected for the

hemolysis of the control suspensions (without added extract and without added hydrogen peroxyde) and that values were plotted against the concentration of the extract. Linear regression analysis was used to calculate IC_{50} values (Table 1).

Table 1. Concentration range, linear regression curves, IC_{50} values and rutin content of water and ethanol/water (50/50 v/v) *Fagopyri herba* extracts

Type of extract	Concentration range (mg/mL)	Linear regression curve; R^2	IC_{50} (mg/mL)	Rutin content (mg/g sample)
water	1.34-4.02	y = -1.2027x+96.82; R^2=0.9966	42.2±7.27	0.251
ethanol/water (50/50 v/v)	1.35-4.04	y = -10.734x + 88.082; R^2=0.9967	3.46±0.185	40.35

Lower IC_{50} values indicate higher antihemolytic activity of ethanol/water extracts which is in accordance with its considerably higher content of rutin.

CONCLUSIONS

The obtained results show that the optimal concentration of hydrogen peroxyde was found to be 0.063%, which causes between 80% and 90% of hemolysis of erythrocytes in the test suspension after two hours of incubation at 37°C. Addition of 0.002 mol×dm^{-3} of sodium azide to erythrocyte suspension was found to cause an efficient inhibition of the catalaze enzyme in order to prevent rapid decomposition of the added peroxyde. The investigated *Fagopyri herba* water and ethanolic extracts showed concentration dependent inhibition of hemolysis in the tested system, with IC_{50} values of 42.2±7.27 mg/mL and 3.46±0.185 mg/mL, respectively. These results were in accordance with the rutin content of these extracts determined by high performance liquid chromatography. It can be concluded that the antihemolytic activity test can be successfully applied to analysis of *Fagopyri herba* extracts, which showed very good antihemolytic activity in such test system, and this can be further indication of the beneficial biological activity of these extracts.

ABSTRACT: Mulberry trees are distributed throughout Serbia. Besides their use in forage and food for animals, they are also used as herbal medicines. This study is carried out to determine total phenolics content, total flavonoids content, total monomeric anthocyanins, as well as DPPH scavenging activity, reducing power and minimum inhibitory concentration (MIC) of the fruits of mulberry species (*Morus alba* L.) grown in Serbia. Fresh fruits of mulberry were extracted by four different solvents (water, ethanol, methanol and acetone). Determination of fruit weight, total soluble solids, total dry weight, pH and acidity was performed. The total phenolics content (TPC) and total flavonoids content (TFC) in mulberry extract were determined spectrophotometrically. The total monomeric anthocyanins (TMA) were estimated by a pH differential method. Antioxidant activity (AA) of mulberry extracts was evaluated using DPPH* radical scavenging method. The reducing power of extracts and standard (ascorbic acid) were determinate by Oyaizu method. MIC of the extract and cirsimarin against tested bacteria were determined based on a microdilution method. Methanolic mulberry fruits extract with the highest amount of total phenolics component was the most potent antioxidant in all the assays used. On the other hand, MIC determination showed that all other extracts have higher antimicrobial activity. This is the first report of *Morus alba fructus* grown in Serbia and determination of the potential antioxidant and antimicrobial activity of mulberry fruits extract. This information will be of considerable value to the commercial producers of mulberry trees, cultivation or pharmaceutical industry for potential new mulberry supplement production.

INTRODUCTION

Plants have received a lot of attention as sources of biologically active substances including antioxidants, antimutagens and anticarcinogens (Diliard et. al., 2000). However, scientific information on antioxidant properties of various plants, particularly those that are less widely used in culinary and medicine are still limited. Therefore, the assessment of such properties remains an interesting and useful task, particularly for finding new sources for natural antioxidants, functional foods and nutraceuticals (Miliauskas et al., 2004; Arabashahi-Delouee et al., 2006).

Mulberry (*Morus alba* L) plant was originally grown in China and widely has been used over thousands of years in folk medicine for its multiple medicinal properties. All species of *Morus* play role both in agriculture and in medicine (Butt et al., 2008). Recently, it has also started to gain an important position in the food industry due to the increasing findings of its healthy benefits such as reduced risk of certain types of cancer, coronary heart disease, stroke, high blood glucose level and ageing (Doi et al., 2000; Harauma et al., 2007; Jia et al., 1999; Lin and Lai, 2009). *M. alba* fruit is a good source of several phytonutritients and contains high amounts of phenols, flavonoids, and ascorbic acid (Zhishen et al., 1999; Tapiero et al., 2002; Bae and Suh, 2007, Memon et al., 2010).

The purpose of the present study was to investigate the effects of used solvent on the antioxidant and antimicrobial capacity and levels of extracted antioxidant compounds in extracts of white mulberry fruits from Serbia. This information will be of considerable value to the commercial producers of mulberry trees in the country.

MATERIAL AND METHODS

Chemicals and reagents

1,1-Diphenyl-2-picryl-hydrazyl-hydrate (DPPH), Folin–Ciocalteu reagent were purchased from Sigma (Sigma-Aldrich GmbH, Sternheim, Germany). Chlorogenic acid and rutine were purchased from Sigma (Sigma, St. Luis, MO, USA). Aluminium chloride hexahydrate, anhydrous sodium carbonate, and sodium acetate trihydrate were purchased from Merck (Darmstadt, Germany). All other chemicals and reagents were of analytical reagent grade.

Sample preparation

Mulberry fruits were harvested from selected *M. alba* from Novi Sad, Serbia. Voucher specimens (*Morus alba* L. No 2-1794, Kać, UTM 34TDR211 det.: Goran Anačkov) were confirmed and deposited at the Herbarium of the Department of Biology and Ecology (BUNS Herbarium), Faculty of Natural Sciences, University of Novi Sad, Serbia (Holmgren and Holmgren, 2003). The fruits were then stored in polyethylene bags at -20°C (up to 1 month) until analysis. Samples were ground in the blender before the extraction.

Fruit slurries were extracted with water and diferent buffers containing acetone/ethanol/methanol, water and acetic acid (70:29.5:0.5, v/v/v). Friut-solvent extraction ratio was 1:10 (w/v). The extraction process was carried out using ultrasonic bath (B-220, Brason and Smith-Kline Company, USA) at the room temperature for 1 hour. After filtration solvent was removed by rotary evaporator (Devarot, Elektromedicina, Ljubljana, Slovenia) under vacuum, and was dried at 60°C to the constant mass. Dry extracts were stored in the glass bottles at 4°C to prevent oxidative damage until analysis.

Determination of fruit weight, moisture, total dry weight, total soluble solids, pH and acidity (of mulberry fruits)

All analyses were performed on 20 samples. Fruit weight was measured by using a digital balance with a sensitivity of 0.0001 g (Kern, Germany). The moisture of samples was determined by drying at 105 ± 2°C until they reached constant weight (AOAC, 1984). Total dry matter of the fruits was determined according to the methods of AOAC (1984). Total soluble solid contents (TSS) were determined by extracting and mixing one drop of juice from each fruit into a digital refractometer (Model ATR-ST, Schmidt-haensch, Germany) at 23.9°C. The pH measurements were made using a digital pH meter (Crison, Basic 20+, Espanola) calibrated with pH 4 and 7 buffers. Titratable acidity (TAc) was measured by the titrimetric method (AOAC, 1984). Titratable acidity of mulberry was expressed as % citric acid. TSS/TAc results are also determined.

Determination of antioxidant compounds in mulberry extracts

The total phenolics content (TPC) in the extracts was determined by the Folin–Ciocalteu method (Singleon, 1965; Kahkoen et al., 1999) and was expressed as mass (mg) of chlorogenic acid equivalents (ECA) per mass (g) of dry extracts. Triplicate tests were conducted for each sample. The total flavonoids (TFC) content has been determined by aluminium chloride colorimetric assay (Ercisli, Orhan, 2007), using rutine as a standard. It has been expressed as mass (mg) of rutine equivalents (ER) per mass (g) of dry extracts. Triplicate tests were done for each sample. Total monometric anthocyanins (TMA) were estimated by a pH differential method (Giusti and Wrolstad, 2005) using a VIS spectrophotometer (Janwey 6300, Germany). Absorbance was measured at 533 and 700 nm in buffers at pH 1.0 and 4.5 using molar extinction coefficient of 29,600. Results were expressed as mg of cyanidin-3-glucoside equivalent in g of dry extract (mg cy-3-glu/g). The results are presented as the mean value of three measurements.

DPPH assay and determination of reducing power of mulberry extracts

The free radical scavenging activity of mulberry extracts was determined as described by Espin (2000). This activity was also expressed as the inhibition concentration at 50% (IC_{50}), the concentration of test solution required to give 50% of decrease in absorbance compared

to the blank sample. The reducing power of mulberry extracts and ascorbic acid were determined by Oyaizu method (1986). Absorbances of samples were measured at 700 nm. Higher absorbance indicates a higher reducing power (reducing capability).

Statistical Analysis

Statistical analysis was carried out using Statistica 6.0. (StatSoft Inc, Tulsa, OK, US). All experiments were performed at least in triplicate unless specified otherwise. Results are presented as mean value ± standard deviation (SD). Significant levels were defined at $p<0.05$.

Microdilution method, determination of minimum inhibitory concentration (MIC) of extracts

The minimal inhibitory concentration (MIC) of the extract and cirsimarin against tested bacteria were determined based on a microdilution method in 96 multi-well microtiter plates **(**Satyajit et al., 2007) Standard antibiotic Amracin was used to control the sensitivity of the tested bacteria, where as Ketokonazol was used as control against the tested yeast. Color change was then assessed visually. Any color change from purple to pink or colorless was recorded as positive. The lowest concentration at which color change occurred was taken as the MIC value. The average of 3 values was calculated and that was the MIC for the tested samples.

RESULTS AND DISCUSSION

The fruit weight, fruit moisture, total dry weight (TDW), total soluble solids (TSS), pH and total acidity (TAc) of mulberry fruits are given in Table 1. Monitored parameters indicate that white mulberry has favorable characteristics for the experimental tests. All measured parameters were within the limits of other studies done on mulberry fruit (Ercisli and Orhan, 2007; Butt et al., 2008).

Table 1. Fruit weight, moisture, TDW, TSS, pH and TAc of mulberry fruits

Spacie	Frut weight [g]	Moisture [%]	pH	TDW [%]	TSS [%]	TAc [%]
Morus alba	2.4543±0.2612	75.18±1.00	5.99±0.02	24.82±1.00	17.85±0.07	0.16

As a chemical structure of phenolic compounds is most responsible for their antioxidant activity, measurement of total phenolics content could be related to antioxidant properties of investigated material. Total phenolics content (TPC), total flavonoids content (TFC), total flavonoids/total phenolics ratio (TFC/TPC) and contant of total monometric anthocyanins (TMA) are presented in the Table 2. Antioxidant potential (DPPH assay and reducing power of mulberry extract) are presented in the same table, also.

Table 2. Total phenols content (TPC), total flavonoids content (TFC), ratio TFC/TPC, total monometric anthocyanins (TMA) and antioxidant activity of mulberry extracts

Solvent	TPC [mg ECA/g]	TFC [mg ER/g]	—	[%]	TMA [mg cy-3-glu/g]	IC_{50} mg/ml	EC_{50} mg/ml
Methanol	8.61±0.19	3.42±0.01	39.72		0.78±0.01	0.2037	0.9615
Ethanol	8.27±0.15	3.53±0.01	42.68		0.53±0.01	0.2465	0.9397
Acetone	8.30±0.19	3.60±0.02	43.37		0.81±0.02	0.2783	0.9713
Water	8.06±0.17	3.86±0.06	47.89		0.35±0.02	0.4281	1.7750

Similar content of total phenols was observed in all extract, around 8 mg ECA/g. The highest content of flavonoids was detected in water extract, 3.86 mg ER/g. The ratio TFC/TPC in

wather extract was some higher than that in the other three extracts. The highest content of total monometric anthocyanins was detected in acetone extract, 0.81 mg cy-3-glu/g. Phenolics, flavonoids and anthocyanins can play a double role in reducing the rate of oxidation, as they participate in iron chelation and trapping radicals (Van Acker et al., 1998). Scavenging effect of mulberry extracts on DPPH˙ radicals increased with the increase of concentrations. Radical scavenging activity was found to exhibit 50% of inhibition value (IC_{50} value) at the extract concentration of 0.4281 mg/ml for investigated water extract (Table 2). IC_{50} values for other extracts were lower than 0.3 mg/ml. As IC_{50} values of all investigated samples could be considered as low, this implicates that all dried extracts could be recommended as antioxidant products. Ferrous ion, which commonly exists in food systems, is well known as an effective pro-oxidant component (Fraga and Oteiza, 2002). For the measurements of the reductive ability $Fe^{3+} \rightarrow Fe^{2+}$ transformation, in the presence of extracts have been investigated. Reducing power of investigated extracts were compared to reducing power of standard antioxidant compounds, Trolox and vitamin C. It is clear that both, Trolox and vitamin C, have better reductive capabilities than investigated extracts. EC_{50} value for vitamin C and Trolox was 0.046 mg/ml and 0.079 mg/ml, respectively. These values are much lower than EC_{50} values of investigated extracts (Table 2). The lowest value EC_{50} has been determined for ethanol extract, 0.9397 mg/ml, but it is still much higher concentration in comparison to EC_{50} values of standard antioxidant compounds vitamin C and Trolox. In comparison to ethanol extract, EC_{50} of other extracts were higher, indicating lower reducing capabilities.

The results on antimicrobial activity obtained by the dilution method are given in Table 3. Minimum inhibitory concentration (MIC) was determined for 15 indicator strains. The results suggest that the all extract of mulberry fruits showed antimicrobial activity within the concentration range of 15.62 to 125 µg/ml. The highest susceptibility to the water extracts was exhibited by *Klebsiella pneumonia* and *Pseudomonas glycinea*, (MIC=15.62 µg/ml), among the test bacteria, and by *Aspergillus glaucus* in mulberry extracts prepared with ethanol and acetone (MIC=15.62 µg/ml), among the test fungi. Conversely, the lowest susceptibility was observed in *Bacillus mycoides* in ethanolic extract (MIC=125 µg/ml) and in the fungi *Trichoderma viride* and *Phialophora fastigiata*, the measured MIC value being 125 µg/ml.

Table 3. Minimum inhibitory concentration (MIC) of mulberry extracts

CONCLUSION

The results of this study clearly indicated that methanol, ethanol, acetone and water mulberry extracts were good scavengers of synthetic DPPH radicals what indicates that they all could be used as antioxidant products. Also, they all possess reductive capabilities. They all are adequate source of phenolic and flavoniods compounds, compounds well known as an antioxidants with high antioxidant activity. The obtained results suggest that the extracts of the species *Morus alba* L. possess antimicrobial activity under *in vitro* conditions against the test fungi and bacteria. Our study has shown that mulberry extracts prepared with different solvents had similar characteristics . We recommend ethanol and water to be used as solvents, because these solvents are not toxic to human body. Antioxidant and antimicrobial properties of various extracts of many plants are of great interest in both fundamental science and food industry, since their potential use as natural additives has emerged from a growing tendency to replace synthetic antioxidants by natural ones. The present study confirmed the antimicrobial and antioxidant activities of the extracts of the Serbian plant *Morus alba* L.

ACKNOWLEDGEMENTS

Financial support of this work by the Serbian Ministry of Science, Project No. TR 31013, is gratefully acknowledged. We are grateful to dr. Goran Anačkov, Department of Biology and Ecology, Faculty of Natural Sciences, University of Novi Sad, for support in term of confirmed and deposited *Morus nigra* L. at the BUNS Herbarium.

ABSTRACT: Wines and beers are a rich source of different compounds that show beneficial effects to the human body and their consummation in reasonable amounts can improve health. Among them, the most important are phenolic compounds (nonflavonoids, flavonoids, tannins), which possess antioxidative properties and could be responsible for prevention of many diseases. The aim of this study was to determine the content of total flavonoids, monomeric and total anthocyanins in samples of wines from different grape varieties produced in Serbia and beers produced with the addition of grapes.
Analysis was performed on 14 samples including 5 red wines made from grape varieties from Serbia, one regular beer, and 7 beer samples enriched with different grape varieties and percentage of grape. Monomeric and total anthocyanins were determined spectrofotometrically by the pH differential method, while the total flavonoid content was determined according to the colorimetric Folin-Ciocalteu method after precipitation with formaldehyde.
Anthocyanins were quantified in all analyzed samples, except in regular beer. The highest values were found in wines made from variety Prokupac (270,80 mg/l and 388,79 mg/l malvidine-3-glucoside equivalents, for monomeric and total anthocyanins, respectively). Flavonoids were present in all analyzed samples. Wine samples showed higher content of flavonoids (the highest in Merlot wine) than beer and drinks from beer and grapes. The content of anthocyanins and flavonoids in beer samples enriched with grapes increased with the increase of added amount of grapes. Obtained results showed that relatively high concentrations of flavonoids and anthocyanins are present in wines produced in Serbia. Also, addition of grape in beer increased content of these beneficial phenolic compounds, which can be important factor for quality of a new developed product.
Key words: *anthocyanins, flavonoids , beer, grape*

INTRODUCTION

Beverages such as wines and beer are rich sources of different compounds that show positive effects on human body and their consummation in reasonable amounts can improve health. Many researches have suggested that compounds present in wine may play a protective role in diseases believed to involve, in part, oxidation, such as coronary heart disease, inflammation and carcinogenesis (Lopez-Velez, Martinez-Martinez and del Valle-Ribes, 2003). Also, regular red wine consumption is linked with decrease of cardiovascular mortality in some populations despite high intake of food rich in saturated fats ("French paradox") (Renaud and de Lorgeril, 1992). The reduction in risk of developing diseases for wine consumers is similar to that for consumers of certain fruits, grains and vegetables, which are core components of a traditional Mediterranean diet. The similarity between wine and these foods is the presence of significant amounts of phenolic compounds (Kinsella et al., 1993; Ness and Powles 1997). Phenolic compounds in wines include the non-flavonoid classes of compounds such as the hydroxycinnamates, hydroxybenzoates and the stilbenes, the flavonoid classes of compounds such as flavan-3-ols, flavonols and anthocyanins and

tannins (Stockley and Hoj, 2005). These substances contribute to sensorial characteristics of wine and possess different biological activities. Final composition of phenolic compounds in wine depends on their content in grapes, the extraction parameters, winemaking technology and chemical reaction, which occur during wine aging (Paixao et al., 2007).
Studies conducted in moderate beer drinkers showed a 20–25% reduction in fatality rate from coronary diseases and a reduction by 50% of death factor risk (Bamforth, 2002; Walzl, 2005). These beneficial effects of beer on human health are related to phenolic compounds, particularly to their antioxidant activity (Preedy, 2009). Phenolic compounds identified in beer include phenolic acids, flavonoids, proanthocy- anidins, tannins, and amino phenolic compounds (Gorinstein et al., 2000; Montanari et al.,1999), all of which have been reported to possess antiradical properties as well as other biological effects (Brand-Williams, Cuvelier and Berset, 1995; Gaulejac, Provost and Vivas, 1998). Polyphenols originate from cereal grains (e.g. barley, maize, rice, wheat, sorghum, millet, oat, rye, triticale) and hop; their level in beer is related to malt and hop varieties, malting and brewing processes (Agu, 2002; Derdelinckx, 2008; Qingming et al., 2010). These substances have also important technological role in beer: they are involved in foam maintenance, physical and chemical stability and shelf life of beer.
The aim of this study was to determine the content of total flavonoids, monomeric and total anthocyanins in samples of wines from different grape varieties produced in Serbia and beers produced with the addition of grapes.

MATERIAL AND METHODS

Analysis was performed on 14 samples including 6 red wines, 7 beer samples with different percentage of grape and regular beer. All samples were produced at the enological station Radmilovac of Faculty of Agriculture, Zemun, Belgrade. Wines were made from varieties Merlot (M), Cabernet Sauvignon (CS), Prokupac (P), and Pinot Noir (PN). Also, blackberry wine was analyzed. During production of beer samples appropriate amounts Prokupac, Cabernet Sauvignon and Pinot Noir grape pomace (20, 30 or 50%) were added.
Analysis was performed using Agilent 8453 UV-Visible Spectroscopy System (Germany). Folin Ciocalteu's phenol reagent was purchased from (Fluka Biochemica, Switzerland). Substances and reagents used in experiment were potassium chloride (Zorka Pharma, Serbia), cc hydrochloric acid (Lach-ner, Czech Republic), sodium acetate (Poch, Poland), ethanol 96% (Zorka Pharma, Serbia), formaldehyde 37% (Carbo-Erba, Italy), phloroglucinol-2-hydrate (Centrohem, Serbia), sodium carbonate (Sinex laboratory, Serbia) and gallic acid (Alfa Aesar, England).

Total anthocyanin content

The determination of the total anthocyanins was conducted by the method proposed by Di Stefano, Cravero and Gentilini (1989). The samples were diluted with a solution consisting of 70/30/1 (v/v/v) ethanol/water/HCl (concentrated) and the absorbance was measured at 540 nm. The total anthocyanin contents were expressed as malvidin-3-glucoside equivalents using the following equation:
$TA_5 = A_{540nm} \times 16.7 \times d$
d-dilution

Monomeric anthocyanin content

Monomeric anthocyanins were determined spectrofotometrically by the pH differential method proposed by Lee, Durst and Wrolstad (2005). The samples were diluted with pH 1.0 buffer and pH 4.5 buffer and apsorbance was measured at 520nm and 700 nm against distilled water as blank. The monomeric anthocyanin contents were expressed as malvidin-3-glucoside equivalents using the following equation:

$$MA = \frac{A \cdot M \cdot d \cdot 10^3}{e \cdot l}$$

$A=(A_{520}-A_{700})pH1-(A_{520}-A_{700})pH4.5$
M-molar mass of malvidin-3-glucoside (463.3 g/mol)
d-dilution
ε- molar extinction coefficient (28000 l/mol*cm)
10^3-factor for conversion of g to mg

Total flavonoid content
To 5 ml of sample, 2.5 ml of HCl:H_2O (1:4, v/v) solution and 2.5 ml of 37% formaldehyde were added and left for 2 h. Then, 2 ml of phloroglucinol (10 mg/ml) is mixed into samples and left for 24h at room temperature. Supernatant was filtered through 0,45 μm filter and total phenolic content was determined by the Folin-Ciocalteu's (FC) method using gallic acid as standard (Woraratphoka, Intarapichet and Indrapichate, 2007). Volume of 100 μl of sample or gallic acid standard was mixed with 500 μl of Folin reagent and left for 6 minutes. After that, 400 μl of 7.5% Na_2CO_3 was added, vortexed, and left in dark for 2h. The absorbance of the standards and samples was measured at 740 nm. The amount of flavonoid was calculated as the differences between total phenols and non-flavonoids in samples. The flavonoid content was expressed in mg/l gallic acid equivalents.

RESULTS AND DISSCUSSION

The total and monomeric anthocyanin content in analyzed samples expressed as malvidin-3-glucoside equivalents is shown in Table 1. Total anthocyanins were detected in range from 34.19 to 388.79 mg/l, while monomeric were in range from 39.82 to 270.80 mg/l. The highest content of total as well as monomeric anthocyanins was detected in wine sample made from cultivar Prokupac (inox). Anthocyanins were not detected in regular beer sample. As expected, the highest content of anthocyanins was observed in wine samples, because of high content of these compounds in grapes which contribute to wine color.
Observed variations in total and monomeric anthocyanin content in wine samples can be explained with the influence of cultivar, winemaking technology as well as wine maturity (younger wines have more monomeric anthocyanins) (Degenhadt, 2000). Also, monomeric anthocyanins are involved in hydrolysis, oxidation and polymerization reactions in wine, which can lead to decrease of their concentration. Total anthocyanin content in analyzed wines was in range from 180.18 to 388.79 mg/l, which corroborates with previously published results for wines from Macedonia (Ivanova, Stefova and Vojoski, 2009). The highest content was found for cultivar Prokupac, while the lowest was in wines made from Pinot Noir. The highest monomeric anthocyanin content was also found in cultivar Prokupac, which is not in concordance with results for Serbian commercial wines where the highest content was found for cultivar Cabernet Sauvignon (Radovanović, Radovanović and Jovančićević, 2009).
In beer samples enriched with grape pomace, it is noticeable that increase of grape pomace quantity lead to increase of anthocyanin content. The highest content of anthocyanins was measured in beer sample with 50% Cabernet Sauvignon, while the lowest was in beer with 20% of Pinot Noir. Although variety Prokupac showed the highest content of anthocyanins in wine samples, the same effect was not observed in beer samples, probably because of different extraction of these compounds from varieties. Also, as it can be seen from Figure 1, comparison between wine and beer made with varieties Cabernet Sauvignon and Pinot Noir showed a proportional increase of anthocyanin content. Additionally, quantity of extracted monomeric and total anthocyanins from Pinot Noir pomace in beer is the same (19% and 44%, respectively) when compared with anthocyanin content in Pinot Noir wine.

Table 1. Total and monomeric anthocyanin content of analyzed samples

Wine and beer samples	MA	TA
Pinot Noir wine	109.68±0.67	180.18±0.49
Cabernet Sauvignon wine	157.46±0.22	250.69±0.54
Merlot wine	130.39±0.57	226.11±0.67
Prokupac inox wine	270.80±0.33	388.79±0.66
Prokupac baric wine	222.49±0.14	349.33±0.71
Blackberry wine	160.64±0.38	245.89±0.52
Beer with 20 % Prokupac	39.82±0.09	56.02±0.49
Beer with 30 % Prokupac	39.99±0.26	57.24±0.61
Beer with 20 % Prokupac (II)	59.23±0.73	100.33±0.29
Beer with 20 % Cabernet	42.51±0.81	70.35±0.28
Beer with 50 % Cabernet	105.26±0.39	157.52±0.34
Beer with 20 % Pinot Noir	20.54±0.21	34.19±0.20
Beer with 50 % Pinot Noir	47.99±0.33	79.99±0.47
Beer	0	0

Results are given as mean ± standard deviation (n = 3)

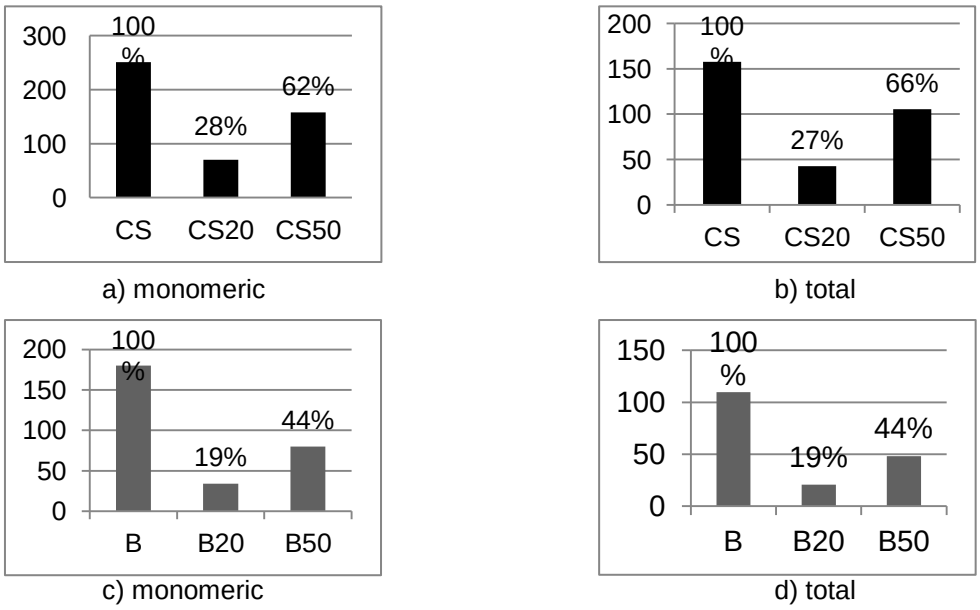

Figure 1. Percentage of extracted monomeric (a,c) and total anthocyanins (b,d) in wine and beer enriched with grape from varieties Cabernet Sauvignon (a,b) and Pinot Noir (c,d)
CS-Cabernet Sauvignon wine, CS20, CS50-beer with 20%, 50% Cabernet Sauvignon grape pomace
B-Pinot Noir wine, B20, B50-beer with 20%, 50% Pinot Noir grape pomace

Table 2. Total flavonoid content of analyzed samples

Wine and beer samples	Total flavonoid content
Pinot Noir wine	1665.39±0.50
Cabernet Sauvignon wine	1687.66±0.35
Merlot wine	1829.22±0.27
Prokupac inox wine	887.94±0.34
Prokupac baric wine	805.41±0.62
Blackberry wine	651.62±0.95
Beer with 20 % Prokupac	284.85±0.40
Beer with 30 % Prokupac	341.88±0.20
Beer with 20 % Prokupac (II)	361.35±0.13
Beer with 20 % Cabernet	172.84±0.17
Beer with 50 % Cabernet	298.33±0.22
Beer with 20 % Pinot Noir	161.85±0.20
Beer with 50 % Pinot Noir	230.60±0.89
Beer	122.07±0.63

Results are given as mean ± standard deviation (n = 3)

The total flavonoid content was in range from 122.07 to 1892.22 mg/l GAE. The highest flavonoid contents were measured in wines from cultivar Merlot, Cabernet Sauvignon and Pinot Noir. The lowest was detected in regular beer (Table 2). Some previously published results for flavonoid content in wine were from 686 to 1104 mg/l GAE (Ivanova, Stefova, Chinnici, 2010), which is lower than our results and could be due to influence of different factors, such as variety, vintage and winemaking technology. In beverages made from grape and beer flavonoid content was from 161.85 to 361.35 mg/l GAE. The highest content of flavonoids was in samples produced with Prokupac grape pomace. Similar to anthocyanis, flavonoid content in beer samples increased with increase of added grape pomace quantity.

CONCLUSIONS

Anthocyanin and flavonoid content was determined in wines and beer enriched with grape. The highest content of monomeric and total anthocyanins was quantified in red wines. The biggest values were found in wines made from variety Prokupac (270,80 mg/l and 388,79 mg/l malvidine-3-glucoside equivalents, respectively). Wine samples also showed higher content of flavonoids (the highest in the Merlot wine) than beer and drinks from beer and grapes. The content of anthocyanins and flavonoids in samples of beer enriched with grapes increased with the increase of added amount of grapes in them. These results show that relatively high concentrations of flavonoids and anthocyanins are present in wines produced in samples from Serbia. Also, it is noticeable that grape enriched beer has increased content of these beneficial compounds, which can improve quality of new developed product.

ABSTRACT: The aim of this study was the development of improved cereal products with various types of extracts prepared from coffee and the evaluation of quality and safety of these novel products. In this study, the addition to cookies of freeze-dried aqueous and ethanol soluble fractions, a microwave-assisted extract, and an oil extract recovered from the coffee residue, was evaluated on acrylamide content and preliminary sensory acceptance by consumers. High and low molecular weight fractions obtained from water soluble coffee were separated using ultrafiltration. All kinds of coffee extracts and coffee oil were incorporated into the formulation of cookies in various concentrations (from 0.1 % up to 5 %). None of coffee extracts increased acrylamide formation. Moreover, in the case of the aqueous fractions, acrylamide elimination up to 10 % was observed (from 223 ± 6 µg/kg to 198 ± 3 µg/kg) which is important from the safety point of view. It was observed that the highest intensity of coffee flavour was in cookies with ethanol soluble fraction in comparison to other coffee extracts.
Key words: *acrylamide, coffee extracts, functional cereal products, quality and safety*

INTRODUCTION

Coffee polysaccharides, which are galactomannans and arabinogalactans (1), present immunostimulatory activity (2,3) and are associated with a decreased risk of a number of disorders including colorectal cancer, constipation, diverticulosis, cardiovascular diseases and type II diabetes. Phenolic compounds, namely chlorogenic and caffeic acids, as well as melanoidins that are formed during roasting, are known for their antioxidant properties (4). On the other hand, some of these components are also potential reagents in the process of Maillard reaction in which acrylamide, a known health-hazardous compound, is naturally formed during baking of cereal products in significant levels (5). Since the presence of acrylamide in heated starch-based foods was discovered in 2002, extensive efforts have been undertaken to investigate tools that may lead to a reduction of acrylamide during food processing. For that reason a special attention is focused on the impact of coffee extracts potential on acrylamide mitigation due to a high content of compounds with antioxidant capacity such as phenolic compounds and melanoidins that were reported to be able to eliminate acrylamide formation (e.g. 7-8 etc.). Evaluation of risk-benefit showed an importance also due to an observation of some health benefit ingredients such as fruit fibre that dramatically increased acrylamide content that was reported before (9). A presented pilot study of bilateral cooperation is aimed at preparing of cereal products with health benefits and regulated safety hazard risk from acrylamide formation point of view.

MATERIAL AND METHODS

Coffee extracts

Five coffee samples were produced in laboratories of University of Aveiro from instant coffee/ coffee residue:

1. Ethanol soluble fraction (EtSn)
2. Low-molecular weight aqueous fraction (LMWaq)
3. High-molecular aqueous fraction (HMWaq)
4. Microwave extract (ME)
5. Oil extract (OE)

For ethanol and aqueous fractions, soluble instant coffee was dissolved in water (80 °C) and precipitated in ethanol. The supernatant material was recovered as the ethanol soluble fraction (ETSn). The ethanol precipitated material was recovered, re-dissolved in water and submitted to a ultrafiltration separation process with a stirred ultrafiltration cell (Millipore Corp., MA, USA) using a 5000 Da filter, from which resulted the low molecular weight aqueous fraction (LMWaq) and high molecular weight aqueous fraction (HMWaq). The microwave extract (ME) was obtained from 20 g of defatted wet coffee residue (≅ 60% w/w of water) suspended in 60 mL of water in a high pressure reactor of 100 mL. The mixture was maintained in homogeneous conditions by mixing with a magnetic stirrer. Microwave power was adjusted to attain 170°C in 2 min, and maintain it for 5 min more. All samples were freeze-dried to powder consistence. Coffee oil (OE) was extracted from pre-dried coffee residues using the Soxhlet method.

Cookies preparation

Coffee extracts were applied to cookie dough in concentration range of 0.1 – 5 % and 10% (w/w), respectively, regarding the extract type in relation to sensory preferences of final product. Dough was prepared from wheat flour, shortening, sucrose, brown sugar, deionized water, salt, non-fat powdered milk, high-fructose corn syrup and raising agents according the standard prescript of AACC Method No. 10-54 (10) using a homogenizer (KitchenAid, USA). Samples of cookies were round shaped to diameter of 6 mm and height of 8 mm and baked at 205 °C for 11 min.

Acrylamide analysis

Final acrylamide content in cookies was analyzed by LC/ESI-MS-MS method using an HPLC system 1200 series (Agilent Technologies, USA) coupled with an Agilent 6410 Triple Quad detector equipped with an ESI interface according to the procedure published in detail before (11).

Sensory evaluation and colour analysis

The impact of coffee extracts and coffee oil on organoleptic properties was evaluated by the panel of 3 dependant judges and 2 - 5 independent assessors with the aim to set the acceptable addition of each extract to cookies. Properties such as colour, texture, appearance, flavour (special descriptors: an intensity of coffee, an intensity of caramel) and taste (special descriptors: an intensity of coffee, an intensity of bitter, an intensity of sweet and caramel) were consider in to account with correlation of consumer preferences.

The colour of a top and a bottom of cookies was measured directly using a Color i5 Spectrophotometer (X-Rite, Germany) at D65/10° UV selection. To distinguish colour changes visual limits in CIELab system were set to: DL=+2/-2, Da=+2/-2, Db=+2/-2 by an X-RiteColor MASTER software.

RESULTS AND DISCUSSION

Acrylamide formation

A presented pilot study was aimed at the development of a new cereal product with functional properties conferred by the addition of various coffee extracts rich in antioxidants. It was proved out that the incorporation of coffee extract represented a safe model of functional food in context with acrylamide formation during thermal processing; moreover some type of extracts resulted in moderate acrylamide mitigation (Fig. 1).

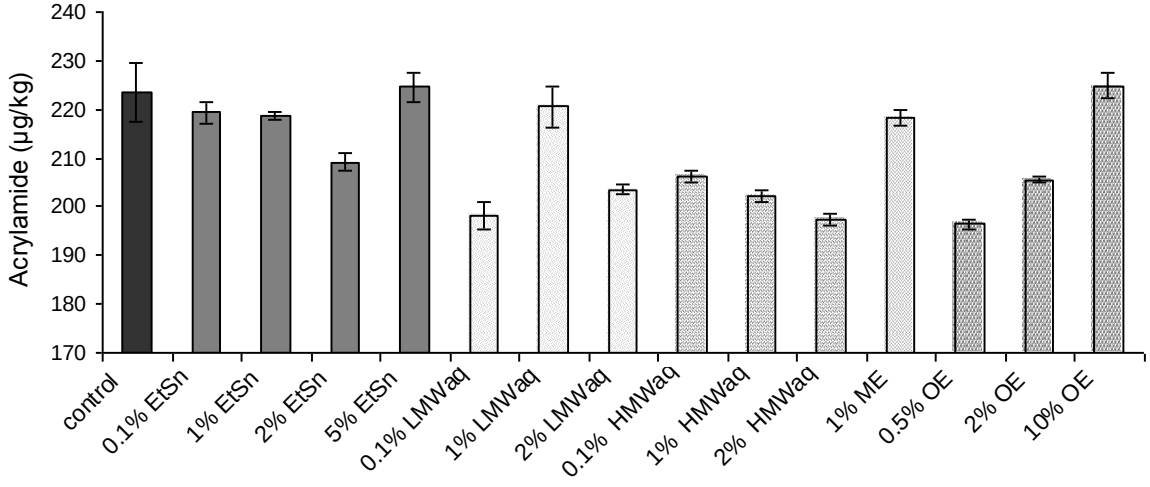

Fig. 1 Influence of coffee extracts addition on acrylamide content in cookies

Approximately a 10% decrease was observed using a LMWaq fraction and a HMWaq in concentration up to 2 % (w/w). The addition of coffee oil also reduced acrylamide content, but only in lower concentration (up to 2%), nevertheless in higher concentration the impact of coffee oil on acrylamide mitigation was not observed (Fig. 1). The addition of a microwave extract in concentration of 1 % (w/w) was not effective.

Sensory evaluation

In case of novel food product development, a sensory evaluation plays an important role. The impact of extracts on organoleptic properties of cookies such as colour, texture, flavour and taste was different. Colour of cookies was measured spectrophotometrically on a top and a bottom of samples and compared with a standard using a CIELab colour system. It could be summarised that LMWaq and HMWaq fractions had the most significant impact on colour. Nevertheless, the impact on the top and the bottom was different. The top of cookies was darker, less yellow and less red; and the bottom, vice versa, lighter, more yellow and more red, especially using the HMWaq fraction. Other extracts, mainly ME and EtSn ones had a small influence on colour of cookies.

According to the preference test, the LMWaq fraction and also EtSn fractions were evaluated in a positive way with the best score of 2 % (w/w) of EtSn (the maximal total score was 3 points) due to the highest harmony in sweet and bitter taste and crunchy delicate soft texture. The addition of 5 % (w/w) of EtSn fraction influenced the intensity of coffee aroma in the highest extends that led to the increase of the total score from 2.0 to 2.5 points in comparison to the control sample. The addition of coffee oil was acceptable up to 2 % (w/w) addition (2 points in total score). The higher content of coffee oil deteriorated preferences of cookies (1 point in total score) due to off-flavour (burned, popcorn-like). The HMWaq fraction was also evaluated in a positive way for their sweet-chocolate taste (2 points). HMWaq fraction did not give coffee smell or taste at all.

Tab. 1 Sensory evaluation score of cookies with coffee extracts

Coffee extract type	Concentration of extract (% w/w)	**Total score** (1- bad quality, 2 – standard/good quality, 3 – improved quality)
EtSn	0.1	2
	1	2.5
	2	2.5
	5	2
LMWaq	0.1	2
	1	2
	2	3
	5	3
HMWaq	0.1	2
	1	2
	2	2
ME	1	2
OE	1	2
	2	2
	10	1

CONCLUSIONS

The novel type of food product was prepared using various coffee extracts without a negative impact on acrylamide formation; moreover with a mitigation potential that is proposed for further research. It was proved out that the most promising was the addition of aqueous coffee extracts (both low and high molecular weight aqueous fractions) that also improved organoleptic properties of cookies.

ACKNOWLEDGEMENTS

This contribution is the result of the project implementation "A strategy of acrylamide elimination in food technology processing" supported by the Research & Development Operational Programme funded by the ERDF. This work was also supported by the Slovak Research and Development Agency under the contracts No. LPP 0310-09 and SK-PT-0027-10. This work is also the result from the a Slovak-Portugal collaboration entitled “Cooperation at the development of improved functional cereal products” established between the VUP Food Research Institute, Department of Chemistry and Food Analysis, Bratislava, Slovak and the Research Unit 62/94 QOPNA (project PEst-C/QUI/UI0062/2011), Department of Chemistry, University of Aveiro, Aveiro, Portugal. The portuguese team was funded by the FCT. Cláudia Passos was supported by a post-doc grant by FCT (SFRH/BDP/65718/2009).

ABSTRACT: Coffee is a wide spread commodity nowadays, which millions of people consume daily. The idea of this work was to enhance the nutritional composition of coffee by inulin and oligofructose enrichment. Inulin and oligofructose are known for its prebiotic properties and have many health benefits. Powdered mixture of inulin and oligofructose was added to three most common coffee beverage types: milled coffee, instant coffee and cappuccino. Physical properties of the control samples (without the addition of functional ingredients) and the samples containing the functional ingredients were monitored. Particle size, moisture content, colour, bulk density, cohesion index, powder flow speed dependency profiles and caking profiles were determined in order to get an insight on the changes caused by the addition of the functional powdered ingredient. Results showed that the addition of inulin and oligofructose lowered the cohesion index of the functional mixtures for all three tested coffee preparations. The addition of the functional ingredient also caused a decrease in cake strength in the case of instant and milled coffee. Colour change was visible for all samples based on the calculated ΔE values (ΔE = 4.64 for cappuccino, ΔE = 5.48 for instant coffee and ΔE = 1.01 for milled coffee). A slight decrease was also detected in Hausner ratio values. Furthermore, moisture content had a significant influence ($p<0.05$) on the cohesion index, caking profiles and Hausner ratio, while particle size strongly influenced cake height ratios recorded during the caking test. These findings suggest that the addition of functional ingredients does not lead to a deterioration of physical properties, and that functional coffee beverages represent an interesting aspect of future research.
Key words: *coffee, enrichment, physical properties*

INTRODUCTION

Coffee, as one of the widest spread beverages nowadays, is known for some of its health benefits, which include the high levels of functional ingredients, such as antioxidants (Brezova et al., 2009). While the health benefits of antioxidants (e.g. polyphenolic compounds) contained in coffee are well described (Bonita et al., 2007), based on the growing market for functional products, there is a growing need for development of enriched coffee beverages, which would contain other functional ingredients such as vitamins, minerals, long chain carbohydrates or even polyunsaturated long chain fatty acids. These coffee beverages would be aimed to ensure at least part of the nutritional requirements of millions consumers around the world which enjoy their coffee on daily basis. So far, there have been several attempts to patent nutritionally enriched coffee beverages (Sartorio et al., 1999, Atkinson et al., 2001), which mostly contain vitamin and mineral premixes. On the other hand, inulin and oligofructose, long chain carbohydrates, as functional ingredients have many health benefits, such as improvement of the bowel health and promoting of the probiotic bacteria growth (Bonnema et al., 2010). Chicory roots, from which inulin is made, is already used in coffee industry for production of e.g. coffee beverages for diabetics (Alves et al., 2010). However, its usage in creating functional milled of instant coffee products has not been recorded yet. Since three most widely used coffee preparations (milled coffee, instant coffee and cappuccino preparations) are powdered products, it is expected that the addition of inulin and oligofructose powder by dry mixing the ingredients, would affect the physical properties of the mixes. This paper aims to detect the overall differences and changes in physical properties of three powdered coffee products (milled coffee, instant coffee and cappuccino) caused by the addition of inulin and oligofructose as functional ingredients.

MATERIALS AND METODS

Materials

Ground coffee, instant coffee and cappuccino products were supplied by Franck, Croatia. Inulin and oligofructose premix was obtained from a local manufacturer (Magdis d.o.o., Croatia). The samples were prepared as follows: three mixtures of 250 grams of coffee (ground, instant and cappuccino) and 12.5 grams of the inulin/oligofructose premix were mixed for 10 minutes in a Turbula mixer (Willy Bachoffen Maschienenfabrik, Switzerland) to obtain a homogenous mixture. Immediately after preparation, moisture content, colour and physical properties were analysed.

Particle size

Particle size of the samples was analysed by laser diffraction using Mastersizer 2000 (Malvern Instruments, UK), equipped with Scirocco 2000 dry dispersion unit. Particle size analysis of instant coffee and cappuccino powders was conducted at following instrument settings: 1 bar air pressure, 50% feed rate and laser obscuration limits ranging from 2 – 6%. Ground coffee samples were dried using an oven dryer for 3 hours at 105 °C prior to measurement, which was conducted at 2-6% laser obscuration, 4 bar air pressure and 100% feed rate, to ensure the optimal flow of the sample through the measurement unit. Results were recorded as d (0.1), d (0.5), d (0.9), D [3,2] and D [4,3]. The measurements were done in triplicate.

Bulk density and Hausner ratio

Bulk density was determined based on the method by Haugaard Sorensen et al (1978). The powder was poured freely into a container, weight of the powder in the container was recorded and the powder was tapped 1250 times using a laboratory made jolting volumeter. Hausner ratio was calculated by dividing the 1250 times tapped density with poured bulk density. All measurements were done in triplicate.

Moisture content

Moisture content of the samples was determined by drying at 105 °C for 3 hours in an oven dryer. The samples were weighed on an analytical balance (Sartorius, Germany) prior to drying and after drying. The difference in weight before and after drying was recorded as the mass of the water contained in the sample. Measurements were done in triplicate.

Colour

Colour measurements were performed using a CM-700d spectro photometer (Konica Minolta Sensing INC., Japan). Prior to measurement white calibration was conducted using a calibration plate supplied by the manufacturer of the instrument. Brightness (L), redness (a) and yellowness (b) were recorded.. The total colour difference (ΔE), as a combination of *L*, *a* and *b* values, also calculated to get a comprehensive insight of the changes in colour caused by the addition of functional ingredients. Samples without the addition of inulin and oligofructose were considered reference samples in ΔE calculation. All the measurements were done in triplicate.

Flow properties

Flow properties of the samples were tested using TA.HDPlus Powder Flow Analyser coupled with the TA.HDPlus Texture Analyser (Stable Micro Systems, Surrey, UK). Three tests were performed: quick test (cohesion assessment), powder flow speed dependency test (PFSD) and caking test. A fixed sample volume (160 mL) was poured into a glass container prior to testing. Prior to testing, the instrument performed a 2 cycle sample preparation step, for each test. Cohesion property was assessed by quick test, with the blade moving upwards through the powder column at the tip speed of 50 mms^{-1}. Cohesion coefficient was calculated by integrating the negative area under the force/ distance curve, and the cohesion index was calculated by dividing cohesion coefficient with sample weight. Powder Flow Speed

Dependency test (PFSD) started with two conditioning cycles which were followed by cycles run at a tip speed of 10 mms^{-1}, 20mms^{-1}, 50 mms^{-1}, 100 mms^{-1} and two final cycles at 10 mms^{-1}. The area under the positive part of the curve, which is the work of compaction, was calculated using Texture Exponent 32 software (Stable Micro Systems, Surrey, United Kingdom). During caking test, the blade levelled the top of the powder column and measured the height of the column, after which it moved down through the column at a tip speed of 20 mms^{-1} and compacted the powder to a pre-defined force (usually 750 g). When the blade reached the required force it sliced up through the powder at 10 mms^{-1} and repeated the compaction cycle four more times. At the beginning of every cycle the blade measured the height of the column and the height of the powder cake was recorded when the target force was reached. The fifth time the target force was reached the blade cut through the formed powder cake at the bottom of the vessel and measured the force required to perform the task. This force was recorded as the cake strength and represented the work required to cut the cake (gmm). Cake height ratio (current cycle cake height divided by initial column height) was recorded to give information about the settlement and compaction of the powder column.

RESULTS AND DISCUSSION

Results for particle size distribution, moisture content and bulk density are shown in Table 1.

Table 1..Moisture content, particle size distribution and bulk density of the samples

Sample	Moisture content [% w/w]	Particle size distribution [µm]					Bulk density [kgm^{-3}]		
		d (0.1)	d (0.5)	d (0.9)	D [2,3]	D [4,3]	Poured	Tapped	Hausner ratio [/]
Ground–control	1.01± 0.01	39.84± 0.72	272.39± 1.57	518.08± 2.79	110.30± 1.39	283.89± 1.95	327.37± 2.77	481.42± 2.44	1.47

Cappuccino-inulin	1.82± 0.03	32.38± 2.51	232.36± 4.95	578.43± 11.92	66.80± 0.20	277.06± 5.72	290.54± 2.98	352.60± 3.16	1.21

As shown in Table 1, addition of inulin/oligofructose premix caused a drop in d(0.1), d(0.5), d(0.9), D[3,2] and D[4,3] values in most cases, with an exception of milled coffee d(0.1) and D[3,2] which exhibited a slight insignificant increase. This increase could be of technical nature. During the measurement it was impossible to achieve stable laser obscuration due to the nature of the ground coffee sample. This might have caused slight discrepancies in the results. Ground coffee showed the highest d(0.1), d(0.5) and D[2,3] values, while instant coffee showed the highest d(0.9) and D[4,3] values. Instant coffee samples had the highest moisture content values, which represents a logical finding if we take into consideration the production process of instant coffee. Addition of inulin caused a slight rise in the moisture content of ground coffee and cappuccino and a slight decrease in the moisture content of instant coffee. Differences in bulk densities of control and enriched samples were slight and insignificant. Furthermore, a slight decrease of the Hr values was detected for enriched samples.

Cohesion indexes of the powders assessed by powder rheometer are shown in Figure 1.

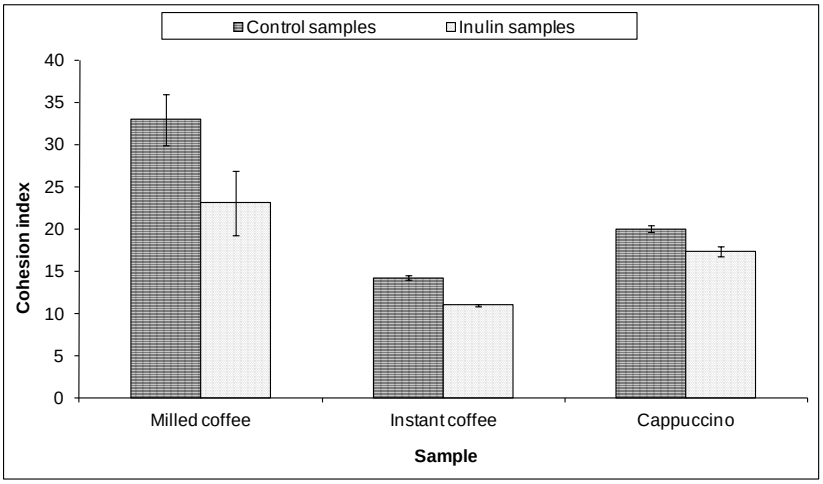

Figure 1. Comparison of the cohesion indexes of the samples

Addition of inulin/oligofructose premix caused a drop in the cohesion index values. The highest drop was detected for ground coffee samples, followed by instant coffee and cappuccino (Fig.1). Based on the cohesion index, both ground coffee samples were categorized as hardened, extremely cohesive, instant control sample as cohesive, enriched instant coffee sample as free flowing, cappuccino control sample as hardened/extremely cohesive and enriched cappuccino sample as very cohesive. In general, instant agglomerated coffee powders show lower cohesion index than ground coffee or cappuccino, whose high cohesion index is due to the presence of small particles, sugars and skim milk powder, which is known to have poor flow properties (Ilari, 2002).
Powder flow speed dependency test resulted in compaction coefficient profiles shown in Figure 2.

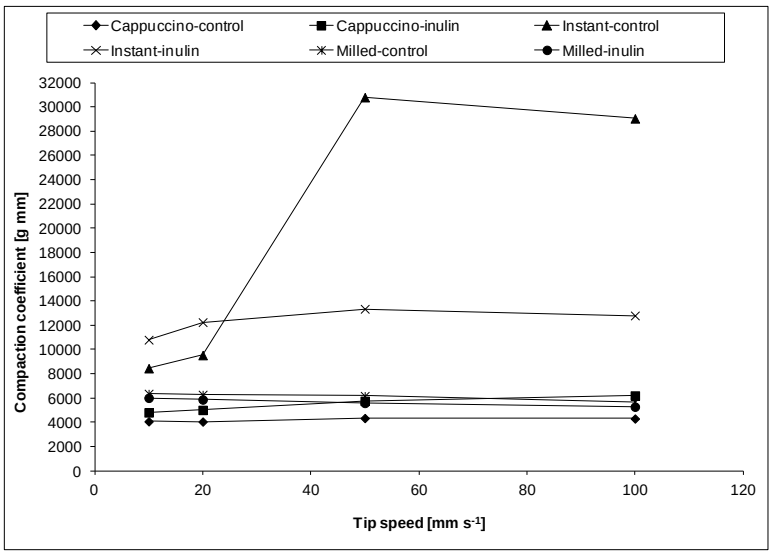

Figure 2. Compaction coefficient profiles of tested samples

Cappuccino showed the lowest compaction coefficient values, followed by ground and instant coffee. In the case of cappuccino, the addition of inulin/oligofructose premix caused a slight increase in compaction coefficient values, while its addition to ground and instant coffee caused a drop in compaction coefficient values. Compaction coefficient values which increased with a rise in tip speed, as detected for instant coffee samples, also meant that the sample flowed harder at higher tip speeds. This deterioration in flow properties was due to agglomerate brakeage which occurred at high tip speeds which resulted in a larger percentage of small diameter particles in the sample. Both ground coffee samples showed a drop of compaction coefficient values with increasing flow speed, which meant they flowed

better at higher conveying speeds. Inulin/oligofructose enriched cappuccino sample showed an increase in compaction coefficient values with higher tip speed, indicating that its flow is harder at higher speeds. The only sample showing a relatively unchanging compaction coefficient profile is cappuccino control sample, indicating it was flow speed independent.
Results of the caking test, recorded as the dependence of cake height ratio towards cycle number, are shown in Figure 3.

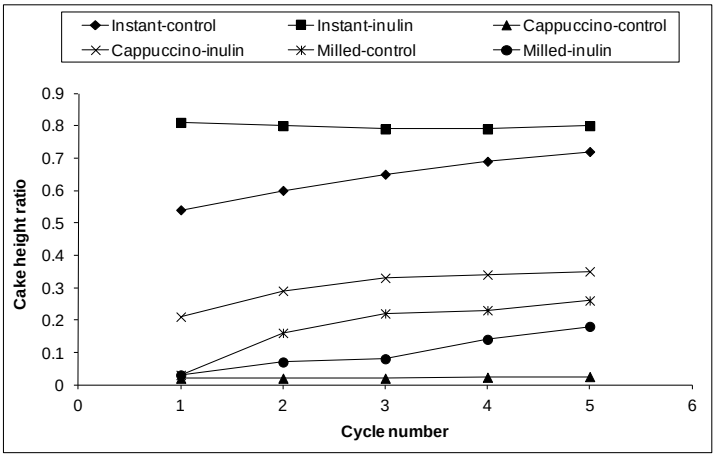

Figure 3. Caking profiles of the tested samples

As shown in Fig.3. instant coffee samples showed the highest cake height ratio values. Instant coffee and cappuccino samples with the addition of inulin and oligofructose showed higher cake height ratio values in comparison to their control samples. The opposite trend was detected for ground coffee – enrichment lead to lower cake height ratio values. Furthermore, cappuccino control sample and inulin enriched instant coffee samples showed an unchanging cake height ratio through out all five caking samples, while all the other samples showed an increase in cake height ratio, which meant they were susceptible to caking. Cake strength values were also recorded during the caking test: for instant-control 4683.93 gmm, instant-inulin 3828.50 gmm, ground-control 2105.93 gmm, ground-inulin 1160.04 gmm, cappuccino control 125.33 gmm and for cappuccino-inulin 432.89 gmm. According to these results, the addition of inulin/oligofructose premix caused a drop in cake strength, which is favourable in transport and handling, while the addition of inulin/oligofructose premix caused an unfavourable increase in cappuccino cake strength. However, since cappuccino already showed by far the lowest cake strength value, enrichment cannot be considered as deteriorating for the cappuccino flow properties.

Table 2. Colour of the analysed samples

Sample	L	a	b	ΔE
Ground-control	28.23±0.04	11.25±0.04	19.29±0.01	1.01
Ground-inulin	28.67±0.01	12.16±0.01	19.22±0.01	
Instant-control	29.78±0.17	13.81±0.08	23.47±0.32	5.48
Instant-inulin	33.07±0.20	12.12±0.28	19.42±0.57	
Cappuccino-control	79.47±0.04	2.21±0.01	7.95±0.06	4.64
Cappuccino-inulin	83.99±0.06	1.55±0.01	7.14±0.02	

As shown in Table 2., L values (brightness) were the highest for cappuccino samples, followed by instant and ground coffee. The addition of inuline/oligofructose premix caused an increase in brightnes for all the samples. Also, the L value was affected the strongest by inulin addition, which represents a logical finding considering the white colour of inuline/oligofructose premix. Redness (a) and yellowness (b) decreased with the addition of inulin, with the exception of redness (a) value for enriched ground coffee. The greatest total

colour difference was detected for instant coffee, followed by cappuccino and ground coffee. These results were somewhat surprising since it was expected that the great colour difference between ground coffee and inulin would result in highest ΔE values. However, it appeared that the darkness of ground coffee particles became dominant over the white inulin particles, thus diminishing the total colour deference between the standard and enriched sample.

Statistical analysis of the overall physical properties of the samples showed the following: significant ($p<0.05$) positive correlations were found between control and enriched samples. Median diameter [d (0.5)] significantly affected cohesion index, compaction coefficient at 10 and 20 mms^{-1}, all cake height ratios and cake strength values. Sauter diameter (D[4,3]) had a significant influence on cohesion index (R=-0.88, p=0.019), while D[4,3] influenced poured bulk density, compaction coefficients at 10 and 20 mms^{-1}, all cake height ratios and cake strength values. Moisture content affected the following properties: compaction coefficients al all four tested tip speeds (with R values ranging from 0.84 for 500 mms^{-1} (p=0.036) cycle to 0.89 (p=0.016) for 20 mms^{-1}), all cake height ratios and cake strength values (R=0.7, p=0.024). Moisture significantly affected d (0.1) (R=-0.93, p=0.007), d (0.5) (R=-0.98, p=0.001) and D[4,3] (R=0.91, p=0.012). Furthermore, a strong correlation was also found between bulk density and all colour parameters, which meant that the way the particles were packed together played an important role in colour of the mixtures. Bulk density showed strong correlation with cohesion index (R=-0.92, p=0.01), d(0.5) (R=-0.83, p=0.041) and D[3,2]. Significant ($p<0.05$) positive correlation was found between compaction coefficient values at 10 and 200 mms^{-1}, all cake height ratios and cake strength values.

CONCLUSIONS

Addition of inulin/oligofructose premix lowered the cohesion index and Hr values of the functional mixtures for all three tested coffee preparations. The addition of the functional ingredient also caused a decrease in cake strength in the case of instant and milled coffee. Furthermore, moisture content had a significant influence ($p<0.05$) on the cohesion index, caking profiles and Hausner ratio, while particle size strongly influenced cake height ratios recorded during the caking test. Colour change was visible for all samples based on the calculated ΔE values. These findings suggest that the addition of functional ingredients does not lead to a deterioration of physical properties.

ABSTRACT: Fish lipids are rich dietary sources of n-3 long-chain polyunsaturated fatty acid (LC-PUFAs). Among n-3 fatty acids, the most important are eicosapentaenoic (20:5 n-3, EPA) and docosahexaenoic (22:6 n-3, DHA) acids which have important roles in the prevention and treatment of different diseases. The aim of this study was to analyze the fatty acid content of fresh marine fish available on the Serbian market. In five species of marine fish (salmon, tuna, mackerel, sardines and hake) the content and composition of fatty acids were analyzed. After lipid extraction, fatty acids were derivatized into volatile methyl-esters. Fatty acids were determined using capillary gas chromatography. Analyses of total lipid content in fresh fish samples and their fatty acid composition revealed that mackerel and sardines were the best dietary sources of LC-PUFAs (4.6 and 4.5 g/100 g, respectively). All analyzed fish samples had significantly higher DHA than EPA content. The highest average EPA content per 100 g of edible fish was observed in samples of sardines (2.0 g). The results showed that the DHA content of sardines, mackerel and salmon were similar - 2.2 g, 2.6 and 2.3 g/ 100 g, respectively. Hake and tuna had significantly lower LC-PUFAs, EPA and DHA contents. Although significant variations in n-3 fatty acids' content were noted among individual fish samples, it could be concluded that fresh marine fish available on Serbian market can be cheap and valuable source of LC-PUFAs in daily diet.
Key words: *n-3 fatty acids, marine fish, analysis*

INTRODUCTION

Marine food and especially marine fish are important sources of long chain polyunsaturated fatty acids (LC-PUFAs). Among the polyunsaturated fatty acids, eicosapentaenoic acid (C20:5n3, EPA) and docosahexaenoic acids (C22:6n3, DHA) are the dominant n-3 fatty acids in marine fish. The importance of n-3 fatty acids in human health is well documented in numerous studies as reviewed by Simopoulos (2011). These fatty acids can be of great importance to humans in prevention of coronary artery disease (Mozaffarian et al, 2005) and other chronic diseases (Simopoulos, 2008). The fat content and the fatty acid composition of fish can vary significanlty. The reasons for fatty acid composition variations are diet, life cycle, temperature, location, gender and environmental conditions (Bandarra et al, 2001; Gockse et al, 2004). Thus, this study was carried out to determine and compare the fatty acid composition in common marine fish available on Serbian market and to evaluate marine fish as sources of dietary n-3 fatty acids.

MATERIAL AND METHODS

Five marine fish species commonly consumed in Serbian diet were chosen and purchased from the local fish market (salmon, tuna, mackerel, sardines and hake). The origin of salmon was Norway (North Sea), while the origin of other four species were Montenegro and Croatia (Adriatic Sea). Skin, head, gills, fins and bones from each fish species were removed, meat was cut into pieces and homogenized. At least three samples from each fish were used for analysis. The total lipids content from each homogenized sample was determined by gravimetric method after Soxhlet extraction. Lipids for further fatty acid analysis were extracted according to the Bligh&Dyer method (1959). The methyl esters of the fatty acids (FAMEs) from the lipid extract were transesterified with HCl in methanol according to the method as described by Ichihara and Fukubayashi (2010). FAMEs were quantified using a

Agilent Technologies 7890A Gas Chromatograph with a flame ionisation detector. Separation of the FAMEs was performed on a 112-88A7, HP-88 capillary column (100 m x 0,25 mm x 0,2 μm) using He as a carrier gas at a flow rate of 105 ml/min. The samples were injected at a starting oven temperature of 175˚C, injector temperature was 250˚C and detector temperature was 280˚C. The oven temperature was programmed to increase from 175˚C to 220˚C at 5˚C/min. Fatty acids were identified by their retention time with reference fatty acid standards (SupelcoTM FAME Mix, USA).

RESULTS AND DISCUSSION

The lipid content was different between analysed fish species and individual samples. The percentage of total lipids was highest in mackerel (14%), while the lowest content was found in tuna (1,2%).
The fatty acid compositions of the investigated fish are presented as mean value in Table 1.

Table 1. Fatty acid composition (% of total amount of fatty acids) of the investigated marine fish

Fatty acid	Hake	Sardine	Mackerel	Salmon	Tuna
14:0	1.4	4.3	3.9	2	0.4
16:0	21.3	21.5	14.5	14.8	17.6
16:1	2.6	5.6	2.3	2	1
18:0	4.9	4.1	3.3	3.3	7.7
18:1n9	10.4	2.8	7.6	22.1	10.6
18:1n7	2.4	3.6	1.4	3.9	1.6
18:2n6	1.2	1.1	2.1	8.2	1.1
18:3n6	0.2	0.3	0.3	0.2	0.1
18:3n3	1.4	1.2	7	2.7	0.3
20:4n6	2	3.5	12	2.1	6.9
20:5n3	8.2	14.7	9.7	6.5	3.2
22:6n3	36.8	27	21.9	21.7	33.3
SFA	27.5	30.4	23.3	20	26.8
MUFA	15.4	12	11.5	27.9	13.4
PUFA	49.7	47.8	52.8	41.4	44.8

SFA - saturated fatty acid; MUFA - monounsaturated fatty acids; PUFA - polyunsaturated fatty acid.

The results showed differences in the individual fatty acids among the marine fish species. In all investigated fish the main fatty acids were palmitic acid (C16:0) and DHA. The fatty acids with the highest percentages, next to C16:0 and DHA, were EPA and oleic acid (C18:1n9). These results are in agreement with previous studies (Zlatanos & Laskaridis, 2007; Zlatanos & Sagrados, 1993). The fatty acid composition of marine fish were found to be 20-30.4% saturated (SFA), 11.5-27.9% monounsaturated (MUFAs) and 41.4-52.8% polyunsaturated fatty acids (PUFAs). These results are also in accordance with the literature (Ozogul et al, 2007).

Analyses of total lipid content in fresh fish samples and their fatty acid composition revealed that mackerel and sardines, were the best dietary sources of LC-PUFAs (4.6 and 4.5 g/100 g, respectively). All analyzed fish samples had significantly higher DHA than EPA content. The highest average EPA content per 100 g of edible fish was observed in samples of sardines (2.0 g). The results showed that the DHA content of sardines, mackerel and salmon were similar - 2.2 g, 2.6 and 2.3 g/ 100 g, respectively. Interestingly, tuna and hake had very low DHA and EPA content in comparison with other fish species.
The total n-3 PUFAs and n-6 PUFAs content are shown in Figure 1. Significant variation of n-3 fatty acids' content was noted among individual fish samples. Among the analyzed species, the highest level of n-3 PUFAs was noted in mackerel, whereas hake and tuna had the lowest level of total n-3 fatty acids. In all analysed marine fish species total n-3 PUFAs content were higher than those of n-6 PUFAs. These results are in accordance with previous results (Abdulkadir, 2006).

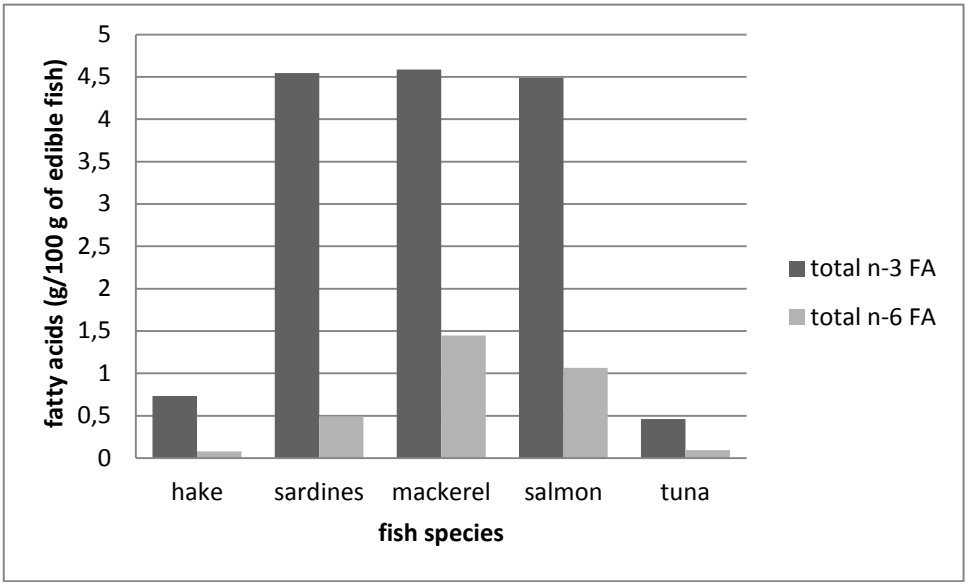

Figure 1. Total n-3 PUFAs and n-6 PUFAs content of the investigated marine fish

CONCLUSIONS

Although there were significant differences in lipid content and fatty acid composition, all five examined marine fish species are rich sources of long-chain n-3 fatty acids, especially DHA. The fish species studied are among the most common found in the Serbian market, and therefore can be regarded as valuable and easily available sources of LC-PUFAs in daily diet.

ABSTRACT: Coeliac disease is characterized by permanent intestinal intolerance to wheat gliadin and related prolamins from barley, rye and oats. The gluten free diet is a life long treatment for coeliac patients. Industrial starch or other ingredients used in manufacturing of dietary products can contain prolamins as impurities. The aim of this work was investigation the presence of gluten in dietary products from the national market: 30 dietary foods for infants and young children and 35 food supplements were analyzed using the Ridascreen Gliadin sandwich R5 enzyme-linked immunosorbent assay with cocktail extraction. The most of the analyzed samples (88%) contained less than limit of quantification of 5 mg/kg for gluten. Gluten content of 5-20 mg/kg was determined in 3 samples. Five of 65 samples (8%) contained mean gluten levels ≥ 20 mg/kg and would not be considered “gluten-free” according to the national Regulation on health safety of dietary products. The systematic control of the presence of gluten in gluten-free dietary products is very important and should be obligatory in order to protect the health of coeliac patients.
Key words: *coeliac disease, gluten, dietary products, food supplements, baby foods*

INTRODUCTION

Coeliac disease (CD), also known as coeliac sprue and gluten sensitive enteropathy, is characterized by permanent intestinal intolerance to wheat gliadin (and related prolamins from barley, rye and oats), which causes damage to small bowel mucosa by an autoimmune mechanism in genetically susceptible individuals (Hill et al., 2005). Epidemiological studies have shown that CD affect approximately 0.5–1.0% of people in developed countries (Catassi and Fasano, 2008) and its prevalence is on the rise (Rubio-Tapia and Murray, 2010). Untreated CD can result in severe malnutrition, and stunted growth in children (Fasano and Catassi, 2005); gynaecological, reproductive and obstetrical dysfunctions (Smecual et al., 1996); skeletal (Blazina et al., 2010), psychiatric, neurological (Collin et al., 1991) and hepatobiliary diseases (Kaukinen et al., 2003); malignomas (Green et al., 2003); increased risk of associated autoimmune diseases (Ventura et al., 2002).
The gluten-free diet is the essential treatment for coeliac patients and requires avoidance of any food or other products containing prolamins from wheat (gliadins), rye (secalins), barley (hordeins) and oats (avenins). However, total avoidance of these prolamins is not so simple because of their presence in unexpected foodstuffs such as meat products, soups, sauces, juices and beers, as well as in food additives like flavorings, emulsifiers, colorings and preservatives that are derived from gluten-containing grains (Gregorek et al., 2006). Some research suggested that some CD patients can tolerate oats, but it also might be contaminated with wheat, barley, and/or rye during harvest, transport, and/or processing (Koerner et al., 2011). Also, industrial starch and other ingredients used in manufacturing pharmaceutical products and food supplements can contain prolamins as impurities.
In the present study, the presence of hidden gluten in a range of dietary products available on the Serbian market has been investigated.

MATERIAL AND METHODS

Thirty five food supplements and thirty samples of dietary foods for infants and young children from Serbian market were analyzed using a commercially ELISA kit (RIDASCREEN® Gliadin, Art. No. R7001) produced by R-Biopharm AG, Darmstadt, Germany. This sandwich ELISA kit has a detection limit of 3 mg/kg of gluten and is based on the monoclonal antibody R5 that reacts with gliadin-fractions from wheat and corresponding prolamins from rye and barley (Valde´s et al., 2003; Mendez et al., 2005). The quantification range of this assay is 5 to 80 mg/kg of gluten. The method has been endorsed by the Codex Committee on Methods of Analysis and Sampling as a type 1 method for determination of the gluten content in gluten-free foods (ALINORM 06/29/23).

Samples extraction and preparation

0.25 g of the homogenized sample of dietary product was weighed into a 10 ml centrifuge tube, a Cocktail-Solution (2.5 ml) was added and the tubes were put on a vortex for 30 s. Samples were incubated for 40 min at 50 ºC, then mixed with 7.5 ml of 80% ethanol and incubated for 1h in a rotary shaker at 45 turns/min. The tubes were centrifuged at 2500 x g for 10 min at room temperature and the supernatants were used for sandwich ELISA analysis. A measured aliquot of the supernatant was removed; diluted 1:12.5 (80 µl + 920 µl) and then 100 µl of this solution were used in the assay.

Gluten determination

Standards and samples were added in duplicate wells on the plate and allowed to incubate for 30 min at room temperature followed by three washing steps. Enzyme conjugate was added to each well and the plate was incubated for 30 min followed by an additional three washing steps. At this point substrate and chromogen were added to each well and allowed to react for 30 min followed by the addition of stop reagent. The absorbance was read at 450 nm on a BioTek EL800 microplate reader (BioTek Instruments, Inc., Winooski, VT) and the data were analysed to determine gluten concentration.

RESULTS AND DISCUSSION

According to the regulations in Serbia (“Sl.glasnik RS”, No.45/2010) the maximum level of gluten in products labelled as gluten-free is 20 mg/kg. In the this study we have determined the content of gluten in thirty five samples of food supplements, produced by different manufacturers, that according to their nature should not contain gluten (Table 1). Among them, only five samples of food supplements had specifically mentioned gluten status. Therefore, these samples are not recognised as gluten-free by CD patients. The obtained results have shown that most of the analyzed food supplements have gluten content less than limit of detection (3 mg/kg) and limit of quantification (5 mg/kg) method. Gluten content of 5-20 mg/kg was determined in three food supplements, and only one analyzed sample had gluten content higher than 80 mg/kg.

Table1. Gluten content in analysed food supplements

Table 2 shows the results for the dietary foods for infants and young children samples analyzed for the presence of gluten in this study. In four of five of samples of instant baby foods containing only naturally gluten-free ingredients the quantity of gluten have exceeded 20 mg/kg. Considering the high amount of gliadin in these samples, gluten contamination possibly occurred during manufacturing of these products.

Table2. Gluten content in dietary foods for infants and young children

Groups of products	Producer	Number	Gluten content (mg/kg)
baby poridge	A	25	-
instant baby food	B	5	
rice cereal with prebiotics			>80
rice and corn with milk			>80
rice and corn cereals with milk and fruits			>80
cereal with vanilla rich vitamins and minerals			>80
skim milk cereal with rice rich in vitamins and minerals			-

Note: "-"= gluten content < 5 mg/kg

CONCLUSIONS

The most of the naturally gluten-free food supplements analyzed in our study, although not bearing the "gluten-free" label, can be safely consumed by coeliac patients. However, our finding of possible contamination with gluten of the products, claimed to be gluten-free, especially grain-based products, suggested that systematic control of gluten-free dietary products should be obligatory. Thus, the printing of information "gluten-free" on the labels of dietary products exclusively on the basis of ingredients without any laboratory analyses should not be allowed.

ABSTRACT: This study aimed to investigate the influence of flaxseed addition on technological and nutritional quality of gluten-free extruded product. Ground flaxseed was added in amounts of 3, 5 and 7 g/100 g to corn meal and rice flour mixture (1:1) and extruded by twin-screw co-rotating extruder. Enrichment with flaxseed resulted in significantly lower expansion ratio and higher bulk density of extrudates, but peak viscosity, water absorption and water solubility indices were barely modified. The content of protein, total fibre, and unsaturated, saturated and omega-3 fats significantly positively correlated to the flaxseed amount. In all extrudates saturated fats were lower than 1 g/100 g, and the average energy value was 379±3 kcal/100 g. In 7% flaxseed enriched sample, the total phenolics content determined by Folin-Ciocalteu method was higher by 45% compared to the non-enriched, and its lignan content determined by GC-ECD method was 14.44 mg/100 g vs. 0.06 mg/100 g in the control sample. However, the antioxidant capacity evaluated using DPPH and ABTS assay was similar among samples. In conclusion, the addition of ground flaxseed in amount of 5% can be recommended for the enrichment of gluten-free snack or breakfast cereal. Such product could be labelled as a source of fibre and high in omega-3 fatty acids according to a valid EU regulation.
Key words: *antioxidants, extrusion, gluten-free, flaxseed, lignans, omega-3 fatty acids*

INTRODUCTION

Gluten-free cereal products are known to be of low nutritive value compared to the standard products that they are intended to replace. They are mostly produced from rice and corn because of their hypoallergenicity. At the same time, these products can be high in calories and fat that has been added in order to enhance overall acceptability (Niewinski, 2008).
Food market offers broad spectrum of snacks and breakfast cereals produced by different processing techniques. One of the most popular technique is extrusion cooking. Snack products are extruded at low moisture content, high temperature and high shear process that is characterised by forming a melt from the starchy ingredient. This leads to a more expanded product that melts in the mouth. Starch is the main constituent of the extruded snacks and is responsible for most of their structural attributes. Thus, extruded products are dense in energy but are nutritionally poor. However, there are many possibilities to incorporate beneficial nutrients into them (Dehghan-Shoar et al., 2010).
Functional ingredient which is often added to cereal-based products is flaxseed. Flaxseed is the leading plant food source of the ω-3 fatty acid, phytoestrogen compounds known as lignans, and soluble polysaccharides. In comparison to cereals, flaxseed is 200-fold higher in lignans and 3 times higher in total phenolics (Čukelj et al., 2011b). Incorporation of flaxseed in the diet is particularly attractive for the development of foods with specific health advantages (Oomah, 2001). For instance, ω-3 fatty acids show great promise in prevention of cardiovascular diseases (Lavie et al., 2009), lignans are associated with a reduced breast cancer risk (Cotterchio et al., 2007), and polyphenols are known antioxidants (El Gharras, 2009).
The aim of this study was to investigate the influence of flaxseed addition on technological and nutritional quality of gluten-free extruded product manufactured from corn meal and rice flour. The flaxseed was added at three levels. Physical and chemical properties, total phenolics and lignan content, as well as antioxidant capacity of flaxseed enriched gluten-free snack were examined.

MATERIALS AND METHODS

Extrusion cooking

Extrudates were produced from corn meal (Naše Klasje, Croatia), rice flour (Davert Muhle, Germany), and flaxseed (Suban, Croatia). Flaxseed was milled to a 1 mm particle size. Equal amounts of corn meal and rice flour were mixed with flaxseed at 3, 5, or 7 kg/100 kg of flour blend. A control sample without flaxseed was prepared in the same way. Blends were extruded in twin-screw co-rotating extruder APV SB 65 (Baker Perkins, UK) consisting of two independent zones of controlled temperature in the barrel set at 130°C and 150°. The average screw speed was 300 rpm. The feeding rate was 312.5 kg/h, water was injected directly at 32.9 L/h, and lecithin was used for lubrication at 1.4 kg/h. The product coming out from the extruder through a circular die of 3.3 mm diameter was cut into short pieces. Extrudates were dried in a forced ventilation air tunnel that was set at 90°C in the first and at 30°C in the second section.

Physical properties of extrudates

Expansion ratio was calculated as the ratio between the average diameter of 30 extrudate samples, measured with calliper, and the die diameter. For the determination of bulk density, volume of 100 g of extrudates was measured in five replicates and the average ratio of mass to volume was calculated. Water absorption index (WAI) and water solubility index (WSI) were determined in duplicates using the method of Anderson et al. (1969). Pasting properties of the milled extrudate (10 g, with correction to 14% of moisture) dispersed in 105 ml of deionized water were determined twice according to AACC Method 22-08.01 (1999) with a MicroViscoAmylo-Graph (Brabender, Germany).

Chemical composition of extrudates

Chemicals of adequate analytical purity were purchased from the local market. Standards of lignans were a kind gift from Oy Separation Research Ab (Turku, Finland). Moisture, protein and ash were determined according to AACC methods (1999). Total dietary fibre was determined following an AOAC 2009.01 method (2011) using Megazyme kit. Fat content of the sample was measured using a Soxhlet extraction, after an acid hydrolysis. Fatty acid composition was determined according to ISO Methods 5509:2000 and 5508:1990. Gas chromatography of fatty acids was performed using an Agilent Technologies 6890N Network GC System equipped with a FID detector and a 60m x 0,25mm capillary column DB-23 (Agilent, USA). Helium was carrier gas at a flow rate of 1.5 ml/min. Sample was injected with a splitting system 1:30. Injector was set at 250°C and detector at 280°C. The column was heated from 60 to 220°C, at a 7°C/min rate. Available carbohydrates and energy value of extrudates were calculated according to Joint FAO/WHO Report (1998).

Prior to determination of phenolic compounds, lignans and antioxidant activity, extrudates were defatted. Total phenolic content (TPC) and antioxidant activity were determined spectrophotometrically (UNICAM Heλios β, England). The extracts of phenolics were prepared as described by Li et al. (2009), but adjusted for quantities using 10-times bigger amounts. TPC was measured according to Yu et al. (2002), with modifications (Čukelj et al. 2011b). The results were expressed as mg of ferulic acid equivalents (FAE) per 100 g of dry sample. DPPH (2,2-diphenyl-1-picrylhydrazyl) radical-scavenging capacity of extracts was assessed by the method of Zhou and Yu (2004) with following modifications: to 1.9 ml of 0.06 mM DPPH in methanol, 100 µL of extract was added, and the free radical scavenging capacity was evaluated by measuring the decrease of absorbance at 517 nm. Antioxidant capacity was expressed as mmol/L Trolox equivalents. The Trolox equivalent antioxidant capacity of extrudate extracts was as well estimated by the ABTS (2,2-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid)) radical cation decolorization assay (Re et al., 1999). Extraction and quantification of lignans in extrudates were done on the same GC as fatty acids but connected to electron-capture detector as described earlier by Čukelj et al. (2011a).

All chemical analyses were the means expressed with standard deviation (SD) of two replicates except total phenolics and antioxidant activity tests that were conducted in triplicates.

RESULTS AND DISCUSSION

Physical properties of extrudates

In this study, we investigated the effect of incorporating ground flaxseed on the nutritional and physical properties of gluten-free extruded product. When developing novel nutritious food, it is necessary to monitor its physical properties as they greatly affect consumer acceptability. Product with the added flaxseed were of lower expansion ratio (ER) and higher bulk density (BD) than non-enriched sample but the difference was statistically significant only at $p \leq 0.1$ (Table 1). BD is an index of the extent of puffing, thus as the volume of extruded products increases the BD decreases. Cheng and Friis (2010) showed that the maximum expansion is obtained with pure starches, while dietary fibre and protein have a negative effect on the expansion. Flaxseed contains considerable amount of both, so negative expansion was expected. Similar trend for the ER and BD was obtained with extruded corn snack enriched with flaxseed flour at 5-20% (Ahmed, 1999). To compensate and produce well expanded product, extrusion processing at high temperature and shear should be tested.

The amount of degraded starch granules is positively related to WSI and inversely to WAI. Flaxseed addition slightly affected WAI and WSI of extrudates (Table 1) and the differences between samples were statistically significant only at level $p \leq 0.1$. Solely the control was different from all the other samples in WAI at $p=0.05$, and in WSI it differed from the sample with 7 % of flaxseed at $p=0.08$. The similar results were obtained by analysing pasting properties. The enriched samples begun to gelatinise earlier at lower temperature, but the peak paste viscosity and the temperature thereof did not significantly differ (Table 1). The viscosity of a paste depends to a large extent on the degree of gelatinisation of the starch granules and the extent of their molecular breakdown (E-Dash et al., 1983). Similar viscosity of extrudates obtained after enrichment could be due to the fact that soluble fibre from flaxseed can enhance starch gelatinisation thus compensate for starch dilution effect.

Table 1. Effect of added flaxseed on the physical properties of the extrudates (average ± SD)

Flaxseed addition (%)	Expansion ratio	Bulk density (g/L)	WAI (g/g)	WSI (g/g)	Peak viscosity (BU)
0	4.60±0.28	59.2±0.2	11.07±0.03	0.27±0.03	38.5±3.5
3	4.33±0.26	60.7±0.2	11.73±0.21	0.24±0.03	51.0±2.8
5	4.08±0.22	62.6±0.2	11.87±0.36	0.23±0.01	45.0±0.7
7	3.66±0.26	86.7±0.4	12.10±0.40	0.21±0.01	42.5±4.1

Chemical characteristics of extrudates

As the proportion of flaxseed in the extrudates was higher, protein, fat, and dietary fiber also reflected a significant growth (Table 2). In the same time, energy value of extrudates did not significantly change and the content of saturated fatty acids remained below 1 g/100 g. The dominant were unsaturated fatty acids: linoleic, oleic and linolenic. By adding flaxseed, the content of α-linolenic acid progressively enhanced, and consequently the ratio of omega-6 to omega-3 fatty acids was almost 1:1. The recommended daily intake of omega-3 fats (250 mg) could be met by consuming 40, 31 or 24 grams of extrudates enriched with 3, 5 or 7 % of flaxseed, respectively. Extrudates with added flaxseed at 5 and 7 % could be labelled as a source of fibre and high in omega-3 fatty acids according to European Regulation 1924/2006 on nutrition and health claims made on foods.

Table 2. Chemical characteristics and energy value of 100 g of extruded products (average±SD)

Parameter	Flaxseed addition level (%)			
	Control (0)	3	5	7
Moisture (g)	7.84±0.01	7.75±0.04	7.81±0.06	7.89±0.21
Ash (g)	0.55±0.01	0.61±0.03	0.63±0.01	0.63±0.02
Protein (g)	7.67±0.02	8.04±0.01	8.19±0.03	8.29±0.04
Fat (g)	2.66±0.01	3.38±0.15	3.95±0.35	4.70±0.05
of which saturated	0.52±0.03	0.65±0.01	0.85±0.10	0.90±0.01
of which unsaturated	2.04±0.05	2.63±0.02	2.96±0.15	3.69±0.01

Energy (kcal/kJ)	375/1566	378/1579	380/1587	383/1600
Antioxidant capacity (mM Trolox/100 g)				
DPPH	397.3±6.3	385.8±1.5	354.5±17.1	329.0±7.6
ABTS	347.9±34.8	349.1±36.3	360.4±17.1	341.8±16.3

In products enriched with flaxseed, the TPC and total lignan content were significantly higher (at $p<0.001$) compared to the control sample (Fig. 2). In the sample with 7% of added flaxseed, TPC was almost two times higher compared to the control sample. In a previous study, TPC in flaxseed was around 3 times higher compared to cereals (Čukelj et al., 2011b), thus the higher level of TPC in extrudates was expected. We applied alkaline hydrolysis prior to extracting phenolics in order to include both free and bound phenolics. It has been proven that bound phenolics make more than 74% of all the phenolics in rice, and more than 69% in corn (Adom and Liu, 2002). The similar growing trend with flaxseed addition was observed for total lignans, and both TPC and lignan content significantly correlated ($r=0.986$, $p<0.05$). In enriched extrudates the main lignan contributing to more than 97% of total lignan content was secoisolariciresinol, while lariciresinol and pinoresinol were also detected. Cotterchio et al. (2007) showed that among Western women, lignans contribute approximately 70% of total phytoestrogen intake, i.e, nearly 2 mg/day. Beneficial effect on menopausal health was observed with the intake of 30 mg/day of soy isoflavones (Kurzer, 2003), thus the intake of extrudates enriched with flaxseed could drastically improve the amount of phytoestrogen in everyday diet and thus, health status.

Antioxidant capacity of extrudates was double examined ABTS and DPPH methods, and in both measurements we compared it with the water soluble vitamin E analogue - trolox (Table 2). The results obtained with both methods showed to be similar. Although the flaxseed enriched extrudates were higher in TPC and lignan content, there was no significant difference in antioxidant capacity between the samples. The DPPH values show even slight decrease in antioxidant capacity of extrudates with more added flaxseed although the phenolics are considered to be one of the main carriers of the antioxidant capacity (Brennan, 2011). We assume that during the one month storage of extrudates at room temperature, before DPPH and ABTS tests were conducted, the oxidation of unsaturated fats occurred. In turn this resulted in a similar antioxidant activity of control and enriched samples, since enriched samples were higher in fats. Not only phenolics, but also other components of flaxseed such as tocopherol and omega-3 fatty acids act as antioxidants. Our study indicates that the lignans and other phenolics are not the most sensitive flaxseed antioxidants quickly used up during processing and storage. This is in agreement with the study by Liukkonen et al. (2002), which showed that rye lignans and alkaline-extractable phenolic compounds remain almost unchanged during baking. On the other hand, tocopherols and tocotrienols showed a decrease in the amount, during sourdough baking process. Further studies should investigate the effect of storage time on the oxidative stability of extrudates enriched with ground flaxseed.

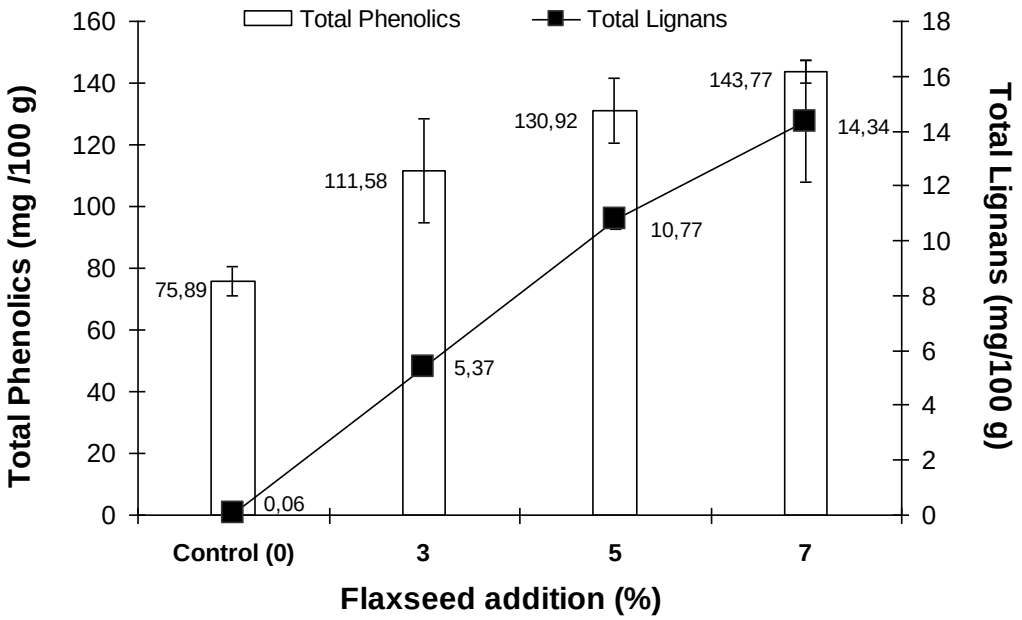

Figure 1. Total phenolic content (TPC; mg FAE/100 g±SD) and total lignan content (mg/100 g±SD) of extruded products (dry basis).

CONCLUSIONS

The proximate composition reflects better nutritive profile of the enriched extrudates in terms of fibre amount, protein content, and fatty acid composition, in comparison to non-enriched. In particular, the content of omega-3 fats, phenolic compounds and lignans improved upon enrichment with flaxseed. However, some physical characteristics of extrudates, especially expansion ratio, were negatively affected by flaxseed addition. Taking into account both physical and nutritive characteristics of the extrudates, 5% of flaxseed could be incorporated in a gluten-free snack or breakfast cereals, depending on the formulation and process conditions. Such information could be helpful to food producers in development of extruded material as a novel product for various consumers demanding gluten-free, nutritionally enhanced or convenience foods.

ACKNOWLEDGEMENTS

We thank the staff of Naše Klasje, Ltd. Zagreb, especially Zoran Šimunić and Matija Ivandić, for their valuable technical help in extrusion process.

ABSTRACT: Today, bread is part of the culture and eating habits of most people and can be considered one of the most consumed foods in the world. The bread is made from a simple mixture of flour, water, salt and yeast, and it is an extremely versatile food and with a very good digestibility. Since it was first produced for thousands of years, it has undergone changes both in terms of production methods and in terms of its constitution, thus giving place nowadays to a wide variety of breads available on the market. The objectives of this study were to compare the sensory and nutritionally attributes of a special healthier bread, "Pão São", which is a recent product in the Portuguese market. Nutritionally this type of bread turned out to be a food with high nutritional value, with a low salt content (0.4%, about half of traditional bread), and being a good source of omega-3 (0.67%), fibre and protein when compared with the traditional bread. These differences are mainly due to the wide variety of raw materials selected to the preparation of this bread, including the mixture of flour (wheat flour type 150 and 65 and rye flour type 70), oatmeal, sunflower and linseed seeds, soy, fish oil extracts rich in omega 3, malt and milk protein. From the results of the sensory analysis, conducted by a panel of 40 untrained tasters aged 7 to 63 years, it was found that the traditional breads from the region closest to the marketing of healthy bread were preferred by the tasters, especially for their wood and bread flavour, as well as elasticity. The healthy bread was evaluated as a denser bread, with a more intense fermented flavour.
With this work it was concluded that the healthy bread is a nutritious and healthy bread, being currently recommended by the Portuguese Foundation of Cardiology. However from the sensory point of view, consumers still slighly prefer the traditional bread.
Key words: *bread, density, texture, colour, salt, sensorial analysis*

INTRODUCTION

Bread is consumed since prehistoric times, and may have been the first food produced by humans. The advantages of a diet rich in fibres are well known, and in present times the concern about the low level of fibre intake in most diets is growing. Among the ingredients used to produce bread, flour is undoubtedly the most important. Wheat or rye flours are an excellent source of fibre, particularly insoluble fibre (Leon and Rosell, 2007), thus having positive effects on human health, such as decreasing the risk of coronary heart disease, hypercholesterolemia, obesity and diabetes (Leon and Rosell, 2007). Besides, wheat is also a major source of antioxidants like phenolic acids or flavonoids (Pathlrana and Shahidi, 2007).
According to Brandt *et al*. (2005), the amount and type of the ingredients of the dough affect its properties; among these are, besides flour, the water, fat or other additives. Also the performance of accurate methods of blending, kneading and fermentation (temperature, intensity, duration, etc.) have a marked influence on the dough quality. The bread presents better organoleptic characteristics when it is cooked from fresh flour. However, when techniques such as storage, distribution and sale of fermented, partially cooked, frozen or refrigerated dough, allows the baking of bread just before it is purchased or consumed, the bread still has a good flavour despite the aroma being slightly compromised (Brandt et al., 2005).
According Hoseney (1991) the bread quality involves the following factors: the gas concentration, elasticity, resistance of the dough and capacity of gas retention. The

prolonged fermentation with artificial yeast, such as lactic acid bacteria, can control the action of bacteria and improve the availability of nutrients (Brandt et al., 2005). The quality of the bread can be evaluated by physical, physico-chemical (macroscopic or microscopic), microbiological and sensory properties (Hoseney, 1991).
In Portugal bread is a very consumed food, presented to the consumer in many different varieties, according to the main cereals used (corn, wheat, rye, mixtures, whole flours), as well as the manufacturing process and type of fermentation (Almeida et al., 2008).

MATERIAL AND METHODS

Samples

Two different types of healthy bread were bought from the manufacturer “Fabrica do Pão” located in Seia, Portugal, and for each type three samples were taken for analysis. The healthy bread samples differed from one another because one contained a different ingredient, being this lupine flour. Also Regional bread samples (seven samples) from Viseu region, in Portugal, were analyzed for comparison.

Chemical analyses

The analysis to the chemical properties done were: moisture content, water activity, ash content, crude fat, crude fiber content, protein content, all done following the official methods of AOAC (2000). The analysis of the salt content was done by the Mohr Method, being the determination of carbohydrates calculated by difference.

Physical analyses

The physical properties evaluated in this study were: size, color, density, alveolar characterization and texture. The dimensions and volume of the loaves were measured in terms of thickness, width and length. The volume was calculated by approximating the form to an ellipsoid.
In this study, the color parameters were evaluated using a colorimeter chroma meter (Minolta, Japan) expressing the results in the CIELab system coordinates: L* which is the brightness and varies between 0 (black) to 100 (white), the a* ranges from -60 (green) to +60 (red) and b* ranging between -60 (blue) to +60 (yellow).
The alveolar characterization was done by image analysis, with the program "Image J". From each sample, 5 fresh slices were prepared with a thickness of 10 mm (pattern cutting).
Textural analysis was made by Texture Profile Analysis with a texturometer TA-XT2 from "Stable Microsystems".

Sensorial analyses

Sensory analysis was performed in a laboratory prepared for that purpose, on the day of delivery of the samples by a panel of 40 untrained tasters, aged between 7 and 63 years, who were asked to rate the following attributes: crumb colour, crust colour, aroma (bread, firewood and fermented), taste (bread, wood or fermentation), elasticity, density, and finally the overall appreciation. In this test the taster expressed the intensity of each attribute through a scale where verbal Hedonic expressions are translated into numeric values in order to allow statistical analysis. The scale of values varied from 0 (less intense) to 10 (more intense).

RESULTS AND DISCUSSION

After analyzing the different types of bread separately, traditional bread and healthy bread, it was intended to compare these two types of bread in terms of the different properties evaluated, chemical, physical and sensorial. The results presented are the mean, and standard deviation, of the values found for different samples of traditional bread (N = 7) or healthy bread (N = 2).

Chemical properties

Figure 1 shows the means values, with standard deviations, of the chemical properties of the two types of bread studied. From the graphs it is observed that the traditional samples have, in average, higher moisture, carbohydrates, ash and salt contents, whereas the healthy bread samples show higher protein, fat and fibre contents. Some of these characteristics can be explained by the flours used in the manufacture of the healthy breads, which are richer in essential fatty acids (so called good fats), proteins and fibres.

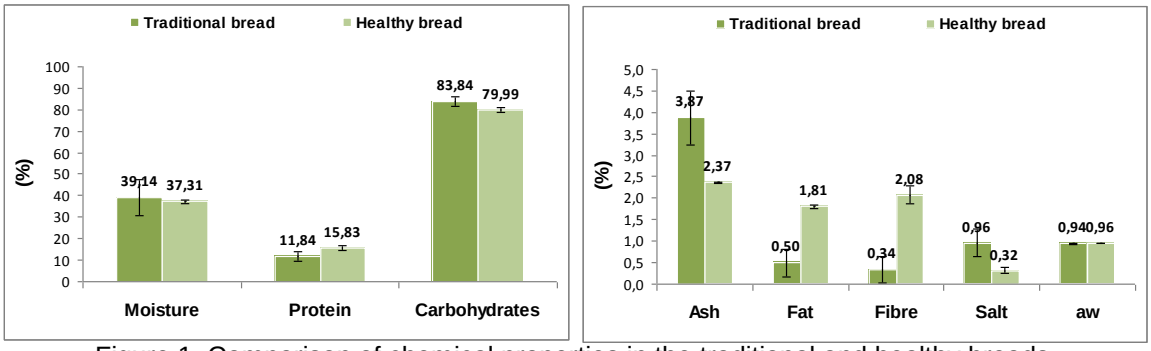

Figure 1. Comparison of chemical properties in the traditional and healthy breads.

Physical properties

From the analysis of the graphs in Figure 2, it is evident that both types of bread do not differ substantially in terms of colour. The healthy bread presents itself darker, with lower L, either in the crust or in the crumb, which is a result of the type of flour used. Regarding a* this parameter is also higher in the healthy bread (crust and crumb), which means that the red coloration is stronger in this case. As to b*, its value is also higher in the healthy bread crumb, being slightly lower in the crust. These results indicate that the healthy bread is browner than the traditional bread.

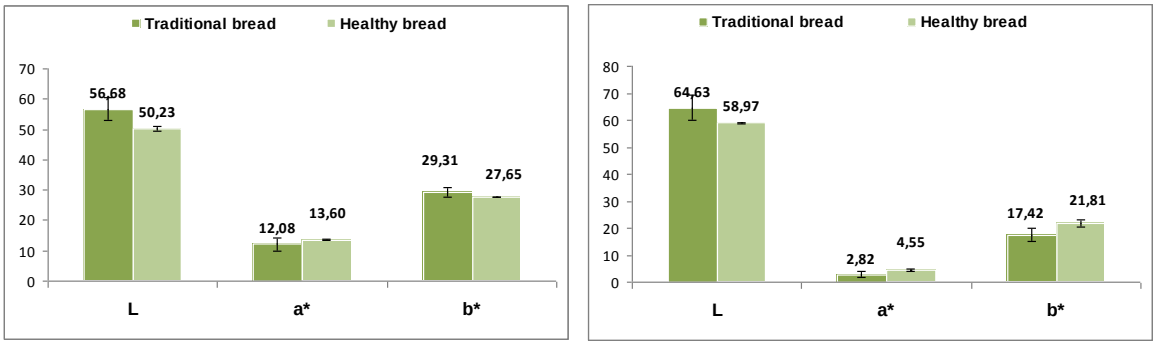

Figure 2. Colour parameters in the traditional and healthy breads. Left: crust, right: crumb.

Table 1 presents the results obtained for the physical properties examined, including alveolar characterization, for both groups of samples, traditional and healthy breads. It can be seen that, in general, the healthy samples showed higher volume and increased porosity, when compared to the traditional samples.

Table 1. Physical properties of the bread samples analyzed.

Type of bread	Whole bread volume (cm^3)	Slice alveolar characterization			
		Area ($pixel^2$)	Nº Alveolus	% Alveolar	Size ($pixel^2$)
Traditional	647,69±135,56	1627995,86±926590,85	241,23±90,75	22,93±11,34	7102,86±3901,10
Healthy	671,22±68,09	2226055,90±220649,70	254,30±9,19	25,70±1,98	8689,90±505,02

Results are given as mean ± standard deviation.

From the analysis of Figure 3, which shows the textural properties of both types of bread studied, it is found that traditional bread show higher elasticity, higher values of springiness, while being softer, lower values of hardness and chewiness. As regards cohesiveness, this is very similar for both types of bread analysed.

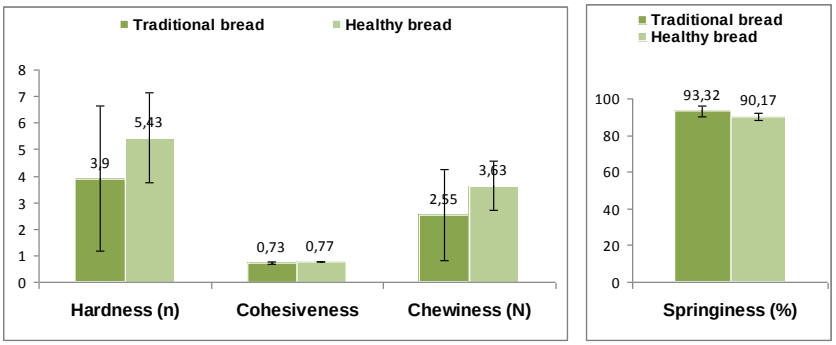

Figure 3. Textural properties in the traditional and healthy breads.

Sensorial properties

The graphs in Figure 4 show the results of sensory evaluations made for the two kinds of bread. Based on the results, it appears that in sensorial terms, and with regard to aroma (bread, wood, fermented), the samples of traditional bread are not distinguishable from those of the healthy bread. However, with respect to colour, either in the crust or the crumb, the healthy bread was identified as having a more intense coloration, which is in accordance with the results obtained when measuring colour. Also the healthy bread was perceived as being less tasty in terms of bread or wood taste, less elastic, more dense and finally in terms of global appreciation it was valued less than the traditional bread. Still the differences were not so important, so that in general terms both breads were considered equally acceptable.

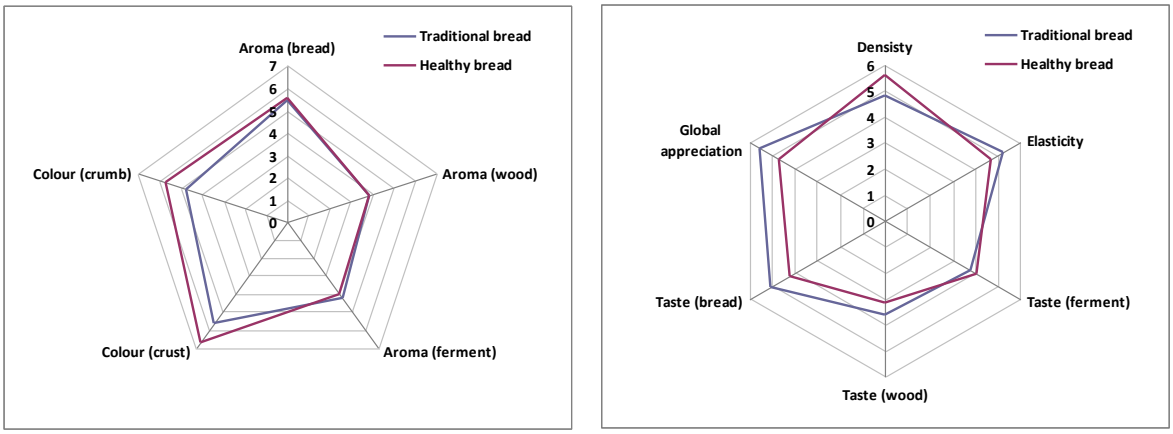

Figure 4. Sensorial evaluation of the traditional and healthy breads.

CONCLUSIONS

The results from this work showed that both types of bread were different in terms of the different properties analyzed. In nutritional terms, the healthy bread showed higher protein content, being also much richer in terms of fibre and fat (due to the presence of important essential fatty acids). Also this type of bread had a much lower salt content, with important health benefits. In terms of physical properties, the healthy bread is browner and with increased porosity. Furthermore, this type of bread is harder when compared to the traditional bread. In sensorial terms, both breads were evaluated in a proximal way, noticing however, that the traditional bread was slightly preferred.

ABSTRACT: *Staphylococcus aureus* is considered the third most important cause of disease in the world among the reported foodborne illnesses. Pathogenesis of *S. aureus* depends on the ability of the strain to survive, multiply under a variety of conditions and produce various extracellular compounds. This study was undertaken in order to investigate the effectiveness of the *Origanum heracleoticum* L. essential oil on growth inhibition and survival of *S. aureus* isolated from food using broth model media and ability of essential oil to reduce coagulase activity. Cell viability assays were carried out with exposure of *S. aureus* to various concentration of the *O. heracleoticum* L. essential oil (1.0, 0.5, 0.3, and 0.1 µL/mL) in time intervals 15, 40, 60, 120 and 240 min.
The results showed that *O. heracleoticum* L. essential oil after only 15 min at 1 µL/mL completely inhibited the growth of *S. aureus.* Lower concentrations of essential oil (0.5, 0.3 and 0.1 µL/mL) inhibited the cell viability of *S. aureus.* After 1.5h, 1 and 0.5 µL/mL of essential oil suppressed physiological attributes of the tested *S. aureus* strains - coagulase activity. After 24h, tested essential oil at 0.3 µL/mL suppressed coagulase activity.
The oil interfered on the coagulase activity in a dose-dependent manner. *O. heracleoticum* essential oil could be a novel antimicrobial with capability to suppress some physiological characteristics, in addition to inhibit the growth and survival of pathogen bacteria in foods, particularly *S. aureus.*
Key words: *Staphylococcus aureus, essential oil, Origanum heracleoticum* L.

INTRODUCTION

Staphylococcus aureus is considered the third most important cause of disease in the world among the reported foodborne illnesses (Boerema et al., 2006). For intoxication caused by *S. aureus* the pathogenesis depends on the ability of the strain to survive, multiply under a variety of conditions and produce various extracellular compounds (Shale et al., 2005). Haemolysins, nuclease, coagulase, lipase and staphylococcal enterotoxins are among the extracellular toxins and enzymes produced by *S. aureus.* As staphylococcal enterotoxins are heat stable, they may be present in food when *S. aureus* is absent (Balaban & Rasooly, 2000).
The growth of *S. aureus* in food presents a potential public health hazard because many strains produce one or most enterotoxins (SEs) that cause food poisoning if ingested (Akineden et al., 2008). Moreover, the ability of this microorganism of acquiring resistance to practically all useful antimicrobials is a cause of great concern for public health (Gibbons, 2004). Staphylococcal food poisoning frequently involves foods that require considerable handling during preparation and that are kept at slightly elevated temperatures after preparation (Le Loir et al., 2003).
Consumers have demanded more natural foods, with low levels of chemical preservatives and less processed, however still possessing a long shelf-life. Also, food legislation has restricted the use of some synthetic antimicrobials based on a possible toxicity for consumers (Burt, 2004). In this panorama, aromatic plants have emerged as effective compounds to provide microbiological safety of foods.
Aromatic plants are rich in essential oils, which are composed of many compounds (carvacrol, thymol, eugenol, cinnamic acid, citral, pinene,) characterized by a prominent

antimicrobial activity. This trend prompts a particular increased interest in the use of essential oils as antimicrobial compounds to be applied in food conservation. Among the aromatic plant from family *Lamiaceae* (*Labiateae*), genus *Origanum* has a special position. This is basically due to their major components carvacrol and thymol, having important antioxidant and antimicrobial properties (Ozkan et al., 2003). Carvacrol and thymol, the two main phenols that constitute about 78–85 % of oregano oil, are mainly responsible for the antimicrobial activity of the oil (Kokkini et al., 1997). It should be mentioned that the biological activity of essential oils depends on their chemical composition, which is determined by genotype and influenced by environmental and agronomic conditions.
This study was undertaken in order to investigate the effectiveness of the *Origanum heracleoticum* L. essential oil in inhibiting the growth and survival of *S. aureus* isolated from foods using broth model media.

MATERIAL AND METHODS

Plant Material

Aerial parts of *O. heracleoticum* L. were collected during blooming stage (August 2009) from the locality Kamendol near Smederevo, Serbia. The plant material was dried under laboratory conditions (20-25 ºC). Institute of Medicinal Plant Research Dr. Josif Pančić identified the plants and voucher specimens were stored in the herbarium of the Institute of Medicinal Plant Research Dr. Josif Pančić.

Isolation of the essential oil

The essential oil was isolated from dried plant material by hydro-distillation according to the standard procedure reported in the Sixth European Pharmacopeia (2008). Distillation was performed using Clevenger type apparatus, for 2.5 hours. The resulting essential oil was dried over anhydrous sodium sulfate and stored at 4 ºC.

Bacterial strain

S. aureus obtained from the Microorganism Collection, Laboratory of Food Microbiology, Institute of Food Technology, Novi Sad was used as test strain in all experiments. This strain was isolated from goat whey sample by the standard procedures according to ISO 6888-1 (2003). Stock culture was kept on Nutrient Agar (NA) slants under refrigeration (7 °C ± 1 °C). Inocula used in the assays were obtained from overnight cultures grown on NA slant at 37 °C. A loopfull of the culture was diluted in sterile saline solution (0.85 g/100 mL) to have a final concentration of approximately 10^8 colony forming unity per mL (cfu/mL) adjusted according to the turbidity of 0.5 McFarland standard tube. Final concentration of the inoculum in the medium used for the antimicrobial assays was approximately 10^6 cfu/mL.

Cell viability assay

Cell viability assays were carried out using the viable cell count method. For this aliquots (100 µL) were taken at 15, 40, 60, 120 and 240 min, serially diluted in sterile peptone water (0.1 g/100 mL) and spread-plated onto sterile Baird–Parker agar. After 24 h of incubation at 37 °C, colonies were counted and the results were expressed in log of cfu/mL. Control flasks without essential oil were tested in the same way.

Effect of oil on the activity of coagulase

After 1.5 and 24 h, 100 µL of culture grown on Brain Heart Infusion Broth (BHI) with addition of essential oil (1.0, 0.5, 0.3 and 0.1 µL/mL) was used to test the activity of coagulase. After the incubation period, the activity of coagulase was estimated by the standard procedures according to ISO 6888-1 (2003), and the results were expressed in level (-; + to +++) of the coagulase test regarding the size of the formed plasma clot. All antimicrobial assays were carried out in duplicate and the results were expressed as average of the parallel assays.

RESULTS AND DISCUSSION

From the collected plant material of *O. heracleoticum* L. total of 2.05 % (v/w) of essential oil has been isolated by the process of hydro-distillation. In our previous investigation (Cabarkapa et al., 2011) twenty six components (92.86 %) were identified as constituents of this essential oil by GC/MS analysis. The major components were carvacrol (69.00 %), p-cymene (10.50 %), thymol (7.94 %) and γ-terpinene (2.86 %). Except β–caryophyllene (1.53 %) and β–bisabolene (1.01 %) the amount of all remaining oil components was less than 1 %. In our previous experiments 0.2 and 0.78 µL/mL were found as minimum inhibitory concentration and minimum bactericidal concentration, respectively, of *O. heracleoticum* L. essential oil toward the assayed strains of *S. aureus* (not published data).
Obtained results of the effect of different concentrations of essential oil (0.5, 0.3 and 0.1 µL/mL) on the cell viability (kill time) of *S. aureus* are shown in Figure 1. Results showed that the growth of *S. aureus* was completely inhibited after only 15 min of exposure to essential oil at concentration 1 µL/mL (this result is not shown in Figure 1 because of its simplicity). After 15 min of exposure to essential oil at concentration 0.5 µL/mL initial cell count was decreased for 1.46 log cfu/mL and after 40 min total elimination of the microbial initial inoculum was evaluated. According to Barros et al. (2009) a compound is considered as having a strong cidal effect when it is able to cause a decrease of 99.9% (3 log cycles) of the initial inoculums. Therefore, strong cidal effect (total elimination of the microbial initial inoculum) was found after 15 min of exposure to the oil at 1 µL/mL and after 40 min of exposure to the oil at 0.5 µL/mL.

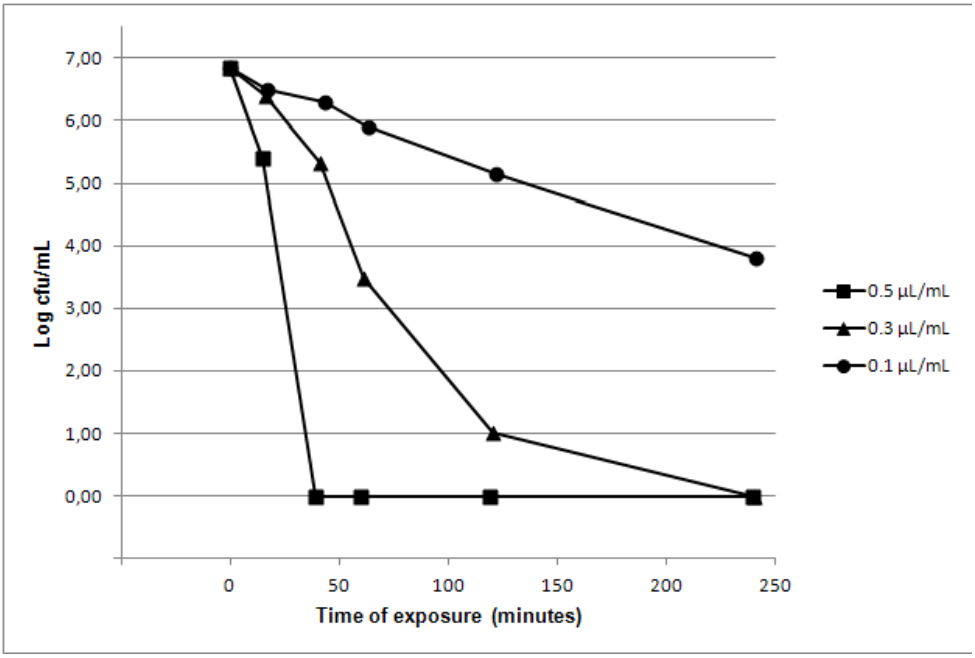

Figure 1. Effect of different concentrations of *O. heracleoticum* L. essential on the cell viability of *S. aureus*

After 15 min of exposure to concentration 0.3 µL/mL, tested essential oil provided a static effect along the evaluated interval (reduction of microbial initial inoculum was ≤0.4 log). The lowest tested concentration of oil (0.1 µL/mL) after 15 and 40 min provided a static effect along the evaluated interval (reduction of microbial initial inoculum was 0.35 and 0.54 log, respectively). Cidal effect was found after 60 min of exposure to the oil at 0.3 µL/mL (reduction was 3.38 log) and after 240 min of exposure to the oil at 0.1 µL/mL (reduction was 3.04 log).
Barros et al. (2009) found that the treatment of *S. aureus* with essential oil of origanum with 54 % of carvacrol had cidal effect after 15 min of exposure to the oil at 1.2 µL/mL. After 120

min, the oil at 1.2 µL/mL decreased the cell count to <2 log cfu/mL. In the same investigation tested essential oil at concentration 0.3 and 0.6 µL/mL provided a static effect along the evaluated intervals. The oil at 0.6 and 1.2 µL/mL caused a significant decrease ($P < 0.05$) in the bacterial count in comparison to the control assay. Otherwise, it was not found at 0.3 µL/mL.

Origanum heracleoticum essential oil is rich in phenolic compounds, which are believed to be responsible for its prominent antimicrobial activity. The major antibacterial components of these oils are carvacrol and its isomer thymol. The precise target(s) of the antibacterial action of essential oils and their components has not yet been fully established. Carvacrol and thymol are capable of damage the outer membrane of bacteria and increase the general permeability of the cytoplasmic membrane, leading to leakage of ATP (Burt 2004). Cytoplasm membrane disturbances, rupture of proton motive force and cytoplasm content coagulation are some mechanisms involved in the antimicrobial properties of essential oils. These findings show an interesting inhibitory effect of *Origanum heracleoticum* essential oil toward the cell viability of *S. aureus*, a fast and steady bacterial kill rate. Kill-time curve also showed a clear relationship among the extent of inhibition and the oil concentration and time of exposure.

The effect of *O. heracleoticum* essential oil on the coagulase activity of *S. aureus* cells is shown in Table 1. The oil at 1, 0.5 and 0.3 µL/mL caused an inhibition of coagulase activity after 90 min (provided large reduction in coagulase activity, where no clot was formed after incubation of the cultures in the presence of rabbit plasma). At 0.1 µL/mL the coagulase activity found for the cells were in a range of +++ (level 3) after 90 min to ++ (level 2) after 24 h.

Table 1. Effect of *O. heracleoticum* L. essential on coagulase activity in *S. aureus* cells

Treatment of essential oil	90 min	24h
1 µL/mL	- - -	- - -
0.5 µL/mL	- - -	- - -
0.3 µL/mL	- - -	- - -
0.1 µL/mL	+++	++ -
Control (0 µL/mL)	+++	+++

It is probable that the much of the reduction in coagulase activity of the cells is due to a prevention of secretion of the proteins as a result of changes in the physical nature of the staphylococcal cytoplasm membrane (Shah et al., 2008).

CONCLUSIONS

The results obtained in this study show high biological potential of essential oils, particularly, the anti - *S. aureus* activity of *Origanum heracleoticum* essential oil. The essential oil studied here provided an interesting inhibitory effect of the cell viability of *S. aureus* and strongly interfered on coagulase activity. In addition, our results support the possibility of the use of *Origanum heracleoticum* derivatives as potential alternative antimicrobial compounds to be applied in food conservation, since this essential oil is considered toxicologically safe. However, further research is needed to verify its antimicrobial effectiveness in food matrices, as well as to evaluate its effectiveness to protect foods against pathogen and spoiling microorganisms throughout shelf-life.

ABSTRACT: The novel nutraceutical foods are today in the focus of the research that refers to healthy food and concerns both the food engineers and the nutricionists. Different kinds of ingredients and food supplements having certain bioregulating function, such as vitamins, antioxidants or antimicrobials, are nawadays readily incorporated in new kinds of funcional foods that are becoming more and more attractive for the consumers of healthy food. The partial glyceride monolaurin that is well known as a food additive with emulsifiing properties is also known for its antimicrobial and antiviral activity. So, it is having both nutritional and health properties that are supporting the immune system of the organism in a unique way. The monolaurin is also known as a food supplement by its commercial name Lauricidin. The aim of the study presented in this paper was to investigate the possibilities for incorporation of this food supplement in emulsified meat products and to evaluate its effect on the sensory characteristics of the products. For this purpose model meat sausages containing different commonly used additives were prepared and sensory characteristics of the different sausage formulations were compared. The antimicrobial activity of monolaurin was also preliminary investigated.
Key words: *nutraceutical meat products, monolaurin, food additives, sensory characteristics, dietary supplement, antimicrobial activity*

INTRODUCTION

The term „Nutraceuticals“ was invented by DeFelice in 1989 and it refers to food products or food supplements that are known to have certain physiological benefit or to provide protection against certain disease. Bioflavonoides derived from fruits and vegetables or meat peptides are some of these food products with known bioactivity, nutritional and functional value (Tapas et al. 2008, Mine et al. 2010). Food additives are ingredients that give the food the attribute „healthy“ if possessing some bioeregulating function in the organism (Kabara and Marshall, 2005). All ingredients used as food additives in meat products have certain functional property. Thus, the table salt and the phosphates are added to meat products in order to enhance the water binding capacity (Keeton, 2001). The curing salt is added in order to improve the colour and thus to increase the sensory characteristics of meat (Lyon and Lyon, 2001). The table and the curing salt have another very important property, they do preserve meat products and prolong their shelf life. The ascorbic and the citric acids are known as curing accelerators and have an antioxidant property that enables quick development of the specific colour and prevent the formation of unwanted nitrosamines (Toldrá and Reig, 2007). They are also known as meat tenderizers, since the acidic conditions affect the solubility of the collagen fibbers (Al-Hajo, 2009). Spices are also widely used since they enhance some sensory characteristics like the flavour and the appearance (Toldra and Reig, 2007). Besides these most common food additives, the food emulsifiers are also being widely used in the meat industry (Moonen and Bas, 2004). Monoglycerides of fatty acids are food emulsifiers approved as GRAS (Generally Recognized as Safe) food additives by the Food and Drug Administration of the USA (Hasenhuettl and Hartel, 2008).

Those biodegradable surface active agents are very popular nowadays when the sustainability is of primarily interest in all production processes (Mladenoska, 2007). Except their function as emulsifying agents, these compounds have another bioactivity that is of great importance in the nutraceutical meat products, they have an antimicrobial and an antiviral activity (Kabara and Marshall, 2005, Batovska et al., 2009). What is even more interesting, these kind of compounds are find to be usual components of some natural foods such as mother's milk or coconut milk (Liberman et al., 2006). The effect of the monoglycerides monolaurin and monocaprilin on some pathogenic microorganisms as well as on some viruses is well documented (Řihakova et al., 2002, Skrivanova et al., 2006). Those researchers suspected that the fatty acids and the partial glycerides fluidise the fats and the phospholipids in the virus's envelope and in the microbial cell membrane and this way act inhibitory to their growth. There are some attempts to incorporate those bioactive compounds in real meat products (Mbandi et al., 2004). However, the effect of the monolaurin on the sensory characteristics of the products is not extensively studied. In the present work the effect of the food supplement Lauricidin (pure monolaurin) used as an emulsifier in meat emulsified products on the sensory characteristics of the products was investigated. Several sensory characteristic such as: flavour, juiciness, tenderness, elasticity and overall acceptability were all investigated. Several most commonly used additives such as: the NaCl, the $NaNO_2$, the ascorbic acid, the citric acid and the mix of spices were all used. Their effect on the sensory characteristics of the emulsified meat products was evaluated and compared to that of Lauricidin added in two different concentrations. The antimicrobial activity of the Lauricidin used in the meat sausages and in meat hamburgers was preliminary investigated.

MATERIALS AND METHODS

Preparation of the emulsified products

Model fresh sausages were prepared according to the process flow diagram presented by Toldrá and Reig, 2007. The Lauricidin (commercial product of monolaurin purchased from Ecological formulas (Concord, California, USA)) was added to the sausages in a concentration of 0.675 and 1.36 g per 100 g sausage. The nitrite salt ($NaNO_2$) and the table salt (NaCl) were added in a concentration of 0.016 g/100 g sausage and 2 g/100 g sausage, respectively. Ascorbic acid and citric acid were added in a concentration of 0.2 g per 100 g sausage. Mixture of spices had the following composition: NaCl 1.25%, Vegeta spice mixture 3.65% and paprika 1.46%. The sausages were drained and then pasteurized at the temperature of 80 $^{\circ}$C (72 $^{\circ}$C in the center of the sausage) in duration of 30 min. A 9-point hedonic scale (9-like extremely, 1-dislike extremely) was used to evaluate sensory attributes like: flavor, juiciness, tenderness, elasticity and overall acceptability according to Lyon and Lyon, (2001). Emulsified meat hamburgers were also prepared.

Inoculation of the sausages

The pasteurized sausages and hamburgers were inoculated by 10 mL portions of seed cultures from *A. niger* MK-15 and *S. cerevisiae* TMF (belonging to the Culture Collection of the Faculty of Technology and Metallurgy, Skopje), both with concentration of approximately 10^7 cfu/mL. The inoculums were injected by a syringe. The infected sausages were kept 72 h on 28 $^{\circ}$C. Cell enumeration of the sausage samples was performed by standard plate counts and calculated as a number of colony forming units on a gram sample. 25 g of sample was diluted in 225 mL of water and homogenized. 1 mL of this solution was inoculated on a Petri dish containing 10 mL Sabouraud agar. The agar plates were incubated at 30 $^{\circ}$C during 5 days. All examined samples were diluted 10^3 times.

RESULTS AND DISCUSSION

From the results presented on the Figures 1 it can be noticed that the different additives gave different attributes to the meat emulsified products.

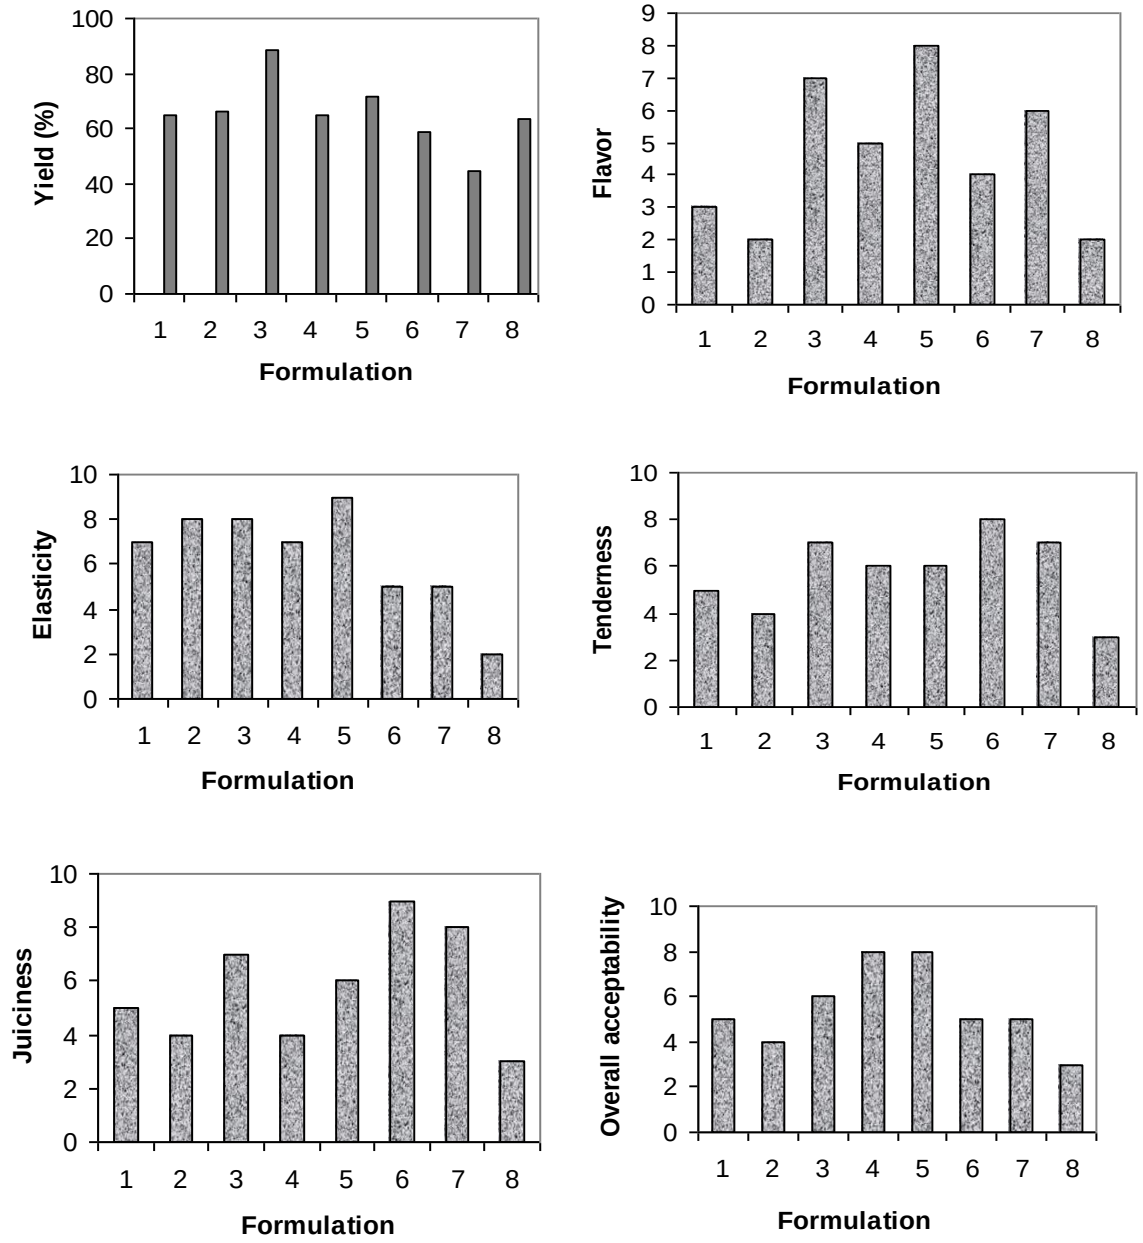

Figure 1. Sensory characteristics of the model pasteurized sausages prepared by using different kind of food additives: **1.** 0.675% monolaurin, **2.** 1. 36% monolaurin, **3.** NaCl, **4.** $NaNO_2$, **5.** mixture of spices, **6.** ascorbic acid, **7.** citric acid and **8.** additive free (the control sausage)

Thus, the mixture of spices enhanced to a great extent the scores for the product flavour and elasticity, but omitted to show high scores for the product tenderness and juiciness. The ascorbic and the citric acid, on the other hand, improved the tenderness and the juiciness of the sausages. The table salt obviously increased the water binding capacity of the meat and thereby increased the juiciness of the sausages compared to the juiciness of the additive free sausages. It was also present in a concentration of 1.25% in the spice mixture and exactly those two sausage formulations, the one with only the table salt and the one with the spice mixture, were the sausages with highest yields achieved. The negative effect of the table salt added as a sole additive was only the effect on the sausage colour (Figure 2).

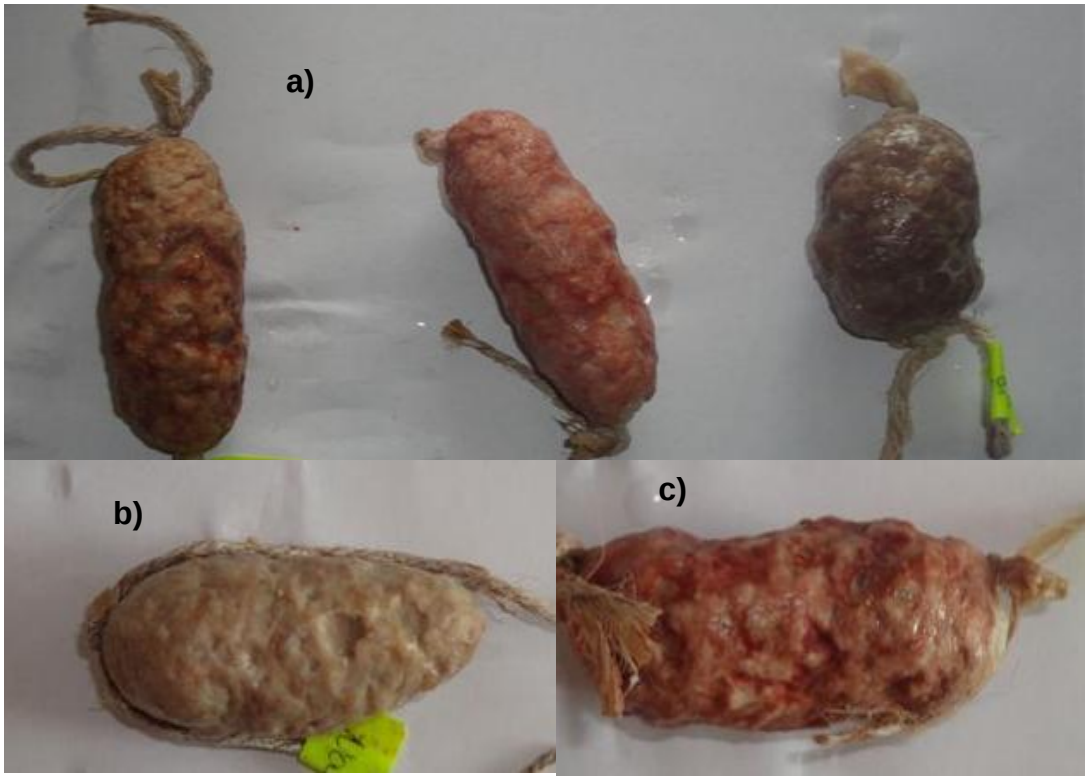

Figure 2. The appearance of the defrosted sausages after storage in a duration of 1 month: a) the additive free sausage (on the left), the sausage with $NaNO_2$ (in the middle), the sausage with ascorbic acid (on the right), b) the sausage with NaCl, c) the sausage with 0.675% monolaurin

However, the addition of the curing salt and the spice mixture, separately, had very positive effects on both the sausage colour and the flavour. Thus, the sausages that contained the curing salt and the mixture of spices yield very high scores on the sensory scale for overall acceptability.

The sausages that contained Lauricidin in a concentration of 0.675 g/100 g sausage showed good properties. They showed high scores for yield and elasticity, moderate values for tenderness and juiciness and moderate overall acceptability. However they showed very good antifungal and antiyeast activity and lowered the values for total cell count for several orders of magnitude (Figure 3).

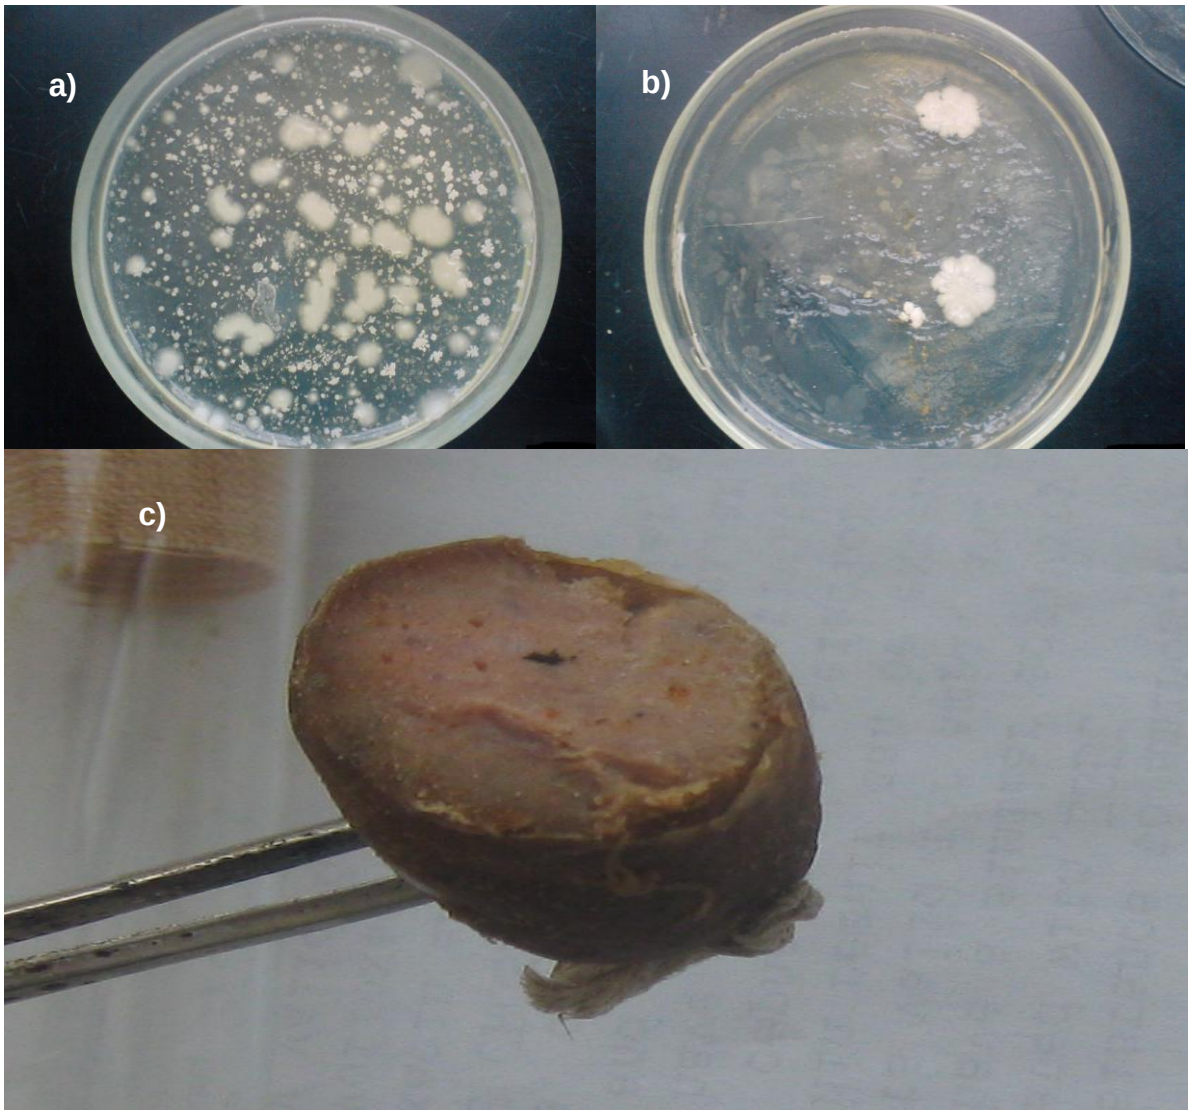

Figure 3. Growh of the *Sacharomyces cerevisiae* TMF strain isolated from the hamburgers that did not contain Lauricidin a) and form the hamburgers with Lauricidin b). c) The appearance of the cross cut of the sausage with Lauricidin infected by *Aspergillus niger* MK-15

Thus, while the total cell count of *A. niger* MK-15 calculated for the inside of the sausages that contained the monolaurin in a concentration of 0.675 g/100g sausage was only $35x10^6$ cfu/g, it's value for the inside of the sausages without monolaurin was as high as $1085 x10^6$ cfu/g. These results were in consistence with the literature data for the antimicrobial activity of the monolaurin (Řihakova et al. 2002, Kabara and Marshall, 2005). The negative effect that the monolaurin had on the product flavour (soapy taste and smell) was the only serious drawback that this additive had.

CONCLUSIONS

The food additive monolaurin could be very successfully used in meat emulsified products and give the product an attribute of healthy functional food only if it is used in low concentrations and in combination with some other food additives and spices that would mask it's soapy taste and smell.

ACKNOWLEDGEMENTS

The authors would like to thank to the Faculty of Technology and Metallurgy in Skopje, the Institute for Preventive Medicine in the General City Hospital "8th of September" in Skopje and to the Institute for Health Protection in Stip, R. Macedonia for all the help given during the research that is now a part of this work.

ABSTRACT: Oleic acid (OA) has many beneficial effects on human health. One of the main dietary sources of OA is olive oil. Non-Mediterranean European countries, including Serbia, have low habitual olive oil consumption, but other vegetable oils, milk and diary products also contain different amounts of OA. Content of oleic and other fatty acids (FA) could markedly vary in the same foods, depending on the region. Thus the aim of this study was to determine proportion of OA in cow's milk and in eight vegetable oils available on Serbian market. FA composition of milk and vegetable oils was determined by gas chromatography. Eight vegetable oils: processed and cold pressed sunflower oil, olive oil, rapeseed oil, pumpkin seed oil, grape seed oil, linseed oil, and light sesame oil, and 5 samples of cow's milk with different fat percentages (0.5-3.5%) were analyzed. OA was found in all investigated vegetable oils in different proportions. Olive oil and rapeseed oil are main sources of oleic acid (67.0±0.4% and 64.3±0.5% of total FA, respectively), which is the least present in grape seed oil and linseed oil (18.1±0.2% and 18.7±0.1%, respectively). Pumpkin seed oil is also rich in OA (45.7±0.4%). Furthermore, significant amounts of OA were found in cow's milk (22.94-25.57% of total FA). In summary, olive oil, rapeseed oil and pumpkin seed oil are good vegetable sources of oleic acid, while cow's milk also contains considerable amounts of this FA. Regarding beneficial effects of OA, its increased consumption would lead to improvement of overall health.
Key words: *oleic acid, cow's milk, vegetable oil*

INTRODUCTION

Dietary fatty acids (FA) serve multiple functions in the body. They are constituents of cellular membranes, precursors for the biosynthesis of macromolecules, a source of energy, and are connected to both health promotion and disease pathogenesis (Bermudez et al., 2011). Therefore, the choice of dietary FA could markedly influence overall health in humans.

Emerging evidences from experimental and epidemiological studies have linked increased olive oil consumption to reduced risk of coronary heart disease, type 2 diabetes mellitus, obesity and hypertension (Kris-Etherton et al., 1999; Lopez-Miranda et al., 2010). Crucial factor in beneficial health effects of olive oil is oleic acid (OA). OA is a monounsaturated fatty acid (MUFA), 18:1n-9. Observational studies from Mediterranean cohorts using diets rich in fruits, vegetables and olive oil, have suggested that dietary OA may be protective against stroke (Samieri et al., 2011), age-related cognitive decline and Alzheimer's disease (Lopez-Miranda et al., 2010). In addition, it has been shown that insulin sensitivity was relatively impaired by diets that were low in OA, or rich in trans MUFA or saturated palmitic acid (Granados et al., 2011).

Oleic acid is found naturally in many plant sources and animal products. The main dietary source of this FA is olive oil, with the content of up to 80% of OA. It is also present in other vegetable oils, nuts, animal fats, milk and dairy products (Araujo de Vizcarrondo C, 1998; Miraliakbari & Shahidi, 2008). However, the content of OA markedly varies in the same food depending on the region.

Unlike people in Mediterranean countries who use significant amounts of olive oil in their diet, consumption of this oil is usually very low in non-Mediterranean regions, including Serbia. For this reason other dietary sources of OA are very important in these countries. The aim of

this study was to determine content of oleic acid in cow's milk and in eight vegetable oils available on Serbian market.

MATERIAL AND METHODS

Oil and milk sampling

Commercially available vegetable oils were purchased in Belgrade, Serbia, in different supermarkets and health food stores. Eight vegetable oils: processed and cold pressed sunflower oil, olive oil, rapeseed oil, pumpkin seed oil, grape seed oil, linseed oil, and light sesame oil were analyzed. Four bottles of each oil mostly from different producers were acquired for the experiment. Expiration date of all oils was at least ten months after the date of purchase. Bottles were opened prior to the experiment. Four samples of each type of oil were pooled and 10ml of the composite sample was taken for further analysis. In addition, cow's milk with 5 different fat percents (0.5%, 1.6%, 2.8%, 3.2% and 3.5%) from different producers was purchased in supermarkets in Belgrade, Serbia. Four bottles with the same percentage of fats were pooled and composite samples were analyzed.

Fatty acid determination

The total lipids from vegetable oils and milk samples were extracted according to the modified method of Folch, as we described previously (Tepsic et al., 2009). Briefly, FA were extracted from 200 µL of vegetable oil, *i.e.* from 500 µL of cow's milk using the chloroform-methanol mixture (2:1 v/v), with 50 mg% of 2,6-di-tert-butyl-4-methylphenol (BHT) added as an antioxidant. The obtained mixture was centrifuged at low speed (1000xg) to separate the two phases. The lower phase containing lipid extract was dissolved in hexane and used for further analysis. The phospholipid fraction was isolated from the extracted lipids by one-dimensional thin-layer chromatography, as we previously described (Cvetkovic, et al., 2011). Fatty acid methyl esters (FAMEs) were prepared by transmethylation with 2M NaOH in methanol (incubated at 85°C for 1h) and 1M H_2SO_4 in methanol (incubated at 85°C for 2h). Nitrogen gas was used for drying and removing solvents from the FAMEs.

FAMEs were analyzed by gas chromatography (SHIMADZU 2014, Japan,) equipped with a flame ionization detector, auto-sampler-AOC-20i and split/splitles injector. The FAMEs sample (1µL) was injected and the separation was carried out on an Optima 240 fused silica capillary column (60m x 0.25mm x 0.25µm) (MACHEREY-NAGEL GmbH& Co.KG, Germany). Helium was used as a carrier gas at pressure of 120 kPa with split ratio 1:45, and flow rate 0.32 mL/min. The oven temperature was held initially at 55ºC, increased from 210ºC at 6ºC/min and then maintained at 210ºC for 50 min. The temperature of the injection port and the detector were set at 220º and 260ºC, respectively. The fatty acids were identified by comparing their retention times with those of standards (Sigma Chemical, St Louis, MO, USA) and SUPELCO® MIX 37 component standards. All samples were determined in triplicate. The OA content was expressed as percentage of total FA.

RESULTS AND DISCUSSION

The proportion of oleic acid in total FA in vegetable oils and cow's milk are presented in Tables 1 and 2, respectively. OA was found in all investigated vegetable oils in different percentages. As expected, olive oil is the main source of OA among vegetable oils (67.0±0.4 % of total FA), but rapeseed oil had a similar content of OA as well (64.3±0.5%). Pumpkin seed oil is also rich in oleic acid (45.7±0.4%), which is also present in light sesame oil (35.1±0.1%) and sunflower oil – both processed and cold pressed (26.6±0.3 and 23.9±0.2%, respectively). The least content of OA was found in grape seed oil and linseed oil (18.1±0.2 and 18.7±0.1%, respectively). The content of the other FA of vegetable oils was also significantly different (manuscript in preparation).

With an average concentration of about 8 g/l in whole cow's milk, milk and dairy products substantially contribute to the dietary intake of oleic acid in many countries (Haug et al.,

2007). Thus we measured proportion of OA in different samples of cow's milk used in human nutrition in Serbia. As it can be seen in Table 2, we found 22.94-25.57% of OA in cow's milk, depending on the total milk fats in the samples. The proportion of OA in total FA slightly decreased with an increase of total fats in milk (from 0.5-3.5%). Regardless of small differences, OA makes around a quarter of total FA in cow's milk samples analysed in this study, suggesting that cow's milk is an important source of OA in our country. However, high consumption of milk and/or dairy products is thought to contribute to cardiovascular disease, primarily by increasing saturated fat intake, and for that reason many advisory bodies recommend avoiding high-fat dairy foods (Lichtenstein et al., 2006). Several studies have shown that the percentage of undesirable saturated FA in cow's milk can be replaced with OA by inclusion of different feed components in cow's nutrition. Komprda et al. have recently shown that feed mixture containing rapeseed, rapeseed oil and rapeseed cakes significantly decreased the content of palmitic acid and increased the content of beneficial stearic, oleic, linoleic and α-linoleic acid in milk of these cows (Komprda et al., 2005). Another study has demonstrated that supplementation of a basic diet with oilseed, linseed and sunflower seed improved the milk quality from a nutritional point of view by a large reduction in the content of saturated FA and an increase in the levels of MUFA and PUFA (Collomb et al., 2004). Thus dietary intervention in cows can contribute to healthier milk composition, particularly in terms of its fatty acid content.

Table 1. The proportion of oleic acid in total FA in vegetable oils

Vegetable oil	OA in total FA (mol%)
Olive oil	66.95±0.39
Rapeseed oil	64.35±0.49
Pumpkin seed oil	45.68±0.42
Light sesame oil	35.08±0.09
Processed sunflower oil	26.6±0.30
Cold pressed sunflower oil	23.91±0.16
Linseed oil	18.69±0.08
Grapeseed oil	18.06±0.20

Results are given as mean ± standard deviation (n = 3). OA – oleic acid, FA – fatty acid.

Table 2. The proportion of oleic acid in total FA in cow's milk samples

Cow's milk (% of fats)	OA in total FA (mol%)
0.5	25.57±0.64
1.6	25.34±0.89
2.8	23.97±0.72
3.2	23.91±1.10
3.5	22.94±0.68

Results are given as mean ± standard deviation (n = 3). OA – oleic acid, FA – fatty acid.

CONCLUSIONS

In conclusion, we have determined the proportion of oleic acid in total fatty acids in 8 vegetable oils and 5 cow's milks with different percentages of fats used in human nutrition. We have found that olive oil, rapeseed oil and pumpkin seed oil are good vegetable sources of OA. Furthermore, in non-Mediterranean countries with low habitual consumption of olive oil, cow's milk is also an important source of OA, with a content of around a quarter in total FA. Considering beneficial effects of oleic acid, its increased dietary intake would lead to improvement of overall health in Serbian population.

ABSTRACT: Citrus peels are a potential source of natural flavanones such as hesperidin, naringin, eriocitrin, etc. Because of their pharmacological activity and antioxidant properties, they are very interesting for pharmaceutical and food industry. In the present work, the influence of extraction parameters on the antioxidant properties of mandarin peel extracts was studied. By Taguchi experimental design four extraction parameters of conventional solvent extraction were tested: extraction temperature, extraction time, material to solvent ratio and number of stages. Antioxidant properties of mandarin extracts were determined by three different methods: radical scavenging activity against 2,2-diphenyl-1-picrylhydrazyl hydrate (DPPH) and Antioxidant Capacity of Lipid soluble (ACL) and Water soluble compounds (ACW), which were analysed by PHOTOCHEM (Analytik Jena AG, Germany). The influence of extraction parameters on antioxidant properties was evaluated by ANOVA method. The composition and content of flavonoids in obtained extract were determined by HPLC method. Using Taguchi experimental design four extraction parameters at three levels were tested. The highest antioxidant properties were determined for mandarin extract obtained at extraction conditions: temperature 60 °C, extraction time 90 min, material to solvent ratio 1:50 g/mL and three stages of extraction. In the obtained extracts three flavanones were identified mainly hesperidin and narirutin and traces of didymin.
Key words: *conventional* solvent *extraction, mandarin peel, antioxidant properties, Taguchi experimental design*

INTRODUCTION

Citrus are an important agricultural crop of the Mediterranean area. Because citrus fruits contain several important nutrients, such as vitamin C, dietary fibre, carotenoids and flavonoids they are an important part of a healthy diet (Tripoli et al. 2007). Citrus fruits such as oranges (C. sinensis), mandarins (C. reticulata), lemons (C. lemon) and grapefruits (C. paradisi) are important for the production of fruit juices and concentrates that are mainly used in food industry for obtaining fruit drinks (Gattuso et al. 2007). There are a lot of citrus peels produced as residues, which can be a potential source of pectin and natural flavonoids (Kim et al. 2004). In citrus peels there are present two main groups of flavonoids, flavanone glycosides and polymethoxylated flavones (Tripoli et al. 2007, Ortono et al. 2006, Nogata et al. 2006). Studies have shown that citrus flavonoids play an important role in the prevention of degenerative and infectious diseases. Due to their anticarcinogenic, antiatherogenic, antimicrobial and anti-inflammatory properties flavanones and polymethoxylated flavone are very interesting for pharmaceutical and food industry (Havsteen 2002, Brunton 1999, Benavente-García et al. 1997).
Application of experimental design is very useful for estimation of the influence of different process parameters on product properties. Many different concepts are used. Genichi Taguchi developed a standard methodology where several process parameters can be tested in a defined number of experiments. By using Taguchi methodology the influence and contribution of a single parameters on the process can be studied and the optimal conditions could be determined. Therefore experimental design by Taguchi methodology is very useful

and applicable in the investigation of parameter influence on product properties (Roj 1990, Tramšek M. and Goršek A. 2007).
The aim of our investigation was to determine by Taguchi experimental design the influence of four extraction parameters (extraction temperature, extraction time, material to solvent ratio and number of stages) on antioxidant properties such as DPPH radical scavenging activity, ACL and ACW. Results were evaluated by Analysis of variance (ANOVA) method. Obtained extracts were analyzed for composition and content of flavanones by HPLC.

MATERIAL AND METHODS

Preparing of material

Mandarin peels were collected from fruits bought at the local supermarket (season 2010). Peels were dried by hot air flow (40 – 50 °C) and stored in dark and cool place. Dried peels were grounded before use and saved in dark at room temperature.

Taguchi experimental design

Taguchi experimental design was used for determining the influence of extraction parameters on antioxidant activity. Four extraction parameters, e.g. extraction temperature, extraction time, material to solvent ratio and number of stages were tested on three levels. Table 1 presents the orthogonal table of experiments L_9 prepared by Taguchi methodology (Roj 1990). For evaluation of the results Analysis of variance (ANOVA) was used. Table 2 presents the equations used for evaluation of the influence of process parameters on present antioxidant properties of obtained extracts (Roj 1990, Tramšek M. and Goršek A. 2007).
Extractions were performed at conditions presented in Table 1. The proper volume of 70 % aqueous solution of acetone was added to 5 g of mandarin peels. After the defined time of mixing by a magnetic stirrer at defined temperature the solution was separated by filtration. The extract was separated from solution by evaporation of the solvent. After drying, the extract was weighed and stored in a cool place. In the case of 2 and 3 stages extraction extract solutions were combined and evaporated to dry.

Radical scavenging activity against 2,2-diphenyl-1-picrylhydrazyl hydrate (DPPH)

Antiradical activity of mandarin peel extracts was determined against stable DPPH (2,2-diphenyl-1-picrylhydrazyl) radical. DPPH radical–scavenging activity of obtained extracts was determined spectrophotometically, as described by Miliauskas et al. (2004) and Majhenič et al. (2007). The radical–scavenging activity was expressed as % of inhibition of DPPH free radical.

Table 1. Taguchi experimental design for determining the influence of extraction parameters on antioxidant properties of products.

Experiment	Extraction parameter			
	Temperature (°C)	Time (min)	R(mat./sol.) (g/mL)	No. of stages (/)
1	20	120	1:20	3
2	40	90	1:20	1
3	60	90	1:50	3
4	20	90	1:30	2
5	60	120	1:30	1
6	40	60	1:30	3
7	60	60	1:20	2
8	20	60	1:50	1
9	40	120	1:50	2

Table 2: Equations used for evaluation of results by ANOVA method.

Expression	Eq.No.	Expression	Eq.No.
$S_T = \sum_{i=1}^{N} Y_i^2 - \left(\sum_{i}^{N} Y_i\right)^2 / N$	(1)	$f_e = f_T - \sum_{j=1}^{M} f_j$	(7)
$S_j = \sum_{k=1}^{L}\left(\left(\sum_{i=1}^{N_k} Y_i\right)^2 / N_k\right) - \left(\sum_{i=1}^{N} Y_i\right)^2 / N$	(2)	$f_T = M - 1$	(8)
$S_e = S_T - \sum_{j=1}^{M} S_j$	(3)	$F_j = V_j / V_e$	(9)
$V_j = S_j / f_j$	(4)	$S_j^{'} = S_j - f_j V_e$	(10)
$f_j = L - 1$	(5)	$X_j = S_j^{'} 100 / S_T$	(11)
$V_e = S_e / f_e$	(6)	$X_e = \left(S_e + \sum_{j=1}^{M} f_j V_e\right) 100 / S_T$	(12)

f_e is degree of freedom of error variance, F_j is variance ratio of process parameter j, f_j is degree of freedom of process parameter j, f_T is degree of freedom of process parameter j, L is number of levels, M is number of process parameters, N is number of experiments, N_k is number of experiments on k level, S_e is error sum of squares, S_j is sum of squares of process parameter j, $S_j^{'}$ is pure sum of squares, S_T is total sum of squares, V_e is variance of error, V_j is mean square (variance) of process parameter j, X_e is relative influence of error on optimization criteria (%), X_j is relative influence of process parameter j on optimization criteria (%) and Y_i is i value of optimization criteria, antioxidant property.

Antioxidant Capacity of Lipid soluble compounds (ACL)
Antioxidant Capacity of Lipid soluble compounds (ACL) were determined by PHOTOCHEM (Analytik Jena AG, Germany) according to the instructions of the producer. For preparation of samples (extracts) methanol was used as solvent. 10 mg of extract was dissolved in a 10 mL flask and filtrated with 45 µm Teflon filter before analysis. Extracts were measured after preparing the calibration curve of ACL standard Trolox. Results were expressed as µg of Trolox per mg of extract

Antioxidant Capacity of Water soluble compounds (ACW)
Antioxidant Capacity of Water soluble compounds (ACW) were determined by PHOTOCHEM (Analytik Jena AG, Germany) according to the instructions of the producer. For preparation of samples (extracts) MiliQ water was used as solvent. 10 mg of extract was dissolved in a 10 mL flask and filtrated with 45 µm Teflon filter before analysis. Extracts were measured after preparing the calibration curve of ACW standard Ascorbic acid. Results were expressed as µg of Ascorbic acid per mg of extract.

Flavanones composition and content in extracts
The composition and content of flavanones were determined by high performance liquid chromatography (HPLC) method. For HPLC analysis of flavonoids Agilent 1220 HPLC system with detector DAD (Agilent) and column Chomsep SS C-18 250 4.6 mm Microsorb 100 stationary phase with 5 µm particle size was used. The mobile phase consisted of two solvents: A: methanol, and B: 2 % (v/v) acetic acid in Milli-Q water. The method started with linear gradient from 35 % A to 46 % A in 30 min. The flow rate was 0.85 mL/min and detection was performed at 282 nm and 330 nm. The standard solutions were prepared by dissolving standards in methanol. Extract solutions were prepared by dissolving 10 mg of extract in 10 mL of methanol, sonicated and filtrated by 0.45 µm filter before analysis. Results were expressed as mass of single flavanone in mg per g of obtained extract.

RESULTS AND DISCUSSION

The influence of four extraction parameters (extraction temperature, extraction time, material to solvent ratio and number of stages) on DPPH radical scavenging activity, ACL and ACW was tested by Taguchi experimental design presented in Table 1. The results of antioxidant properties are presented in Table 3. All measurements were performed in triplicates. The highest activity against stable DPPH radical, 14.7 % inhibition was determined for extract obtained during extraction experiment 9: temperature 40 °C, time 120 min, material to solvent ratio 1/50 g/mL and in 2 stages of extraction. Similarly high activity against stable DPPH radical (14.4 % inhibition) was determined also for experiment 3 (60 °C, 90 min, 1/50 g/mL and 3 stages of extraction). Generally the DPPH radical scavenging of obtained extracts varied between 12.1 and 14.7 %. The highest ACL (77.26 µg of Trolox per mg of extract) was determined for extraction experiment 3, performed at 60° C, 90 min, material to solvent ratio 1/50 g/mL and 3 stage of extraction. The ACL of extracts were established between 58.78 and 77.26 µg of Trolox per mg of extract. The highest ACW of extract, 52.18 µg of ascorbic acid/mg of extract was determined for extraction experiment 9 performed at 40 °C, 120 min, material to solvent ratio 1/50 g/mL and 2 stages of extraction. The ACW values varied between 29.94 and 52.18 µg of ascorbic acid/mg of extract.
The influence of extraction parameters on presented antioxidant properties was determined by ANOVA method. High relative influence on radical scavenging activity against DPPH was determined for number of extraction stages (35.85 %) and for material to solvent ratio (34.83 %) while time and temperature of extraction were less influencing parameters (14.71 and 14.61 %). For ACL of extract all tested parameters influence at a similar extent; temperature of extraction – 24.99 %, time of extraction – 24.17 %, material to solvent ratio – 23.46 % and number of extraction stages – 27.38 %. The main influence on ACW belonged to the time of extraction (83.76 %) while other parameters (number of extraction stages, material to solvent ratio and temperature) had small influence (7.69, 6.07 and 2.48 %).

Table.3 Antioxidant properties of extracts of mandarin peel.

	DPPH	ACL	ACW
Experiment	% of inhibition	µg Trolox / mg of extract	µg Asc. acid / mg of extract
1	13.4	58.78	44.10
2	12.1	62.25	24.55
3	14.4	77.26	30.12
4	12.5	74.76	29.94
5	13.1	67.81	40.32
6	13.8	68.42	44.16
7	13.3	68.95	40.93
8	12.9	58.97	41.90
9	14.7	68.02	52.18

In a further investigation the composition and content of flavonoids were determined (Figure 1). The two main flavanones hesperidin and narirutin were determined by HPLC method. Didymin was present in traces. The content of hesperidin in extract varied between 71.2 and 110.7 mg of hesperidin per g of extract, while the content of narirutin was much lower, between 16.8 – 20.8 mg of narirutin per g of extract. The highest content of hesperidin, 110.8 mg/ g of extract, was obtained by extraction at 40 °C, 120 min, 1/50 g/mL and in 2 stages of extraction (experiment 9). Similarly high content of hesperidin (104.4 and 103.8 mg per g of extract) was determined also for extract of experiment 3 and experiment 7. The highest content of narirutin, 20.8 mg/ g of extract, was extracted at conditions: 60 °C, 60 min, 1/20 g/mL and 2 stages (experiment 7).

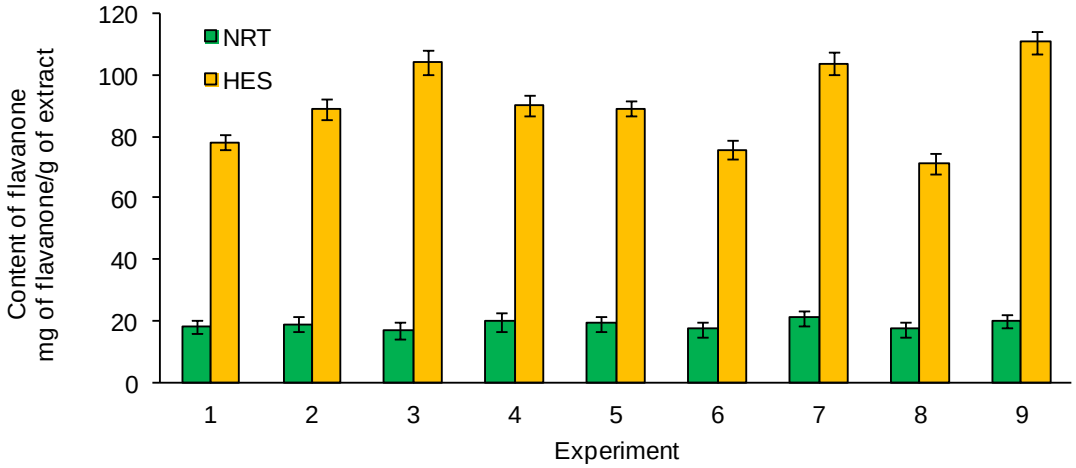

Figure 1. The content of the main flavanones hesperidin (HES) and narirutin (NRT) in extracts.

CONCLUSIONS

In the present work Taguchi experimental design was applied for the first time for evaluation the influence of different extraction parameter on antioxidant properties of mandarin peel extracts. The highest influences on the radical scavenging against DPPH have the number of extraction stages and material to solvent ratio. All studied parameters have similar influence on ACL property. The material to solvent ratio has predominating influence on ACW property of extracts.

The presented methodology can be applied also for the determination of the optimal extraction conditions to obtain extracts with the best antioxidant properties. Two very good combinations of tested antioxidant properties were determined for extracts obtained at extraction experiment 3 (60 °C, 90 min, 1:50 g/mL and 3 stages of extraction) and experiment 9 (40 °C, 120 min, 1/50 g/mL and 2 stages of extraction). In the obtained extracts three flavanones were identified: mainly hesperidin and narirutin and traces of didymin.

ABSTRACT: Oligosaccharides from legume species produced in few regions of Croatia were investigated. Eight traditionally cultivated legumes were analyzed: common bean *(Phaseolus vulgaris* L.*),* faba bean *(Vicia faba* L.*),* lentil *(Lens culinaris* Medic.*),* white lupin *(Lupinus albus),* chickpeas *(Cicer arietinum* L.*),* cowpea *(Vigna unguiculata* L.*),* soybean *(Glycine max* (L.) Merr.*)* and grass pea *(Lathyrus sativus).*The soluble saccharides (monosaccharides, sucrose, raffinose and stachyose) were extracted with water and separated by high performance liquid chromatography. Saccharides were identified by their retention time and quantified by peak area using external standard procedure.The results showed that the total water soluble saccharides content ranged from 3.71% to 7.5%, and oligosaccharides represented 36.38% to 69.29% of the total saccharides in investigated dry legume grains. Stachyose was the main oligosaccharide in all grains, except for chickpeas, in which the main oligosaccharide was raffinose. Different amounts of sucrose and small amount of glucose, galactose and fructose were present in all legume grains. Significant difference in total saccharides, raffinose and stachyose content was found between investigated legume species. The discriminant analysis showed that legume species can clearly classify according to content of water soluble saccharides. According to obtained results, the investigated legumes can be considered a good source of oligosaccharides.
Key words: *legume species, oligosaccharides, HPLC separation*

INTRODUCTION

Oligosaccharides are functional food ingredients that have great potential to improve the quality of food. Oligosaccharides have been associated with many health-promoting functions, which had been identified in many clinical studies, such as promoting the growth of *Bifidobacterium* in human intestine and balance of intestinal bacteria, modulation the immune response, inhibition of cancer and tumour and stimulation of mineral absorption (Mesina, 1999).

Legume grains are a rich source of galactooligosaccharides, namely raffinose and stachyose: raffinose is a trisaccharide containing a galactose linked -(1-6) to the glucose unit of sucrose; stachyose is a tetrasaccharide containing a galactose linked -(1-6) to the terminal galactose unit to raffinose. Humans cannot digest these oligosaccharides because they do not possess the enzyme α-galactosidase necessary for hydrolysing the linkage present in oligosaccharides in consumed food. Intact oligosaccharides reach the colon, where they are preferentially fermented by beneficial bifidogenic microorganisms that contain the enzyme. Fermentation of nondigestible oligosaccharides results in production of gases and short chain fatty acids, which are interesting because of their prebiotic activity associated with health benefits (Roberfroid and Slavin, 2000). Oligosaccharides potential as an ingredient of functional food makes the search for new sources interesting, as well as the development of methods that allow its isolation and purification in a simple and effective way (Guillon and Champ, 2002).

The objective of this study was to investigate the composition of oligosaccharides in legume species produced in few regions of Croatia.

MATERIAL AND METHODS

Eight traditionally cultivated legumes: common bean (*Phaseolus vulgaris* L.), faba bean (*Vicia faba* L.), lentil (*Lens culinaris* Medic.), white lupin (*Lupinus albus*), chickpeas (*Cicer arietinum* L.), cowpea (*Vigna unguiculata* L.), soybean (*Glycine max* (L.) Merr.) and grass pea (*Lathyrus sativus*) were used for analysis.
To prepare a sample for analysis, one gram of ground legume was weighed into a test tube and mixed with water. The tube was placed horizontally on a shaker for 20 min at room temperature. After cooling, sample was centrifuged and 5 mL of the clear supernatant was transferred into a new test tube. A total of 7 mL of acetonitrile was added to precipitate soluble proteins and incubated at room temperature for two hours. The mixture was then centrifuged and the supernatant was collected and evaporated to dryness in a rotatory evaporator. The dried extract was disolved in water and passed through 0.45 μm syringe filter, just before high performance liquid chromatography (HPLC) analyses. The separation was carried out by Perkin-Elmer High-Performance Liquid Chromatography system series 200 equipped with degasser, isocratic pump, oven, refractive index detector and TotalChrom Navigator (HPLC software). The separation was performed on MetaCharb Ca Plus column (300 x 7.8), thermostated at 90^0C. 20 μL aliquot was injected onto the column and eluted with deionized water of flow rate of 0.5 mL/min. A standard solution composed of stachyose, raffinose, sucrose, glucose, galactose and fructose at concentration of 1; 2; 2.5; and 3 mg/mL respectively. Saccharides from aqueous sample extract were identified by their retention time and quantified by peak area using external standard procedure. Oligosaccharides were representeed as the sum of raffinose and stachyose.
One-way analysis of variance (ANOVA) and multiple comparisons (Duncan's post hoc test) were used to evaluate the significant difference of the data at $P < 0.05$. Comparative analyses of legume were performed using linear discriminant analysis. All statistical analyses were performed using statistical-graphic system "Statistica" version 7.0 (Stat Soft software Inc., Tulsa, OK, USA).

RESULTS AND DISCUSSION

The composition of water soluble saccharides in legume grains, determined by HPLC, is shown in Fig.1 and 2. The results indicate that the legume grains contain oligosaccharides, disaccharide and monosaccharides.

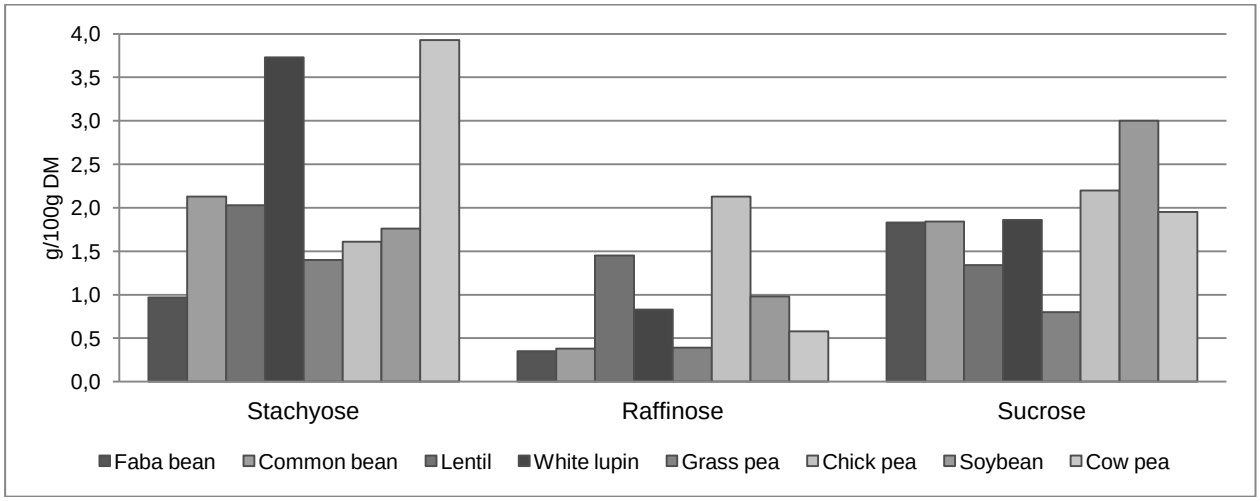

Figure 1. Concentrations (%, dm) of stachyose, raffinose and sucrose in legume grain

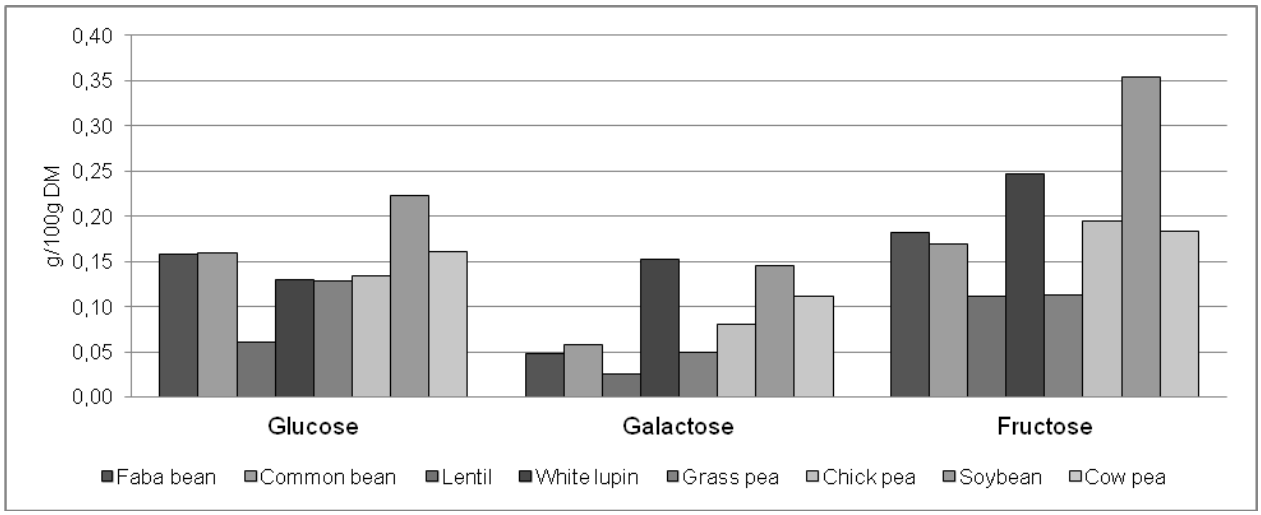

Figure 2. Concentrations (%, dm) of glucose, galactose and fructose in legume grain

Most dominant oligosaccharide was stachyose. Among legume species, high level of this oligosaccharide was found in cow pea (3.93%) and white lupin (3.73%), and the least in faba bean (0.93%). Stachyose has been reported as main oligosaccharide in most legumes, i.e. lentils, chickpeas, common bean and white lupin (Kueo et al., 1988; Guillon and Champ, 2002; Berrios et al., 2010; Hou et al., 2006). The content of stachyose detected in this legume was within the range 2.21-3.23 % reported by Pilar (1998). Wide range of stachyose was found in soybean (Wilcox and Shibles, 2001; Kim et al., 2003; Espinosa-Martos and Ruperez, 2006; Giannoccaro et al., 2008). Hou et al. (2010) analyzed worldwide soybean germplasm and found stachyose content ranged from 0.2 to 69.6 mg/g and several samples contained less than 10 mg/g. Raffinose amount was highest in chick pea (2.13%) and lowest in faba bean (0.35%), common bean (0.38%) and chick pea (0.39%). Sucrose, as only disaccharide found, was the second most abundant water soluble saccharide, with amounts ranging from 0.80% (grass pea) to 3.00% (soybean). In the soybean, sucrose is dominant sugar ranging from 3% to 10% and it is responsible for the sweet taste of soy food (Giannoccaro et al., 2008). Small amounts of monosaccharides: glucose, galactose and fructose (<1%) have also been found (Fig. 2). Besides small but different amounts of glucose and fructose, it is interesting to note that galactose, not previously detected in legume, was found in all species.

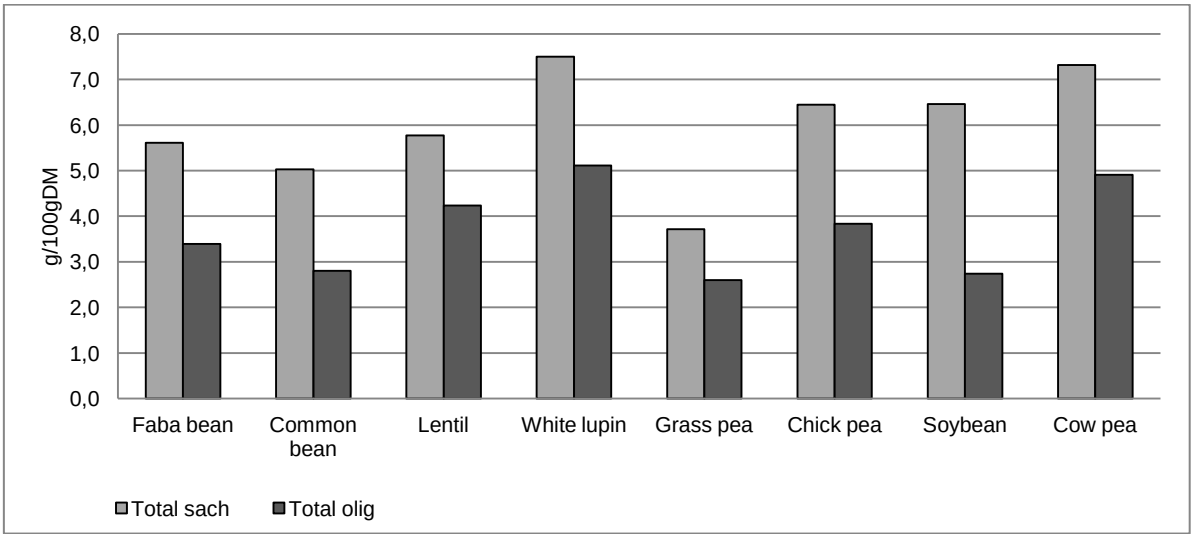

Figure 3. Concentration (%, dm) of total saccharides and oligosaccharides in legume grain

The content of total water soluble saccharides ranged from 3.71% (gras pea) to 7.50% (white lupin), and oligosaccharides represented 36.38% to 69.29% of the total saccharides in investigated dry legume grains (Fig. 3). In this study, the results of total water soluble saccharides and oligosaccharires in legume species were in agreement with some published data (Ruperez, 1998; Han and Baik, 2006). The analyses of the saccharides profiles indicated that high total saccharides content is attributed to high content of sucrose and oligosaccharides.

Table 1. Results of ANOVA for total water soluble saccharides in legume species

EFFECT	DF	Stach	Raf	Suc	Glc	Gal	Fru	Total sacch	Total oligo
Total	75	0.84	0.33	0.52	0.00	0.00	0.01	2.09	0.87
Blocks	3	0.00	0.00	0.01	0.00	0.00	0.00	0.04	0.01
Species	7	8.38**	3.43**	4.63**	0.01**	0.02**	0.05**	17.79**	7.99**
Residual	65	0.07	0.01	0.10	0.00	0.00	0.00	0.50	0.15
C.V.		13.10	16.30	18.10	29.90	28.01	16.06	12.90	11.41

Analysis of variance showed significant difference ($p<0.05$) between investigated legume species for: stachyose, raffinose, sucrose, monosaccharides, total saccharides and oligosaccharides content (Tab. 1).
Individual saccharides content as the variables in discriminant analysis were used for classification and differentiation of legume species.

Table 3. Results of cannonical discrimant analysis on legume species

Variable	Pooled with cannonical structure		
	Can1	Can2	Can3
Stahiose	-0,17	0,48	-0,47
Raffinose	0,61	0,31	-0,19
Sucrose	0,12	-0,06	-0,45
Glucose	-0,01	-0,08	-0,14
Galactose	0,01	0,02	-0,43
Fructose	0,09	-0,57	-0,57
Variation %	54,65	26,01	16,32
Total variation %	54,65	81,66	97,98
Discriminate r>±0,40	Raffinose	Stahyose Fructose	Sucrose Galactose

All multivariate difference tests between legume groups were significant on the 0.001 level and the credibility test indicated significance of the first three out of six newly created canonical variables. The first three variables explained 97.98 % of the total variance (Table 3.) with the square canonical correlation percentage of R^2= 80.51%. The first canonical variable (54.66%) had the strongest legume group discrimination through raffinose influence. The raffinose content (0.61) proved to be a trait that discriminates population the most and clearly differentiates legume species. In the second canonical variable stachyose and fructose dominated. These are variables which are similar in influence but of different directions.

CONCLUSION

In investigated legume grain wide variation were found among individual and total water soluble saccharides. Stachyose was the main oligosaccharide in all grains, except for chickpeas, in which the main oligosaccharide was raffinose. Sucrose was the second most abundant water soluble saccharide, while glucose, galactose and fructose were presented in small quantities. According to obtained results, the investigated legumes can be considered a good source of oligosaccharides for functional food. The discriminant analysis showed that

the legume species can be clearly classified according to content of water soluble saccharides.

ACKNOWLEDGMENT

This research was supported by SEERANET 168 (Sustainable preservation of indigenous South East European legumes and their traditional food and feed products) project. We wish to thank the project Continued genetic improvement of soybean by modern breeding strategies (073-0730489-0344) for the financial support.

ABSTRACT: In the present work the curcumin extract was formulated using supercritical fluid technology, namely Particles from Gas Saturated Solution technique (PGSS™). The PGSS™ formulation was carried out using supercritical carbon dioxide, which results in an organic solvent-free powderous product. The investigated carrier materials were fat and different natural polymers.
Powderous products obtained after the PGSS™ micronization showed good colour stability, which gives good bases for potential applications in the future. The products are homogenously coloured fine powders with colours from light yellow to orange; what depends on contents of curcuminoids.
The radical-scavenging activities of powderous products was evaluated using the stable free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH). All powderous products displayed radical-scavenging properties.
Key words: *curcumin, PGSS™, DPPH*

INTRODUCTION

One of the newest trends in food science and technology is functional food. Curcumin, a natural yellow-orange polyphenol found in the plant *Curcuma longa* (turmeric), is widely used as a food colourant and as a potential protective agent against several chronic diseases, including cancer, HIV-infection, neurological, cardio-vascular and skin diseases (Paramera et al., 2011). It has a wide range of pharmacological activities including anti-inflammatory, antioxidant, antiproliferative and antiangiogenic properties. Curcumin is unstable at neutral and basic pH values. It would be stable in the stomach and small intestine since degradation of curcumin is extremely slow at pH between 1 and 6 (Setthacheewakul et al., 2010).
The aim of this study was to formulate powdereous products from curcuma and test their antioxidant activity.

MATERIAL AND METHODS

Curcumin liquid extract (10 wt. %) was purchased from Etol (Celje, Slovenia). CO_2 was provided by Messer (Ruše, Slovenia).

Formulation with PGSS™

Curcumin extract was first formulated with various carriers using supercritical fluid technology, namely Particles from Gas Saturated Solution technique (PGSS™). The melted fat (glycerol tristearate) was mixed with the emulsifier and the curcumin extract in different concentrations using a homogenizer. Then pure cellulose or pure starch was added to the mixture to make better texture of the products. The autoclave was filled with the substance and CO_2 was introduced by a high pressure pump to the desired pressure, depending on prexpansion parameters (160 bar). The autoclave was then heated up to the operating temperature which was slightly higher than the melting point of the fat (~60 °C). Simultaneously the pressure reached the operating value. The autoclave with its content was shaken constantly until reaching the equilibrium (approximately 2 h). The solution saturated with gas was then expanded through the nozzle and the compressible gas evaporated

instantly in the expanding chamber causing the micronization of the particles (Mandžuka et al., 2010).

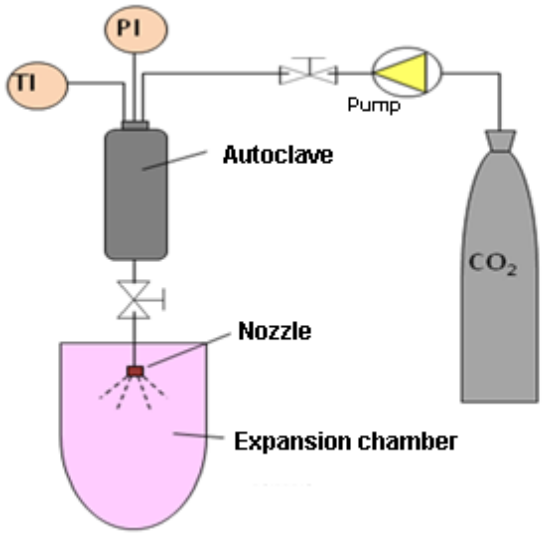

Figure 1. Scheme of PGSS^{TM} equipment

DPPH radical scavenging activity

DPPH radical-scavenging activity of the curcuma extract was measured with the stable 2,2-diphenyl-1-picrylhydrazyl (DPPH, Sigma Aldrich, Slovenia) free radical. The reduction capability (on the DPPH radical) is determined by the decrease in its absorbance at its absorption maximum at 515 nm that is induced by antioxidant. This is visualized as a change in colour from violet to yellow. Extract solutions were prepared by dissolving 0.01 g of micronized powder in 10 ml of methanol. The solution of DPPH in methanol was prepared daily, before UV measurements. 3 mL of this solution were mixed with 77 µl extract solution in the flask. The samples were kept in the dark for 15 min at room temperature and then absorbance was measured at 515 nm. Radical-scavenging activity was calculated by the following formula:

$$\% \text{ Inhibition} = \frac{\quad}{\quad}$$

where *Ab*, absorption of blank sample (*t=0* min); *Aa*, absorption of tested extract solution (*t=15* min) (Al-Reza et al., 2010).

RESULTS AND DISCUSSION

Results of micronizations

Table 1 shows the composition of samples and the operating parameters applied for the formulations. The obtained curcuma products were homogenously coloured fine free-flowing powders with colours from light yellow to orange.

The used operating parameters were about 170 bar and 70 °C in all experiments. By using cellulose or starch the texture of obtained powder was better and drier in all cases.

Results of antioxidant activity

The results of DPPH radical-scavenging activities of the micronized powders are represented in Figure 1. The micronized powders showed potent DPPH radical - scavenging activities in range between 6.98 to 14.46 % and are applicable as colorants in food or pharmaceutical industry. The highest radical-scavenging activity of 14.46 % was observed for sample 3 (50 % curcumin extract, 45 % glycerol tristearate and 5 % pure cellulose). The lowest radical - scavenging activities were observed for sample 1 and 2 (20 % curcumin extract, 65 % glycerol tristearate and 5 % pure cellulose or starch).

Table 1. Results of formulation of curcumin extract

Samples	Curcumin extract (%)	Emulsifier (%)	Glyc. trist. (%)	Cellulose (%)	Starch (%)	p (bar)	T (°C)	Yield (%)	Product
1	20	1	65	15	-	160	64	77.7	
2	20	1	65	-	15	160	63	92.4	
3	50	1	45	5	-	160	70	90.6	
4	50	1	45	-	5	160	70	75.1	
5	50	1	30	20	-	160	60	80.2	
6	50	1	30	-	20	160	59	70.6	

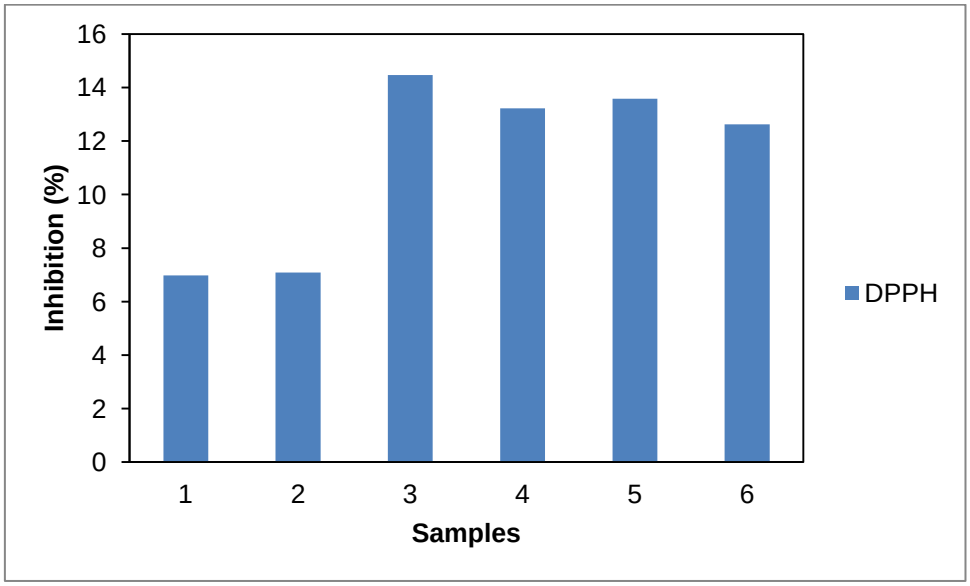

Figure 1. Antioxidant activities of the micronized powders

CONCLUSIONS

In this work application of environmentally friendly technology was applied for the formulation of curcuminoids from curcumin extract in the powderous form. The obtained dense curcumin extract was formulated in high pressure process (PGSS^{TM}) by using CO_2 as processing media and glycerol tristearate fat mixed with cellulose or starch as carriers.
The obtained products were homogenous fine powders with colours from light yellow to orange with high radical-scavenging properties. The obtained products are interesting for the application in the food industry.

ACKNOWLEDGEMENTS

Authors are grateful to the Slovenian Ministry of High Education, Science and Technology for the financial support of this work.

ABSTRACT: Aromatic herbs have long tradition of use in medicine, nutrition and cosmetics. Among them, oregano (*Origanum vulgare* L., Lamiaceae) has been appreciated as a spice and food flavouring agent owing to the presence of essential oil. However, postdistillation waste, remaining after the isolation of essential oil, is still unused. Thus, in this study antioxidant and antimicrobial activity of oregano herb postdisillation waste material was investigated. After the hydrodistillation of essential oil of oregano herb, postdistillation waste material extracts were made from decoction and used herb (with 45% v/v and 75% v/v ethanol). Chemical composition was determined by means of high performance liquid chromatography. *In vitro* scavenging activity was evaluated using DPPH (2,2-diphenyl-1-picrylhydrazile) ($DPPH^{\cdot}$) and hydroxyl ($OH^{\cdot}$) radical. The effect on the peroxidation of membrane lipids was assayed by thiobarbituric acid (TBA) test, following the effect of investigated extracts on Fe^{2+}/H_2O_2 induced lipid peroxidation (LP) in corn oil as a model system. Minimal inhibitory concentration (MIC) was determined with broth microdilution assay against selected gram-positive (*Staphylococcus aureus* and *Bacillus cereus*) and gram-negative bacteria (*Salmonella* Infantis, *Escherichia coli*). All investigated extracts were rich in phenolcarboxylic acids (rosmarinic, protocatechuic, gallic and chlorogenic acid) and flavonoids (rutin and apigenin). They exhibited strong antioxidant and antibacterial activity (especially extract obtained with 75% ethanol from used herb) when compared to standardised oregano herb extract. This study confirms postdistillation plant waste material for possible use in pharmaceutical and food industry and gives very informative insight into antioxidant and antibacterial profile of investigated oregano extracts.
Key words: *Oregano, postdistillation plant waste material, phenolics, antioxidant, antibacterial*

INTRODUCTION

Many species of *Oregano* genus, native to central and southern Europe, the Balkans and Asia are widely used as culinary and medicinal herbs (Bisset and Wichtl, 2001). *Origanum vulgare* L., (Lamiaceae) is the most frequently used and cultivated worldwide. Numerous studies confirmed antioxidant, antibacterial, spasmolityc and carminative effect for the essential oil (Dorman and Deans, 2000; Burt, 2004). Oregano is widely used as spice in food processing and in many pharmacological preparations as herbal remedies (Tepe et al., 2004). Besides essential oil, various oregano extracts (mainly ethanol) have been studied for their antioxidant and antimicrobial activity in various commercial or food models (Chun et al., 2005; Hernandez-Hernandez et al., 2009; Camo et al., 2011). It is considered that high content of phenolic compounds in oregano, especially caffeic acid oligomers (e.g. rosmarinic acid) and flavonoid glycosides contributed the most to the radical scavenging activity of the herb and investigated extracts (Gomez-Estaca et al., 2009). The antioxidant activity of phenolic compounds in plants is mainly due to their redox properties and chemical structure, which can play an important role in neutralizing free radicals, chelating transitional metals and quenching singlet and triplet oxygen, by delocalization or decomposing peroxides.

Moreover, phenolic compounds from plant extracts have been used in different food matrices to improve stability of food lipids. Oregano herb contains minimum 2.5% of essential oil and it is mainly used for its hydrodistillation (Ph. Eur. VI, 2007). As a result, majority of plant material remains unused.
Considering these facts, the aim of the present study was to evaluate antioxidant and antimicrobial potential of chemically well characterized oregano herb postdistillation waste material.

MATERIAL AND METHODS

Plant material

Oregano herb (*Origanum vulgare* L., Lamiaceae) was obtained from the Institute for Studies on Medicinal Plants „Dr Josif Pancic" in Belgrade in 2011. Voucher specimen of purchased plant material (oregano no. Ov-16/10) was confirmed and deposited at the Herbarium of the Laboratory of Pharmacognosy, Department of Pharmacy, Faculty of Medicine, University of Novi Sad (Tutin et al., 2001).

Extraction procedure

Oregano herb was macerated with 45% ethanol (EtOH) for 24 h at room temperature (1:10 w/v, 10 g dried leaves) to prepare standard extract 1 (E1). Essential oil was isolated by hydrodistillation, and decoction remained after this procedure was used to prepare extract 2 (E2). Deodorized extracts were obtained after distillated plant material was dried and re-extracted with 45% (E3) and 75% (E4) ethanol using cold maceration process. All extracts were filtered and evaporated to dryness under vacuum. For the evaluation of total phenolic and flavonoid content and antioxidant activity, residues were immediately dissolved in water to make 10% (w/v) stock solutions. For HPLC analysis residues were dissolved in methanol:1% formic acid mixture (50:50 w/w) to make 10% (w/v) stock solutions. For antibacterial testing residues were reconstituated in solvents used for extract preparation (water, 45% or 75% EtOH).

Chemical composition

Determination of total phenolic content: The amount of total phenolic compounds in extracts was determined spectrophotometrically with Folin-Ciocalteu (FC) reagent (Lakic et al., 2010). The concentration of total phenolic compounds was expressed in mg of gallic acid equivalents (GAE) per g of dry extract (d.e.) using a standard curve of gallic acid (concentration range 0.08-0.24 mg/mL). All measurements were done in triplicate.

Determination of total flavonoid content: Total flavonoid content in the extracts was determined spectrophotometrically, using a method based on the formation of a flavonoid-aluminium complex with an absorptivity maximum at 430 nm (Jia et al., 1999). Flavonoid content was expressed in mg of quercetin equivalents (QE) per g of dry extract using a standard curve of quercetin (concentration range 10-100 µg/mL). All measurements were replicated three times**.**

HPLC analysis: HPLC analysis was performed using a liquid chromatograph (Agilent 1200 series), equipped with diode array detector (DAD) and Eclipse XDB-C18, 1.8 µm, 4.6×50 mm column, at a flow-rate of 1 mL/min. Solvent gradient was performed by varying the proportion of solvent A (methanol) to solvent B (1% formic acid in water (v/v)) (Misan et al., 2011). The total running time and post-running time were 45 and 10 min, respectively. The column temperature was 30 ºC. The injected volume of samples and standards was 5 µL and it was done automatically using autosampler. The spectra were acquired in the range 210–400 nm and chromatograms plotted at 280, 330 and 350 nm with a bandwidth of 4 nm, and with reference wavelength/bandwidth of 500/100 nm.

Antioxidant activity

Free radical scavenging capacity (RSC) of the extracts was evaluated by measuring scavenging activity on DPPH and OH radicals and combined with determination of influence on lipid peroxidation for the assessment of antioxidant activity. All measurements were done in triplicate. Percent of RSC or inhibition of lipid peroxidation process was calculated by the following equation:

$$RSC/I\ (\%) = 100\% \times (A_{control} - A_{sample})/A_{control}$$

From the obtained RSC/I (%) values the IC_{50} value, which represents the concentration of an extract that caused 50% neutralization or inhibition, was determined by regression analysis.

DPPH assay: DPPH assay was performed as described previously (Bozin et al., 2008). The disappearance of DPPH radical (DPPH$^{\bullet}$) was detected spectrophotometrically at 515 nm.

To standardize DPPH results, the antioxidant activity index (AAI) was calculated as follows:

$$AAI = \text{DPPH concentration in reaction mixture } (\mu g/mL)/IC_{50}\ (\mu g/mL)$$

Samples were classified as showing poor antioxidant activity AAI<0.5; moderate 0.5<AAI<1; strong 1<AAI<2 and very strong AAI>2 (Sherer and Godoy, 2009).

Neutralisation of OH radical (OH$^{\bullet}$): The scavenging capacity of oregano extracts for OH$^{\bullet}$ was evaluated by measuring the degradation of 2-deoxy-D-ribose with OH$^{\bullet}$ generated in the Fenton reaction (Bozin et al., 2006).

Inhibition of lipid peroxidation: The extent of LP was determined by measuring the colour of the adduct produced in reaction of TBA with malondyaldehide (MDA), as the final oxidation product in the peroxidation of lipids (Milic-Torres et al., 2011). After cooling and centrifugation at 3500r/min for 20 min, the content of the MDA was determined by measuring the absorbance of the adduct at 532 nm (test tubes were kept at 0 °C during measurement).

Antibacterial testing

Bacterial strains and growth conditions: Four bacterial strains, namely *Bacillus cereus* WSBC 10530 (clinical isolate), *Staphylococcus aureus* ATCC 25923 (clinical isolate), *Salmonella* Infantis ŽMJ 106 (poultry meat isolate) and *Escherichia coli* O157:H7 ŽM 370 (clinical isolate) were used for antibacterial testing. The cultivation/assay medium for used bacterial strains was Müeller Hinton Broth or Agar (MHB, MHA, Oxoid, Hampshire, UK). For antimicrobial testing, bacterial cultures were prepared by picking colony from 24-h-old MHA plates and they were suspended in an appropriate medium (MHB) (5 mL). Cultures were grown aerobically for 24 h and continuously shaken at 100 rpm at 37 °C. For antibacterial activity assays 1 mL of each culture was diluted with MHB medium to 10^6-10^7 CFU/mL.

Broth microdilution method: For the broth microdilution test 50 µL of each bacterial suspension in suitable growth medium was added to the wells of a sterile 96-well microplate already containing 50 µL of two-fold serially diluted investigated extracts. The final volume in each well was 100 µL. Control wells were prepared with culture medium, bacterial suspension only, extracts only and ethanol in amounts corresponding to the highest quantity present. After the incubation period of 24 h, minimal inhibitory concentration (MIC) values were determined as the lowest concentration where no viability was observed on the basis of metabolic activity. To indicate respiratory activity the presence of colour was determined after adding 10 µL/well of 2-(p-iodophenyl)-3-(p-nitrophenyl)-5-phenyl tetrazolium chloride (INT) (2 mg/mL) dissolved in water and incubation under appropriate cultivation conditions for 30 min

in the dark (Klančnik et al., 2010). All measurements of MIC values were repeated in triplicate.

Statistical analysis: The data were reported as mean values ± standard deviation (SD). Values representing the concentrations of investigated extracts that cause 50% neutralization or inhibition (IC_{50}) were determined by linear regression analysis of RSC (%) and LP inhibition results (Microsoft Excel program for Windows, v. 2007).

RESULTS AND DISCUSSION

The total phenolic content (Table 2) in examined oregano extract E1 is in accordance with previously published data (Chun et al., 2005). In postdistillation waste material extracts comparable values were obtained, and they are slightly higher then earlierly demonstrated (Albano and Miquel, 2011). Total flavonoid content in examined extracts was determined for the first time. E1 proved to have the highest concentration of flavonoids, followed by E4 (Table 2). Detailed chemical analysis showed that oregano extracts E1, E3 and E4 were abundant in rosmarinic, gallic and protocatechuic acid (Table 1) which is in correlation with previously published data (Chun et al., 2005). Also, flavonoids rutin, apigenin and quercetin were present in high amounts. The quantity of determined phenolcarboxylic acids and flavonoids does not vary significantly between normally produced and deodorised oregano herb extracts.

Table 1. The results of HPLC-DAD phenolic identification and quantification of investigated *Origanum vulgare* postdistillation waste extracts

Identified compound (mg/g d.e.)	**E1**	**E2**	**E3**	**E4**
Gallic acid	0.54	1.87	2.4	3.19
Protocatechuic acid	0.34	1.41	1.88	2.48
Caffeic acid	0.32	0.62	0.93	1
Chlorogenic acid	0.68	0.86	1.15	1.59
Syringic acid	0.04	0.47	0.68	0.92
Vanillic acid	0.11	0.44	0.59	0.85
Rosmarinic acid	**89.63**	**4.95**	**8.52**	**11.3**
Rutin	0.4	1.35	2.68	4.73
Naringenin	0.03	0.24	1	1.79
Quercetin	1.01	0.36	1.61	2.82
Apigenin	2.66	0.57	4.07	8.5

Antioxidant potential of investigated extracts partially follows the obtained results of chemical analysis. E1 possesses the strongest antioxidant activity in all investigated test systems. E3 and E4 are very similar in activity, whereas E3 is slightly more active. DPPH test on deodorised extracts was done by Albano and Miguel (2011), yet other assays regarding antioxidant capacity of oregano postdistillation waste material have not been performed. Interestingly, almost all samples were more active than synthetic antioxidant BHT in applied tests.

Table 2. Total phenolics (TP), total flavonoid (TF) and antioxidant activity (DPPH-RSC, OH-RSC and LP) of examined *Origanum vulgare* postdistillation waste extracts

Analyte	**TP** (mg GAE/g d.e.)	**TF** (mg QE/g d.e.)	**DPPH-RSC** IC_{50} (µg/ml)	**DPPH** AAI	**OH-RSC** IC_{50} (µg/ml)	**LP** IC_{50} (µg/ml)
E1	38.16	31.69	0.79	11.25	25.79	9.82
E2	25.16	18.13	2.74	3.24	41.55	25.78
E3	32.98	22.59	1.75	5.08	31.44	10.35
E4	36.2	29.31	2.14	4.15	33.71	12.89
BHT	/	/	**6.95**	**1.28**	**nr***	**14.71**

Antimicrobial activity of oregano herb on various bacterial strains has been well documented (Castilho et al., 2012). However, there is no data on antibacterial potential of postdistillation waste materials. All investigated extracts exhibited strong inhibition of growth of tested bacterial strains.

Table 3. Antimicrobial activity (expressed as MICs, in mg TP/mL) of oregano posdistillation waste extracts on investigated bacterial strains

Analyte	***Staphylococcus aureus*** **MIC** (mg TP/mL)	***Salmonella* Infantis MIC** (mg TP/mL)	***Escherichia coli*** **MIC** (mg TP/mL)	***Bacillus cereus*** **MIC** (mg TP/mL
E1	0.03	0.15	0.03	0.3
E2	0.06	0.18	0.13	0.13
E3	0.03	0.14	0.07	0.05
E4	0.05	0.10	0.05	0.02
BHT	0.55	0.55	0.55	0.28

E1, E3 and E4 were very similar in reached MIC values and all of them expressed a very high antimicrobial potential of oregano posdistillation waste extracts. Therefore, they should be further tested in food model studies for potential use as a relatively cheap source of effective natural preservatives in food industry.

CONCLUSIONS

In conclusion, results of this study confirmed *in vitro* antioxidant and antibacterial potential of ethanol extracts of oregano herb. High concentrations of rosmarinic acid, which has numerous pharmacological activities, such are antioxidative and antibacterial activities, were determined. Moreover, most of presented results, regarding chemical analysis, antioxidant and antibacterial activity of postdistillation plant waste material were obtained for the first time. Deodorised oregano herb extracts were found to be rich in active phenolic compounds and could be in the focus of future studies for isolation of caffeic acid oligomers or flavonoids. Also, their possible application in pharmaceutical and food industry should be considered.

ABSTRACT: Resistant starch (RS) from different sources has attracted huge interest, mainly because of its health benefits and functional properties. From technological aspect, positive advantage of RS is its lower impact on the sensory properties of food compared with traditional sources of fibre. The objective of this study was to observe functional properties of two types of RS (type 3 and type 4) as parts of dietary fibre, as well as, the possibility of its application in short dough cookies production.
Partial substitution of the flour with the RS (commercial sources) has contributed to significant changes in rheological and textural properties of the dough. In all samples the use of the RS resulted in the increase of storage and loss moduli of the dough, and the lowering of loss tangent, which indicates its more elastic character. Increasing the portion of RS, type 3 and type 4, as substitutes for flour, contributed to dough elasticity, due to the ability of RS to bind water.
The study involved baking test, as an important criterion for evaluating the quality of flour and RS. The application of RS in the formulation of short dough resulted in the products of improved sensory and nutritional quality. Addition of the starch, type 3, showed better results in terms of overall sensory quality. The findings show a good potential of the RS as a functional ingredient referring to its application in the production of cookies and related products rich in dietary fibre.
Key words: *resistant starch, dough, cookies, rheology, sensory properties*

INTRODUCTION

Recently, the use of starch in foods for health and well-being reasons has surged, resulting from the preponderance of perceived physiological benefits attributed to resistant starch (Sharma et al., 2008). As defined by Asp (1992), resistant starch is the „sum of starch and starch degradation products not absorbed in the small intestines of healthy individuals“. It is included in the definition of dietary fibre (Anon., 2001; Institute of Medicine, 2002). Four classes of resistant starch have been proposed (Sharma et al., 2008) on the basis of mechanisms of enzyme indigestibility, including inaccessibility of starch to amylases due to physical entrapment (RS1), inherent granular structure of raw starch (RS2), molecular association of amylose or retrogradation (RS3) and chemical modification (RS4). As discussed in a number of reviews (Nugent, 2005; Sajilata et al., 2006; Sharma et al., 2008; Fuentes-Zaragoza et al., 2010), resistant starch demonstrates the following physiological benefits in humans: modulation of blood glucose and insulin levels, positive effects on gastrointestinal health, increased absorption of minerals, prebiotic or bifidogenic effect, increased fat oxidation and fermentation into butyrate, which is touted to be protective against colorectal cancer.
Besides physiological benefits in human, RS has been reported to have potential as a unique ingredient that can yield high-quality foods (Yue and Waring, 1998; Baixauli et al., 2008a). RS has desirable physicochemical properties (Fausto et al., 1997) such as swelling, viscosity increase, gel formation and water-binding capacity, making it useful in a variety of foods. Application tests of RS show improved crispness and expansion in certain products and better mouthfeel, colour and flavour as compared with products produced with traditional, insoluble fibres (Sajilata et al., 2006). Applications of RS in foods have become a trend among food manufacturers to improve the health and well-being of consumers.

The objective of this study was to observe functional properties of two types of RS (type 3, type 4) as parts of dietary fibre, as well as, the possibility of its application in short dough cookies production.

MATERIALS AND METHODS

Materials

Flour ("Jaffa", Crvenka, Serbia) (composition data provided by the supplier: 13.9% moisture, 9.6% protein, 62.5% starch).
Resistant starch (type RS3) ActiStar C 11700 (CARGILL, Inc. Food and Pharma Specialties NA, USA). Moisture content was 12% and declared level of RS was 50.0%.
Resistant starch (type RS4) ActiStar RT 75330 (CARGILL, Inc. Food and Pharma Specialties NA, USA). Moisture content was 12% and declared level of total dietary fibre was 80.0%.
Seven formulations were prepared. One without addition of resistant starch (control) and six in which resistant starch (RS3 or RS4) was added as partial replacement of the flour in following concentrations: 5%, 10% and 15% (calculated on flour weight used in control sample). The formulations were prepared with 20% of water content in dough. Full recipes are given bellow in table 1.

Table 1. Full recipes of each formulation (given in presentage of each ingredient)

Ingredient	Control	Sample 1/4 (5% RS3/RS4)	Sample 2/5 (10% RS3/RS4)	Sample 3/6 (15% RS3/RS4)
Flour	55.6	52.8	50.0	47.3
Resistant starch	0	2.8	5.6	8.3
Sugar	19.4	19.4	19.4	19.4
Vegetable fat	11.7	11.7	11.7	11.7
NaCl	0.3	0.3	0.3	0.3
$NaHCO_3$	0.2	0.2	0.2	0.2
NH_4HCO_3	0.1	0.1	0.1	0.1
Distilled water	12.7	12.7	12.7	12.7

Viscoelastic properties of dough

Dough properties were determined after the three-hour relaxation using Haake Rheo Stress 600 (Karlsruhe, Germany). Elastic (storage) modulus (G') and viscous (loss) modulus (G'') were measured by a plate-plate sensor geometry at 20°C (60 mm in diameter with a 1-mm gap). Amplitude sweep was performed on 1Hz frequency, modulating shear stress values form 0-50 Pa in order to determine LVE regime. On the basis of determined LVE (linear viscoelastic) regime measuring for frequency sweep conditions were defined (Mezger, 2006). Dynamic oscillatory measurements (frequency sweep parameters) were observed modulating the ω value from 6.28-628 rad/s (frequency 1-10 Hz); in a constant value of shear stress (0.2 Pa). At least three replicates of each oscillatory shear test were conducted and good reproducibility was achieved since the differences between triplicates were less than 10%.

Baking test

Following the recipe and presentage of ingredients given in table 1 dough was prepared. Each ingredients was weighted in required quantities in order to form 350 g of dough. A required flour quantity was dosed in a z-mixer (Stephan-Werke Hamelin, ZD2245) and mixed for 0.5 min. Vegetable fat and sugar were added and mixing continued for 5.5 min (mixing speed 60 rev/min). Upon this resistant starch was added, mixed for 0.5 min, and then rising agents and distilled water were added. The mixer bowl was closed and dough was mixed during 15 min. Dough was shaped manually and placed into polyethylene bags. Dough relaxation time was 3 hours in the ultra thermostat at 20^{o}C. Before shaping the dough (50g)

was taken and viscosity measurement was carried out. Dough was pressed manually in a shape of a compact low cylinder. After 2 min of the relaxation time a dough stripe was developed by putting dough twice in either direction between two rollers of the laminator (Laminoir Marchand LA4-500). First lamination was with a 10-mm gap and second one was with 6-mm gap. After each lamination dough relaxed for 0.5 min. To avoid an adhesion a cloth stripe was floured by a small quantity of starch. After the relaxation time (2 min) dough was shaped by impressing a round mould (50 mm in diameter) on the surface of the dough stripe. Twelve pieces of shaped dough were moved to previously scaled perforated sheet-metal for baking, and again scaled to calculate a mean weight of shaped dough. Cookies baking time was 15 min at 230±2^{o}C. During baking the oven was closed and without the vapour connection. Cookies were cooled for 30 min on the baking sheet under ambient conditions.

Sensory evaluation

The sensory analysis of cookies was conducted by a six-member trained panel (Kamel and Stauffer, 1993). The sensory properties of cookies were determined by means of the sensory evaluation of the basic sensory parameters: external appearance, upper and bottom surface, snap, structure, mastication and taste (odor and taste). All seven sensory attributes were rated on a 1-5 scale where 1=lowest score and 5=highest score of each property.

Statistical analysis of data

Two batches of each dough formula were prepared on different days. Data reported for viscoelastic measurements was assessed by analyses of variance (ANOVA) and Duncan`s multiple test was used for any significant differences at the $P<0.05$ level between the means. All the analyses were conducted using statistical software package STATISTICA 8.1. (StatSoft Inc. USA).

RESULTS AND DISCUSSION

Viscoelastic properties of the dough are very important, as they influence the machinability of the dough as well as the quality of the final product. In all dough samples, regardless of the RS contents and the RS type, the elastic modulus G' dominated over the viscous modulus G" ($\tan \delta < 1$), indicating the prominence of elastic properties in the viscoelastic system (Figure 1). Because G' depended on angular frequency, and $\tan \delta > 0.1$ (Table 2), the observed rheological properties were typical for weak gels. Similar results were reported by Korus et al. (2009) in the gluten-free dough formulations with the addition of resistant starch (Hi-Maize 260 and ActiStar 11700).

Table 2. The values of tan δ of dough samples with resistant starch addition*

Sample	tan δ	
	RS3 addition	RS4 addition
Control	0.187 ± 0.001 a	0.187 ± 0.001 ab
5% RS	0.141 ± 0.015 c	0.190 ± 0.013 a
10% RS	0.134 ± 0.007 cd	0.166 ± 0.012 c
15% RS	0.184 ± 0.038 ab	0.155 ± 0.011 cd

** Different letters in the same column indicate statistical significance ($p < 0.05$).*

The supstitution of flour by RS3 or RS4 resulted in the increase of both dynamic moduli of dough compared to control sample once. The differences between control sample and samples with 5% and 10% of RS3 were statistically significant ($p=0.05$). The amount of RS3 of 15% significantly affected viscoelastic properties of the dough (G' of the sample was about 4 times higher than the control and other samples with the addition of RS3 and RS4).

Further, the differences between control sample and sample with 5% of RS4 were not statistically significant (p=0.05). The values of G' and G'' in the case of samples with 10% and 15% RS4 addition were statistically different than samples with 0% and 5% RS4 addition. Influence of the RS4 in the mechanical spectra of dough samples is not presented.

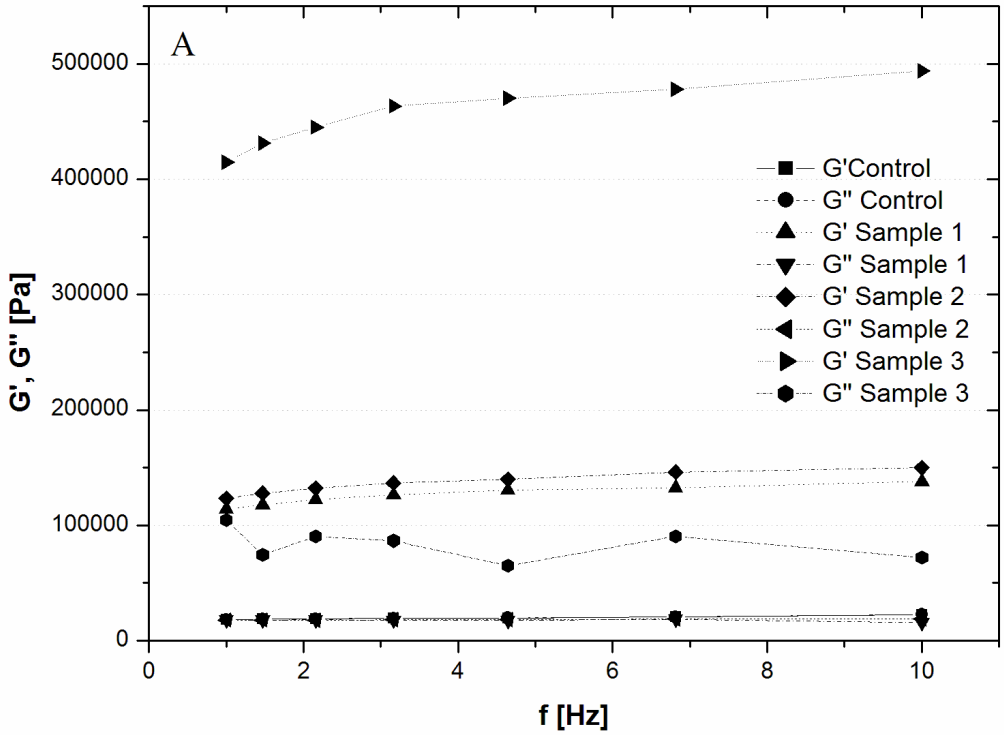

Figure 1. Influence of the RS3 in the mechanical spectra of dough samples at 20°C.

Increasing the portion of resistant starch, RS3 and RS4, as substitutes for flour, contributed to dough elasticity, due to the ability of resistant starch to bind water. With the rising level of resistant starch, water absorption of the dough is increased (the results are not given), and the addition of water has to be adjusted (in case of the highest dosage of RS3) in order to obtain proper consistency of the dough.

There are a numerous studies about partial replacement of flour with dietary fibres and the impact of the supplements on dough rheology and product quality. Most studies, however, referred to bread dough and breadmaking (Hung et al., 2007; Hung et al., 2005; Miyazaki et al., 2006). Hung et al. (2005) observed weakening of dough structure after addition of high amylose wheat flour. However, resistant starch (RS1 type) produced harder doughs for cookies production (Laguna et al., 2011). Differences in study results can be attributed to the existence of differences in physical and chemical characteristics of the applied sources of RS and studied rheological systems.

Sensory estimation of cookies

Sensory evaluation data (Table 3) shows that the RS3 addition in smaller quantities (5% and 10%) enhanced the appearance of the upper surface (the results are not given). The upper surface of cookies was smooth, slightly convex. The cookies structure was mealier and the change in odor and taste were detected (better than control). During mastication the tested samples dissolved well without mush making. The cookies with 5% of the RS3 had a desirable shape. The snap was distinctive; the structure was regular and homogeneous. The properties after mastication were adequate. The sample with 5% of RS3 addition was highly graded by 20 points after the sensory evaluation. With the increased RS3 content in the

formulations fat separated on the cookies surface. Beside that, the addition of 15% of RS3 in sample 3 resulted in the modification such as a denser and inadequate structure, which led to the decrease of total sensory quality compared to cookies without the RS3 addition.
The cookies with 5% RS4 addition had a regular shape and smooth upper surface. Its structure, snap and taste were identical to the control. During mastication the samples dissolved worse, while the odor was better than the control. The other two samples, with 10% and 15% of the RS4, had worse scores for features in mastication, odor and taste, resulted in decrease of the overall sensory quality compared to the samples with 0% and 5% of the RS4. Therefore, the partial substitution of the flour with the RS4 at the lowest dose (5%) gives the same total sensory quality as control sample.

Table 3. Sensory characteristics of short-dough cookies made from different blends of resistant starch and wheat flour*

Quality factors	Control	RS3 (%)				RS4 (%)		
		5	10	15		5	10	15
Appearance	5.0 a	5.0 a	5.0 a	4.3 c		4.0 d	4.5 b	4.0 d
Snap and structure	4.0 d	5.0 a	4.6 b	4.2 c		4.0 d	3.5 e	4.0 d
Mastication	4.6 b	5.0 a	5.0 a	4.0 c		3.5 d	3.5 d	3.5 d
Odor	4.0 c	5.0 a	5.0 a	4.5 b		5.0 a	3.5 d	3.0 e
Taste	4.5 b	5.0 a	5.0 a	4.5 b		4.5 b	3.5 c	3.0 d

** Values in a row followed by same letters do not differ significantly ($p < 0.05$).*

Formulating bakery products with resistant starches resulted in products with modified sensory properties (Baixauli et al., 2008b). However, these modifications did not affect the "overall acceptability" of these products to consumers. Sanz et al. (2008) also found that RS3 could be incorporated into the battered food up to a concentration of 20%, without comprising consumer acceptability.

CONCLUSION

Partial substitution of the flour with two types of RS has contributed to significant changes in rheological properties of short dough. By increasing the portion of RS (RS3, RS4) in the formulation of cookie dough, there was a significant increase in elasticity of the system, due to the ability of RS to bind water. The addition of 15% of the RS3 resulted in the modification such as an inadequate structure of the dough. In that case there is a need for modifications of the manufacturing process or the dough formula. Application of the resistant starches in the formulation of short dough resulted in a product of improved sensory and nutritional quality. Better results in terms of overall sensory quality were obtained by applying the starch type RS3. The results show good potential of resistant starch as a functional ingredient in terms of its application in the production of cookies and related products rich in dietary fiber.

ABSTRACT: Oil hemp and linseed can be a complete and balanced source of fatty acids. Oil hemp has an optimal ω-6 / ω-3 ratio of 3:1 (Callaway, 2004), but with limited use in Romania because of the stigma of drug, and linseed, due to the oil quality which contains ω-3 and ω-9 fatty acids and the pleasant taste, in addition to traditional uses, increasingly finds new uses in areas where until recently there were no data on the use of those cultures: food industry (pastry/bakery), medicine and cosmetics. The biological material used consisted of two monoecious hemp varieties (Zenit and Denise), one dioecious hemp variety (Armanca) and three flax oil varieties (Lirina, Florinda and Iunia 96) authorized in Romania. The oil content of the studied varieties was determined by Soxhlet method with a Velp block of mineralization. Investigation of fatty acid profile was performed by gas chromatography GC-MS whit Shimadzu GC MS QP 2010. The compounds separated and identified from the hemp and linseed oil were: linoleic acid ω-6, alpha-linolenic acid ω-3, oleic acid ω-9, palmitic acid, stearic acid. Due to the fatty acid profile, linseed and oil hemp are highly suitable dicotyledonous crops for the human health.
Key words: *fatty acid, oil hemp, linseed*

INTRODUCTION

The great economic value of hemp and linseed is defined by the multiple possibilities of use. Hemp can be used for fiber, seeds and oil, wood, manure and chaff in medicine by hypnotic and psychotropic alkaloids blossom while linseed is used in the varnish, paints and printing inks industry (Tabără, 2005), medicine, food industry and cosmetics.
Hemp seeds (*Cannabis sativa* L.) are distinguished by their complex and original composition of fatty acids, proteins, vitamins and minerals they contain. Whole hemp seeds have oil content of about 25-35 % (Şandru et al., 1996), but in Russia there is a cultivated variety called "olifera" which contains 40 % oil (Deferne et al., 1996). About 30–35 % of the weight of hemp seed is an edible oil that contains about 80 % essential fatty acids (EFAs): linoleic acid ω-6 (LA, 55 %), alpha-linolenic acid ω-3 (ALA, 22 %), in addition to gamma-linolenic acid ω-6 (GLA, 1–4 %) and stearidonic acid ω-3 (SDA, 0–2 %).
Hemp oil is valued primarily for its nutrients and for health benefits, because of the content of saturated fatty acids (myristic acid, stearic, palmitic, eicosanoic), especially rich unsaturated fatty acid (oleic acid, alpha-linoleic acid). The major components of hemp oil are triglycerides together with sterols, tocopherols, phospholipids, terpenes and so on, all of which have a beneficial effect on the body.
Hemp seeds not only contain essential fatty acids, but come with substantial contribution of 20-25 % protein, essential amino acids, which make hemp seed an ideal food for vegetarians, successfully replacing the lack of animal protein, with a high nutritional value for human consumption in salads, bread and even chocolate.
On the other hand, cold pressed linseed (*Linum usitatissimum* L.) oil is 100 % natural. It has special qualities, containing two times more ω-3 fatty acids than fish oil and a mixture of essential ω-3 and ω-9 fatty acids. All these amino acids have a role in cell recovery, being very useful in various diseases. Protein from linseed oil is easily digestible and contains all the amino acids necessary to maintain a strong and healthy body. Linseed oil has positive

effects on blood pressure, lower cholesterol, constipation, psoriasis, eczema, burns and a role in preventing heart attacks.
Flax seeds contain oil which has in its composition 55 % ω-3 fatty acids in a ratio of 2/1 from ω-6. Flaxseed germs contain: ω-3 fatty acids; lignite, pectin, linamarine; 35 % vegetable oils, of which 75 % essential fatty acids; mucilage; vitamins (A, B, C, D and E); minerals. Flax seeds have very important fiber content. One cup (50 g) of flaxseed contains 20 grams of fiber.
The aim of the study presented in this paper was to investigate fatty acid composition in hemp oil and linseed, and to obtain overall picture about their nutritional suitability, from the point of fatty acids.

MATERIAL AND METHODS

The analyzed samples consisted of two monoecious hemp varieties (Zenit and Denise), one dioecious hemp variety (Armanca) and three flax oil varieties (Lirina, Florinda and Iunia 96) authorized in our country, according to the Official Catalogue of varieties of crop plants in Romania. The oil content of the studied varieties was determined by Soxhlet method with a Velp block of mineralization. Investigation of fatty acid profile was performed by gas chromatography GC-MS whit Shimadzu GC MS QP 2010.

Oil content determination

Soxhlet method with a Velp block of mineralization was used for oil content determination. This method is a lengthy process requiring up to a day for a single analysis. The solvent extraction step alone takes six hours. The fat content was determined by extracting the fat from the samples using a solvent (petroleum ether), and after that the weight of the fat recovered was determined. The sample is contained in a porous thimble that allows the solvent to completely cover the sample. The thimble is contained in an extraction apparatus (Figure 1) that enables the solvent to be recycled over and over again. This extends the contact time between the solvent and the sample and allows it time to dissolve all of the fat contained in the sample. In order for the solvent to thoroughly penetrate the sample it is necessary for the sample to be as finely comminuted as possible. Necessary equipment consists of analytical balance (at least 1 mg sensitivity), electrical drying oven operated at 102 ºC ± 1 ºC, Soxhlet extraction unit (150 ml round bottom flask, Soxhlet extractor with 60 ml siphoning capacity and condenser, 28 x 80 mm cellulose extraction thimbles), fume cupboard, heat source, desiccator with silica gel desiccant, glass rod. Oil content is determined by the formula: % crude fat = (W2 – W1) x 100/S

W1 = weight of empty flask (g)
W2 = weight of flask and extracted fat (g)
S = weight of sample

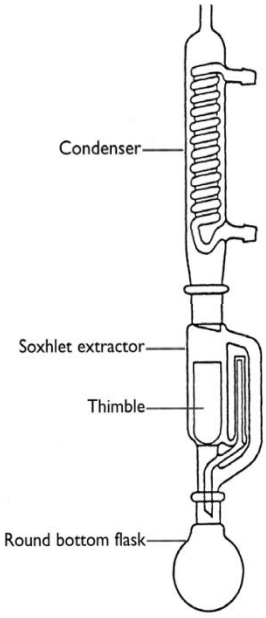

Figure 1 – Soxhlet extraction apparatus

Fatty acid determination

Fatty acids were determined by gas chromatography. Lipids were extracted following the Folch method. Fatty acid profiles of samples were separated and identified by using a GCMS-QP 2010+SHIMAGZU gas chromatograph, equipped with a AT-5MS (30 m x 0.32 mm inside diameter) capillary column of silica. The oven program was the following: 70 ^{0}C for 2 minutes, than it was heated to 150 ^{0}C with a gradient of 10 ^{0}C / minute and than, a floor of 3 minutes, after that it was raised again to 235 ^{0}C with a gradient of 4 ^{0}C / minute. The temperature of the injector was 260 ^{0}C, injection mode split, split ratio 1:20. Helium was used as carrier gas (Fota et al., 2010).

RESULTS AND DISCUSSION

The results of fatty acid analysis made from the oil obtained by extraction with petroleum ether (Figure 2), are shown in Table 1.

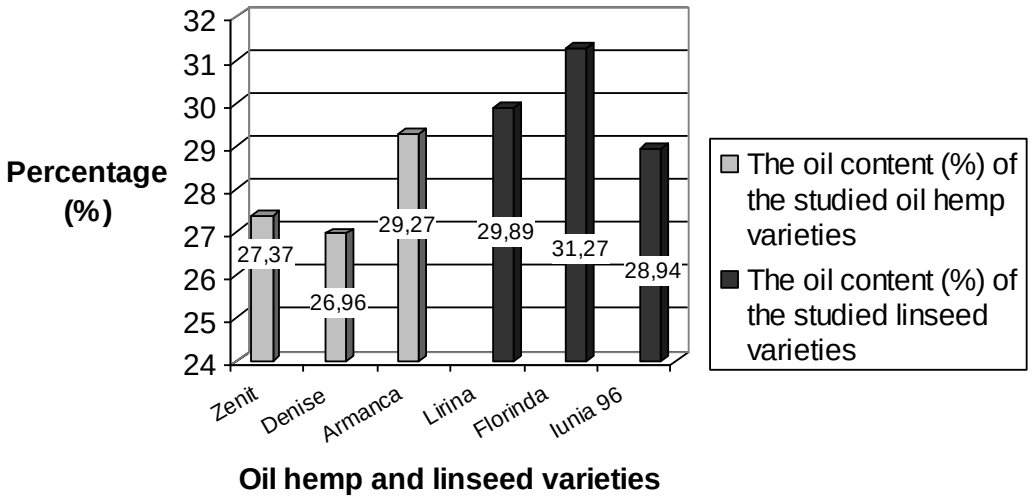

Figure 2 – The oil content (%) of the studied oil hemp and linseed varieties

As it can be seen from the results, most prevalent fatty acids in oil hemp are 18:2 ω-6 (linoleic acid) and 18:3 ω-3 (alpha-linolenic acid). Instead, linseed has a higher concentration of 18:3 ω-3 (alpha-linolenic acid) and 18:1 ω-9 (oleic acid) fatty acids. These results are expected and in consistence with other literature data (Sauvant et al., 2004).
Saturated fatty acids (SFAs) have been generally labeled as the cause of cancers and coronary heart disease. The mean ratio of polyunsaturated fatty acids (PUFA) / saturated fatty acids (SFA) recommended by the FAO experts is above 0.4 (Wood et al., 2008). From this point of view, of saturated fatty acids concentration, all examined samples have had favorable values between 2.9 and 7.1 in oil hemp and between 2.82 and 5.5 in linseed (figure 3).

Table 1. Fatty acid composition (% w/w) of oil hemp and linseed

Variety / Fatty acid	OIL HEMP			LINSEED		
	Zenit	Denise	Armanca	Lirina	Florinda	Iunia 96
Palmitic acid (16:0)	7,10	6,64	6,75	5,50	5,40	4,65
Stearic acid (18:0)	2,90	2,68	1,21	3,32	4,92	2,82
Oleic acid (18:1) ω-9	13,97	14,02	8,58	21,73	19,95	27,40
Linoleic acid (18:2) ω-6	57,57	57,80	64,79	17,26	15,40	14,39
Alpha-linolenic acid (18:3) ω-3	14,98	15,85	18,67	52,17	54,30	50,71

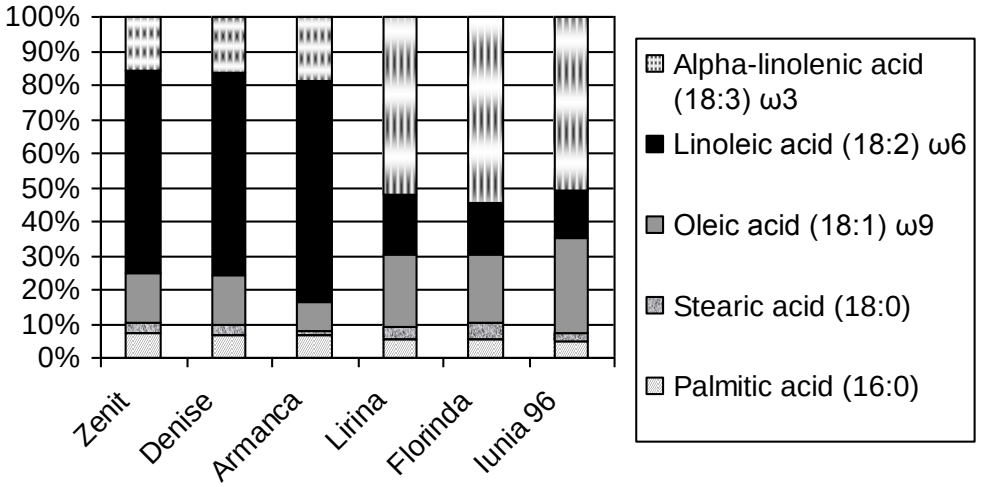

Figure 3 – Oil hemp and linseed fatty acid composition in examined samples (% w/w)

The optimum ratio between monounsaturated, polyunsaturated and saturated fatty acids it has to be 1:1:1. Equally important is the ratio between the essential fatty acids ω-6 and ω-3. Between the two types of polyunsaturated fatty acids there must be a relationship of the following type: ω-6/ω-3 = 5:1 (ω-6 = 5 g/day, ω-3 = 1 g/day).
It has been estimated that the present Western diet is deficient in ω-3 fatty acids, with a ratio of ω-6 to ω-3 of 15-20/1. It is therefore recommended increased consumption of foods rich in ω-3 fatty acids like fish (trout, salmon) or linseed oil.
The results obtained from the analyzed samples show the optimal ω-6 / ω-3 ratio of fatty acids in hemp oil and the appropriate mixture of essential ω-3 and ω-9 fatty acids in linseed. Therefore, both linseed and oil hemp can be used in human nutrition as a balanced source of essential fatty acids, with a plus for linseed.

CONCLUSIONS

If we analyse the fatty acid composition of the studied oil hemp and linseed varieties, we can say that they are suitable for food and feed usage. Linseed varieties have had a concentration of ω–3 fatty acid between 50.71 and 54.3 and low saturated fatty acids values that make it one of the essential foods for a balanced diet. On the other side, oil hemp has lower levels of ω–3 fatty acids but compensates with higher ω–6 levels and, like linseed, it has low concentrations of SFAs. Knowing this, we can say that linseed and oil hemp are highly suitable dicotyledonous crops for the human health.

ACKNOWLEDGEMENTS

The results of this study are part of a PhD program, having as theme: "The contribution of some ecological and technological factors in quality formation of the production in flax oil" and "The contribution of some ecological, biological and technological factors in quality of the hemp seed oil", funded by the European Social Fund, the Pilot Program PhD Research Scholars Support Contract from the POSDRU/CPP107/DMI 1.5/S/80127.

ABSTRACT: The functional food is a modern concept in human nutrition, considering the fact that this type of food contains ingredients which have useful effects on one or more purpose functions in the organism and contribute to the general medical health and/or decrease the risk of some diseases. The ingredients of functional food are: macronutritients with special physiological treatment (polysaccharides, omega-3 fatty acids, etc.), essential micronutritients (folic acid, vitamin B6, B12), nonessential ingredients (some of oligosaccharides), biologically active phytonutritients (carotenoides, flavons, catechins, etc.), friendly bacteria – probiotics. Modern research indicates expansive development and production of functional food around the world. That requires appropriate legislation which defines the field of functional food production. The objectives of this study are to emphasize the importance of functional food in daily nutrition. Furthermore, using sensory analysis for three different product types with functional characteristics, it was proved that the food with functional characteristics does not differ in total values from the similar conventional products.
Key words*: functional food, omega-3, omega-6, bioactive substances, conventional products*

INTRODUCTION

While food has been used to improve health for a long time, our knowledge of the relationship between food components and health is only at the outbreak to improve food. Roughly speaking, all food is functional if it provides energy and nutrients necessary for survival. But the term “functional food” that is in use today conveys health benefits that extend far beyond mere survival. Food and nutrition science has moved from identifying and correcting nutritional deficiencies to designing foods that promote optimal health and reduce the risk of disease (IFT Expert Report, 2005). According to the definition functional food is part of everyday diet and is demonstrated to offer health benefits and to reduce the risk of chronic disease beyond the widely accepted nutritional effects (Hasler, 1998). The concept of functional foods was developed in Japan in the 1980s, with a formal definition of “foods for specified health use”(FOSHU) in 1991, accompanied by a regulatory system to approve the statements made on labels and in advertising, based on scientific evaluation of the evidence of efficacy and safety (Shimizu, 2003). The functional food comprises of: conventional foods containing naturally occurring bioactive substances (e.g., dietary fibre), food enriched with bioactive substances (e.g., probiotics, antioxidants), synthesized food ingredients introduced to traditional foods (e.g., prebiotics) (Raghuveer and Tandon, 2009).
Breadbury et al. (1996) have mentioned that adding of vitamins and minerals especially in the breakfast cereals, is an established concept. Following that trend, the range of food product which contain added vitamins and minerals has been increasing, as well as introduction of different antioxidants, vitamins A, C, E and beta-carotene in composition of

the varius products. They also reported the existing bond between consumption of oily fishes, which are rich in omega-3 fatty acids and the reducing rates of coronary heart desease. Therefore, those are added to margarine, biscuits, bread and cakes. This is supported by the health claims, which are made on the basis of the fact that the consumption of these products could reduce the risk of coronary heart disease. Scientific evidence, based on controlled intervention trials in humans, suggested dietary omega-6/omega-3 fatty acids recommendations depending on specific physiological situations (adults with different pathologies, infants, newborns, etc.) (Simopoulos, 2002). A frequently used definition of probiotics is "living food supplements or components of bacteria that have been shown to have beneficial effects on human health" (Sheil et al., 2007; Weichselbaum, 2009). The most common type of probiotic functional foods are dairy products such as yoghurts and yoghurt/dairy drinks which have been modified by the addition of a particular strain of live microorganism in the form of lactobacteria such as *Lactobacillus* and *Bifidobacterium* and in some cases prebiotics such as inulin as well. The additional health benefits claimed by probiotic dairy products are related to the gastrointestinal functions and include improving digestion and immunity and managing digestive disorders such as IBS (irritable bowel syndrome) and diarrhoea (ILC-UK, 2010). Soymilk is alternative source of the soy protein, which can replace the dairy animal milk in everyday consumption and it is present on the market in different flavours, including chocolate, vanilla, plain etc. Also it can be used as dairy milk substitute in coffee, tea or cereals (Hajirostamloo, 2009). A number of dietary agents, including soluble fibres and plant sterols/stanols, were found to interfere with cholesterol absorption and to lower its levels in serum. Plant sterols and stanols, also called phytosterols and phytostanols, have chemical structures resembling that of cholesterol but are only available to humans through plant foods such as vegetable oils, nuts, seeds, cereals, legumes, fruits, and vegetables or industrial supplements from plant origin (Piironen et al., 2000).

The addition of probiotic bacteria in yoghurt is made not only because of certain claimed health-promoting effects in the intestinal tract. Other beneficial health effects suggested to include the enhancement of the immune system, reduction of lactose intolerance, control of diarrhea and reduction of LDL cholesterol (so called "bad cholesterol") (Scheinbach, 1999). Soy milk seems to be a healthier choices because it is low in calories, carbohydrate, fat and fatty acids and is important for people who are allergic to cow milk protein and lactose (Hajirostamloo, 2009). Besides being a suitable options for the lactose intolerants (Potter et al., 2007), soy-based desserts mixed with fruit juices are a new trend of products that include soy-protein in the regular diet (Granato et al., 2010). Also new trend for consumption of healthy, innovative and practical food, which has occurred recently, has leaded the market of cereal-bars to a gradual growth. Cereal-bars are considered healthy type of food, because they are rich in fiber, however, poor in fat (Bower and Whitten, 2000; Palazzolo, 2003; Gomes and Montenegro, 2006).

All the nations have a different regulatory framework for functional food. Although each country is in process of creating adequate regulatory structure for the functional foods but there are certain challenges ahead for the regulatory bodies, food scientists, manufacturers and even consumers which needs to be addressed for the success of functional foods (Kaushik and Kaushik, 2010).

From a marketing perspective, it is important to understand that consumers weigh different factors when making a purchase decision and these include not only health and nutrition but also price, convenience, and taste (Verbeke, 2008). Taste, in particular, has been regarded as the critical factor for functional food's acceptance, along with trustworthiness of health claims—consumers will rarely compromise on taste for foods with potential health benefits (Verbeke, 2006; Urala and Lähteenmäki, 2004).

The aim of this study was to evaluate using sensory analysis various types of functional products in comparison with conventional products. The foods that were sensory analyzed were probiotics in compare with natural yoghurts, chocolate pudding with chocolate soya dairy-free dessert and functional food cereal bars with conventional bars.

MATERIAL AND METHODS

Three different brands of probiotics (Viva, AB and Balans +) and three conventional yoghurt brands (Dukat, Family and Jogurt), Alpro chocolate soya dessert enriched with calcium and vitamins B2, B12 and D2 along with three different manufacturer chocolate puddings (Dukat, Campina and Zott), three types of functional cereal bars (Mond, KitKat and Albeni) and three various brands of conventional sweets (Cerbona, Bonžita and Vitanova), were purchased from mega markets and retails in Novi Sad.
The method which is used in this research was descriptive rating test. The appropriate attributes for the evaluation of yoghurts and puddings were appearance, odor, flavor/taste, texture and aftertaste. In case of cereal bars, categories were appearance, flavor, audition (crunchiness) and texture. During the quantitative assessment, 3 panelists have evaluated samples using a numeral ordinal 5-unit scale. Every unit is described by certain descriptors, which are discussed and agreed upon the definitions by the panelists, with the end values labeled as not appropriate or imperceptible (1) and all rounded or satisfactory (5). Before the sensory evaluation all the samples were prepared in the same conditions. The yoghurts were in identical transparent glass cups, the puddings were served in plastic cups, and the cereal bars were without wrapper. Every sample got his personal digit code.

RESULTS AND DISCUSSION

Individually and summary ratings, by upon discussed attributes, of probiotic and conventional yoghurts are shown in Table 1.

Table 1.. Sensory evaluation of functional and conventional yoghurt

Categories	Brands						Summary	
	VIVA (P)	Dukat	AB (P)	Family	Balans + (P)	Jogurt	Probiotics	Conven-tionals
Appearance	4.00	3.67	4.67	3.67	3.33	4.67	4.00	4.00
Odor	4.33	4.67	4.67	4.00	4.00	3.67	4.33	4.11
Flavor	3.67	3.33	4.00	4.00	3.33	4.00	3.67	3.78
Texture	3.67	3.67	4.67	4.00	4.33	4.67	4.22	4.11
Aftertaste	4.33	3.33	4.33	4.33	4.00	4.00	4.22	3.89
Average score	4±0.76	3.73±1.03	4.47±0.64	4±0.85	3.8±1.08	4.2±0.86	4.09±0.87	3.98±0.92

The average values in total of probiotic and conventional yogurt were 4,09 and 3,98 with a standard deviation of 0.87 and 0.92 respectively. The noticeably higher sensory quality of the sample “AB Subotica“, containing probiotic cultures *Lactobacillus acidofilus* LA-5 and *Bifidobacterium* BB-12 and Inulin as prebiotic, which could be attributed to certain different properties of texture and appearance. In general, differences between probiotics and conventional yoghurts are minor, with marginally higher organoleptic quality in most categories for probiotics, beside the flavor, which rate is slightly higher in case of conventional yoghurts (Figure 1).
The results of the sensory evaluation of chocolate puddings and chocolate soya dessert are represented in Table 2.

Table 2.. Sensory evaluation of chocolate pudings and soya dairy-free dessert

Categories	Brands				Summary	
	Dukat	Campina	Zott	Alpro soya (F)	Alpro soya (Functional)	Conventionals
Appearance	4.33	4.33	3.67	4.00	4.00	4.11
Odor	4.00	4.33	4.00	3.67	3.67	4.11
Flavor	4.00	4.33	3.00	4.00	4.00	3.78
Texture	4.33	4.33	3.67	4.00	4.00	4.11
Aftertaste	4.33	4.33	3.33	4.33	4.33	4.00
Average score	4.2±0.86	4.33±0.49	3.53±0.83	4±0.76	4±0.76	4.02±0.81

From the table 2 it is obvious that the average value for the functional dessert is 4, while the average score for the conventional products is almost the same (4.02). Standard deviations for soy dessert and conventional puddings are 0.76 and 0,81, respectively. The best overall result is obtained for Campina conventional pudding, with very good taste and better odor then other samples. In summary, soya dessert is better in flavor and aftertaste category in compare with conventional puddings. Deficiency for this functional dessert is insufficiently original pudding odor (Figure 2).

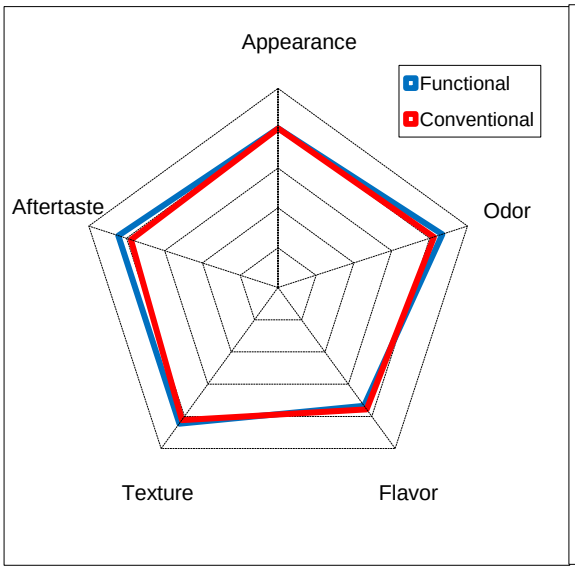

Fig. 1. Ratings by categories for yoghurts

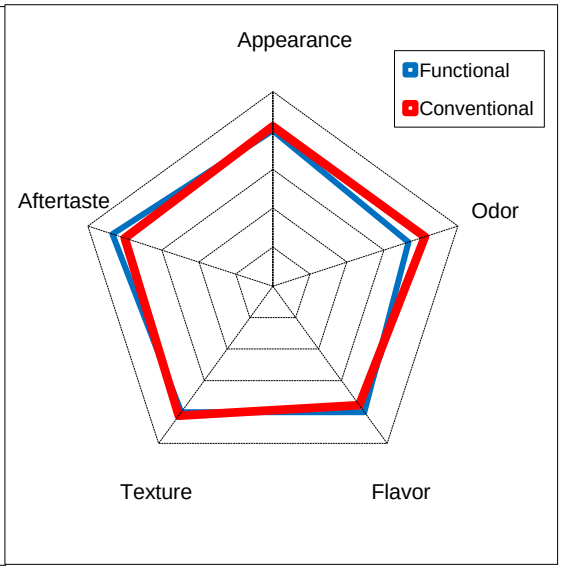

Fig. 2. Ratings by categories for puddings

Table 3 shows average values of sensory analysis for the functional cereal bars and the conventional sweets.

Table 3.. Sensory evaluation of functional and conventional cereal bars

Categories	Brands						Summary	
	Mond	Cer-bona(F)	KitKat	Bonžita (F)	Albeni	Vita-nova(F)	Functio-nals	Conven-tionals
Appea-rance	4.67	4.33	4.67	4.33	4.33	4.33	4.33	4.56
Audition	3.67	4.67	5.00	4.33	2.67	4.67	4.56	3.78
Flavor	4.00	3.67	4.33	4.67	3.67	4.67	4.33	4.00
Texture	4.33	5.00	4.33	4.67	3.67	4.67	4.78	4.11
Average score	4.17±0.94	4.4±0.67	4.58±0.51	4.5±0.52	3.58±1	4.58±0.67	4.50±0.61	4.11±0.92

According to the values from table 3, the functional cereal bars have higher average ratings compared to the conventional bars (4.5±0.61 vs. 4.11±0.92). The conventional treat KitKat (Nestle) is evaluated with the best score from the category of non-functional bars, especially concerning crunchiness. Vitanova macrobiotic with dietary fibers from Pionir Subotica has exactly the same average value like KitKat and this product is the leader in the functional bars category, characterized by the very good audition, flavor and texture. The weakest point of the functional cereal bars was the appearance and the best characteristic was homogeneous structure. Lack of chewiness and crunchiness were the major disadvantages of the conventional sweets (Figure 3).

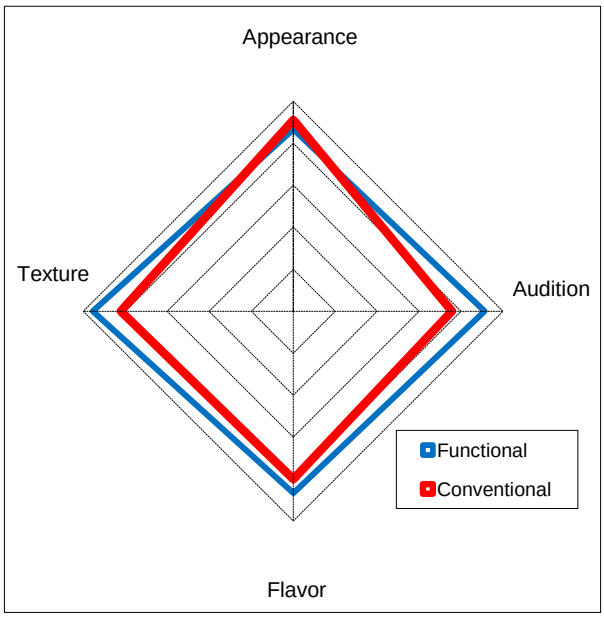

Fig. 3. Ratings by categories for cereal/conventional bars

CONCLUSIONS

For the reason of nonregulated legislation framework in many countries, trust in the certain health claims is still optional for individuals, also as consuming of functional food. Still, there are strong evidences that functional food can reduce the risk of chronic disease. As mentioned earlier, some prejudices about taste of the functional food reject certain group of consumers. Appearance, flavor and texture are the important factors, which determine the acceptance or rejection of a food article. According to this investigation, differences in sensory quality of some functional and conventional groceries are minimal. Conventional products with ingredients which may lead to detrimental long term health effects, can easily be replaced in daily nutrition with functional food of the same category. That means that

consumers can affect their general medical health with slightly modifying their nutrition habits. Also, consumers must be aware that functional food is not a magic bullet that works alone, but may promote good health when is included as part of a healthful diet, regular exercise, stress reduction and healthy body weight. The ultimate goal may be reduction of overall medical expenses for treatments and achieving a healthier nation.

ABSTRACT: Strict gluten-free diet, the only treatment for patients with celiac disease, is necessary to prevent malabsorption and to reduce the risk of complications. Such diet excludes all food and beverages that contain gluten and therefore may result in a nutritionally unbalanced diet. Mediterranean diet is a synonym for healthy and balanced diet. It has been shown that greater adherence to Mediterranean diet is correlated with reduced mortality. Adherence to Mediterranean diet can easily be determined using Mediterranean dietary quality index (MDQI). MDQI is consisted of seven components (saturated fatty acid, cholesterol, meats, olive oil, fish, cereals, fruits + vegetables), whereas each component depending on intake may achieve 0 to 2 points. Total index score might be between 0 and 14 points, where 0 points indicate great adherence to Mediterranean diet. The aim of this study was to evaluate the quality of a gluten-free diet based on a MDQI in Croatian celiac patients. MDQI was calculated based on a seven-day food record from 23 celiac patients from Mediterranean region and 38 celiac patients from continental region. Statistical difference was observed only for saturated fatty acid intake among observed regions ($p<0.05$). Celiac patients from Mediterranean region achieved 9.79 points while celiac patients from continental region achieved 10.68 points, however there is no statistical significant difference between these regions. In conclusion, celiac patients adhering gluten-free diet, probably due to specific dietary restriction, as expected have lower diet quality according to MDQI.
Key words: *diet quality, gluten-free diet, Mediterranean diet*

INTRODUCTION

Strict gluten-free diet is the only currently available treatment for patients with celiac disease. It is necessary to prevent malabsorption and it will results in symptomatic, serologic and histological remission in the majority of patients (Pietzak, 2005). Gluten-free diet excludes all food and beverages that contain gluten, a protein found in wheat, rye, barley and oats. Previous research showed that gluten-free diet may result in a nutritionally unbalanced diet (Grehn el al., 2001; Mariani et al., 1998; Hopman et al., 2006). Mediterranean diet has been promoted as a model for healthy and balanced diet. Adherence to Mediterranean diet is correlated with reduction in cardiovascular diseases and cancer mortality (Trichopoulou et al., 2003; Knoops et al., 2004; Dontas et al., 2007). Although, there is no single Mediterranean diet (Noah and Truswell, 2001), Mediterranean diet pattern is characterized by a high intake of vegetables, fruits, legumes, cereals, olive oil, low consumption of meat and moderate alcohol consumption (Trichopoulou et al., 1995). Adherence to Mediterranean diet pattern can easily be determined using a Mediterranean dietary quality index (MDQI) (Gerber, 2006). The aim of this study was to evaluate the quality of a gluten-free diet using a MDQI in Croatian celiac patients.

SUBJECTS AND METHODS

The survey was carried out on a 61 celiac patients, aged 18 to 69 years, from two different regions in Croatia: Mediterranean (n=23) and continental region (n=38). All patients had biopsy proven celiac disease and were adhering gluten-free diet in average 9 years.

Subjects compiled a 7-day food record for which they were instructed by trained dietitians to record completely all food and drinks consumed in observed period. Subjects were provided with forms that were designed to collect information such as food item, brand, type and preparation method. They were asked to weigh food and to use cups or tablespoons for estimation when weighting was not possible. The intake of energy and nutrients were calculated using national food composition table (Kaić-Rak i Antonić, 1990). Patients were asked to provide food labels of all gluten-free products consumed in that period because these products are not included in food composition table.
Mediterranean dietary quality index was calculated based on 7-day food records. Scores 0, 1 and 2 were assigned to each of the seven component (saturated fatty acid, cholesterol, meats, olive oil, fish, cereals, fruits + vegetables) depending on achieved intake (Gerber, 2001). The meat group included all processed and fresh meat; fish included white and fatty fish; the cereals group included all types of bread, pasta, rice and breakfast cereals; the fruit and vegetables group consisted of cooked and raw types of red, yellow and green vegetables and fresh fruit (Scali et al., 2000). Scores were summed for each subject, giving the total score for the MDQI. Results are presented as mean ± SD, or percentage. Differences between regions were assessed using Student's t-test. All statistical analysis was performed with SPSS software v. 15.

RESULTS AND DISCUSSION

In the present study, MDQI was used to evaluate the quality of the gluten-free diet in Croatian celiac patients from two different regions (continental and Mediterranean). Subjects from both regions consumed too much saturated fat (>10 % kJ) and meat and insufficient amount of cereals, fruits and vegetables, olive oil and fish (Table 1). High intake of saturated fat was also observed among healthy Croatian population (Primorac et al., 2003). High consumption of red meat was found among Croatian population in the first Croatian Health Project conducted in 1995-1997 (Turek et al., 2001). Low intake of cereals may be due to special restriction in the gluten-free diet. Adherence to gluten-free diet primarily affects consumption of cereals. Mariani et al.,1998 found higher energy intake from fat and lower energy intake from carbohydrates in adolescents celiac patients on a gluten-free diet. All fruits and vegetables are allowed in the gluten-free diet. However, 89% of subjects consumed less then 400 g fruits and vegetables per day. Individuals who consume very low amounts of fruits and vegetables have the greatest risk of colorectal cancer (Terry et al., 2001). Low consumption of fish among subjects from Mediterranean region was very surprising. Pucerin Cvetković et al., (2006) found that 35% of Croatian island population consume fish 3 to 4 times a week while 9.8% consume 5 to 7 times a week. Very low consumption of olive oil (< 5 mL/day) was observed in both regions. Although Croatia is a country in the Mediterranean region the consumption of olive oil is less than 1L per capita per year unlike some countries from Mediterranen region such as Greece, Italy and Spain where consumption exceeds 10 L per capita per year (Grigg, 2001). High intake of olive oil, because of its high levels of monounsaturated fatty acids and polyphenolic compounds, have a role in a prevention of cardiovascular disease and cancer (Owen et al., 2004).
Since the MDQI was calculated based on seven day food record it is possible that some of the diet pattern are underestimated due to recording period. An individual's nutrient intake may fluctuate on a daily basis and season of the year (National Research Council, 1986).

Table 1. Average daily intake of components included in MDQI based on seven day food record in celiac patients (n=61)

Component	Mediterranean region (n=23)	Continental region (n=38)	p
Saturated fatty acid (% kJ)	12.41 ± 3.22	15.17 ± 3.27	0.005*
Cholesterol (mg)	341.44 ± 290.68	329.86 ± 148.16	0.848
Meats (g)	179.84 ± 121.44	150.91 ± 94.30	0.339
Olive oil (mL)	2.24 ± 3.08	1.20 ± 2.65	0.201
Fish (g)	23.52 ± 28.72	13.30 ± 19.86	0.133
Cereals (g)	186.68 ± 152.96	172.01 ± 77.17	0.644
Fruits and vegetables (g)	276.96 ± 147.86	242.80 ± 169.81	0.466

*Results are given as mean ± standard deviation, *p<0.05*

The average score for each component included in the MDQI is shown in Table 2. Difference between regions was observed only for saturated fatty acid. Subjects from continental region had statistically higher intake of saturated fatty acid than subjects from Mediterranean region ($p<0.05$) (Table 1). The proportion of energy intake provided by saturated fat was over 10 % in 97% of the subjects from continental region. Subjects from Mediterranean region had lower total MDQI score (9.79) than the subjects from continental region (10.68), however no statistically significant difference was observed ($p=0.083$) (Table 2). Although some authors have found the difference in dietary pattern among different regions in Croatia (Doko Jelinić et al., 2009), according to Šatalić et al., (2004) Croatian students have lower diet quality evaluated with MDQI, with no significant difference between the regions.

Table 2. Average score of components included in the Mediterranean dietary quality index calculated from seven day food record provided by celiac patients adhering gluten-free diet (n= 61)

Component	Score		p
	Mediterranean region (n=23)	Continental region (n=38)	
Saturated fatty acid (% kJ)	1.32 ± 0.75	1.74 ± 0.57	0.042*
Cholesterol (mg)	0.53 ± 0.70	0.82 ± 0.87	0.207
Meats (g)	1.58 ± 0.51	1.50 ± 0.51	0.589
Olive oil (mL)	1.84 ± 0.37	1.91 ± 0.29	0.452
Fish (g)	1.63 ± 0.60	1.74 ± 0.57	0.534
Cereals (g)	1.05 ± 0.62	1.12 ± 0.54	0.691
Fruits and vegetables (g)	1.84 ± 0.50	1.85 ± 0.44	0.935
Total MDQI score	9.79 ± 1.81	10.68 ± 1.72	0.083

*Results are given as mean ± standard deviation, *p<0.05*

No subject scored between 0 and 4 (Figure 1). Only 5% of subject from Mediterranean region had score 5, which may be categorized under “medium-to-good MDQI”. The majority of subjects (68%) from Mediterranean region had “medium-to-poor MDQI” (5 to 10), while the majority of subjects from continental region (53%) had “poor MDQI” (11 to 14).

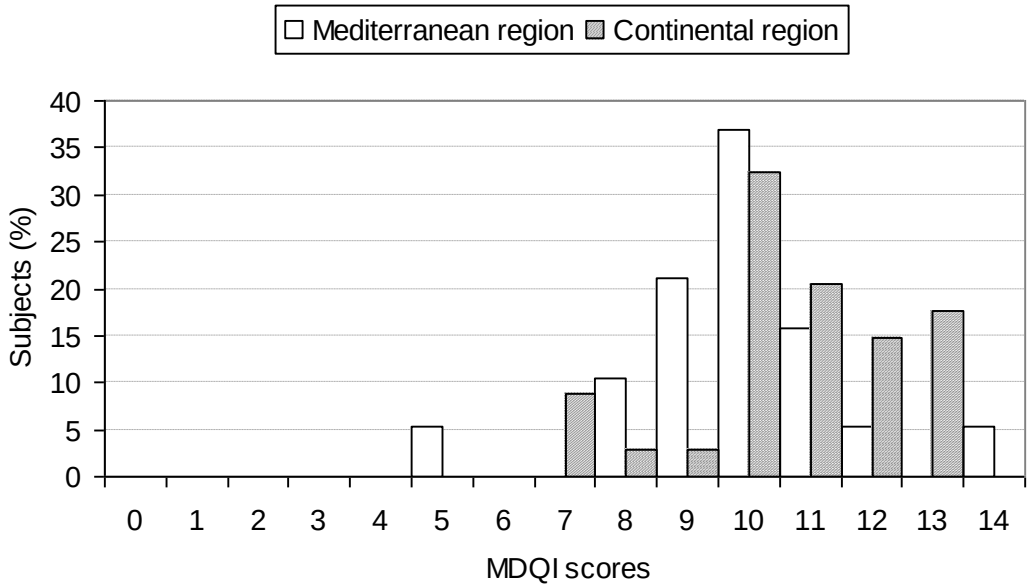

Figure 1. Distribution of subjects from Mediterranean and continental regions classified by the total MDQI score

Adherence to gluten-free diet is having a significant impact on the dietary pattern in celiac patients. Mediterranean diet as a synonym for healthy and balanced diet may serve as a healthy pattern for this sensitive population. To achieve healthy dietary pattern celiac patients should decrease intake of saturated fatty acid and increase the intake of olive oil, fish, fresh fruits and vegetables, as well as naturally gluten-free cereals.

CONCLUSIONS

In conclusion, celiac patients adhering gluten-free diet have lower diet quality according to MDQI. Celiac patients living in Mediterranean region did not have better overall diet quality comparing to celiac patient from continental region. The only difference in the diet pattern was observed for saturated fatty acid, whereas subjects from continental region had statistically higher intake of saturated fatty acid than subjects from Mediterranean region.

ABSTRACT: Aromatic plants and their extracts have been used in human and veterinary medicine since ancient times. However, the exact mode of action and kinetics or these compounds are generally poorly understood. The aim of this work was to determine the degradation and absorption kinetics of thymol in the pig stomach. An improved GC method was developed to easily measure the thymol content in samples extracted into ethylacetate. The GC separation was achieved on a 30 m × 0.25 mm × 0.25 mm film thickness Equity™ - 1701 fused silica capillary column, resulting in a standard curve over 1–500 mg/L. Isolated pig stomach was incubated for 360 min at 37 °C in an incubator with 95% O_2:5% CO_2 atmosphere on an oscillating plate at 40 rpm. Tyrode's solution pH 6.5 was used as incubation fluid. Pig stomach contents were inoculated with thymol (1.7 mM), and samples were collected at intervals during incubation and were extracted as is or after treatment with a lysis buffer. The lysis buffer was used to release thymol that may have been internalized by endogenous bacteria. Thymol concentrations in unlysed stomach samples decreased rapidly, being reduced more than twofold during 30 min incubations. Conversely, thymol concentrations in lysed samples increased rapidly, following 60 min incubations, concentrations were achieved at twice those measured in unlysed stomach contents at the beginning of the incubation. Thymol concentrations in lysed samples remained nearly double those in unlysed samples even after 360 min. Differing thymol concentrations measured in lysed and unlysed samples suggest luminal depletion resulting from bacterial uptake of thymol. Upon ingestion, luminal depletion would be expected to occur rapidly in stomach contents, but whether this sequestration would make thymol unavailable for absorption in the stomach or more distally is not known. Further investigation is needed to identify the bacteria responsible for this "thymol sequestration" phenomenon.
Key words: *gas chromatography, thymol, pig stomach*

INTRODUCTION

In the past, antibiotics provided in small amounts were used to halt the growth of bacteria, prevent outbreaks of diseases and enhance the rate of growth in intensively reared animals. In recent years the use of antibiotics as growth promoters in the European Union (EU) countries has been curtailed by legislation (Dibner and Richards, 2005). The reason for this ban has been the concern over potential development of resistant bacterial strains, which was clearly shown in the case of the *Salmonella enterica* serovar Typhimurium DT104 outbreak in the late 1990's (Mølbak *et al.*, 1999), and the potential of transferring resistance to other strains of bacteria. There is concern that if pathogenic bacteria gain resistance to antibiotics used against human infections, then these infections may become untreatable. Therefore, finding alternatives to antibiotic growth promoters has currently become the ultimate goal. Candidates used to replace antibiotic growth promoters must be evaluated for their ability to kill bacteria, assessed for successful delivery to the animal gut, and evaluated for their ability to enhance feed efficiency. Aromatic plant extracts and plant based products offer an opportunity in this regard, as many plants produce secondary metabolites which have antimicrobial or antiparasitic properties. Certain of these active components are generally recognized as safe for human and animal consumption in the USA, which has

prompted scientists to examine their potential to improve production efficiency and health in livestock. Aromatic plants and their extracts have been used in human and veterinary medicine since ancient times. However, the exact mode of action and kinetics of these compounds are generally poorly understood (FDA, 2004).
It was demonstrated that thymol can reduce the growth, survivability and ammonia production of *Campylobacter jejuni* and *Campylobacter coli* (Anderson *et al.*, 2009a). Food-producing animals can be reservoirs for *Campylobacter*, a leading bacterial cause of human foodborne illness. *Campylobacter* differ from other gut bacteria in that they have a limited capacity to ferment carbohydrates but can utilize amino acids as a major energy source, a process that can be inhibited by thymol (Anderson *et al.*, 2009b). Previous *in vitro* fermentations of pig gut demonstrated that a concentration of thymol at 258 mg/L, carvacrol at 255 mg/L, eugenol at 223 mg/L or *trans*-cinnamaldehyde at 56 mg/L reduced the number of total anaerobic bacteria compared to the control with a probability of 99.7% (Michiels *et al.*, 2009). Michiels *et al.* (2008) found that carvacrol and thymol were very effective against coliform, lactobacilli and streptococci bacteria, while *trans*-cinnamaldehyde mainly inhibited the growth of coliform bacteria. The same authors reported that in cecal incubations carvacrol, thymol, eugenol and cinnamon oil showed a high-efficacy against *S. enterica* Typhimurium DT104, *Escherichia coli* O157:H7 and *E. coli* K88, while showing little inhibition towards pig endogenous lactobacilli and bifidobacteria.
Other than the work of Michiels *et al.* (2008) who studied degradation of thymol in piglet intestines, no data has been published on absorption of thymol in the pig stomach when thymol was administered orally. Information on thymol absorption is necessary for application and dosage of thymol in pig feeds and also with regard to potential resistance/tolerance development of intestinal bacteria to thymol. The aim of this work was to determine the degradation and absorption kinetics of thymol in the pig stomach.

MATERIAL AND METHODS

Isolated pig stomach was incubated for 360 min at 37 °C in an incubator with 95% O_2:5% CO_2 atmosphere on an oscillating plate at 40 rpm. Tyrode's solution pH 6.5 was used as incubation fluid. Thymol (1.7 mM) was inoculated internally into the stomach contents and samples were collected at intervals during incubation, and were extracted as is or after treatment with a lysis buffer. The lysis buffer was used to release thymol that may have been internalized by endogenous bacteria.

Incubation procedure

Isolated pig stomach was placed into 5000-mL flasks containing 2000 mL of Tyrode's solution, and the pH was adjusted to 5.8. Thymol (100 mg/mL in absolute ethanol) was inoculated into the stomach contents to a final concentration of 1.7 mM. The flask was incubated for 360 min at 37 °C in an incubator with a modified atmosphere (95% oxygen, 5% CO_2), while simultaneously being rotated on an oscillating plate at 40 rpm.

Sample preparation for GC analyses

Samples were collected from incubated fluid or from stomach contents at 0, 15, 30, 60, 120 and 360 min incubation time. Samples were extracted for the determination of thymol content as is or after treatment with a lysis buffer. Lysis buffer was used to release thymol that may have been internalized by endogenous bacteria. The extraction method used to extract thymol from samples was a modification of the method used by Michiels *et al.* (2008). Briefly, extraction of thymol as is was carried out in 2.0 mL microcentrifuge tubes. Absolute ethanol (15 µL) and ethyl acetate (1 mL) were added to 0.25 mL of each sample. The mixture was vortexed for 30 sec and then left to equilibrate overnight at 8 °C. The extraction mixtures were then centrifuged at 10,000 rpm for 5 min at 25 °C. The supernatant was removed for GC analyses. Samples for the determination of the thymol internalization by endogenous bacteria were first treated with lysis buffer (1:1) and then later extracted as described.

Thymol determination by gas chromatography (GC)

The GC methods of Nozal *et al.* (2002) and Michiels *et al.* (2008) were modified and carried out on a HP 6890 GC System (Agilent Technologies, Santa Clara, CA, USA) equipped with a capillary split/splitless inlet, total electronic pneumatic control of gas flow, autosampler and flame ionization detector (FID). A 30 m × 0.25 mm × 0.25 μm film thickness Equity™-1701 fused silica capillary column (#28372-U, Supelco, Bellefonte, PA, USA) was utilized for the GC separation of thymol. Hydrogen was used as the carrier gas at 1 mL/min. The mode used was split, with a split ratio of 5:1. Initial oven temperature was set at 130 °C and held for 1 min. A double temperature ramp program was used at the rate of 6 °C/min to 180 °C, then increased at 40 °C/min to 230 °C with a hold time of 4 min. Finally, the oven was brought back to 130 °C with a hold of 1 min, resulting in a total run time of 14.58 min. The injector and FID detector temperatures were 250 and 280 °C, respectively. Helium was used as makeup gas for the FID. Chromatographic data were collected and analyzed using the Agilent ChemStation Software (Rev. B.03.02 [341]). Results are expressed as % of thymol recovery.

RESULTS AND DISCUSSION

The results of thymol recovery in pig stomach content during incubation at 37 °C, for a period of 360 min, are shown in Figure 1. As it can be seen in Figure 1, thymol concentrations decreased in both lysed and unlysed stomach samples during incubation.

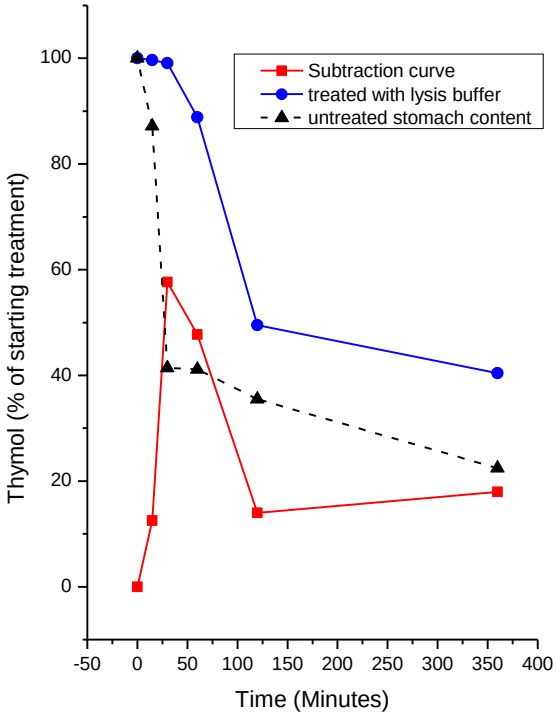

Figure 1. The concentration of thymol in the stomach contents during incubation at 37 °C. The starting thymol concentration of untreated and lysed stomach contents was 252.9 and 253.8 mg/L, respectively.

However, thymol concentrations declined more rapidly in the unlysed than in the lysed samples, with 99.1% of the added thymol recovered from lysed samples collected after 30 min incubation and only 41.4% thymol recovered from unlysed samples collected after 120 min incubation. Thymol concentrations in lysed samples (40.4% recovery) remained nearly double those in unlysed samples (22.4% recovery) even after 360 min. When presented as the difference (■) between thymol concentrations measured in lysed samples (reflecting both intracellular and luminal thymol recovery) and unlysed samples (reflecting only luminal thymol recovery), we can see that considerable amounts of thymol are initially taken up and sequestered by bacterial cells (Figure 1). This sequestration results in 57.7% of the starting thymol concentration at 30 min from the start of incubation. This intracellular sequestration appears to be transient and likely reflects leakage of thymol following thymol-caused cell wall disruption, a proposed mechanism of action of thymol and other essential oils (Burt, 2004).
Our results are different from the results of Broudiscou *et al*. (2007) who found no degradation of thymol over 24 h during *in vitro* caprine ruminal fermentation at a dose of 2000 mg/L. However, it needs to be mentioned that Broudiscou *et al*. (2007) investigated caprine rumen thymol degradation, and we have investigated pig stomach thymol degradation so these two results are difficult to compare. Varel (2002) found that thymol and carvacrol were stable in swine waste under anaerobic conditions (nitrogen atmosphere) for 62 days, with 90–95% of the thymol being recovered. Although this finding is different than our findings, it does indicate that different bacteria are present in the pig stomach and swine waste, which emphasizes the need to further identify the microorganisms responsible for thymol luminal depletion. Michiels *et al.* (2008) found that thymol was not significantly degraded in the pig jejunal gastrointestinal tract *in vitro* fermentation simulations, but significant losses of up to 29% were found in cecal *in vitro* fermentation simulations. The results of Michiels *et al.* (2008) can be justified by the fact that we have measured significant "thymol sequestration" in the pig stomach; therefore, the "sensitive" microorganisms which may uptake thymol are expected to be dead in the proximal part of the intestines. The findings of Anderson *et al.* (2009b) are similar, who evaluated palatability issues pertaining to feeding thymol. Growing pigs were provided *ad libitum* access to standard growing diets supplemented with or without 0.0067% or 0.0201% thymol on a dry weight basis. No effect of the treatment was observed on ileal or cecal *Campylobacter* or on cecal total cultureable anaerobes as well as on the accumulation of major fermentation end products within the collected gut contents. These findings suggested that appreciable quantities of thymol were absorbed or degraded in the proximal alimentary tract and that new encapsulation technologies will be needed to deliver effective concentrations of these compounds to the lower gut to achieve *in vivo* efficacy against *Campylobacter*.
No thymol was determined in the incubation fluid and suggested that no thymol uptake by the stomach itself or passive transfer to incubation fluid occurred in this *in vitro* trial. Therefore, we hypothesize that significantly different thymol concentrations measured in lysed and unlysed samples of the stomach contents are the result solely from bacterial uptake of thymol and not from absorption in the stomach. This hypothesis needs to be further evaluated and confirmed by *in vivo* studies.

CONCLUSIONS

The overall results of our trial confirmed that thymol was not absorbed in the pig stomach. However, different thymol concentrations measured in lysed and unlysed samples suggest that upon ingestion, significant amounts of thymol were internalized by endogenous bacteria. This luminal depletion would be expected to occur rapidly in stomach contents but it is not known whether this sequestration would make thymol unavailable for absorption in the

stomach or more distally. Further investigations are needed to identify the bacteria responsible for this “thymol sequestration” phenomenon.

ABSTRACT: Buckwheat (*Fagopyrum esculentum* Moench) is an alternative crop belonging to the *Polygonaceae* family. In comparison to antioxidant activity of frequently used cereals, buckwheat has been reported to possess higher antioxidant activity, mainly due to high rutin content.
The objective of this work was to determine the main antioxidant compounds and antioxidant activity of buckwheat grain and fractions (wholegrain, hull and groat). Buckwheat grain fractions were extracted with ethanol/water (80/20, v/v), followed by determination of total phenolic content and DPPH radical scavenging activity. Determination of phenolic compounds and tocopherols was performed by HPLC.
Significantly higher content of total phenolics was found in buckwheat hull than in wholegrain and groat. Protocatechuic acid, siringic acid, ferulic acid, sinapic acid, rutin and quercetin were quantified in all tested fractions, whereas vanilic acid was found in wholegrain and hull. The content of total tocopherols in investigated samples ranged from 9.95 μg/g for hull to 25.8 μg/g for groat. Hull was superior in scavenging activity on DPPH radicals as evidenced by its lower IC_{50} value.
Obtained results can broaden the utilization of buckwheat, especially a share of hull in wholegrain flour production. Bakery products containing wholegrain buckwheat flour may be regarded as health-promoting functional foods.
Key words: *buckwheat grain fractions, phenolics, tocopherols, DPPH radicals*

INTRODUCTION

Buckwheat (*Fagopyrum esculentum* Moench) is highly nutritious pseudocereal known as a dietary source of protein with favorable amino acid composition and vitamins (Bonafaccia et al., 2003a), starch and dietary fiber (Skrabanja et al., 2004), essential minerals (Steadman et al., 2001) and trace elements (Bonafaccia et al., 2003b). Phenolic compounds are also found in abundance in buckwheat, including rutin, orientin, vitexin, quercetin, isovitexin, kaempferol-3-rutinoside, isoorientin, and catechins (Dietrych-Szostak and Oleszek, 1999). A number of studies have shown that buckwheat possesses strong antioxidant activity, mainly due to high rutin content (Kreft et al., 2006). Although other parts of the buckwheat plant can be used for human consumption, buckwheat is now mainly grown for the production of seeds (Wijngaard and Arendt, 2006). Buckwheat seeds are usually processed into flour, and they are dehulled before milling or the flour is sieved afterward.
Hung and Morita (2008) investigated 16 buckwheat milling fractions and concluded that the phenolic acids and flavonoids are mainly located in the outer layers of grain.
In our previous studies (Sedej et al., 2010; Sedej at al., 2011), significantly higher content of phenolic compounds and tocopherols was found in wholegrain buckwheat flour than in refined one. Wholegrain buckwheat flour possessed better scavenging abilities on 1,1-diphenyl-2-picrylhydrazyl ($DPPH^{\bullet}$), hydroxyl ($^{\bullet}OH$) and superoxide ($O_2^{\bullet-}$) radicals, as well as better reducing activity, antioxidant activity (AOA) by β-carotene bleaching method, and chelating activity on Fe^{2+}, according to their IC_{50} values.
The objective of this work was to investigate antioxidant capacity of buckwheat hull in comprasion to wholegrain and groat in order to get insight into the possibility of hull

supplementation of wholegrain buckwheat flour, resulting in improved ingredient of functional foods.

MATERIAL AND METHODS

Materials

Buckwheat (*Fagopyrum esculentum* Moench) grain fractions: wholegrain (10.0% water content, 1.93% db ash content, 12.4% db protein content), hull (8.33% water content, 1.44% db ash content, 4.11% db protein content) and groat (9.97% water content, 2.11% db ash content, 14.2% db protein content) were obtained from Hemija Commerce, Novi Sad, Serbia. Buckwheat grains were imported from Ukraine and dehulling was carried out at Jazak Mill, Serbia.

Extraction Procedure

Buckwheat grain fraction (50.0 g) was mixed with 200 mL of ethanol/water (80/20, v/v). Extraction was carried out by shaking the mixture at room temperature for 1 h, supernatant was filtered through the filter paper (Whatman, Grade 4 Chr, UK), and the procedure was repeated twice. Combined extracts were dried by vacuum-evaporator. The dried extract was resolved in ethanol/water (80/20, v/v) to 10 mL volume. The extract obtained by this procedure was used for further investigation of total phenolic content, and antioxidant activity.

Determination of Total Phenolic Content

Total phenolic content of buckwheat grain fractions extracts was determined spectrophotometrically at 750 nm by using Folin-Ciocalteu's reagent (Singleton et al., 1999). Gallic acid was used as a standard and results were expressed as gallic acid equivalents (GAE) (μg GAE per g of sample on wet mass basis).

HPLC Determination of Phenolic Compounds

Five grams of buckwheat grain fraction was extracted with 20 mL methanol/water (90/10, v/v) at room temperature during 24h, ultrasonicated for 10 min and filtered through 0.45 μm pore size PTFE filter (Rotilabo-Spritzenfilter 13 mm, Roth, Karlsruhe, Germany) before injection into the HPLC system.

HPLC analysis was performed by using a liquid chromatograph (Agilent 1200 series), equipped with a diode array detector (DAD), on an Agilent, Eclipse XDB-C18, 1.8 μm, 4.6 x 50 mm column, at a flow-rate of 1.000 mL/min. A single rapid resolution reverse phase HPLC method suitable for the determination of 17 phenolic compounds was developed and validated as previously reported (Mišan et al., 2011).

HPLC Determination of Tocopherols

Extraction of tocopherols from the samples and HPLC analysis were carried out according to the method of Sedej et al. (2010).

DPPH Radical Scavenging Activity

Effect of the examined extracts on the content of DPPH radicals was estimated according to the method of Hatano et al. (1988). Buckwheat grain fractions extracts at various concentrations (1.00–5.00 mg/mL) were tested and the absorbance of the reaction mixture was measured at 517 nm. The IC_{50} value (mg/mL) was defined as the concentration of an antioxidant extract which was required to quench 50% of the initial amount of $DPPH^{\bullet}$ under the experimental conditions given. Butylated hydroxytoluole (BHT) was used as a control.

Statistical Analysis

All analyses were performed in triplicate, and the mean values with the standard deviations are reported. Analysis of variance and Duncan's multiple range test were used. Statistical data analysis software system STATISTICA (StatSoft, Inc. (2011) data analysis software

system, version 10.0. www.statsoft.com) was used for analysis. *P* values < 0.05 were regarded as significant.

RESULTS AND DISCUSSION

Total Phenolic Content

Total phenolic content of buckwheat grain fractions extracts is shown in Figure 1. The total phenolic content of buckwheat grain fractions differed significantly ($P < 0.05$) ranging from 1.69 ± 0.42 mg GAE/g in groat to 2.09 ± 0.42 mg GAE/g in hull (Figure 1). Results with similar trend of increased content of phenolics in outer layers of grain were obtained in the studies of Hung and Morita (2008). The results of Velioglu et al. (1998) confirmed higher level of phenolic content in buckwheat hull than in seeds.

Figure 1. Total phenolic content of buckwheat grain fractions extracts (mg GAE/g sample)
Values are means of three determinations ± standard deviation.
Bar values with the same superscript are not significantly different (P < 0.05).

HPLC Determination of Phenolic Compounds

Using HPLC-DAD, rutin was determined as major compound in crude methanolic extracts of buckwheat grain fractions. Protocatechuic, syringic, ferulic, and sinapic acid, and quercetin were quantified in all tested fractions, whereas vanilic acid was found in wholegrain and hull (Table 1).

Table 1. Phenolic compounds of buckwheat grain fractions (µg/g)

Phenolic compounds	Wholegrain	Hull	Groat
Protocatechuic acid	92.6 ± 0.94^{a}	168 ± 0.48^{c}	103 ±1.21^{b}
Vanilic acid	15.0 ± 0.46^{a}	37.1 ± 2.38^{b}	n.d.
Syringic acid	52.3 ± 1.49^{b}	36.3 ± 1.6^{a}	63.5 ± 0.35^{c}
Ferulic acid	17.2 ± 0.13^{a}	17.5 ± 0.59^{a}	17.4 ± 0.21^{a}
Sinapic acid	28.13 ± 1.68^{a}	29.8 ± 0.47^{a}	30.4 ± 3.44^{a}
Rutin	146 ± 4.56^{b}	225 ± 7.25^{c}	116 ± 0.26^{a}
Quercetin	3.04 ± 0.14^{a}	33.2 ± 1.74^{b}	2.48 ± 0.06^{a}
Total	354.5	546.9	332.8

Values are means of three determinations ± standard deviation. Values in each row with the same superscript are not significantly different (P < 0.05). n.d.-not detected

Hung and Morita (2008) published that rutin and ferulic acid were the most represented phenolic compounds in 16 buckwheat milling fractions. In addition, Alvarez-Jubete et al. (2010) identified syringic acid and caffeic acid in buckwheat grain. In buckwheat groat vanilic acid, syringic acid, ferulic acid, and coummaric acid were quantified (Zielinski et al., 2006).

The highest content of all identified compounds, with an exception of syringic acid, was established for hull. Total phenolic compounds content of buckwheat grain fraction was present in the following order: hull > wholegrain > groat. This trend is in accordance with results of Gallardo et al. (2006), who concluded that milling and fractioning of grains greatly influenced the phenolic composition of the final milled product. The highest concentration of rutin in hull, and similar trend of rutin and quercetin distribution in buckwheat milling fractions was confirmed by Steadman et al. (2001).
Content of phenolic compounds determined by HPLC is in significant correlation with the results obtained for Folin-Ciocalteu method (r = 0.87, P < 0.05).

Tocopherols Content

Grains are relatively good sources of vitamin E, α-, β-, γ-, δ-tocopherols and tocotrienols, and therefore content of α-, γ-, δ-tocopherols is determined in buckwheat grain fractions. The results are shown in Table 2. The content of total tocopherols in buckwheat grain fractions ranged from 9.95 μg/g for hull to 25.8 μg/g for groat.
The highest content of α-tocopherol was found in wholegrain. Content of γ-tocopherol was significantly higher in both wholgrain and groat in comparison to hull. Within the grain, tocopherols are primarily located in the germ and aleurone tissue, the metabolically active parts of grain (Engelsten and Hansen, 2009). The data show that the content of tocopherols strongly depends on the milling process, namely refining process of flour, in which the outer layer of grain is removed.

Table 2. Tocopherol content of buckwheat grain fractions (μg/g)

Buckwheat	α-Tocopherol	γ-Tocopherol	δ-Tocopherol	Total
Wholegrain	9.44 ± 0.92^{c}	10.1 ± 0.89^{b}	0.37 ± 0.05^{a}	19.8
Hull	8.13 ± 1.07^{b}	1.36 ± 0.11^{a}	0.46 ± 0.01^{a}	9.95
Groat	3.32 ± 0.04^{a}	22.1 ± 0.2^{c}	0.42 ± 0.03^{a}	25.8

Values are means of three determinations ± standard deviation. Values in each column with the same superscript are not significantly different (P < 0.05)

Antioxidant Activity

All extracts showed significant (P < 0.05) difference in their ability to reduce the initial concentration of DPPH$^{\bullet}$ which was confirmed by their IC_{50} values (Figure 2). The hull extract showed higher DPPH$^{\bullet}$ scavenging activity in comparison with reference antioxidant, BHT as evidenced by its lower IC_{50} value. Scavenging activity on this radical was 18-fold higher for buckwheat hull (0.39 ± 0.02 mg/mL) than for groat (1.66 ± 0.01 mg/mL). These findings are in accordance with published results of Hung and Morita (2008) who reported that the outer layers of grains contain higher total phenolics contents and possess significantly higher antioxidant capacity than the inner fractions when the DPPH assay was used. Also, Sun and Ho (2005) reported powerful antiradical activity of ethanolic extract of the whole buckwheat grain on DPPH$^{\bullet}$, but our results are not fully comparable because of differences in applied methods.

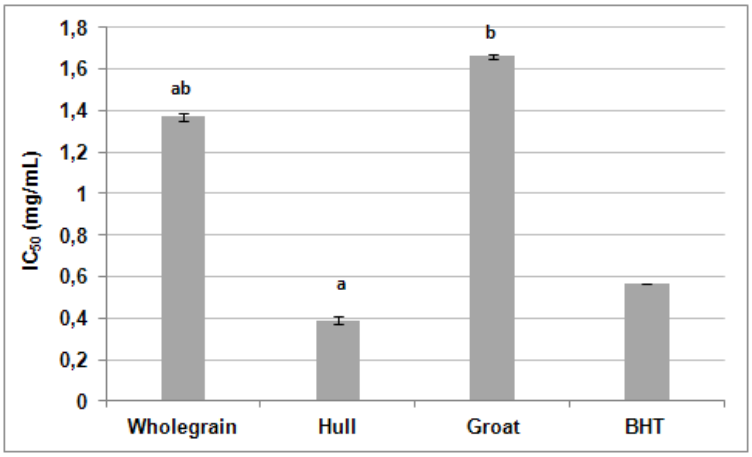

Figure 2. Scavenging activity of buckwheat grain fractions extracts on DPPH$^{\bullet}$ radicals, expressed as IC_{50} (mg/mL)
Values are means of three determinations ± standard deviation.
Bar values with the same superscript are not significantly different (P < 0.05)

CONCLUSIONS

The results of this paper confirm that buckwheat hull is superior in antioxidant compounds content and antioxidant activity in comparison to wholegrain and groat. These findings suggest the potential improvement of the antioxidant properties of wholegrain buckwheat flour, and consequently bakery food products through addition of hull. The suggested improvement has significant implication for use of by-product and design of cereal-based functional foods.

ABSTRACT: Oxidative stress is characterized as imbalance between the content of free radicals and antioxidants in favour of radicals. Dietary nutrients may limit or encourage lipid damage therefore influence urinary oxidative stress biomarker excretion. The aim of this study was to evaluate nutrient intake in comparison to reference values (DACH, 2004) and to examine the influence of daily nutrient intake, as positive and negative factors, on urinary levels of malondialdehyde (MDA) and 4-hydroxy2nonenal (4HNE) in healthy human. Only one subject participated in this pilot nutritional study, which was undertaken using the food diary weighing method for 15 consecutive days. Nutrient intake was assessed with Prodi 5.7 Expert plus (Kluthe, 2010) computer nutritional programme. Morning urine samples were used for lipid oxidation marker analysis and normalized with creatinine values. MDA and 4HNE were analysed by GC/MS system. Results were statistically evaluated by using PASW Statistics 18 programme. The results showed that average daily macronutrient intake in terms of energy caloric profile was sufficient, but not in compliance with DACH Reference for Nutrient Intake. MDA and 4HNE levels were on average 25.85±9.51 and 0.31±0.30 ng/mg creatinine, respectively. Normalized MDA and 4HNE were correlated (r=0.52), but not statistically significant. Positive factors such as antioxidant vitamins, total dietary fibre and β-carotene showed no influence on MDA neither on 4HNE values. However there was a statistically significant correlation between PUFAs and 4HNE (r=0.620) compared to MDA, where correlation was not found. Moreover there was also significant correlation between linoleic acid, as major precursor for lipid oxidation, and 4HNE urinary excretion (r=0.642). Intake of PUFAs and linoleic acid as a substrate for lipid oxidation had influence on urinary excretion of 4HNE, but not on MDA. None of the expected positive factors showed statistically significant effect on analyzed biomarkers.

INTRODUCTION

In observational studies, high intake of fruit and vegetables is frequently associated with decreased risk of coronary heart disease and many cancers (Riboli and Norat, 2003; Dauchet et al., 2006). Various plant-derived compounds may have direct protective effects in tissues or enhance cellular defence mechanisms and thus restrain pathophysiological processes associated with degenerative diseases (Liu, 2003). The inverse association between the intake of fruit and vegetables and the risk of degenerative diseases has often been at least partly attributed to the high content of antioxidants in plants. The role of diet in pro- and antioxidative processes is an intriguing concept and, at least in theory, diet can both decrease (for example, by antioxidant vitamins; McCallnd Frei, 1999; Frei, 2004) and increase (for example, by polyunsaturated fatty acids, PUFA; Turpeinen et al., 1998; Eritsland, 2000) oxidative stress in the body. The assessment of oxidative stress status though specific biomarkers has acquired great importance. Measurement of antioxidant capacity may also involve the assessment of specific oxidative stress biomarkers. Most of the studies that have examined the association between diet and oxidative stress consider the effects of antioxidant supplements (vitamins and minerals), drinks and foods with bioactive compounds or dietary patterns on oxidative stress biomarkers. The major biomarkers include the products of the attack of free radicals and reactive species to various substrates: lipids, proteins and nucleic acids (Barbosa et al., 2008).

Lipid peroxidation proceeds by a free radical chain reaction mechanism. It most often affects polyunsaturated fatty acids (PUFA), because they contain multiple methylene interrupted double bonds (Guichardant, 2009). Several markers of lipid peroxidation are available with different degrees of specificity, from malondialdehyde (MDA) as a global marker, to F2-isoprostane, which is specifically produced from arachidonic acid. Among these, 4-hydroxynonenal (4-HNE) is recognized as a breakdown product of fatty acid hydroperoxides, such as 15-hydroperoxy-eicosatetraenoic acid and 13-hydroperoxy-octade cadienoic acid from the *n*-6 fatty acids (Guichardant, 2004). These biomarkers, measurable in urine, are noninvasive that give an indication of the oxidative stress. Taking into account the limitations of the different biomarkers available, more than one biomarker should be measured in a particular sample to obtain an overview on the oxidative stress (Guichardant, 2009).
The aim of this study was to evaluate nutrient intake in comparison to reference values (DACH) and to examine the influence of daily nutrient intake, as positive and negative factors, on urinary levels of malondialdehyde (MDA) and 4-hydroxy2nonenal (4HNE) in healthy human.

MATERIAL AND METHODS

This pilot nutritional study was done on only one healthy 29 years old female subject (weight 55 kg, high 169 cm). She completed food intake diary using the weighing method for 15 consecutive days. Nutrient intake was assessed with Prodi 5.7 Expert plus (Kluthe, 2010) computer nutritional programme. Participant collected each morning urine samples while recording food intake. Aliquote urine samples were stored in -80°C until analysis. 4-hydroxy2nonenal (4HNE) and malondialdehyde (MDA) analysed by GC/MS system were used as urinary lipid oxidation biomarkers. The measured 4HNE and MDA concentrations were normalized using the corresponding creatinine levels in each sample. Results were statistically evaluated by using PASW Statistics 18 programme.

4HNE and MDA determination

4HNE and MDA aldehydes were determined together with slightly modified stir bar sorptive extraction-thermal desorption-gas chromatography/mass spectrometry method (Stopforth et al., 2006). 4-hydroxy nonenal-d_3 (Cayman Chemical) was used as internal standard. Stir bar sorptive extraction (SBSE) was done using twister stir bar (10 mm x 1 mm x 1 mm d_f polydimethylsiloxane (PDMS)) from Gerstel. PFBHA in ultrapure water was used for derivatization procedure. GC/MS was carried out on an Agilent 7890 gas chromatograph that was interfaced with an Agilent 5975C mass selective detector. The derivatives were separated on a DB-5 capillary column (30 m x 0.25 mm x 0.25 µm, Agilent) using helium as carrier gas at a flow rate of 1mL min^{-1}.

RESULTS AND DISCUSSION

Average daily intake of energy is 7254±1260 KJ, which is under the lower limit for healthy female between 25 to 51 years old (PAL = 1.4), but still in accordance with DACH reference values. Total daily protein intake is with 1.12 g/kg BW statistically significantly different than recommendations (DACH, 2004). The amount of the dietary energy supplied by carbohydrates is on average 47.2% which is significantly lower than reference values (2004), consequently fats (35 % of energy) are significantly higher. Average daily intake of dietary fiber is with 27.1±9.4 g/day in compliance with recommendations (DACH, 2004). Total amount of vitamins A and E consumed on average is the same as DACH recommendations, whereas vitamin C is statistically significantly higher (Table 1).
On average urinary MDA and 4HNE levels were 25.85±9.51 and 0.31±0.30 ng/mg creatinine, respectively (Figure 1). MDA level in morning urine samples varied between 13.1 (day 12) and 46.4 (day 6) ng/mg creatinine. Morning 4HNE also peaked at day 6 with 0.96 ng/mg creatinine, while it was not detected on day 10 and 14, minimum was on day 15 (0.03 ng/mg

creatinine). Interestingly, 4HNE concentrations at the beginning of the trial (first six days) were significantly higher than the following nine days, whereas MDA was dispersed during the whole trial. Normalized MDA and 4HNE were correlated (r=0.52), but not statistically significant.

Morning spot urine levels of MDA and 4HNE were compared to all macronutrients and antioxidant vitamins, as well as fatty acids as aldehyde oxidation precursors. 4HNE values on day 10 and 14 were excluded from correlation calculations due to levels below the detection limit. Dietary nutrient intake values were compared to the next day morning urine sample biomarkers.

Table 1. Average nutrient intake in comparison to Reference Values for Nutrient Intake (2004)

	Mean	Std. Deviation	DACH Reference Value for Nutrient Intake (2004)	Sig. (α = 0.05)
Nutrient				
Energy (KJ)	7254	1260	7800	0.115
Charbohydrates (% energy)	47.24	6.86	55	0.001
Proteins (g/kg BW)	1.12	0.28	0.8	0.001
Fat (% energy)	34.98	7.58	30	0.023
PUFA (% energy)	6.66	2.87	7	0.649
SFA (% energy)	11.68	3.49	10	0.083
TDF (g)	27.11	9.37	30	0.252
Vit A (µg retinol equivalent)	859.9	288.2	800	0.434
Vit E (mg tocopherol equivalent)	11.13	3.53	12	0.356
Vit C (mg)	152.39	61.47	100	0.005

BW – body weight; PUFA – polyunsaturated fatty acids; SFA – saturated fatty acids; TDF – total dietary fibre

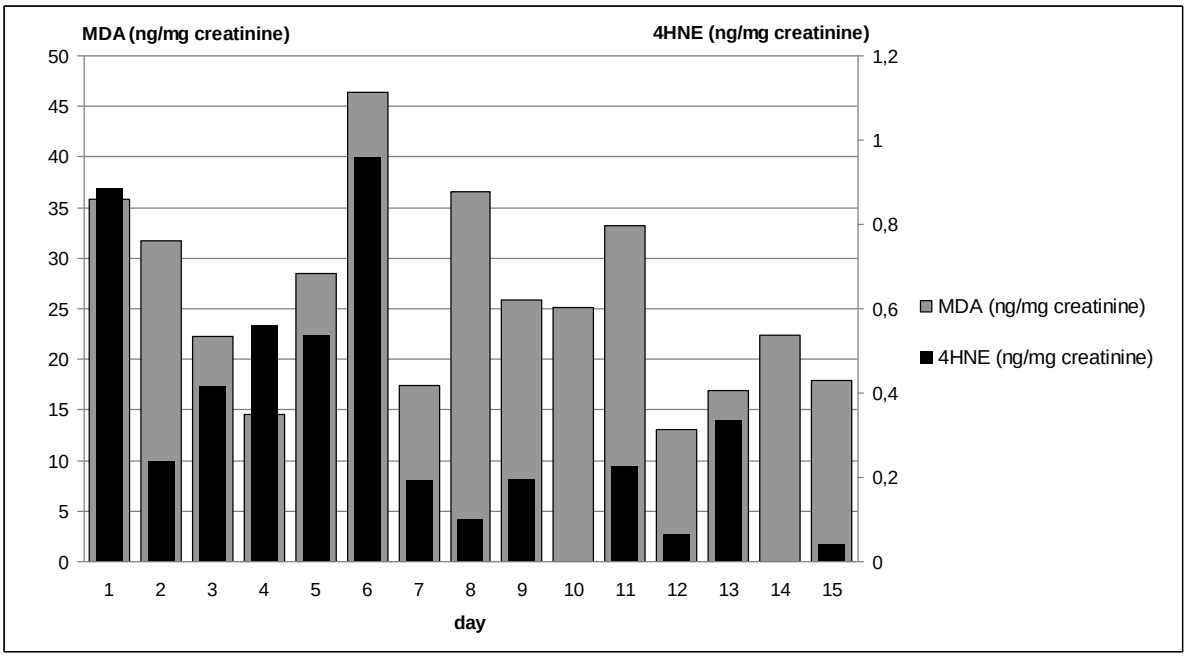

Figure 1. MDA and 4HNE concentration in morning urine samples during the trial

Positive factors such as antioxidant vitamins, total dietary fibre and β-carotene had no influence on MDA neither on 4HNE values. Results showed statistically significant correlation between PUFAs and 4HNE (r=0.620) in comparison to MDA where correlation was not found. Moreover there was also significant correlation between linoleic acid, as major precursor for lipid oxidation, and 4HNE urinary excretion (r=0.642) (Figure 2). Pearson coefficient correlations showed that levels of excreted 4HNE was more influenced by fatty acid intake than by any positive dietary factors, whereas with MDA this was not the case. Therefore, when researching lipid oxidation biomarkers, fatty acid intake must be taken into account prior to dietary intake of antioxidants.

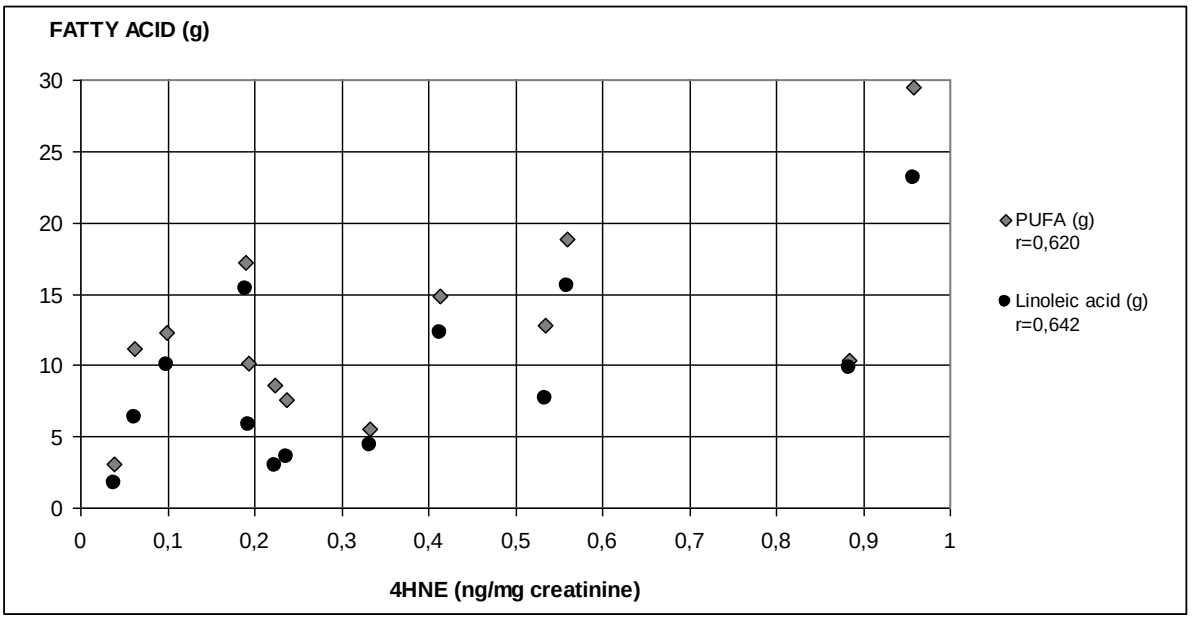

Figure 2. Morning urinary 4HNE excretion in correlation with daily PUFA and linoleic acid intake

CONCLUSIONS

Average daily macronutrient intake in terms of energy caloric profile was sufficient, but not in compliance with DACH Reference for Nutrient Intake. Intake of PUFAs and linoleic acid as a substrate for lipid oxidation had influence on urinary excretion of 4HNE, but not on MDA. None of the expected positive factors showed statistically significant effect on analyzed biomarkers. No apparent agreement could be made between the intake of antioxidants and the reported urinary 4HNE and MDA concentrations.

ABSTRACT: Linseed is one of the most useful crops that has been cultivated as a commercial plant all over the world. Recently there has been a growing interest in linseed oil due to the high concentration of linoleic and especially α-linolenic acid. Since animals are not able to synthesize these essential fatty acids, changes in fatty acid content in meat can be achieved through the changes in animal diet. The aim of this study was to evaluate the influence of diet supplemented with linseed rich additive on fatty acid profile and ω-fatty acids content in pig meat. Furthermore, fatty acid composition of roasted meat of pigs fed with control and experimental diet was investigated.
Twelve pigs were divided in a control and experimental group and grown to 110 kg of live weight. The experimental group was fed a standard diet enriched with 2.5% of commercial additive. Fatty acid composition of fresh meat samples and heat treated meat were determined by GC-FID. Meat was roasted in oven at the temperature of 80 - 85^{0}C until the temperature in the centre reached 69^{0}C (about 1 hour). STATISTICA software, version 10 was used for performing ANOVA and Fishers comparison of means.
Samples from the experimental group fed with linseed enriched diet showed significantly higher ($p < 0.01$ and $p = 0.01$, respectively) content of both ω-3 (8.25% vs. 1.33%) and ω-6 fatty acids (25.68% vs. 20.68%) in all tissues, thus making it better for a human consumption from a health perspective. Heat treatment significantly decreased ($p < 0.05$) the content of stearic and linoleic acid in control tissue samples, but decrease was insignificant ($p > 0.05$) in samples from the experimental group.
In conclusion, diet enriched with linseed had a beneficial effect on the majority of monitored parameters in the study.
Key words: *linseed diet, essential fatty acids, pork, heat treatment*

INTRODUCTION

Dietary fats, especially essential fatty acids, which cannot be endogenously synthesized by humans and other mammals, play an important role in human health and well being (Beare-Rogers *et al.*, 2001). Many clinical, epidemiological and biological studies ascribe a particular significance to ω-3 polyunsaturated fatty acids (PUFA). Results from those studies confirmed their anti-inflammatory, antithrombogenic, and hypotriglyceridemic properties; they are also active against some types of cancer like colon, breast and prostate cancer (Rose *et al.*, 1999; Connor, 2000; Simopoulos, 2002). However, these beneficial effects are limited by the fact that the modern western diet is rather low in ω-3 fatty acids, while it is very high in ω-6 fatty acids content, and it is well known fact that increased levels of ω-6 fatty acids are associated with an increase in chronic diseases (Givens *et al.*, 2006; Enser *et al.*, 2000).
Since animal diet determines the fatty acid composition in meat, changes in fatty acids ratio and composition in meat can be achieved through the changes in animal diet (Mourot, 2001). Most common way to perform this is by enriching the animal feed with fish oil/fish meals or with plant oils rich in ω-3 PUFA or seed meals such as linseed (Raes *et al.*, 2004; Kouba *et al.*, 2003). Linseed, containing about 40% of oil, has long been used in human and animal diet. Oil from the seeds contains remarkably high content of linoleic (LA, 18:2, n-6) and especially α-linolenic acid (ALA, 18:3, n-3). Furthermore, linseed is the richest oilseed source of ALA (Juárez *et al*., 2010, Łukaszewicz *et al*., 2004, Ivanov *et al.*, 2012). Monogastric animals (like pigs) are better target for this approach, because the dietary fatty acids are absorbed from the intestine unchanged (Enser *et al.*, 2000). In this way, composition of fatty

acids in meat could be modified by dietary means ultimately improving nutritional and health value of the meat.
The objective of presented study was to investigate the influence of linseed enriched diet (rich in ω-3 PUFA) on fatty acid composition of pig meat. This was done by supplementing the standard, commercial feed with linseed and observing the effects of such feeding (with standard diet used as a control) on changes in fatty acid composition of various pig tissues. Furthermore, the samples were roasted in order to obtain information about fatty acid degradation caused by the heat treatment.

MATERIAL AND METHODS

Animals and diet

The total twelve pigs, Pietrain x (Landrace x Great Yorkshire) were used in the study, which was conducted at the pig farm „Sabo Janos", Jermenovci, Serbia.
Twelve pigs were divided into two groups and fed with two types of diet, a standard diet and diet enriched with 2.5% of Vitalan® (Vitalac, France), until reaching approximate 110 kg of live weight, when they were slaughtered. Vitalan® contains 85% extruded linseed, which made the diet rich in omega-3 acids and the rest were wheat bran and antioxidants. The composition of the diets is shown in Table 1.

Table 1. Composition of diets for pigs

Components (%)	Control group	Experimental group
Vitalan®	0	2.5
Maize	51.0	50.0
Barley	28.0	26.8
Soybean meal	18.0	17.7
Premix	2.5	2.5
Acidifier	0.5	0.5
Total	100.0	100.0

Slaughtering and sampling

The animals were slaughtered and samples of pig meat (*M. Longissimus dorsi,* bacon and back fat), 3 pieces (200 g each) from both groups were collected and kept in the refrigerator at 4^0C. A half amount of every sample was roasted in the oven at the temperature of 80 - 85^0C until the temperature in the centre of the meat reached 69^0C (about 1 hour). After 24 hours, the samples were sent to the laboratories of Institute of Food Technology in Novi Sad, where fatty acid analysis was performed. Each sample was coded with a letter: C for samples from control group and E for samples from experimental group.

Fat extraction for fatty acid analysis

Supercritical fluid extraction with CO_2 was used for preparation of fat extracts, as recommended for fatty acid analysis (Ivanov *et al.*, 2012). Extractions were performed on a LECO TFA2000 fat analyzer with the method adopted from existing LECO procedures (Leco corporation, 2003). Infusorial soil (flux calcined infusorial soil, up to 54% crystalline silica, cristobalite < 50%, quartz < 4%, produced by LECO Corporation, MI, USA) was used as absorbent to remove traces of water from samples. The preselected meat samples were homogenized with food processor. 1.0 g of homogenized meat was vigorously mixed with 2.2 g of absorbent and this way prepared mixture was transferred into a metal extraction thimble (12 cm length and 10 mm diameter) for the extraction. After finishing the extraction step, the instrument was depressurized, and extracts in collection vials were de-gassed for ten minutes, until achieving constant weight of extracts.

Fatty acid determination
From the extracted lipids, fatty acid methyl esters were prepared with method that uses boron trifluoride/methanol solution (Veresbaranji, 1996). Nitrogen gas was used for drying and removing solvents from fatty acid methyl esters. Obtained samples were analyzed by a GC Agilent 7890A system with FID, auto-injection mode, equipped with fused silica capillary column (DB-WAX 30 m, 0.25 mm, 0.50 μm). Helium was used as a carrier gas (purity > 99.9997 vol. %, flow rate = 1.26 ml/min). The fatty acids peaks were identified by comparison of retention times with retention times of standards from Supelco 37 component fatty acid methyl ester mix (Cat. No. 47885-U, Supelco, PA, USA) and with data from internal data library, based on previous experiments and fatty acid methyl ester determination on GC-MS. Results were expressed as mass of fatty acid or fatty acid group (g) per 100 g of fatty acids, and as a ratio between ω-6 and ω-3 fatty acids.

Soxhlet extraction – free fat determination
Soxhlet extractions were performed with a Büchi 810 Soxhlet fat extraction apparatus (Soxtec system HT, 1043 Extraction Unit, Foss Tecator AB, Höganäs, Sweden) in accordance with manufacturer procedure and AOCS Method Ba 3-38 (AOCS, 2001). Extractions were performed with petroleum ether (40 - 60º) solvent. Sample size was 3g and extraction time was 1.5h, at 80 ºC. After removal from the apparatus, extracted lipids were allowed to cool at room temperature while passing air over the samples for 1 minute, and then dried in desiccant pouch until they reached constant weight (approximately 60 minutes). Fat content was expressed as the percentage, by weight (gravimetrical method).

Statistical analysis
STATISTICA software version 9 (Statsoft, Tulsa, OK, USA) was used for analyzing variations (analysis of variance – ANOVA), and for Fishers LSD comparison of means and pairwise comparison. Differences among means with probability (p) ≤ 0.05 were accepted as representing statistically significant differences, and differences among means with 0.05 ≤ p ≤ 0.10 were accepted as representing tendencies to differences.

Results and Discussion
Effects of the diets used in the experiment on composition of fatty acid group and total fat content of pig tissues are presented in Table 2. Samples of *M. longissimus dorsi* of the control and experimental groups showed significant differences in fatty acid composition. Saturated fatty acid (SFA) content decreased significantly ($p = 0.006$), monounsaturated fatty acids (MUFA) content also significantly ($p = 0.04$) decreased, and PUFA and unsaturated fatty acids (UFA) contents significantly ($p = 0.03$ and $p = 0.02$, respectively) increased in experimental groups. Experimental diet had less influence on back fat fatty acid composition, but increase in ω-3 fatty acid content was still significant ($p < 0.05$).

Table 2. Diet effects on composition of fatty acid group and total fat content of pigs tissues

		Fatty acids (% of total lipids)					*n-6/n-3* ratio	UI*	Total fat content (%)
		SFA	MUFA	PUFA	*n-6*	*n-3*			
Meat	C	17.28 ± 0.47	59.63 ± 0.30	23.09 ± 0.31	19.61 ± 0.26	2.49 ± 0.17	7.88	1.09	5.11 ± 0.08
	E	13.30 ± 0.38	52.17 ± 0.35	36.44 ± 0.33	24.22 ± 0.06	10.89 ± 0.35	2.22	1.37	5.57 ± 0.06
	Probability	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$			
Back fat	C	17.95 ± 0.40	57.10 ± 0.26	23.95 ± 0.34	22.36 ± 0.16	0.71 ± 0.38	31.49	1.07	86.50 ± 0.01
	E	17.73 ± 0.43	56.61 ± 0.20	24.31 ± 0.23	27.20 ± 0.17	7.20 ± 0.16	3.78	1.34	82.90 ± 0.03
	Probability	$p > 0.05$	$p > 0.05$	$p > 0.05$	$p < 0.05$	$p < 0.05$			
Bacon	C	16.98 ± 0.35	61.14 ± 0.16	21.59 ± 0.14	20.07 ± 0.13	0.79 ± 0.12	25.41	1.05	28.10 ± 0.03
	E	14.69 ± 0.30	51.23 ± 0.18	35.87 ± 0.16	26.11 ± 0.14	6.67 ± 0.16	3.91	1.25	26.10 ± 0.04
	Probability	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$			

The results are presented as mean ± SD

** UI – Unsaturation index = average number of double bonds per fatty acid residue*

Linseed diet positively affected ω-6/ω-3 ratio of all samples by decreasing it below the desirable level. Being aware of ω-3 PUFA benefits and health promoting effects, the nutritionists recommend a diet rich in ω-3 fatty acids, as well as a lower ω-6/ω-3 ratio from the currently common 15-20:1 to 1-4:1 (Gebauer et al., 2006, Raes *et al.*, 2004).
It is known that UFA containing double bonds that are easily oxidized, and thus fatty acid composition can influence the palatability of meat, as well as that the effect of fatty acids on meat tenderness is due to the different melting points of individual fatty acids, especially stearic and linoleic acid (Jeong *et al.*, 2010). Changes in the content of these two acids in *M. longissimus dorsi* are shown in Table 3, as a result of the differences in composition of standard (control) and linseed enriched diet used for feeding of pigs.

Table 3. Changes in content of stearic, linoleic and omega fatty acids in pigs *M. longissimus dorsi* muscle after roasting

		Fatty acids (% ot total lipids)			
		Stearic acid	Linoleic acid	*n-6*	*n-3*
Control diet	Fresh	7.33 ± 0.19	19.96 ± 0.09	19.96 ± 0.09	2.49 ± 0.17
	Roasted	6.83 ± 0.40	19.61 ± 0.26	19.61 ± 0.26	0.69 ± 0.25
	Mean difference	0.5	0.35	0.35	1.8
	Probability	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$
Experimental diet	Fresh	4.94 ± 0.17	24.22 ± 0.06	24.53 ± 0.12	10.89 ± 0.35
	Roasted	4.85 ± 0.19	24.53 ± 0.12	24.22 ± 0.06	7.21 ± 0.31
	Mean difference	0.09	0.31	0.31	3.68
	Probability	$p > 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$

The results are presented as mean ± SD

After heat treatment, the contents of both fatty acids were lower in control, as well as in experimental samples. The differences were significant ($p < 0.05$) in all cases, except for the stearic acid in samples of meat of pigs fed with experimental diet. Linseed enriched diet positively influenced the content of linoleic acid, and therefore the tenderness of *M. longissimus dorsi* muscle. Previous experiments reported that meat from piglets fed with diet enriched in linseed by adding commercial additives had pleasant color and juicy taste (Okanović *et al.*, 2011).
Roasting of meat caused increase in ω-6/ω-3 as shown in Fig. 1, thus making it less desirable and suitable for human consumption.

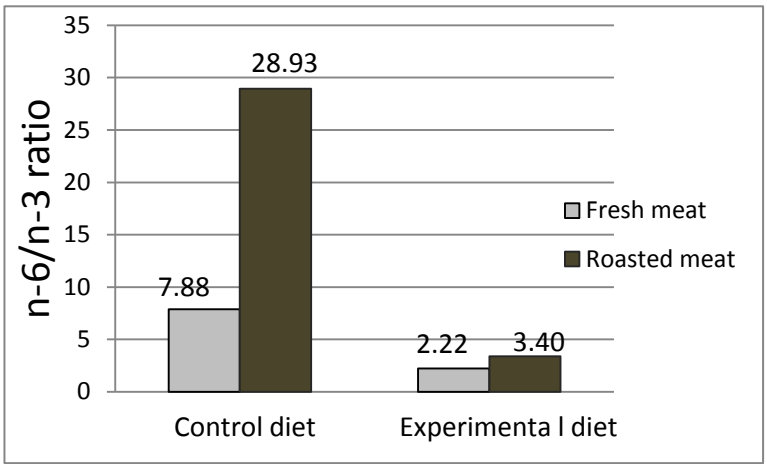

Fig. 1. n-6/ n-3 ration in *M. longissimus dorsi* muscle before and after roasting

Positive effect of linseed diet is reflected in the fact that increase of ω6/ω3 ratio was statistically significant ($p < 0.01$) only for meat samples of pigs fed with control diet. The content of ω-3 fatty acids in control samples was notably low even before roasting, and the heat treatment decreased it below the content of 1%.

CONCLUSION

Presented results have proven that addition of linseed in diet for pigs has multiple benefits considering healthy, nutritional and sensory characteristics of pig meat. Therefore, use of linseed enriched diet in pig feed can be recommended for obtaining meat with desirable fatty acid composition. Enhanced fatty acid composition of fresh meat provides better quality of heat treated meat from the lipid nutrition standpoint.

ABSTRACT: Considering the world demographic situation, especially **t**he role of nutritional factors in the pathological aging process, geronto-dietetics has become an independent branch of science. However, food assortments for elderly people are currently insufficient in diversity and amount. Geronto-dietetics production is based on increase in useful substances to the level consistent with physiological consumption rates of the elderly (15-50% of daily requirement). The study of senescence discovers the symptoms of aging which reveal age-related changes in functional systems. For over 100 years the scientists have known about the connection between aging and the state of thyroid gland. The physicians diagnose elderly hypothyreosis at 99%. To prevent hypothyreosis in the elderly one should improve iodine and selenium deficit by increasing food share containing fruit and vegetable sources of selenium and antioxidant vitamins.
Key words: *geronto-dietetics, smoothie, system approach, appetite, elderly, nutritional correction*

INTRODUCTION

Modern ideas about creating new generations of geronto-dietetical foods can be classified as follows: first – nutritionally balanced meals which completely correspond to physiological needs of the elderly; second – food products for dietary correction of nutrition (this area implies processing of foods enriched with one or more ingredienta); third – nutrient premixes which can correct a meal or a daily intake; fourth – producing foods enriched with biologically active components which fortify definite nutritive properties of a product (this category of foods is widespread in economically developed countries); fifth – foods which conduce to prevention of hypothyreosis development (Yudina S.B., 2009).
The necessity of producing such food products is based on the special dietary requirements of elderly people and focuses on specialized nutrition support.
When producing foods for the elderly it is quite challenging to achieve chemical equilibrium only at the expense of their natural reserves. The most promising solution to the problem is to achieve the benefits of several areas simultaneously (Petrov A.N. at al., 2009).
Clinical and physiological studies of human bodies as they age have discovered a number of aging symptoms which reveal age-related changes in functional systems. For over 100 years the scientists have been aware of the connection between aging and the state of thyroid gland. The physicians diagnose elderly hypothyreosis prevalence at 99% (Culicova V.V., 2007)**.** Hypothyreosis or hypofunction of thyroid gland is the disease associated with insufficient supply of organs and tissues with hormones of thyroid gland. Primary hypothyreosis starts because of congenital anomalies of thyroid gland, inflammation due to infectional processes, as complication after surgical operations and radioactive iodine therapy, and as a result of lack of iodine in the environment. The main symptoms of primary hypothyreosis are: weakness, inertia, excessive sleepiness, memory degradation, indifference, absence of interest to surroundings, decrease of capacity for work. The patients suffering from hypothyreosis have inhibited speech, diminished hearing, low hoarse voice. They are lethargic, eye expression is indifferent. Typical symptom of hypothyreosis is edema

of hypodermic cellular tissue which has its own peculiarity: pressing edematous tissues does not leave any fossula (Fadeev V.V., 2004).
The phenomenon is stipulated by complicated disfunctioning of numerous regulation systems of the body which are influenced by a complex of social and economic factors. Only for the last few decades this problem has got a lot of attention in the aspect of pharmacological correction, quite less in applying healthy diet for disease prevention.
To prevent hypothyreosis development in the elderly, besides obligatory pharmacological correction, iodine and selenium deficit should be improved by increasing food share containing fruit and vegetable sources of selenium and antioxidant vitamins, and also hydrobionts which are sources of iodine.

MATERIAL AND METHODS

The ingredients which contain dietary fibers, crucial vitamins and microelements (banana, orange, bilberry, sweet cherry, celery, carrot, sweet pepper, parsley), particularly ground seeds (ground pumpkin seeds, ground flax seeds, ground milk thistle seeds) and non-traditional vegetable oils, have been selected to engineer a smoothie with a polynutrient composition – a gerodietical product.
Swelling analyses of ground milk thistle seeds in tomato juice and ground flax seeds in kefir have been carried out at 18 °C and hydro modules (HM) 1:10, 1:15, 1:20. The mass of functional raw materials used in the experiment is 1.0 g. The swelling index has been estimated for 2 hours. The swelling rate analysis of ground flax seeds in kefir have been carried out on the same conditions as for ground milk thistle seeds in tomato juice.
The viscosity analyses of a “banana – orange” fruit purée with ground pumpkin seeds and a “banana – bilberry – sweet cherry” fruit purée with ground milk thistle seeds being added have been carried out for the samples with ground seeds content of 2…10%.

RESULTS AND DISCUSSION

The aim of the present study is to analyze process variables of ground seeds and model systems “fruit or vegetable purée – ground seeds” for engineering the technology of definite assignment smoothie production.
The ground seeds have already proved to be the nutritional ingredients which enrich foods with minerals, vitamins, dietary fibers, polyunsaturated fatty acids, microelements (zinc, chromium, manganese, selenium) and prevent diseases development.
The chemical compositions of five different ground seeds items produced by Scientific and Production Company “Zhytomyrbioprodukt” have been studied in the experimental laboratory at Ukrainian Institute of Livestock Breeding of the Steppe Regions. According to the obtained results, the ground seeds which contain the highest cellulose content, antioxidant vitamins and mineral substances are ground milk thistle seeds, ground flax seeds, and ground pumpkin ones. They have been selected for further studies.
Swelling indices of ground seeds and viscosity of model systems “ fruit or vegetable purée – ground seeds” have been analyzed to substantiate technological characteristics of swelling. Swelling of vegetable polysaccharides depends on the nature of a solution. According to the food intake monitoring, there is deficiency in vitamin A1, β-Carotene, and calcium in elderly diet. Because of this cultured milk food (kefir) and tomato juice have been used to dissolve vegetable smoothies.
Figure 1 reflects the data which show that the swelling speed of the mixture “milk thistle seeds and tomato juice” has been remaining intensive for 45-60 minutes and comprises 550-560% ground seeds weight per a sample at HM 1:10, 558-570% at HM 1:15, and 563-578 % at HM 1:20 accordingly. The swelling speed of the mixture “ground flax seeds and kefir” (the analysis has been carried out at 18 °C) has been remaining intensive for 45-60 minutes and comprises 710-715 % ground seeds weight per a sample at HM 1:10, 725-730 % at HM 1:15, and 740-745 % at HM accordingly (Figure 2). According to our study, when swelling

ground flax seeds keep moisture twice as much as ground milk thistle seeds and three times as much as ground pumpkin seeds do.

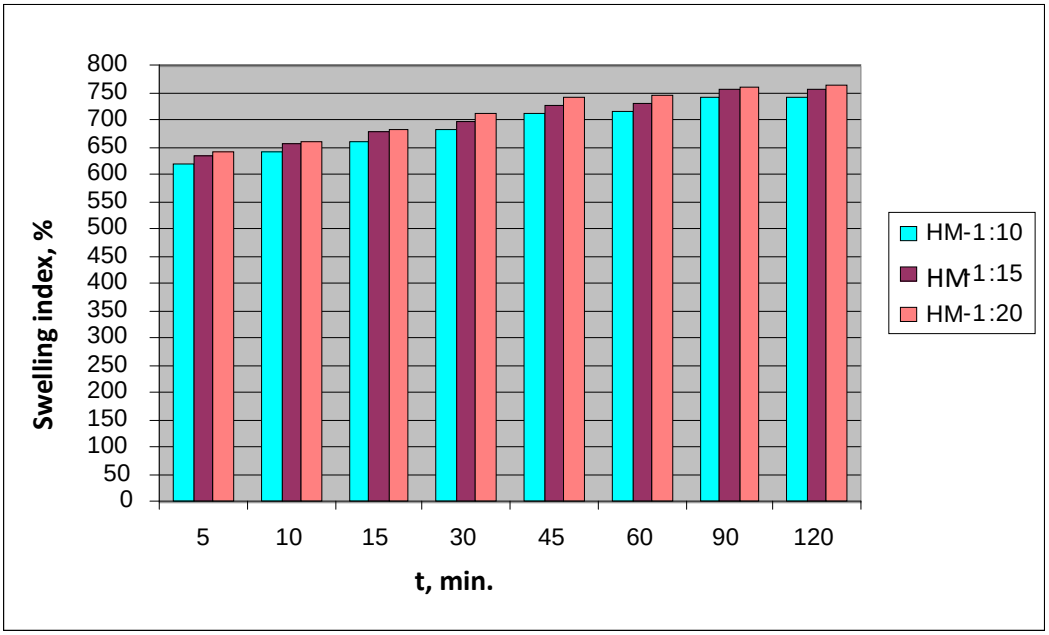

Figure 1. Dependence of swelling index of ground milk thistle seeds in tomato juice on hydro module and time

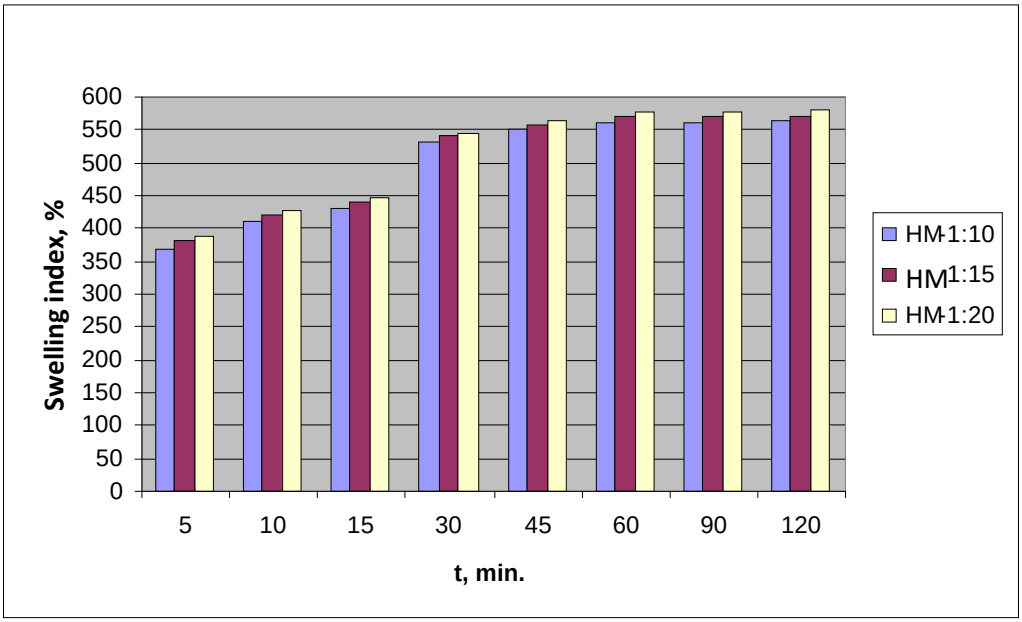

Figure 2. Dependence of swelling index of ground flax seeds kefir on hydro module and **time**

The swelling process stopped after 45-55 minutes. After this time the swollen ground seeds didn't practically change their weight.

According to the results, the most optimal viscosity of model systems is that with 2% ground pumpkin seeds and 4% ground milk thistle seeds.

The results of viscosity studies of "banana – orange – ground pumpkin seeds" mixture and "sweet cherry – bilberry – banana – ground milk thistle seeds" mixtures which contain 2…10% ground seeds are in Fig. 3 and Fig. 4. According to the obtained results, the most

optimal viscosity of model systems is that with 2% ground pumpkin seeds and 4% ground milk thistle seeds. When being defrosted cherries and bilberries exudes enough liquid to make cellulose ground milk thistle seeds swell without worsening thickness and taste properties of a smoothie.

The results of viscosity studies of "celery – carrot" and "carrot – sweet pepper – parsley" vegetable purées with ground flax seeds and with the addition of ground milk thistle seeds have been carried out for the samples with a ground seeds concentration of 2%. The obtained data show that viscosity of a swelling mixture (at 18°C) changes intensively. Then the process is slower but the densest systems are formed by model mixtures which contain ground milk thistle seeds from 6% to 10%. It means that increases in viscosity of vegetable model systems with ground milk thistle seeds and ground flax seeds have the same tendency. Dense systems form model mixtures which contain ground seeds from 6% to 10%.

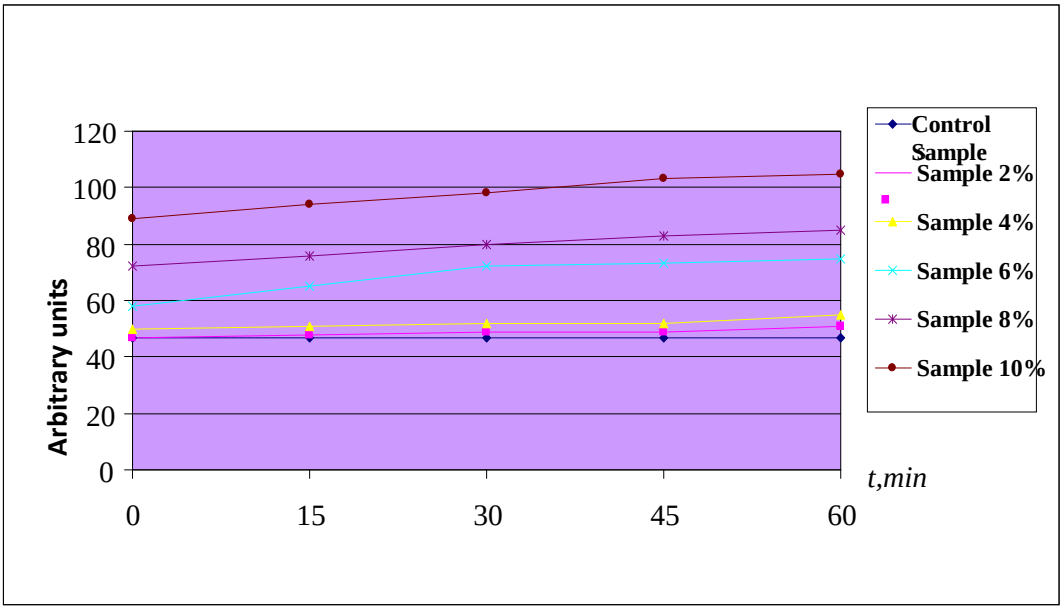

Figure 3. Viscosity analysis of a "banana – orange" fruit purée with ground pumpkin seeds dependent on time for swelling

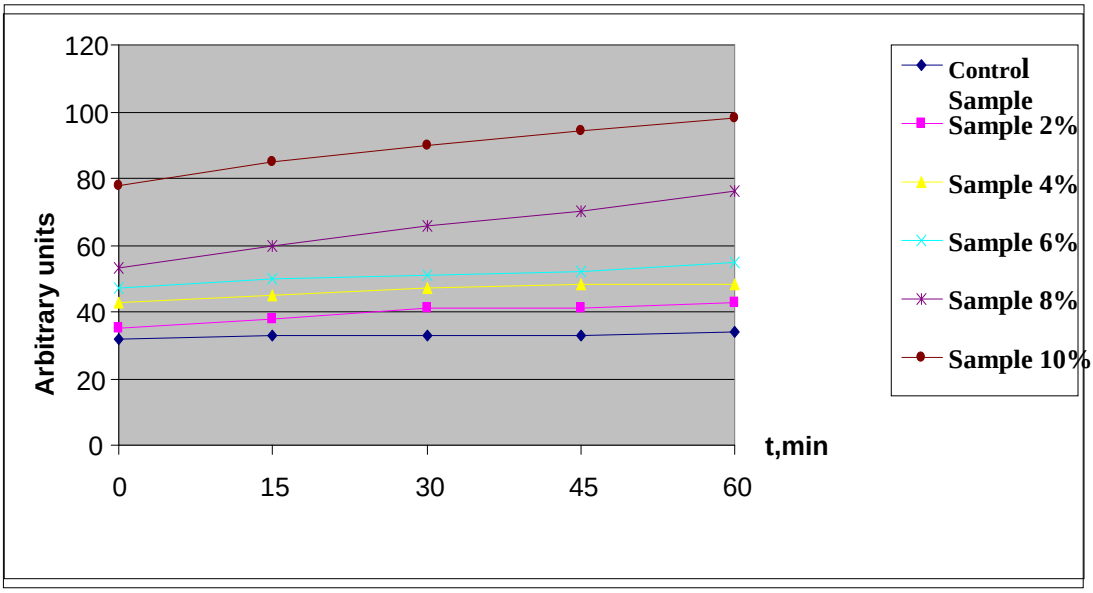

Figure 4. Viscosity analysis of a "banana – bilberry – sweet cherry" fruit purée with ground milk thistle seeds dependent on time for swelling

A system approach to smoothie making technology is represented as an integral system within which fundamental systems – C_1, C_2 and subsystems A, B are singled out. Their functioning is aimed at obtaining the initial result of system operation – engineering gerodietetical smoothies. (Fig. 5).

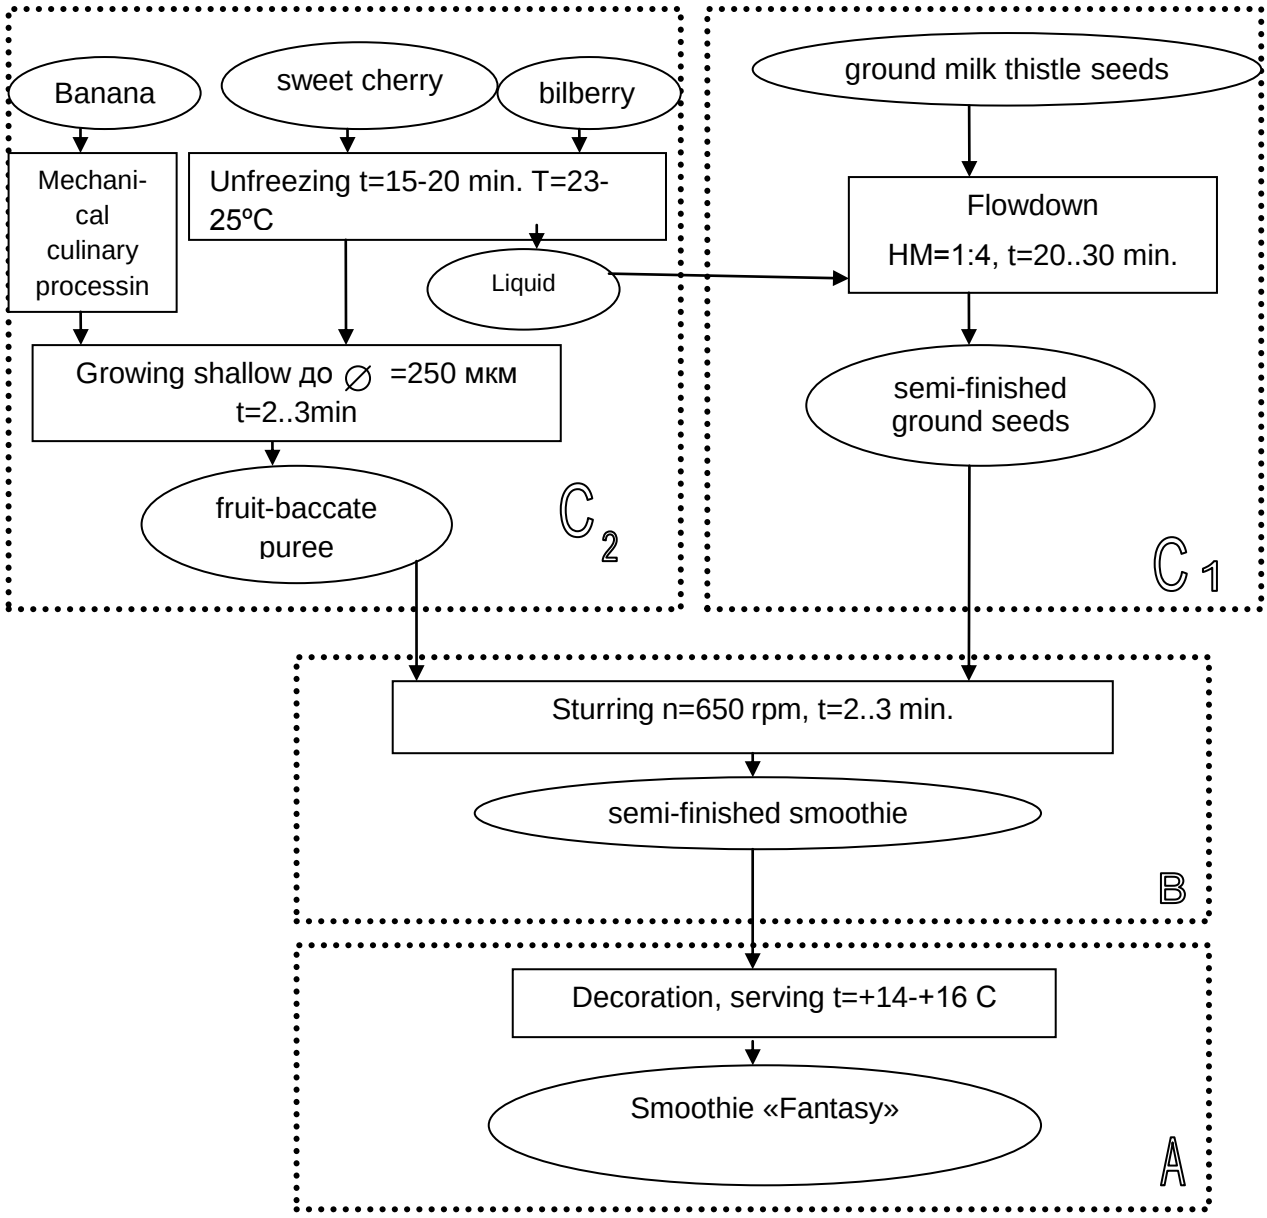

Figure 5. Engineering scheme of Vegetable Smoothie «Fantasy»

CONCLUSIONS

The vegetable, fruit and berry geronto-dietetical smoothie production has been engineered to prevent nutritive hypothyreosis in elderly.The smoothie-gerodietical processing has been designed and engineered on a system approach. The smoothie products which have been studied provide an elderly organism with 40…80% minerals, dietary fibers, and antioxidant vitamins of daily requirement and help it improve.

ABSTRACT: Spray drying is an appropriate process for heat sensitive products such as fruit juices rich in polyphenols. However, because of the high sugar content, fruit juices are difficult to dry without carriers and are affected by different drying parameters. Therefore, the influence of two types of malt dextrin (MD) (4-7 dextrose equivalent and 13-17 dextrose equivalent) added in different concentrations (30%, 35% and 40% (w/v)) and inlet air temperature (160, 170 and 180 °C) on total phenols (TP) and antioxidant activity (AOA) of spray-dried sour cherry Marasca juice was studied. Type of malt dextrin used as carrier agent significantly affected the TP content which was higher when using MD 13-17 DE, while there was no significant influence on AOA of powders. The highest TP content was determined in powders with lower concentration of carrier agent, although using MD 13-17 DE in concentration of 35 % resulted in higher content of TP then at concentration of 30 and 40%. Temperature of 160 °C was found to be optimal for spray drying of sour cherry Marasca juice. All studied parameters affected significantly TP content and AOA of sour cherry Marasca powders. The highest content of phenolic compounds was determined in powders obtained using 35 % of MD 13-17 DE at inlet air temperature of 160 °C.
Key words: *sour cherry Marasca, spray-drying, juice powder, total phenols, antioxidant activity*

INTRODUCTION

Sour cherry Marasca (*Prunus cerasus* var. Marasca) is a Croatian autochthonous cultivar characterized with high content of dry matter and sugars, dark red colour and intensive sweet-bitter aroma. It is a very rich source of biologically active compounds, especially anthocyanins which are responsible for its colour. Nevertheless, Marasca cherry contains high concentration of colourless polyphenols which together with anthocyanins contribute to its high antioxidant activity. Due to its high biological value, sour cherry Marasca presents valuable fruit for processing into functional food products.

Spray-drying is a suitable process for drying of heat sensitive products, such as fruit juices rich in biologically active compounds. Spray dryer uses hot air as drying medium which enables the application of high temperatures because of their rapid decrease caused by water evaporation from the product being dried. Therefore, the drying process lasts for a short time, enabling the preservation of valuable compounds present in fruit powders. (Mani et al., 2002). However, fruit powders are natural thermoplastic and hygroscopic properties of fruit juices give rise to problems during the process such as stickiness, caking, etc. (Chegini and Ghobadian, 2007). The stickiness problem is attributed to low molecular weight sugars such as fructose, glucose and sucrose and organic acids such as citric, malic and tartaric acid which constitute more than 90% of the solids in fruit juices (Bhandari et al.,1997). These materials have low glass temperature (Tg) and therefore, are very hygroscopic in amorphous state and loose free flowing nature at high moisture content (Roos and Karel, 1991). Because of the above mentioned, the use of carriers is necessary in order to obtain the free flowing fruit powder, as carrier materials reduce the hygroscopicy by increasing the Tg. Malt dextrin is nowadays one of the common used carriers because of its reasonable price and availableness. Furthermore, it has a beneficial role of an encapsulating agent, increasing the stability of biologically active compounds.

The aim of this study was to study the influence of malt dextrin type, concentration and drying temperature on the content of total phenols and antioxidant activity of sour cherry Marasca juice powders.

MATERIAL AND METHODS

Sour cherry Marasca concentrated juice, produced in 2011, was purchased from "Marasca" factory, Zadar, Croatia. Concentrated juice (65 °Brix) was diluted to 15 °Brix with distilled water. Juice was mixed with malt dextrin (MD) 4-7 DE and 13-17 DE (Sigma Aldrich) added in different concentrations, namely 30, 35 and 40 % (w/v).
Spray drying experiments were conducted on a laboratory scale spray-dryer SD-06A (Labplant, UK) with 1 mm spray nozzle at constant feed rate and air flow, varying the inlet temperature (140 °C, 160 °C, 180 °C). Obtained powders were collected and stored in silica-gel containing desiccators before extraction.
Phenols were extracted from 5 g ± 0.001 powder with 20 mL of 80% aqueous methanol solution containing 0.1 % HCl, in water bath at 60 °C for 20 minutes. Afterwards, extracts were filtered through Whatman No. 40 filter paper (Whatman International Ltd., Kent, UK), transferred in 25 mL volumetric flasks, made up with solvent and used for total phenols and antioxidant activity determinations. All extractions were carried out in duplicate.
Total phenols (TP) were determined by Folin-Ciocalteu method, according to the procedure of Ough and Amarine (1980) with some modifications. The aliquots (250μL) of each extract were added to 25 mL volumetric flasks followed by addition of 15 mL of distilled water, 1.25 mL of Folin-Ciocalteu reagent and 3.75 mL of saturated sodium carbonate and were made up to 25 mL with extraction solvent. The absorbance at 765 nm was measured after tempering for 30 minutes in water bath at 50 ºC. All determinations were carried out in duplicate. The TP content was calculated according to the gallic acid standard calibration curve and expressed as mg of gallic acid equivalents (GAE) per 100 g of powder ± standard deviation (SD).
Antioxidant activity (AOA) was determined using FRAP method as described by Benzie and Strain (1996). Absorbance was measured at 593 nm. All determinations were carried out in duplicate. Results are expressed as mean values mmol of Trolox equivalents (TE) per 100 g of powder.
Analysis of variance (ANOVA) was carried out to determine any significant differences ($p<0.5$) among the applied temperatures, used malt dextrin and their concentrations. The data were analysed using Statistica v. 9 (Statsoft Inc, Tulsa, OK, USA).

RESULTS AND DISCUSSION

The results of TP determination in obtained sour cherry Marasca powders are shown in Table 1. The amount of TP varied from 276.14 mg GAE/100 g in powder produced with 35% MD 4-7 DE at 180 °C to 467.27 mg GAE/100 g in powder produced with 35% MD 13-17 DE at 180 °C. As it can be observed from the results, powders produced with MD 13-17 DE contained significantly higher amount of TP, than those produced with MD 4-7 DE. Statistical analysis also confirmed significant influence ($p<0.05$) of MD type on the content of TP (Table 2.). A malt dextrins characterization study published by Raja et al. (2006) showed that malt dextrins with dextrose equivalent between 10 and 20 fit in the best for use as carriers. Although there was no significant influence of MD concentration and temperature on TP content, it can be seen, that use of higher concentrations of MD 13-17 DE resulted in higher TP content, especially with concentration of 35 %. This can be explained wit role of MD as encapsulating agent, protecting the sensitive ingredients against degradation (Bakowska-Barczak and Kolodziejczyk, 2011). Temperature between 140 and 180 °C did not affect significantly the TP content, although the higest concentrations wer obtained at 160 °C. Kha et al. (2010) also reported that there was no significant difference between temperatures of 140 and 160 °C, and between 160 and 180 °C. The lack of significance may be due to the

drying mechanism during the process. The liquid feed is atomized into a fine droplets in hot air stream, so during the drying step, water evaporation has a cooling effect during the critical drying period. Furthermore, because of the short time of exposure to the high temperatures, sensitive materials are preserved in higher rate when compared to the other drying methods.

Table 1. Total phenols in sour cherry Marasca powders, spray-dried with different carriers added in different concentrations, at three different inlet temperatures

	Source of variation	F_{exp}	p-value
Total phenols	MD type	8,273	0,014*
	MD concentration	0,199	0,822
	Temperature	0,383	0,689
Antioxidant activity	MD type	0,873	0,369
	MD concentration	5,069	0,025*
	Temperature	5,783	0,017*

**Results are expressed as mean (n=4) ± standard deviation*

Table 2. Influence of malt dextrin type, concentration and inlet temperature on total phenols and antioxidant activity os sour cherry Marasca powders

Maltdextrin	Concentration %	Temperature °C	TP mg GAE/100 g*
4-7 DE	30	140	360.35 ± 0.75
		160	387.18 ± 0.69
		180	354.72 ± 0.89
	35	140	365.10 ± 0.67
		160	371.52 ± 0.96
		180	276.14 ± 0.54
	40	140	361.00 ± 0.95
		160	356.11 ± 0.63
		180	359.90 ± 0.51
13-17 DE	30	140	335.43 ± 0.74
		160	454.09 ± 0.69
		180	399.88 ± 0.88
	35	140	366.31 ± 0.61
		160	449.38 ± 0.98
		180	467.27 ± 0.72
	40	140	417.27 ± 0.65
		160	429.09 ± 0.77
		180	376.71 ± 0.85

** Significant differences obtained at p<0.05*

Results of AOA determination are shown on Figure 1. Contrary to TP, AOA of obtained powders was significantly influenced by temperature and concentration of added MD, while MD type did not have influence (Table 2.). AOA was higher in powders produced with the lowest concentration of MD (30 %), because those powders had the highest content of fruit solids in total mass. The temperature effect was similar to the one in the TP content, so temperature of 160 °C was the optimal for production of sour cherry Marasca powders with the highest AOA.

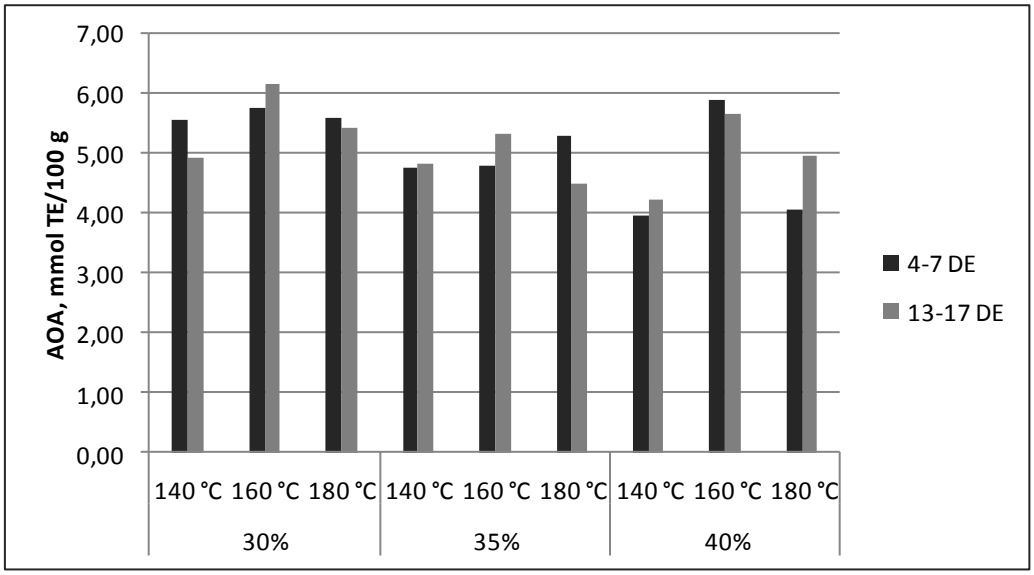

Figure 1. Antioxidant activity (AOA) in sour cherry Marasca powders produced with different carriers added in different concentrations, at three different inlet temperatures

CONCLUSIONS

Type of used malt dextrin significantly affected the total phenolic content of sour cherry Marasca powders, while concentration of added malt dextrin and inlet temperature had significant effect on antioxidant activity. AOA was higher in powders produced with lower concentrations of MD at 160 °C. The highest concentration of total phenols was determined in powder produced with 35 % of MD 13-17 DE at 160 °C.

ACKNOWLEDGMENTS

This paper is a result of the research within the IPA III C project “Marasca Sour Cherry (Prunus cerasus var. Marasca) as an Ingredient for Functional Food”, financed by the European Union.

ABSTRACT: This study determined that the juice of pumpkin, carrot, celery root, parsley, Jerusalem artichoke, and also corn extrudates with their use possess bifidogenic properties. The results indicate that from all types of grain a most bifidogenic effect is possessed by grain of corn after extruding.
Key words: *bifidobacteria, cereal foods, pumpkin, carrot, celery root, parsley, Jerusalem artichoke, bifidogenic factors.*

INTRODUCTION

As early as 2002, Milner (2002) forecasted, that in the coming decades the stake of functional foods could make about 30% of all the food market and could replace many traditional medicinal preparations by 35-50%. Today specialized departments of most food supermarkets sell functional foods. The level of consumption of such products has grown substantially, especially in countries with a developed economy. Depending on the method of receipt, most functional foods are from two basic groups: products from sour-milk and from corn. The corn products such as quick-cooking dry breakfasts, obtained by extrusion, are most common.

The utility of the extruded corn products is not only in higher nutritional value but in a prebiotic effect, which strengthens growth of bifidobacteria (Otles and Cagindi, 2006). Prebiotic properties give food stuffs by creation of effective compositions or by the special technological ways. It acquires large popularity among the producers of products of the functional foods (Ohr, 2004).

Bifidoflora is the basic group of bacteria of the human alimentary tract (Ishibashi et al., 1997). In the organism of a healthy man, the basis of microbiota composition of large intestine is made by bifidobacteria, although in course of time, and also at different diseases the amount of bifidobacteria sharply diminishes and increases the risk of disease disbacterioses (Mitsuoka, 1990). Support of the development of bifidobacteria by the prebiotic factors of basic food stuffs is an important stage of prevention of different diseases. Bifidobacteria produce bioactive substances that regulate many functions of organisms: the work of human gastrointestinal tract, metabolic processes, the work of liver, heart vascular system, blood producing organs, cholesterol reduction, anticancer activity and other health benefits. They promote a vitamin production function – take part in synthesis and suction of vitamins of group B, folic and nicotine acids, in the synthesis of essential amino acids, the best mastering of ions of calcium, iron, vitamin D, own antianaemic, antirachitis, and another actions (Kantha, 1999).

The application of extrusion opened new prospects of enriching of corn products with bioactive substances, which garden- and green-stuff are rich in. It is allows substantially to extend the assortment of functional products on the basis of the cereals. Above all things such green-stuffs, as carrot, pumpkin, Jerusalem artichoke, celery root, and parsley, deserve attention, because of their bifidogenic properties discovered in previous research investigations by many authors (Masanori and Zenzo, 1971).

The purpose of our research was to determine the effect of extrusion of different cereal grains and green-stuff on bifidogenic properties of cereal extrudates.

MATERIAL AND METHODS

Research of bifidogenic properties of samples was carried out by growing of collection cultures of Bifidobacterium adolescentis, Bifidobacterium bifidum, and Bifidobacterium longum in a corn-lactose nutrition medium (reference). The extracts of green-stuff and finely divided samples of cereal extrudates were added to the culture medium after sterilization. After cultivation for 24 - 48 hours at 37 °C, probiotic strains were inoculated in thioglycolic semi-fluid culture medium. Survival of different probiotic strains was monitored by the standard plate count method. Reference cultures of Bifidobacterium adolescentis, Bifidobacterium bifidum and Bifidobacterium longum were grown using a culture medium, which contained 20% more corn extract than the standard medium.

RESULTS AND DISCUSSION

In the first stage of this investigation bifidogenic properties of the extruded grain without additives were studied (Figure 1).

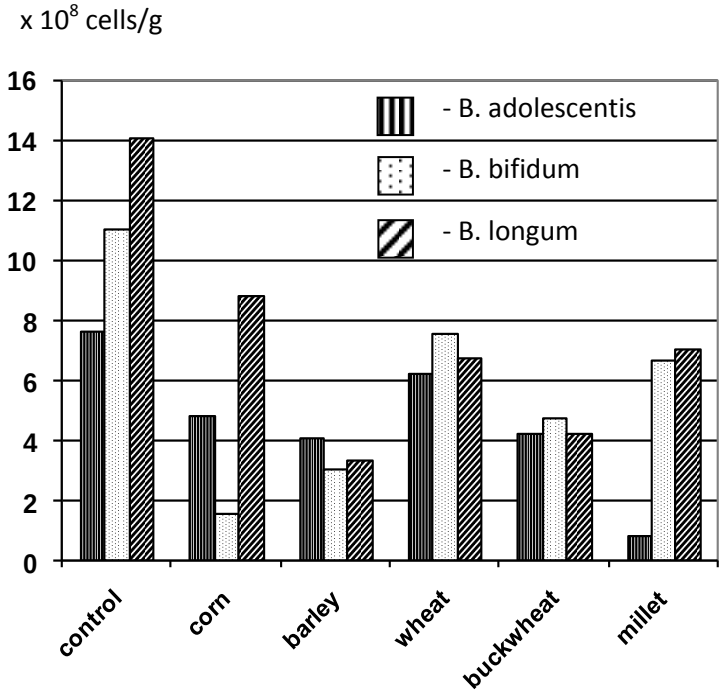

Figure 1.The influence of addition of extruded cereals to a nutrition medium on growth of bifidobacteria

Samples of the extruded corn, barley without a husk, wheat, buckwheat, and millet were added to the nutrition medium. As results in Figure 1 show, none of tested grain samples exceeded the reference. These results indicate that there was insufficient amount of nutrients and bioactive compounds necessary for the successful development and growth of bifidobacteria. There was a different intensity of growth of cultures of B. adolescentis, B. bifidum B. longum with the same composition of the nutrition medium. It is important to note that B. longum grew the best of all bifidobacteria in the controlled culture broth and also after addition of the extruded corn grain the culture broth. By adding of extruded buckwheat to the nutrition medium, as well as wheat and barley without husks, a difference in intensity of cultures growth of Bifidobacterium group was not observed.

The lowest results were marked at adding to the nutrition medium of the extruded millet at growing of culture of B. adolescentis and the extruded grain of corn at growing of culture of B. bifidum.
The next stage of this work was conducted by adding of extrudates of mixtures of grain and green-stuff to the culture broth. They were obtained by the extrusion of mixture of cleared grain and 10-30 % of the cleared grain and the grounded green-stuff. Results from this stage are presented on the Figure 2.

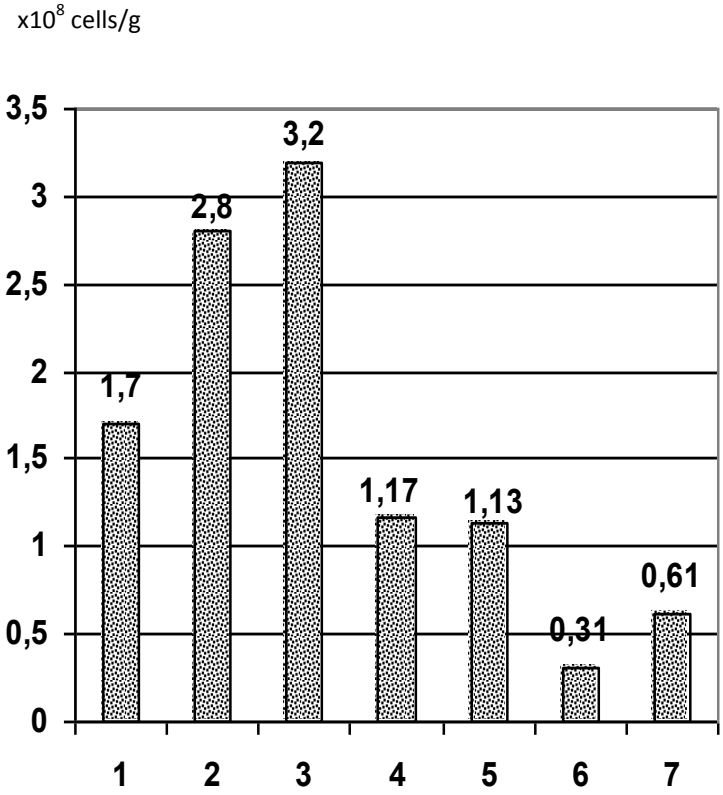

Figure 2. The Influence of addition some products with carrot to a nutrition medium on growth of bifidobacteria: 1- reference; 2- juice of carrot; 3- corn+carrot; 4- barley+carrot; 5- wheat+carrot; 6- buckwheat+carrot; 7- millet+carrot.

Apparently, the addition of 20 % of carrot juice to the nutrition medium increased the amount of B. adolescentis cells by 1.65 times compared to the reference. The addition of the raw carrots to corn resulted in 1.88 fold increase of B. adolescentis cells compared to the reference. In the case of all other combinations of cereals with carrot, the growth of bifidobacteria was slower than in the reference. Similar results were observed in the study with the samples of extruded buckwheat and millet, to which raw carrots were added. They were 5.48 and 2.78 times lower than in the reference, respectively.
Adding pumpkin to grain samples that were subjected to extrusion affected the development of B. adolescentis culture ((Figure 3). The addition of 20 % pumpkin juice to the culture medium resulted in 1.45 fold B. adolescentis growth increase of compared to the reference. The best result was observed by adding extruded mixture of corn grain and pumpkin to the nutrition medium (2.1 times more than reference). Mixing barley and pumpkin during extrusion promoted the growth of B. adolescentis culture in the same way as the reference medium. The lowest results (5.5.and.2.75 times less than reference) were obtained again when pumpkin was mixed with buckwheat or millet, therefore, allowing us to exclude them from subsequent studies.

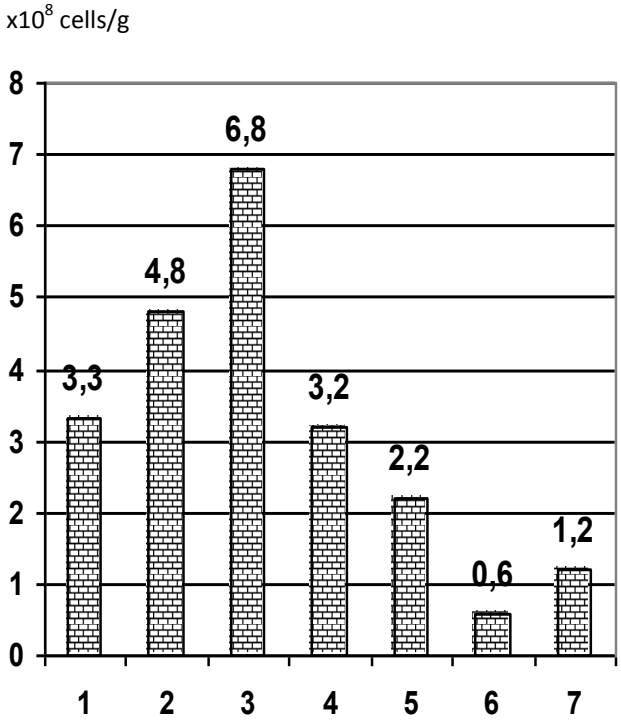

Figure 3.The influence of addition some products with pumpkin to a nutrition medium on growth of bifidobacteria: 1- control; 2- juice of pumpkin; 3- corn+ pumpkin; 4- barley+ pumpkin; 5- wheat+ pumpkin; 6- buckwheat+ pumpkin; 7- millet+ pumpkin

The data in Figure 4 show the results of the effect of celery juice on the growth of bifidobacteria. From the results in Figure 4, it is evident that adding celery root juice to the nutrition medium improved the cells growth of culture of B. adolescentis by 1.72 times in comparison with the reference. A better result was obtained by adding medium samples of the extruded mixture of corn and celery root to the nutrition medium (2.1 times more cells of B.adolescentis than the reference).

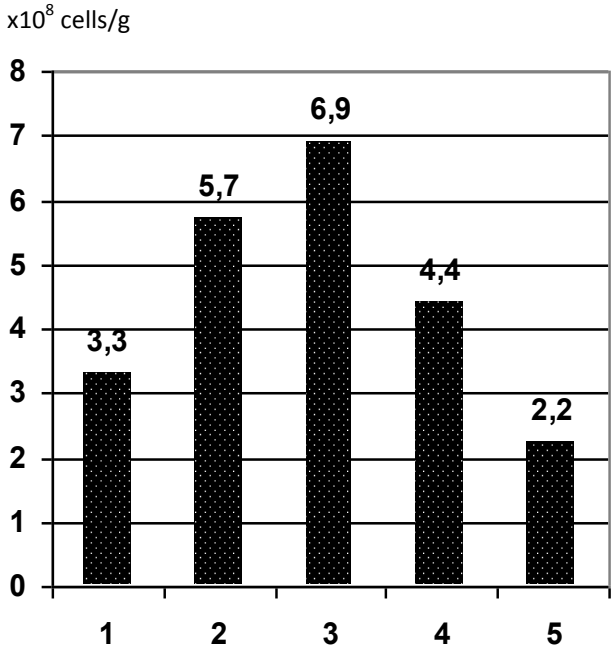

Figure.4. Influence of addition some products with roots of celery to a nutrition medium on growth of bifidobacteria: 1- control; 2- celery juice ; 3- corn+ celery; 4- barley+ celery; 5- wheat+ celery.

A higher number than the reference was also obtained by adding extruded mixture of barley and celery root to the nutrition medium (1.33 times more than the reference). Our previous experiments conducted with extruded mixtures of corn grain, Jerusalem artichoke and/or parsley root suggested that extruding of such mixtures could substantially improve bifidogenic properties of the samples (Figures 5 and 6). For example, by adding extruded mixture of corn and Jerusalem artichoke to the nutrition medium the growth of B. adolescentis culture was 1.86 greater than the reference.

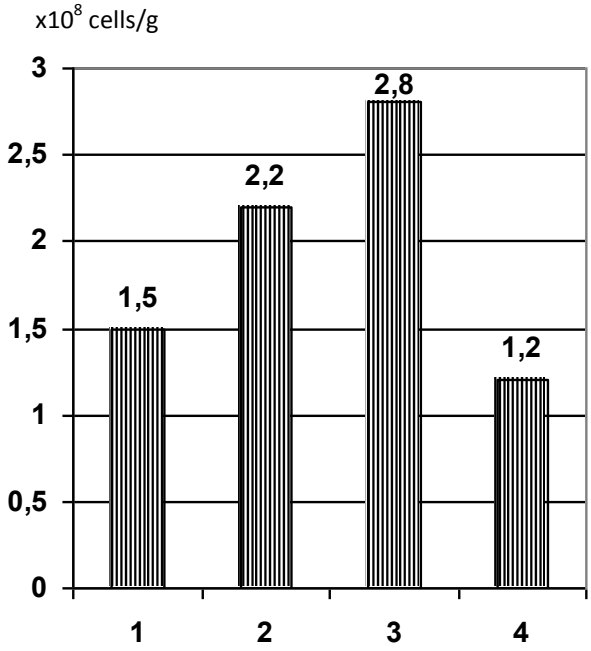

Figure 5. The influence of addition some products with J.artichoke to nutrition medium on growth of bifidobacteria: 1- control; 2- juce of J.artichoke; 3- corn+J.artichoke; 4- barley+ J.artichoke.

The results with parsley root juice alone (Figure 6) confirm its high bifidogenic effect (2.2 times higher than reference). Extruding of parsley root mixed with corn or barley did not have positive effect on the growth of bifidobacteria.

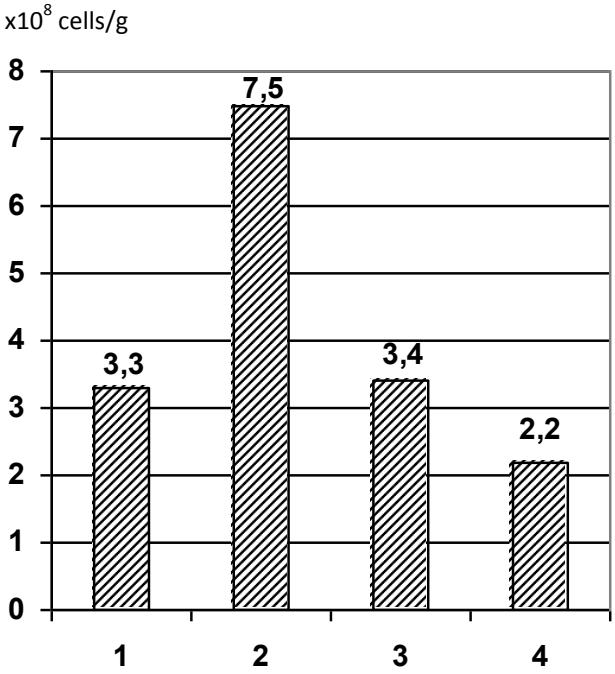

Figure 6. Influence of addition some products with roots of parsley to a nutrient medium on growth of bifidobacteria: 1- control; 2- parsley juice; 3- corn+ parsley; 4- barley+ parsley.

CONCLUSIONS

This investigation demonstrated that extrusion of corn grain and green-stuff could substantially improve of bifidogenic properties of dry corn breakfasts, especially by extruding mixtures of corn with carrots, pumpkin, Jerusalem artichoke, and celery root, as well as, by extruding mixtures of barley and celery root.

ABSTRACT: A model for the development of consumer-oriented properties for new functional foods was developed. This model contains a procedure for the development of a new product and considers the ways to promote a culture of foods consumption as well as consumer development in terms of improved knowledge of nutrition and healthy lifestyle, thus helping a consumer to lay down his requirements accurately and eventually become a full participant in the development of new competitive and high-quality functional food.
Key words: *consumer, consumer properties, model, functional food*

INTRODUCTION

One of the biggest challenges to improve the food patterns of the population is the increase in production of mass-consumption foods of a high nutritional and biological value. Modern food must not only meet the physiological needs of a human body in nutritional, biologically active substances (BAS), and energy, but also to perform preventive functions and, of course, be absolutely safe.
The solution to these problems is possible through the production development of a new generation of foods – functional foods, which meet the requirements and realities of today's life. Ever growing army of supporters of a healthy diet encourages manufacturers to develop a new foods, enriched with vitamins, minerals, dietary fibers, beneficiall bacteria and other nutritional additives. The consumer now believes that "food should not only be delicious, but useful as well" and the statement that was made by Hippocrates some 2.5 thousand years ago "Let food be thy medicine and medicine be thy food" is relevant today more than ever.
Currently, each food producer, which is expecting to take a strong position in the market, should pay great attention to the principles of healthy eating. This is due to the fact that a competition in a food production is very high and the consumer is always making his choice between similar foods. It is simply not enough to produce a new product and introduce a successful advertising campaign, as the product has to offer an extra value that would encourage consumers to buy this particular product. We can say that one of the main principles of modern development of the food industry is the development of new functional foods, contributing to the improvement and preservation of health.
To create a new type of functional food capable of satisfying the customer requirements, it is necessary to develop and produce a food with improved attributes, taking into account all possible factors influencing the consumer while selecting a food. Existing models of development of functional foods are mostly passive, which is complicating the promotion and sale of new foods in the market (Belinskaya S.E., 2010, Minko, E.V. et al, 2005). We have introduced an active model for the development of consumer-oriented properties for new functional foods, which is shown in Figure 1.

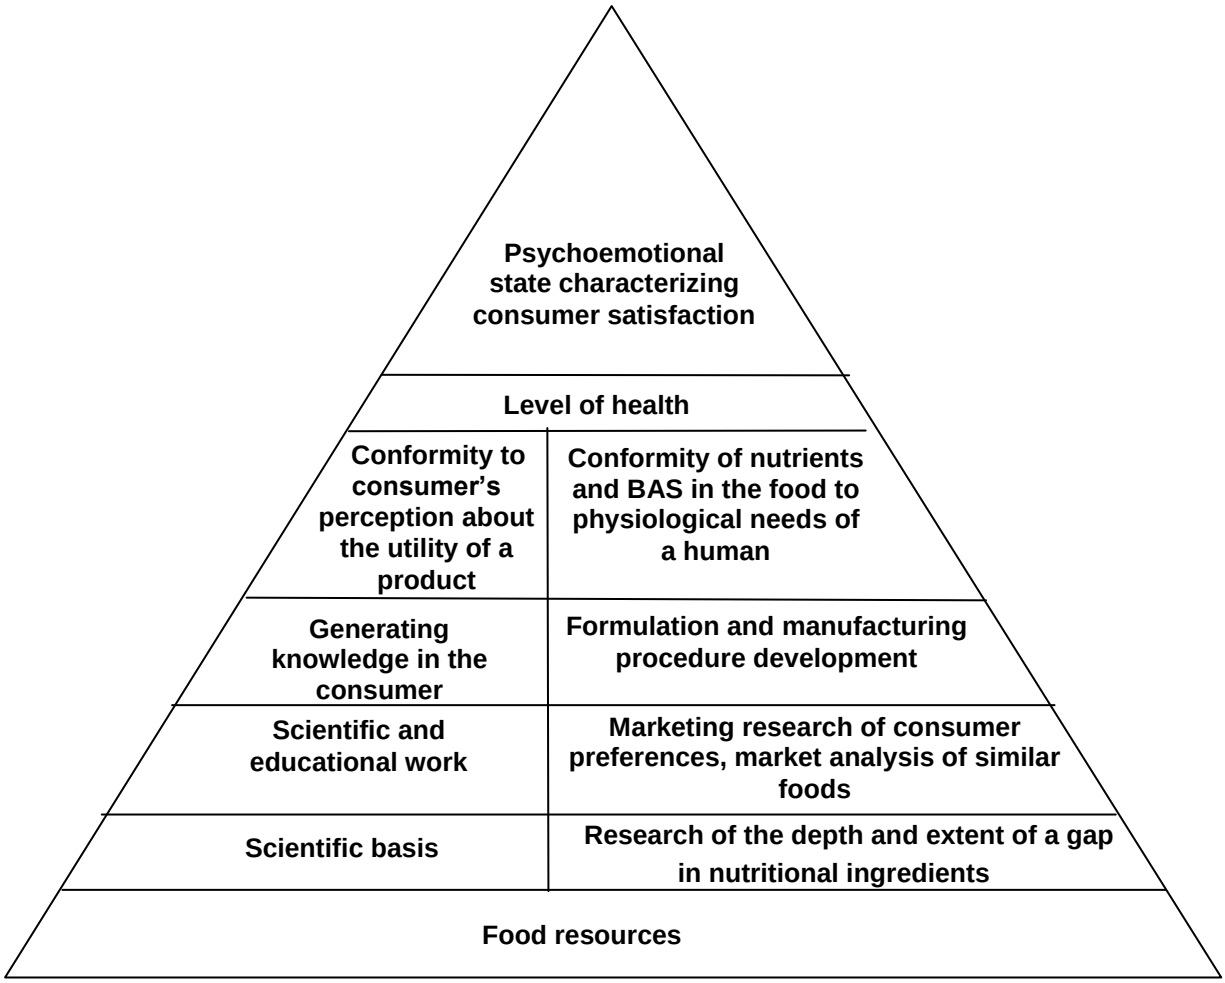

Figure 1. Model for the development of consumer-oriented properties for new functional foods

RESULTS AND DISCUSSION

The basis of the developed model are food resources as the development of functional foods is based on a high quality food economy.

Development of functional foods should start with monitoring the current level of nutrition and health in a population as well as studying the reasons for emersion and extent of shortage of some nutrients. These results are the basis for selecting additional nutrients and BAS, to be introduced into the product, and their amount.

Consideration of the consumer's requirements, desires and behavior is critical to the success of the new food in the food industry (Earl M. et al, 2007). To turn the concept of food into a new product we need a scientific basis in the area of quality of raw materials, enriching additives, manufacturing procedures, physiology of nutrition, "consumer-product" relations, knowledge of marketing, etc. All these disciplines are interconnected as the knowledge of qualitative variables of raw materials effect the knowledge of processing technology. It is important that the developer (producer) considers not only the knowledge in some specific area at the development of a new product but uses a complex approach based on the knowledge obtained from different areas of science. We can say that the development of a product is a knowledge-intensive process and definition of new ideas and concepts requires for a deep knowledge of both the product and the consumer (Earl M. et al, 2010). The consumers may be willing to have a liquid product sold in bottles while the technology may provide for cardboard packaging only, so you need to know how consumers will react to a

cardboard packaging and whether they will accept it at all. The consumer's description of a product may be translated into quantitative indicators which is why it is necessary to know the consumers' requirements for the properties of a product and possess certain methods of measuring those properties. Information like that may be acquired through a marketing research of both existing and potential consumers. This stage is used to define consumer preferences, possible consumption of a new product, and primary and secondary sources of essential nutrients to influence the selection of additives and their amount. If the developer (producer) is focused on the needs of the market, consumers will contribute to the development of a product thus becoming a sort of developers. In the meantime, the developer (producer) performs market analysis of similar existing products and raw materials to determine the manufacturing capabilities of the enterprise in terms of developed goods to establish product requirements, which, if satisfied, will contribute to their sale.

Scientific and educational work among the potential consumers should be provided in order to have a successful promotion and sale of a new type of functional food. This work is supposed to develop knowledge on the dangers and benefits of certain nutrients and BAS as well as their standards of consumption and contents in food raw materials and products among the consumers. Based on this information is the development of the consumers themselves, resulting in a change of their level of knowledge, which influences the decision on whether to buy a product or not. We have created a model for the development of consumer preferences with the consumers, depending on the knowledge they've received. Under this model, the consumers may be subdivided into 3 levels according to their level of knowledge (Figure 2). A consumer with a low level of knowledge is buying a product while

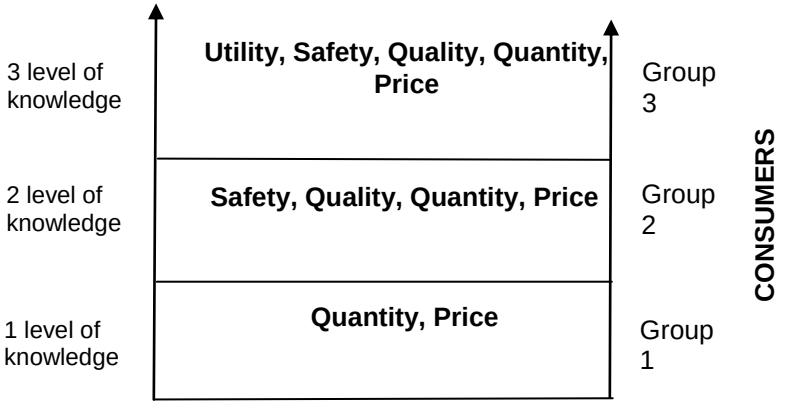

Figure 2 Model for the development of consumer preferences depending on the knowledge they've received

paying major attention to his knowledge on the cost and relying primarily on the material side of the issue, i.e. price, quantity, and their relationship are considered while buying a product.

As the level of consumers' knowledge on nutrition and healthy lifestyle grows, they start to consider the safety and quality of the product besides the price. Consumers with high level of knowledge will turn their attention to functional or organic food, i.e. they'll be primarily concerned with such criteria as utility, quality, natural ingredients, and safety while looking at the cost, quantity, and their relationship after all the others. The result of scientific and educational work among the population is the evolution of consumer in terms of nutrition, healthy lifestyle, and ability to lay down his requirements while ultimately influencing a decision on whether to buy a new product, development of consumer preferences, and consumer demand.

The purpose of pre-production stage in the life cycle of a functional product is to develop a formulation and technology of its production with the subsequent release of pilot batch. This stage is the most important in developing of a functional food as this is when the quality and consumer-oriented properties (including functional) of a new product are shaped, which largely determine its competitiveness and demand with the consumers. Design and development of new formulation for a functional product should provide for assimilability and

effectiveness of enriching additives as well as their safety. The purpose of this stage is to maximize compliance of developed product with the quality requirements.
The second stage in the life cycle of a product is a specific set of actions taken to ensure a production of high quality food and its sale on the market. All activities related to a production of food with improved consumer-oriented properties should be planned at the design stage and provide for an introduction of high-performance management in compliance with ISO, use of modern manufacturing procedure with consideration to operating conditions, high efficiency of equipment handling, quality of personnel performance, etc. (Earl M. et al, 2010). Manufacturing procedure (conventional or modified), apart from providing consistent quality and safety of a product, has to ensure maximum shelf life of enriching additives in the process of production and storage. This stage includes the development and adoption of product manufacturing documentation and obtaining permissions of competent organizations to release the functional product. The release of a pilot batch of the new product and comprehensive quality trade analysis complete the production phase allowing for further steps to be made (manufacturing application). Since the developed product is positioned as a functional product, a biomedical research should be provided to study the preventive qualities of a new product, i.e. determine the suitability of the contents of food and biologically active substances to the physiological needs of a human body.
It is important not only to develop and manufacture a product with improved consumer properties but to keep these properties during product promotion. In this case, the manufacturer should pay particular attention to the use of high-quality packaging material, compliance with the conditions and requirements for transportation, storage and sale of goods.
The last stage in the development of a functional product is to bring a product to the consumer. It is difficult to overestimate the importance of this stage, as all the previous stages are nothing without it. This is because the developer (producer) of food should not only produce the products with improved consumer properties, but to develop and implement all necessary measures to bring a new product to the consumer effectively. Market promotion of functional products has its peculiarities – in this case it is not only about marketing development but the encouragement of people to buy a new product as well, it is about maintaining the health of every citizen, regardless of education, age, social status, etc.
The developed model provides for the consideration of selected system – functional product in its dynamics, thus the logical conclusion of a model would be the monitoring of nutrition and health of population. It allows you to evaluate the effectiveness of the system: if the positive result was reached – reduce the content of enriching additives or increase the content of enriching additives and expand the range of functional foods if the deficiency level of essential nutrients was not changed.
When deciding to buy a product that was produced with consideration to all activities proposed under this model, the consumer gets the product with improved consumer properties. The result – human body is healing and he derives a satisfaction from the purchased product. At the same time, developer (producer) derives satisfaction from developed and manufactured goods as well, while receiving an economic benefit.

CONCLUSIONS

An introduced model for the development of consumer-oriented properties is of an active type. It allows one not only to create a high-quality food product bringing satisfaction to consumer and producer, but, what is more importantly, to establish culture of food consumption, evolution of consumer in terms of nutrition, healthy lifestyle, and ability to lay down his requirements while ultimately influencing the consumer demand that will result in the production of high quality, popular and rival product.

ABSTRACT: The influence of operating parameters on extraction of caffeine and chlorogenic acid from Green coffee beans and Guarana seeds was studied. Extractions were performed using two different processes, conventional extraction with methanol and supercritical fluid extraction (SFE) with carbon dioxide. Conventional extraction was performed with maceration at solvent boiling temperature. SFE was performed with supercritical carbon dioxide on a semi continuous flow apparatus at pressures 200 and 300 bar, and temperatures of 40, 60 and 80 °C. The raw material, residual material and the extracts were analysed on caffeine and chlorogenic acid content using HPLC method. With conventional extraction both, caffeine and chlorogenic acid, were concentrated in the extract while by SFE with CO_2, the caffeine was concentrated in extract and chlorogenic acid was concentrated in the residual material. The highest total extraction yield in case of Green coffee beans was obtained at 300 bar and 80 °C and it was 13.8 wt.% and in case of Guarana it was 3.63 wt.%. The content of caffeine from Green coffee beans was the highest at 200 bar and 60 °C where the extract contained 13.44 mg of caffeine/g material and decreases with higher pressure. The content of caffeine from Guarana seeds was the highest at 300 bar and 80°C where the extract contained 9.97 mg of caffeine/g material. The results were compared with those obtained using conventional extraction with methanol where both, caffeine and chlorogenic acid were extracted.
Key words: *extraction, green coffee beans, guarana seeds, caffeine, chlorogenic acid*

INTRODUCTION

Among natural sources of caffeine, including cocoa beans (0.2 wt.%), tea leaves (1.5 – 2.5 wt.%) and coffee beans (0.9 – 2.4 wt.%), guarana seeds are likely the richest vegetable source of caffeine (3 – 6 wt.%) (1). Green coffee beans (*Coffea Arabica*) are raw, unroasted coffee beans with content of caffeine up to 2.4 wt. %. Beside caffeine, green coffee beans also contain nicotinic acid, some proteins, polysaccharides, trigonelline, chlorogenic acid, etc. Roasting is a complex process that causes thermal degradation mainly of chlorogenic acid and trigonelline to phenolic substances. According to literature, during roasting about 30 wt. % of caffeine was lost and the degradation of trigonelline and chlorogenic acid was up to 83 and 95 wt. %, respectively (2). Guarana (*Paullinia cupana*, Sapindaceae) is a Brasilian native plant. Guarana seeds also contain theophylline and theobromine, catechins, proanthocyanidins, phenolic acids, nicotinic acid, taninns and many other components. Because of that, guarana seed extracts are mainly used in concentrates and soft drinks and as ingredients of a variety of pharmaceutical products (3).
The removal of caffeine is usually achieved with organic solvents (as methylene chloride) or with hot water and both can be environmentally harmful. Alternative process is supercritical fluid decaffeination. Supercritical extraction of caffeine from green coffee beans results in undamaged beans, no solvent residue and no colour or flavour losses (4). Supercritical fluid extraction of guarana seeds has been reported by several authors where supercritical CO_2 was used as solvent for decaffeination of seeds (1,3,5). For the process of decaffeination authors were using wet seeds, where the extraction allowed the removal of up to 98 % of initial caffeine content. Extraction of dry seeds is exceedingly slow, as can be also found in this work. Chlorogenic acid was extracted and purificated using organic solvents from plant materials such as coffee beans, apple, potato and other (6).

The aim of this work was to investigate the influence of operating parameters on conventional and supercritical fluid extraction of caffeine and chlorogenic acid from Green coffee beans and Guarana seeds. Supercritical fluid extraction was performed with supercritical carbon dioxide on a semi continuous flow apparatus at pressures 200 and 300 bar, and temperatures of 40, 60 and 80 °C. The constant flow rate of carbon dioxide in range from 0.06 to 0.1 kg/h was maintained during extraction. The raw material, residual material and the extracts were analysed on caffeine and chlorogenic acid content using HPLC method. The results were compared with those obtained using conventional extraction with methanol.

METHODS AND MATERIALS

Material

Solvents for extraction and analysis procedure were purchased from Merck (Darmstadt, Germany). Standard of caffeine (purity 99 %, Cat.No. 2760) was supplied from Fluka (Germany) and chlorogenic acid (purity 99 %, Cat. No. C3878) from Sigma-Aldrich (USA). CO_2 (2.5) was supplied by Messer (Ruše, Slovenia). Seeds from guarana (*Paullinia cupana*, Sapindaceae) and green coffee beans (*Coffea Arabica*) were purchased from a local market.

Analysis

Components in raw material and in extracts were analysed using HPLC analytical methods. For the quantitative determination of chlorogenic acid, HPLC apparatus used was composed of Agilent 1100 Quaternary HPLC pump and Agilent 1100 DAD detector. The column Kromasil C-18 (250 x 4.6 mm, with 5 µm particles) was used. The method was isocratic using 50 mM phosphatic buffer pH 4 /methanol (90/10 v/v) as mobile phase with flow rate 1 mL/min. Extracts were diluted in methanol and analysed at wavelength 314 nm. The same HPLC system was used for quantification of caffeine at 274 nm. The mobile phase water / methanol / acetic acid (5.75/4/0.25 v/v/v) was pumped through Zorbax C-18 (150 x 4.6 mm, with 5 µm particles) column with flow rate 0.5 mL/min. Determination of components in raw material and in residue was performed with extraction procedure at 40°C for 2 h using 1 g of material and 50 mL of methanol. After extraction, the mixture was filtered through 0.45 µm Teflon membrane filter and analysed. The results of analysis were expressed as content of compound per mass of material (Eq. 2).
Each data point represents the average of at least three measurements and the relative standard deviation between measurements was less than 1 %.

Calculations

The results of extraction procedures and analysis were calculated as:

$$extraction\ yield\ (wt.\%) = \frac{m_{extract}\,(g)}{m_{material}\,(g)} \cdot 100 \quad (1)$$

$$content\ (mg/g) = m_{compound}\ / m_{material}\ = \frac{extraction\ yield}{100} \cdot \frac{m_{compound}\ (mg)}{m_{extract}\,(g)} \quad (2)$$

$$extraction\ efficiency\ (wt.\%) = \frac{m_{compound}\ (g)}{m_{extract}\,(g)} \cdot 100 \quad (3)$$

Supercritical fluid extraction (SFE). The SFE experiments using CO_2 were performed on a semi continuous flow apparatus (7). Approximately 15 g of ground material was charged into the extractor (V = 60 mL). The temperature in the water bath was regulated and maintained at constant level (± 0.5 °C, LAUDA Königshofen, Germany). The liquefied gas (CO_2) was continuously pumped with a high pressure pump (ISCO syringe pump, model 260D, Lincoln, Nebraska) through the preheated coil and over the bed of sample in extractor. The solvent

flow rate was measured with a flow meter. The product precipitated in separator (glass trap), where the separation was performed at 1 bar and at room temperature. As result of supercritical extraction the extraction yield (Eq. 1) was calculated.
Conventional extraction. The conventional extraction experiments were performed at boiling temperature using methanol as solvent (10 g of grinded material in 150 mL of solvent). Grinded raw material with defined particle size was extracted using methanol as solvent at mass ratio material: solvent = 1:15. Extractions were carried out for 4 h at boiling temperature, which was for methanol 70 °C. After extraction, the solution was filtered through 0.45 µm filter and solvent was evaporated on vacuum evaporator. Extract was than prepared for analysis with HPLC methods described for determination of caffeine and chlorogenic acid content.

RESULTS AND DISCUSSION

SFE experiments of green coffee beans and guarana seeds were performed using CO_2 as solvent on semi continuous flow apparatus in lab scale. Extractions were performed at pressures 200 and 300 bar and temperatures 40, 60 and 80 °C. The constant flow rate of carbon dioxide in range from 0.06 to 0.1 kg/h was maintained during extraction. The extraction yield and extraction rate increased with increasing pressure from 200 bar to 300 bar at all temperatures investigated.

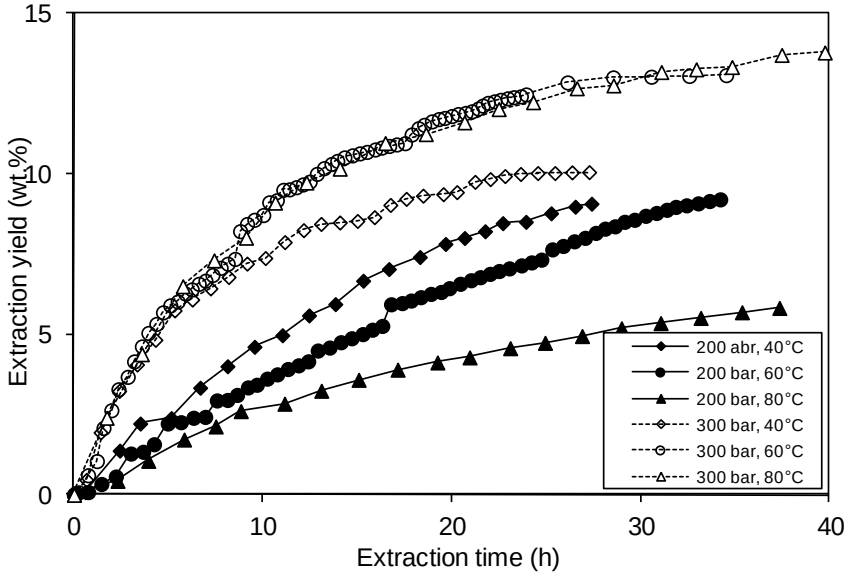

Figure 1. SFE of Green Coffee beans with CO_2.

In case of green coffee beans the highest extraction yield (13.8 wt.%) was obtained at 300 bar and 80 °C. At the same conditions, the highest extraction yield (3.63 wt.%) was obtained for guarana extraction. The extraction curves, shown on Figure 1 and 2 for Green coffee beans and Guarana seeds, respectively, shows that long extraction times are needed to reach constant cumulative extraction yields, to reach full depletion of material.
On Figures 3 and 4, the content of compounds (in mg) per g material (Eq.2) in raw material, methanolic and supercritical extracts, residual material after extraction is presented for Green coffee beans and Guarana seeds, respectively. In raw material, the content of compounds in Green coffee beans was 23.93 mg caffeine/g material and 52.56 mg chlorogenic acid/g material. Guarana seeds contained 46.68 mg caffeine/g material and 8.38 mg chlorogenic acid/g material. Figure 3 shows, that supercritical extracts mainly contained caffeine while chlorogenic acid remained in residual material. Supercritical extracts contain less than 0.1 % of chlorogenic acid due to low solubility in supercritical CO_2. The content of caffeine from

Green coffee beans was the highest at 200 bar and 60 °C where the extract contained 13.44 mg of caffeine/g material and decreases with higher pressure. The content of caffeine from Guarana seeds (Figure 4) was the highest at 300 bar and 80°C where the extract contained 9.97 mg of caffeine/g material. The results were compared with those obtained using conventional extraction with methanol where the content of caffeine was 23.21 and 45.43 mg of caffeine/g material for Green coffee beans and Guarana seeds, respectively. At supercritical extraction, the caffeine was concentrated in supercritical extract, while the chlorogenic acid remained in the residual material.

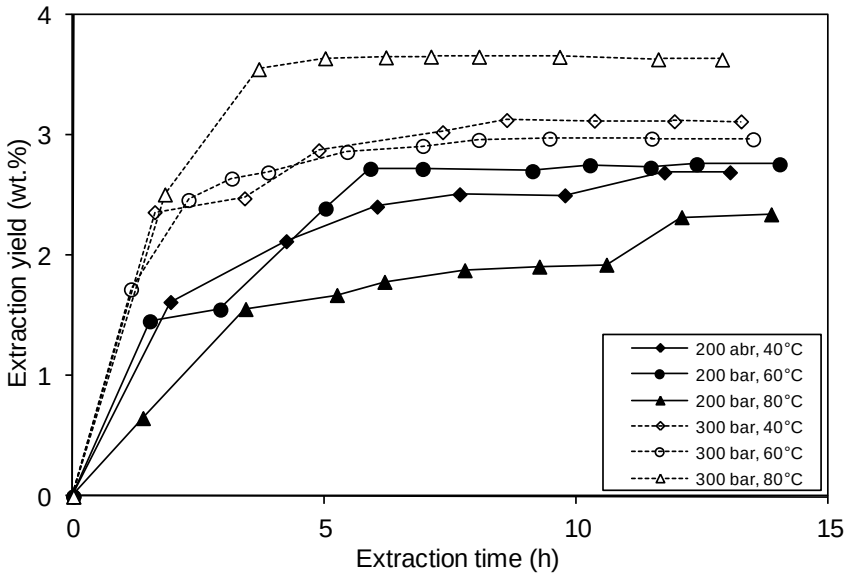

Figure 2. SFE of Guarana seeds with CO_2.

The removal of caffeine using supercritical CO_2 was 56 % and 22 % for Green coffee beans and Guarana seeds, respectively. The raw material used in this research contained less than 5 wt.% of water. According to literature cited (1), authors proposed the usage of wet Guarana seeds for caffeine extraction. The removal of initial caffeine up to 74.7 % from wet Guarana seeds (saturated with water, up to 40 wt.%) was obtained at 70°C and 400 bar. To achieve removal of 97 wt.% of initial caffeine from the wet seeds, also water-saturated CO_2 was used (3).

The extraction efficiency (Eq. 3) of caffeine from Green coffee beans was the highest at 200 bar and 60°C where the extract contained 14.59 wt. % of caffeine. The residual material after extraction at 300 bar and 80 °C was subsequently extracted by conventional extraction procedure and the highest value of chlorogenic acid in extract was 5.15 wt. %. The same results for Guarana seeds extraction were obtained. The extraction efficiency of caffeine from Guarana seeds was the highest at 300 bar and 80 °C where the extract contained 31.75 wt.% of caffeine. Extract obtained with conventional extraction using methanol as a solvent reaches the highest value of chlorogenic acid (2.93 wt.%).

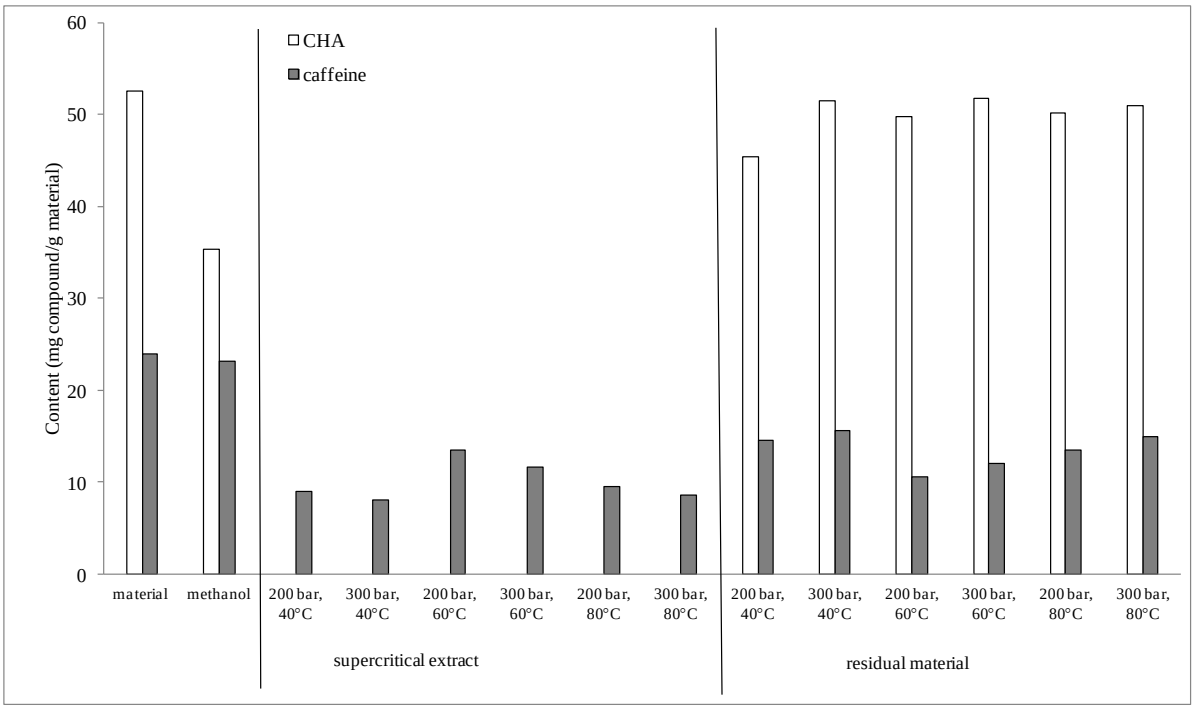

Figure 3. Content (mg compound/g material) of chlorogenic acid (CHA) and caffeine (CAF) in Green Coffee beans after conventional and supercritical extraction.

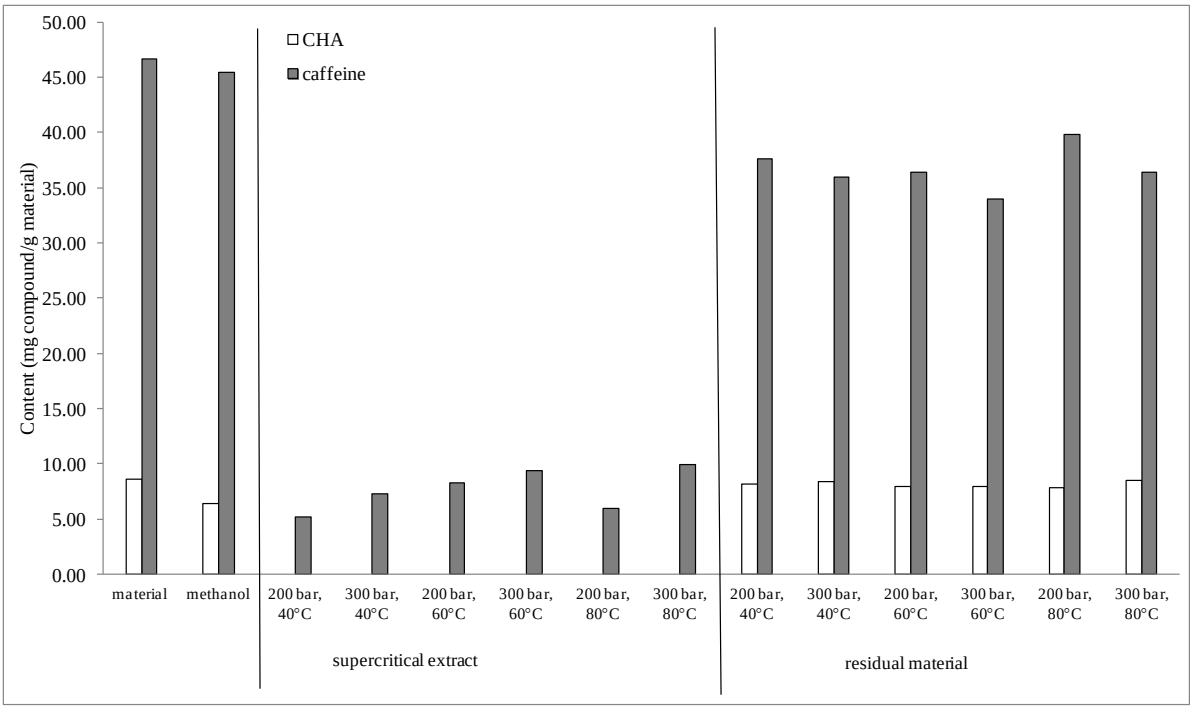

Figure 4. Content (mg compound/g material) of chlorogenic acid (CHA) and caffeine (CAF) in Guarana seeds after conventional and supercritical extraction.

CONCLUSIONS

It can be concluded:

- The best conditions of SFE with CO_2 were 300 bar and 80 °C where the extraction yield reaches 13.8 wt.% for Green coffee beans and 3.63 wt.% for Guarana seeds.
- Extraction yield increased with increasing solvent density and at constant solvent density the extraction yield was increased with increasing temperature.
- The SFE extracts mainly contained caffeine, while the chlorogenic acid remained in the residual material.
- The extraction efficiency of caffeine from Green coffee beans was the highest at 200 bar and 60 °C where the extract contained 14.59 wt. % of caffeine and from Guarana at 300 bar and 80 °C where the extract contained 31.75 wt.% of caffeine.
- Conventional extraction using methanol as solvent gives the highest content of caffeine and chlorogenic acid in extracts, regarding the extraction of both components.
- Removal of caffeine using supercritical CO_2 was 56 % and 22 % for Green coffee beans and Guarana seeds, respectively.

ABSTRACT: Oil cake is a by-product which remains after the pressing of pumpkin seeds. Until recently, it was mainly used as animal fodder, but lately it has been increasingly used for nutritious food products or ingredients. As the cake retains a considerable portion of oil, the aim of this research was to determine the content of oil in the cakes obtained after pressing 7 samples of naked pumpkin seeds and 3 samples of husk pumpkin seeds, and the nutritional value of the residual oil. The content of oil varied from 11.0 to 16.0 % in dry matter. After that, in the next 24 hours, the oil left behind in the cake was extracted by hexane, at room temperature. The composition and content of fatty acids and the total content of tocopherols were determined. The dominant acids were oleic acid (37.1 – 43.9%) and linoleic acid (30.8 – 44.5%), an ω-6 fatty acid. There was also a small portion (0.1 – 0.3%) of linolenic acid, an ω-3 fatty acid. The total content of tocopherols was considerably high (28.7 – 64.5 mg/100g), with the γ-isomer being the dominant one (73.6 – 85.3% of the total content).
Key words: *pumpkin seed, oil cake, fatty acids, tocopherols*

INTRODUCTION

The utilization of by-products of oil processing is a very important issue for the edible oil industry. Oil cakes, remaining after pressing the seeds, contain considerable amounts of oil, proteins and nutrients, which contribute to the nutritional value of the cake. However, certain kinds also contain antinutrients, which are unacceptable and must be removed in order to ensure the edible status of the cake.

But this is not the case with the pumpkin seed oil cake, a by-product of cold pressing. To date, scientific papers have reported data regarding the use of pumpkin seed oil cake flour in producing cookies, bread and a spread similar to peanut butter (Radočaj et al., 2011).

Since oil, present in a significant percentage in the cake, has not been, so far, a subject of scientific research, the objective of this study was to assess the remained oil by the means of organic solvent extraction, and then estimate the nutritional quality of the oil. To that end, the composition of fatty acids and the total content of tocopherols were determined.

According to the majority of literature data, linoleic (C18:2), oleic (C18:1), palmitic (C16:0) and stearic acid (C18:0) are the most abundant ones. These four acids make up 98% of the total fatty acid content, while the content of other acids does not exceed 0.5% (Murkovic et al., 2004; Nakić et al., 2006; Vujsinović et al., 2010). Fatty acid content may vary depending on diverse factors, such as: the variety of pumpkin, the area of cultivation, weather conditions, stage of ripeness, etc (Griffith et al., 1997; Younis et al., 2000; Siegmund and Murkovic, 2004).

Tocopherols belong to non-glyceride constituents of vegetable oils. Given that they slow down the autoxidation process, their presence is of high importance to the stability of vegetable oils. They have the ability to stabilize free radicals and transform peroxides into stable products, thus ending the chain reaction (Schuler, 1990). Variations in total tocopherol content are relatively high, as a result of the influence of genotype and cultivation conditions,

and the method of oil extraction. However, regardless of these variations in total content, the composition of tocopherols in the pumpkin oil is quite stable. The predominant tocopherol isomers in the pumpkin oil are γ- and α-isomers (Murkovic and Pfannhauser, 2000; Fruhwirth et al., 2003; Gorjanović et al., 2011).

MATERIAL AND METHODS

The starting materials were 7 samples of pumpkin naked seed oil cakes and 3 samples of pumpkin husk seed oil cakes, remained after cold pressing.

Total oil content and moisture content

Contents of oil and moisture were determined according the standard analytical methods, respectively: ISO 659: 2007 and ISO 665: 2008.

Oil extraction

The oil that was left over after cold pressing was extracted from the cake by organic solvent, hexane, at room temperature, over 24 hours. The proportion of cake and solvent was 1:3. After that, the solvent was evaporated in the rotary vacuum evaporator, at the temperature of 40 ^{o}C.

Fatty acid determination

Fatty acids were transformed to fatty acid methyl ester by direct transesterification for the neutral samples and with boron trifluoride solution for samples with higher content of free fatty acids (*ISO 5509,2000).* Fatty acid composition was determined by gas chromatography (GC; VARIAN chromatograph, model 1400; Varian Associates, Walnut Creek, CA), equipped with a flame ionization detector and a 3.0 m × 0.32 cm steel column, packed with LAC-3R-728 (20%; Cambridge Ind. Co., Cambridge, UK) on ChromosorbW/AW(80-100 mesh; Merck, Darmstadt, Germany). Nitrogen was used as a carrier gas (flow rate, 24 mL/min) (*ISO 5508,1990).* Fatty acids were identified by comparison of their retention times (Rt) with those of standards (SupelcoTM FAME Mix). All determinations were carried out in triplicates.

Tocopherol content

Quantification of tocopherols was carried out using high performance liquid chromatography (Waters M600E, USA) on a Nucleosil 50-5 C18 reversed phase column with fluorescence detection and external standard solutions of different tocopherols. The following procedures were applied: n-hexane extraction, extract vaporization and reconstitution in methanol using membrane filtration. Mobile phase was 95% ethanol with a flow rate of 1.2 ml/min. The fluorescence detector (Shimadzu RF-535, Japan) operated with the excitation wavelength at 290 nm and the emission wavelength at 330 nm.

Statistical analysis

Data are reported as means ± SD (n = 3). Statistical analysis was performed using Statistica 7 software package.

RESULTS AND DISCUSSION

Contents of oil and moisture in the samples of cakes remained after pressing the seeds are displayed in Table 1.

Table 1. Amounts of remained oil and moisture content in the samples of cakes

Cake sample	Oil content		Moisture content (%)
	(% tel quel)	(% d.m.)	
Pumpkin naked seed oil cake			
OLINKA	11.2	12.1	7.93
SB	11.1	12.1	8.28
F1 OLINKAxG	10.3	11.2	8.31
F1 OLINKA x 371B	14.1	15.2	7.63
GLEISDORFER EXPRESS	14.7	16.2	8.84
GLEISDORFER DIAMANT	13.5	14.8	8.77
K2	12.4	13.5	8.15
Pumpkin husk seed oil cake			
OLIVIJA	12.7	13.8	8.06
DAKI 802	10.0	11.0	8.80
K1	13.3	14.2	8.23

Data are the means ± standard deviation values (n = 3)

As shown in Table 1, the moisture contents in the cakes were rather steady, ranging from 7.63 to 8.84%. On the other hand, the results regarding the amounts of oil remaining in the cakes were not so homogenous – the contents varied from 11.0 to 16.2 % d.m. and were considerably high. Berenji (2007) reports that the content of remained oil may vary from 10 to 18%, depending on the pressing method.

Table 2 shows the composition and content of fatty acids in the samples of oil extracted from press cakes. As for the composition of fatty acids, pumpkin seed oil belongs to the oleic-linoleic type. As seen in Table 2, oleic acid content ranged from 37.1±0.11 to 43.9±0.04%, while that of linoleic acid, belonging to ω-6 fatty acids, varied from 30.8±0.09 to 44.5±0.015%. In addition, the presence of a small percentage (0.1 do 0.3%) of α-Linolenic acid, an ω-3 fatty acid, was detected, which increased oil's nutritional value. The measured data are in accordance with the results obtained for the oil extracted from seeds, reported by various authors (Schuster, 1983; Wentzel, 1987; Karlović et al., 2001; Fruhwirth et al., 2003; Vukša et al., 2003; Vujasinović et al., 2010). Namely, the literature does not provide specific data on the composition of fatty acids in the oil extracted from pumpkin seed press cake.

Considering that the composition of fatty acids is a major indicator of both nutritional value and oxidative stability of vegetable oils, it was important to determine the total saturated fatty acids (SFA), monounsaturated fatty acids (MUFA) and polyunsaturated fatty acids (PUFA) content as well. A higher SFA content contributes to oxidative stability, but from the nutritional point of view and in terms of preventing coronary disease, oils with higher MUFA and PUFA contents are preferred. The total content of unsaturated fatty acids in the examined oils was on average four times higher than that of saturated fatty acids.

Table 2. Fatty acid composition (% w/w) of the oil extracted from pumpkin seed press cake

Data are the means ± standard deviation values (n = 3)

Total tocopherols were measured and the results are shown in Figure 1.

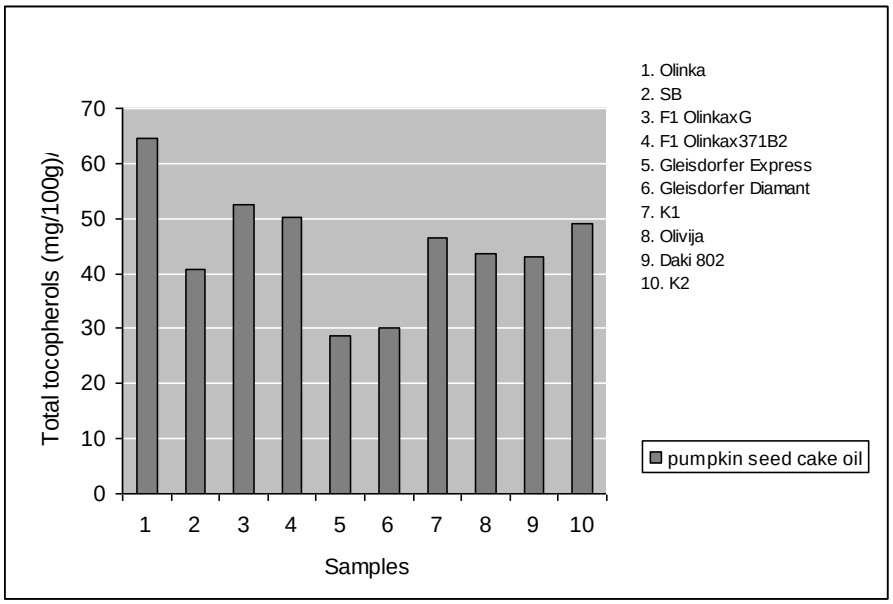

Figure 1. Total tocopherols content in oil from pumpkin seed press cake

The total content of tocopherols in the oil extracted from pumpkin seed press cakes was relatively high, ranging from 28.76 to 64.53 mg/100g and contributing to the nutritional value of the samples. The content was highest in the oil obtained from the Serbian “Olinka” pumpkin cake, and lowest in the oil extracted from the cake remained after pressing the seeds of the Austrian “Geisdorfer Express” hybrid. γ-Tocopherol as the dominant tocopherol isomer in all samples, accounting for 73.64 – 85.28% of total content.

CONCLUSIONS

From the point of view of the composition of fatty acids all samples regardless of the type of cake used for their extraction corresponded to the oleic-linoleic type, which indicates a high nutritional value of the oil. Considering that the amount of tocopherol detected in the examined oil was considerably high, we can draw a conclusion that a large percentage of tocopherol remains in the cake. Therefore, the oil left over in the cake should be considered for use, taking into account its nutritional value and its high presence in the cake.

ABSTRACT: Rheological properties of the spread based on hull-less pumpkin seed flour were determined. Sunflower oil, as fat phase of control sample, was totally replaced with colloidal wheat fibre gel. The gels were prepared in different concentrations, 0.1 to 10%, and were added in different amounts, 60, 70 and 80%, calculated on the total mass of the spread. Wheat fibres formed liquid gels in water at low concentrations, 0.1 and 0.5%. Stable gel structures were obtained at concentrations above 1% and had anti-thixotropic flow properties. The spreads of hull-less pumpkin seed flour and wheat fibre gel were thixotropic systems. Statistically insignificant ($p>0.05$) changes pointed that application of fat replacer, compared to control spread, regardless amount and concentration of the gel, did not affect the yield stress of the spreads. The interaction of these factors, as well as their separate influence, were statistically significant ($p<0.05$) for rheological parameters thixotropic loop area and tan δ. Creep and recovery compliance increased with increasing amount of the gel in spread composition. Optimal rheological properties of the spreads were achieved with low concentrated gel, 0.5 or 1%, in amount of 70%.
Key words: *wheat fibre gel, hull–less pumpkin seed flour, functional spread, rheological properties*

INTRODUCTION

Hull-less oil pumpkin, *Curcubita pepo L.*, is the form of ordinary pumpkin with specific hull-less seeds. Hull-less pumpkin seed is rich in oil (35-50%), proteins (30-40%), minerals and vitamins. The hull-less pumpkin oil is an important source of linoleic acid (40-57%), plant sterols, carotenoids, phenols and vitamin E. (Kreft et al.,2002) Mechanical process is usually used to produce the pumpkin oil. The hull–less pumpkin seed is cold pressed by hydraulic presses or screws. During that mechanical process significant amount of by-product, the oil cake is obtained. The oil cake is rich in proteins (60-65%), with a number of essential amino acids. (Čorbo et al., 2007; Tarek et al., 2001). Also, the proteins are specific by strong pharmacological activity antifungal, antibacterial, antioxidant and anti-inflammatory. (Peričin et al., 2008). The hull-less pumpkin seed cake, unlike the majority of oilseed cakes, does not contain antinutritive ingredients such as chlorogenic acid from sunflower seeds or tannins and phytic acid from rape seed.

Milled pumpkin oil cake represents flour with valuable nutritional composition and good sustainability. The flour contains metabolically very adoptable proteins, minerals (P, K, Mg, Mn, and Ca) and antioxidants. The content of all amino acids, except lysine, in the hull-less pumpkin seed flour is higher than in soy flour, and it is in accordance to suggested daily amount and quality of protein for human consumption by the World Health Organization. (Radočaj, 2011)

The hull-less pumpkin seeds flour can be especially used in food products that are in accordance with the principles of functional food. Functional food products contain biologically active micro and macro nutritients (vitamins, minerals, fibres), that provide adequate nutrition and health effects. The development of functional food is directed to a variety of low-energy products. Also, the trend of reducing the fat content in food products led to the development of fat replacers.

Fat replacers should imitate all functional characteristics of the fat, sensory properties (taste and odour), rheological properties (viscosity, consistency and texture), thermostability and

emulsifying properties that provide liposoluability of flavour and vitamins. The energy value of fat replacer should be significantly lower than energy value of the fat, 0 kcal/g is preferably. (Akoh, 1998)
The chemical structure of fat replacers can be similar to the chemical structure of proteins, fats or carbohydrates. Carbohydrate based fat replacer include native starch, modified starches, maltodextrin, polydextrose, gums and dietary fibres. (Cho and Prosky, 1999). Important technological characteristics of dietary fibre that can act as fat replacers are water holding capacity, fat binding capacity, adequate viscosity, gel formation capacity, chelating capacity and influence on the texture of the product. Soluble fibres form a gel structure by networking of polymer units. The water or other solvent is trapped into gel structure. Properties of the gel and gel formation ability depend on many factors: concentration, temperature, presence of certain ions and pH. Some fibres have a synergistic effect during the formation of a gel and are usually used in conjunction with starch, xanthan gum or carrageen. (Borderias et al., 2005). Dietary fibres can be used as fat replacer at numerous food products, baked goods, confectionery, cereal products, meat and dairy products, spreads, sauces, salad dressings, frozen products and that depend on its chemical composition. (Jones, 1996)
The aim of this work was to determine the influence of wheat fibre based fat replacer on the rheological properties, flow characteristics and viscoelastic properties, of the spread with hull-less pumpkin seed flour. The spreads contained colloidal wheat fibre gel instead the fat phase. The gels were prepared in different concentrations from 0.1 to 10% and were added into the spreads in different amounts 60, 70 and 80%, calculated on the total mass of the spreads. The possibility to obtain a nutritionally and biologically valuable food product that belongs to the group of functional low-energy products is examined.

MATERIAL AND METHODS

The hull-less pumpkin seed flour was obtained by oil producer “Linum" doo, Čonoplja, Serbia. The flour contained oil (15.41%), protein (55.02%), moisture (7.16%), cellulose (3.49%), ash (8.28%) and carbohydrates (10.63%). The fractions of the flour that passed through sieve with diameter 1 mm were used.
Fat replacer based on wheat fibres was used. It is commercial product named Vitacel® WFG HS73 by J. Rettenmaier & Sonho GMBH + CO Rosenberg Germany, and it is consisted of colloid wheat fibres (70%) with maltodextrin (30%). Applied emulsifier was sunflower lecithin, Topcithin® SF produced by Cargill, Italy. Salt (NaCl) and distilled water were used also.

Preparation of wheat fibre gels

Different concentration (0.1%, 0.5%, 1%, 5% and 10%) of wheat fibres were dispersed in distilled water and were homogenized 4 min at homogenizer (Ultraturaks T-25, Janke Kunkel) with S25 N-18G tool at 6500 min^{-1}. The solutions were stored at 25°C for 24 hours to form a gel.

Preparation of the spreads

The control spreads contained hull-less pumpkin seed flour, sunflower oil, salt (NaCl) and emulsifier-sunflower lecithin. The spread with 40% of oil, including the oil content of the flour, calculated on the total spread mass was optimal from rheological and textural aspect by previous analysis. Fat phase of the test spreads was totally replaced with wheat fibre gel. The amounts of gel were different, 60, 70 and 80% calculated on the total mass of the spread in the aim to achieve adequate consistency of the spread. The amounts of salt and the emulsifier were 0.5% and 0.4%, respectively, calculated on the total spread mass.

Rheological measurements

Rheological properties of the gels and spreads were determined by rotational viscometer HAAKE Rheostress RS600 (Thermo Electron Corporation, Karlsruhe, Germany) with plate–plate sensor PP60 Ti (plate diameter was 60 mm and gap 1 mm). The measurements were

done at 25 ± 0.1°C. Flow properties were defined by hysteresis loop method. The samples were exposed for 3 min to shear rate ramped up from 0-100 s^{-1}, following 3 min the shear rate was constant at 100 s^{-1} and finally ramped down to 0 s^{-1} for 3 min. The flow curves were characterised by yield stress τ_0 and thixotropic loop area A_0. Storage modulus (G') and loss modulus (G") were defined by dynamic oscillatory measurements in the range of linear viscoelastic regime (LVE). The moduli were observed during increased frequency from 1 to 10 Hz and at constant shear stress of 5 Pa and expressed as value tan δ = G"/ G'.
Viscoelastic response of the samples at constant stress, as well as their behaviour after removing the stress, were determined by creep and recovery test. The test was performed in the LVE regime in which the deformation amplitude was proportional to applied stress amplitude. The creep time with constant stress of 5 Pa was 150 s and the recovery period after removing the stress was 450 s. Statistical analysis of the data and significant differences at the significant level 0,05 for n=3, were determined by the ANOVA procedure and Duncan's multiple range tests.

RESULTS AND DISCUSSION

Rheological properties of gel

Low concentrations of wheat fibre, 0.1% and 0.5% formed lightly gelled systems in water. Stable gel structures were obtained with higher concentrations of fibres, 1%, 5% and 10% (Figure 1). Table 1 represents rheological parameters of the gels.

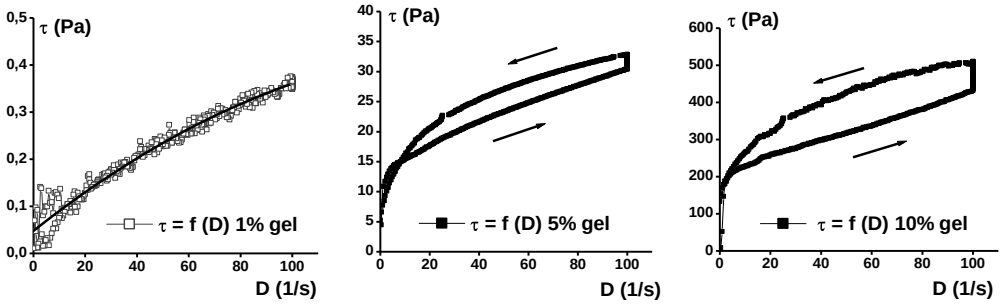

Figure 1. Flow curves of gels with 1, 5 and 10% of wheat fibre

Table 1. Rheological parameters of the wheat fibre gels

Gel concentration [%]	τ_0 [Pa]	A_0 [Pa/s]	tan δ
1	–	–	0.567
5	4.551	-290.13	0.232
10	5.191	-5456.67	0.205

The 1% gel showed the typical pseudoplastic flow properties. The concentrations of 5 and 10% of wheat fibre formed anti–thixotropic gels that occurred as result of internal structure established by linkages due to elongation and parallel placement of fibre filaments in shear gradient. The parameters of dynamic oscillatory measurements, tan δ, for high concentrations of the gels (5 and 10%) were lower than for 1% gel. Thus, the contribution of elastic components increased at these viscoelastic systems with high concentration of wheat fibre.

Rheological properties of the spreads

Figure 2 represents flow curves of the spreads with different amount of wheat fiber gel. The applied gels varied in concentration (0.1, 0.5, 1, 5 and 10%).

The obtained spreads with wheat fibre gel as well as the spread with sunflower oil were thixotropic systems. Statistically insignificant ($p>0.05$) changes pointed that application of the fat replacer, compared to the control spread, regardless amount and concentration of the gel did not affect yield stress of the spreads and for all spreads it was approximatelly 5 Pa.
Rheological measurements for spreads with 10% gel in amounts of 60 and 70% could not be performed because of high viscosity of these spreads. The flow ability had only the spread with 80% of this gel. The rheological parameter of the spreads, thixotropic loop area, was influenced by amount and concentration of the gel. Statistical analysis ($p<0.05$) confirmed the interaction of these factors, as well as their separate influence.

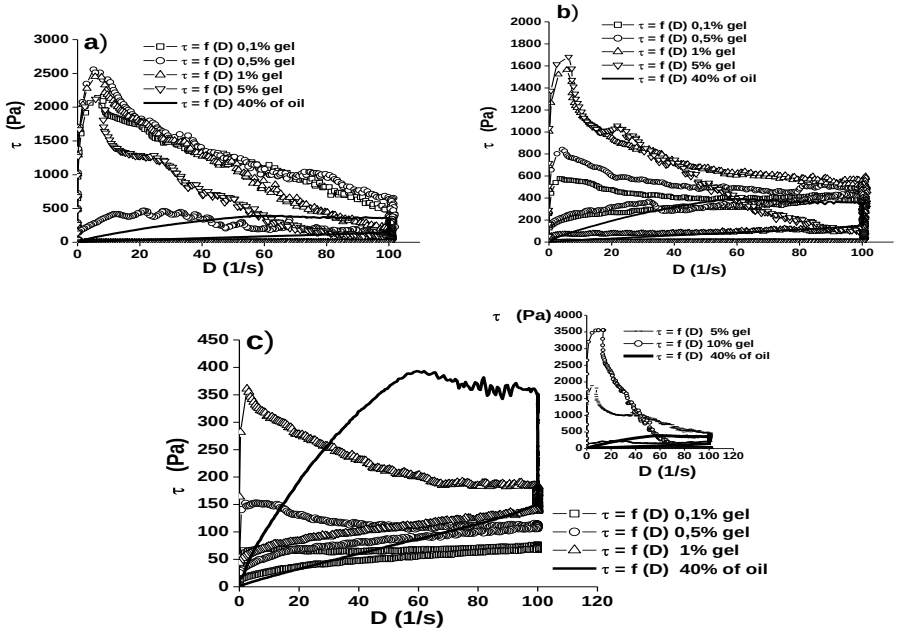

Figure 2. Flow curves of the spreads with a) 60%, b) 70% and c) 80% of wheat fibre gel

Figure 3a represents the changes of thixotropic loops area of the spreads affected by gel concentration at constant amount of the gel. The structure of the spreads with wheat fibre gel compared to the spread with sunflower oil was more complex, stronger and with more order. The influence of gel concentration on thixotropic loops area was the most evident at spreads with high amount of the gel, 80%. Increase in gel concentration contributed to firmness and the consistency of the spreads, thus the thixotropic loops area increased. The flour solids at the spreads with enough gel were coated and embedded in network gel structure. Decrease in amount of the gel reduced the influence of the gel concentration. With small amounts of the gel, 60%, high values of thixotropic loops area were caused by friction between solids and significant viscosity of the systems.

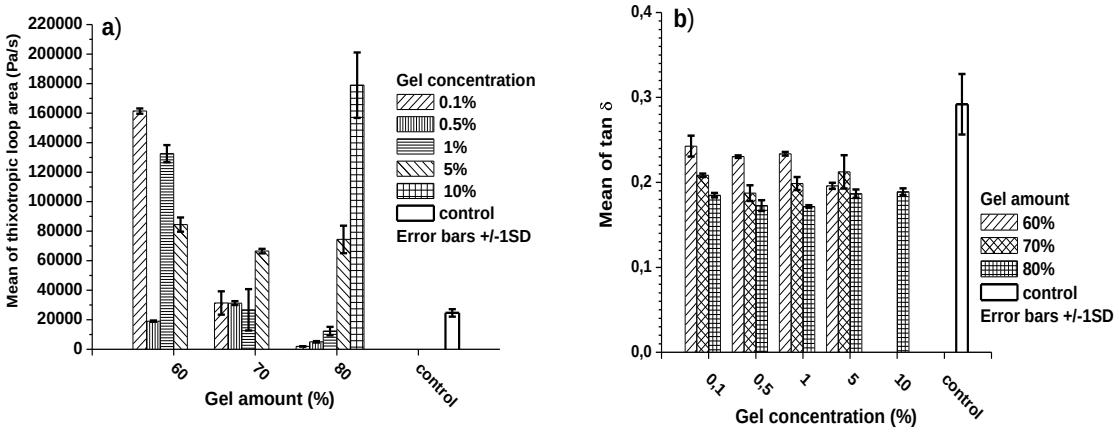

Figure 3. a) The influence of gel concentration on thixotopic loop area; b) the influence of gel amount on tan δ

The contribution of elastic and viscous components to viscoelastic properties of the spreads was determined by dynamic oscillatory measurements. Loss modulus G'' versus storage modulus G' represents value tan δ (Figure 3b). The influence of gel concentration on value tan δ was statistically insignificant ($p>0.05$), but the influence of gel amount and the influence of interaction of these factors were statistically significant ($p<0.05$). The increase in amount of the gel decreased the value tan δ, thus the difference between modulus decreased. All the spreads were viscoelastic systems (tan δ<1) with dominant storage modulus G' and similar behaviour caused by less or more firm structure.

The consistency of the spreads was defined by creep and recovery analysis. Viscoelastic response to applied stress described the compliance of the examined spreads. Figure 4 represent the influence of two factors, the amount of the wheat fibre gel and the concentration of applied gel, on the creep and recovery curves of the spreads. Increase in amount of the gel at all gel concentrations decreased the consistency of the spreads. More gel caused higher compliance and softer consistency of the spreads that were difficult to recover. The gel acted as continuous phase that coated solid particles and reduced their interactions. The spreads with same gel amount with increase in gel concentration were less susceptible to applied stress, accordingly increase in gel concentration led to increase in firmness of the spreads.

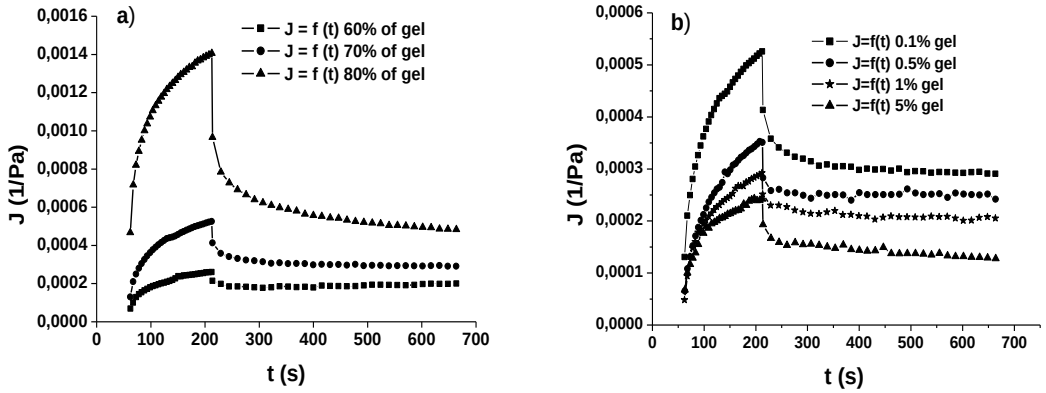

Figure 4. The influence of a) the amount of the wheat fibre gel; b) the concentration of applied gel on the compliance of the spreads

CONCLUSION

Colloidal wheat fibers gel can replace the fat phase of the examined spreads. Obtained spreads were viscoelastic systems that exhibited thixotropic flow properties and certain recover ability. The concentration of applied gel and amount of the gel defined the structure and consistency of the spreads. Optimal rheological properties of the spreads were achieved with low concentrated gel, 0.5 or 1%, in amount of 70%. A low-energy functional spread can be obtained.

ABSTRACT: Basil (*Ocimum spp.* L., family *Lamiaceae*) has been grown traditionally in Serbia for decorative, medicinal, and as a spice used in cooking. In Orthodoxy it is used in religious services , and in India and Pakistan basil it is an herb dedicated to the Goddess Tulsa. Secondary metabolites from *Ocimum* species possess an exceptional biological activity and have: bactericide, fungicide, repellent, antiinflammatory, antioxidative, antidiarrheic, chemopreventive and radioprotective effects. The antioxidant potential of different genotypes was examined of Basil from Serbia according to their anti-radical capacity (Free Scavenging Capacity - RSC).The analyzed genotypes included: *Genovese, Lattuga, Fino Verde, Holanđanin, Compact, Lime*, *Cinnamon, Siam Queen, Blu Spice, Purple Ruffles, Purple Opal, Osmin* and *Holy Red.* The DPPH assay was used to measure stable free radicals. The analysis of these genotypes indicate that *Purple Opal* has the highest antioxidant potential of IC_{50}=0,14 mg/ml.
Key words: *basil genotype, antioxidant potential, DPPH, Serbia*

INTRODUCTION

Basil (*Ocimum spp.* L., family *Lamiaceae*) has been grown traditionally in Serbia as a decorative, medicinal, seasoning and ritual herb. Basil was introduced to Serbia by monks, who received the plant during a pilgrimage in the 12th century. Since then it has been used in Orthodox Church ceremonies. Additionally, the Serbian nation has grown basil in home gardens for centuries. This reputable 'holy' plant has been used as a decorative, repellent, in traditional medicine, and in culinary arts (Jelačić et al., 2010).

The genus *Ocimum* (*Lamiaceae*) consists of 30-150 species, distributed in the tropical regions of Asia, Africa and Central and South America. This highly variable species has a complex taxonomy which is a consequence of the inter-specific hybridization and polyploidy of the species (Grayer et al., 1996). Their morphological diversity has been developed through centuries of cultivation, and their delineation has been further complicated by the existence of chemotypes within the species that do not differ significantly in morphology (Simon et al., 1990; Paton et al., 1999).

Secondary metabolites from *Ocimum* species possess an exceptional biological activity and have: bactericide, fungicide, repellent, antiinflammatory, antioxidative, antidiarrheic, chemopreventive and radioprotective effects (Opalchenova et al., 2003; Pascual-Villalobos and Ballesta-Acosta, 2003; Lukmanul Hakkim et al., 2008; Gajula et al., 2009; Runyoro et al., 2010).

Basil herb (*Basilici herba*) is used in traditional homeopathic medicine for treating a large number of diseases. It is used as a carminative, sedative, lactagogue, for increasing appetite, for cough reduction and in cosmetology as an exceptional antiseptic. In the perfume industry the essential oil of basil (*Basilici aetheroleum*) is used, as well as some of its components, for the production of perfumes and other products (Simon et al., 1990).

Basil is cultivated in Serbia mostly in home gardens. In most cases the morphology of the varieties grown in Serbia are large leaved and small leaved, green in color, with linalool being the dominant component of their essential oil (Jelačić et al., 2010). Through many

years of systematic collection a large number of genotypes has been compiled which have not been cultivated in Serbia until now. This process has introduced many new varieties and has enlarged the number of Basil accessions in our gene bank.

MATERIAL AND METHODS

Plant material and cultivation conditions

Seeds of 13. *Ocimum spp.* cultivars were planted in the greenhouse in March of 2010, in polystyrene containers with 40 holes, and stuffed with commercial substrate (Beatović et al., 2006). Seedling production lasted 48 days. During May of 2010, nursery plants were transplanted into the experimental field in a randomized complete block design with four replicates in a 50x50 cm model, at Surčin, Serbia (44° 49' N, 20°17' S, altitude 96 m, degraded chernozem). Plants were harvested at the full flowering stage in July of 2010. Plants were air dried in the shade, and then packed and stored.

Seeds of *O. basilicum* cultivars (Table 1.) were obtained from the Institute for Crop Sciences of the Faculty of Agriculture in Belgrade and the Plant Gene Bank of Serbia where plants were designated and deposited under DB codes (Beatović et al., 2008)

Table 1. Introduced genotypes of basil

Radical scavenging activity

Air-dried aerial parts of 13 basil genotypes were extracted with MeOH for 48 h at room temperature. The ratio between plant material and solvent was 1:20, w/v. These extracts were measured using the DPPH assay.

The DPPH method was originally published by Molyneux (2004). The method is simple and rapid for determining the antioxidative activity of food, plant extracts and chemical compounds by using DPPH as the stable radical. The reaction mixture (1ml) contained 500µl of daily prepared DPPH solution in methanol (150µM) and 500µl of various concentrations (1, 0.5, 0.25, 0.125, and 0.0625 mg/ml) of the tested methanol extract of basil. After thorough mixing, the solutions were kept in the dark for 20 min at room temperature. Thereafter, the absorbance was measured at 517 nm. All tests were performed in triplicate, with trolox and ascorbic acid as a positive control. The percent inhibition of the DPPH radical by basil extracts was calculated according to formula:

$$\% \text{ Inhibition} = [(A_{blank} - A_{test}) / A_{blank}] \times 100$$

The IC_{50} values were calculated by linear regression of plots where the abscissa represented the concentration of tested samples and ordinate the average percent of inhibition activity from three separate tests. Data are presented as mean ± standard deviation (SD).

RESULTS AND DISCUSSION

Basil is used as a spice in food preparation, and since it is an important ingredient it is necessary to identify its antioxidative potential. This study tested the antioxidant potential of

13 basil genotypes which differ according to their morphological characteristics and composition of essential oil (Beatović et al., 2010).
In Table 2. is presented the DPPH radical scavenging activity of the tested Basil genotypes.

Table 2. DPPH radical-scavenging activity of tested Basil genotypes

No.	Genotypes	DPPH radical scavenging activity IC_{50} (mg/ml)
1	Genovese	0.68 ±0.01
2	Lattuga	0.33 ±0.02
3	Fino Verde	0.32 ±0.02
4	Holanđanin	0.31 ±0.01
5	Compact	0.31 ±0.01
6	Cinnamon	1.82 ±0.04
7	Lime	0.19 ±0.01
8	Siam Queen	0.21 ±0.01
9	Blu Spice	0.33 ±0.01
10	Purple Opal	0.14 ±0.01
11	Purple Ruffles	0.28 ±0.01
12	Osmin	0.18 ±0.01
13	Holy Red	0.25 ±0.02
14	ASA	0.003 ±0.00
15	TROLOX	0.004 ±0.00

The Purple Opal genotype had the greatest antioxidant activity 0.14 mg/ml among the 13 genotypes tested. This genotype belongs to the group anthocyanin colored Basils. The remaining anthocyanin colored genotypes also showed high antioxidant activity including; Osmin, Purple Ruffles and Holy Red (Table 2.).
Of the genotypes that belong to the green colored group (those without anthocyanin coloring) the Lime genotype had the greatest antioxidant activity 0.19 mg/ml. The large leaved genotype Genovese had a lower antioxidant activity 0.68 mg/ml, while the lowest activity was from the Cinnamon genotype 1.82 mg/ml (Figure 1.).

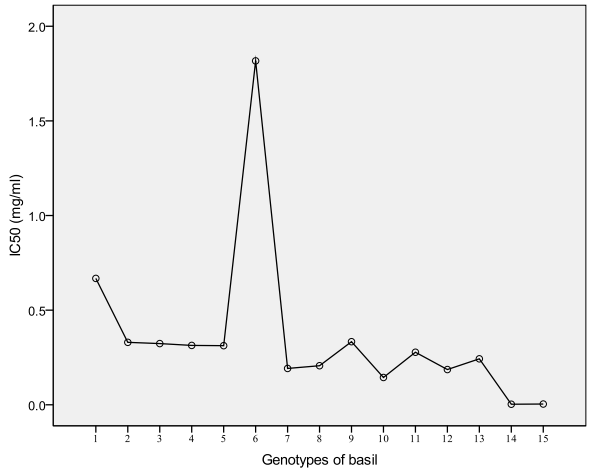

Figure 1. Basil genotype IC_{50} values

Many authors have analyzed the antioxidant capacity of basil (Lee et al., 2005; Hussain et al., 2008; Kwee and Niemeyer, 2011).
Most studies have concentrated on analyzing essential oils, whereas less have focused on the directly analyzing the herbal material. Hinneburg et al. (2006) studied the antioxidant potential of Basil grown in Finland. When comparing their result of 0.49 mg/ml it can be concluded that Basil grown in Serbia has a higher antioxidant capacity.
While Lukmanul Hakkim et al. (2008) had a greater antioxidant capacity from *Ocimum gratissimum* grown in India compared to the genotypes analyzed in this study.

Figure 2 and 3. Herbal material of tested Basil genotypes

CONCLUSIONS

Basil is widely used in the culinary arts and the food processing industry. It is used as an aroma to improve the taste, smell, and digestibility of food. Basil leaves are used often as a spice therefore it is important to know its antioxidative potential and associated health benefits. The Purple Opal genotype had the greatest antioxidative capacity of all 13 tested genotypes, while Osmin and Lime genotypes were also considered to have a high antioxidative capacity. These results show that a significant antioxidative potential can be achieved by cultivating introduced Basil genotypes under the agroecological conditions in Serbia.

ACKNOWLEDGEMENTS

This paper is a result of the research within the projects III 46001 “Razvoj i primena novih i tradicionalnih tehnologija u proizvodnji konkurentnih prehrambenih proizvoda sa dodatom vrednošću za domaće i svetsko tržište (Development and implementation of new traditional technologies in production of competitive food products with the value added for domestic and world market) and OI 173015 (Biotechnology in vitro – crop, medicinal and endangered plant species). The realization of the project was financed by the Ministry of Education and Science Republic of Serbia.

ABSTRACT: The most important role in wheat protein complex belongs to gluten with its components: glutenin and gliadin. Majority of conducted and published research related to investigation of glutenin and gliadin fractions composition is directed to high molecular weight subunits and their relation to expressed technological properties of wheat varieties. Differentiation of wheat varieties in relation to low molecular weight subunits composition with molecular weight of up to 30 kDa gains in importance under the fact that some of low molecular protein fractions found in wheat express bioactive properties with confirmed curative and preventive properties proven *in vivo* or/and *in vitro* in relation to cardiovascular diseases, cancer, immune and other disorders. Determination of glutenins and gliadins of wheat varieties from different regions was conducted by LoaC (Lab-on-a-chip capillary electrophoresis) method with previous separation of glutenin and gliadin fractions. PCA was utilized to identify the varieties which are characterized with the most expressed differentiation in the low molecular weight glutenins and gliadins composition. Ten wheat varieties, including wide spread in production but also those with high differentiation of composition and shares of protein fractions in the interval from 13 to 28 kDa were compared, and the significance of differences was analyzed with ANOVA test.
Key words: *wheat, functional properties, bioactive peptides, electrophoresis*

INTRODUCTION

Today wheat is one of the most important crops in the world, considering the area of approximately 240 million of hectares under cultivation and the total yields (Mastilović et al., 2011). These facts make wheat also one of the most suitable potential sources of functional ingredients, including bioactive proteins and peptides, both from the technological and economical points of view (Belović et al., 2011). From the technological point of view, wheat proteins can be divided to proteins that are constituents of gluten and those that are not. Gluten proteins (gliadins and glutenins) are the most abundant and major proteins (approximately 85% of total proteins) (Korhonen and Pihlanto, 1998) located in the endosperm of wheat, and they are considered to play a dominant technological role. Low and middle molecular weight glutenin subunits (LMW-GS) constitute about one third of total kernel protein content, and approximately 60% of total glutenins, while other part of kernel is constituted of less abundant high molecular weight glutenin subunits (HMW-GS) (Song and Zheng, 2007). Among wheat proteins with low molecular weights there are proteins that can potentially have bioactive properties (Korhonen and Pihlanto, 2003).
The fact that bioactive peptides can help reduce global epidemic of chronic diseases that is responsible for 58 millions of premature deaths per year (Wang et al., 2007) should not be neglected. Many researches carried out by biological *in vitro* and/or *in vivo* tests are dedicated to consideration of action of bioactive peptides encrypted in protein sequence/protein hydrolysates from plant sources. They have physiological effect on the major body systems − the cardiovascular, digestive, endocrine, immune and nervous system. The most investigated peptide of plant origin with anticarcinogenic action is lunasin, which is firstly discovered is soybean, and later in some cereals and pseudocereals, such as wheat, barley, rye, rice and amaranth (Belović et al., 2011).

Immunomodulatory peptides, beside improvement of immune system function, can enhance mucosal immunity in the gastrointestinal tract and reduce allergic reactions (Hartman and Meisel, 2007). In addition to commonly investigated anticarcinogenic action of lunasin, Dia et al. (2009) reported its anti-inflammatory action.
The aim of research presented in this paper was to identify wheat varieties that are distinguished by structure and proportion of glutenins and gliadins in range of molecular weights from 13 to 28 kDa, with emphasis on identification of varieties which could based on low molecular weight glutenins and gliadins content and structure be potential source of peptides with bioactive properties.

MATERIAL AND METHODS

Wide range of wheat varieties was investigated, including current varieties present in the assortment and genetic material from different parts of the world, on the basis of glutenin and gliadin fractionation and their separation using chip electrophoresis technique.Total number of analyzed samples was 247 wheat varieties. First phase of investigation of samples was their preparation, actually grinding and fractionation of anatomical parts of the grain during milling. Wheat was milled using Sedimat mill (Brabender Ohg., Germany). Reagents used for fractionation and denaturation of wheat flour proteins were: SDS (10%), 4 x STACKING GEL BUFFER (0.5 M tris (base) – Cl pH 6.8) and 2 x TREATMENT BUFFER (0,125 M tris-Cl pH 6.8, 4% SDS, 20% glycerol, 10% 2-mercaptoethanol).
Fractionation of wheat flour proteins was carried out on the basis of their different solubility. First step of fractionation was the extraction of albumins and globulins, considering their solubility in water and saline solution, respectively. Further procedure included extraction of:

- Gliadins (prolamins) – proteins soluble in 70% ethanol;
- Glutenins (glutelins) – proteins soluble in dilute solutions of acids and alkalis.

Separation of proteins in previously prepared samples was performed using chip electrophoresis technique on Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA) with Protein 230 Plus Lab-on-a-Chip kit. For each investigated wheat variety, analysis was conducted in two independent replications. Preparation of samples and their deposition on chips was performed according to protocol for analysis with Protein 230 Plus Lab-on-a-Chip kit. Results of chip electrophoresis were expressed by software in two different ways – as quantitative profiles and simulated gel images. Qualitative analysis included the determination of molecular weights of separated protein fractions, and quantitative analysis included determination of concentrations of each defined protein fractions. All samples were analyzed in three replications. Results of chip electrophoresis were presented graphically (electrophoregrams) and in table (values) for each sample of wheat flour.
Software used for processing of experimental values obtained for low molecular weight protein proportions (13-28 kDa) of analyzed wheat varieties was Microsoft Office Excel 2007 (Microsoft Corporation, 2007) and STATISTICA (StatSoft, Inc. (2011), version 10.0 (www.statsoft.com)). Data bases obtained by STATISTICA were processed using PCA (Principal Component Analysis) multivariate technique and ANOVA (analysis of variance), followed by Duncan's multiple range test in order to compare means of selected samples at 5% significance level.

RESULTS AND DISCUSSION

Characteristics of data base created from analysis results for low molecular weight glutenin and gliadin fractions in all 247 wheat varieties are presented in Table 1.
In observed interval of molecular weights from 13 to 28 kDa, on the basis of analysis of large number of different wheat varieties, three characteristic intervals with low molecular weight glutenin and gliadin peaks can be noticed:

- Interval from 13 to 19 kDa with highest average content of glutenins and gliadins and highest concentration of varieties in range from 15 to 17 kDa.

- Interval from 19 to 24 kDa with highest average content of glutenins and gliadins and highest concentration of varieties in range from 20 to 22 kDa.
- Interval from 24 to 28 kDa with highest average content of glutenins and gliadins and highest concentration of varieties in range from 25 to 27 kDa.

Table 1. Characterization of data base on low molecular weight glutenins and gliadins in wheat varieties

Interval of molecular weight, kDa		Average content, ppm	Min, ppm	Max, ppm	Standard deviation	Coefficient of variation
13-28	**Glutenins**	2147.15	316.66	7705.8	1030.18	48.0
	Gliadins	7094.61	0	22866.49	3188.84	44.9
13-19	**Glutenins**	1179.34	0	3887.27	658.18	55.8
	Gliadins	30.44	0	2744.76	276.2	907.3
19-24	**Glutenins**	584.72	0	2959.93	398.29	68.1
	Gliadins	139.45	0	3252.15	451.75	323.9
24-28	**Glutenins**	383.09	0	3845.62	625.45	163.2
	Gliadins	628.62	0	9348.37	1450.13	230.6

Processing of complex data from obtained data base included analysis of glutenin and gliadin fractions by emphasized intervals of molecular weights in ranges from 13 to 19, 19 to 24 and 24 to 28 kDa by principal component analysis. Results of principal conmponent analysis for glutenins and glidins are presented in figures 1 and 2 respectively.
For both, glutenins and gliadins the first two principal conponens accounted to over 85 % variability of the whole population. Based on the separation of varieties in the factor plane 5 varieties which were the most distiguishing among others were selected for gliadins and for glutenins and illustrative and comparative display and analysis of glutenins and gliadins electrophoregrams for selected varieties was provided.

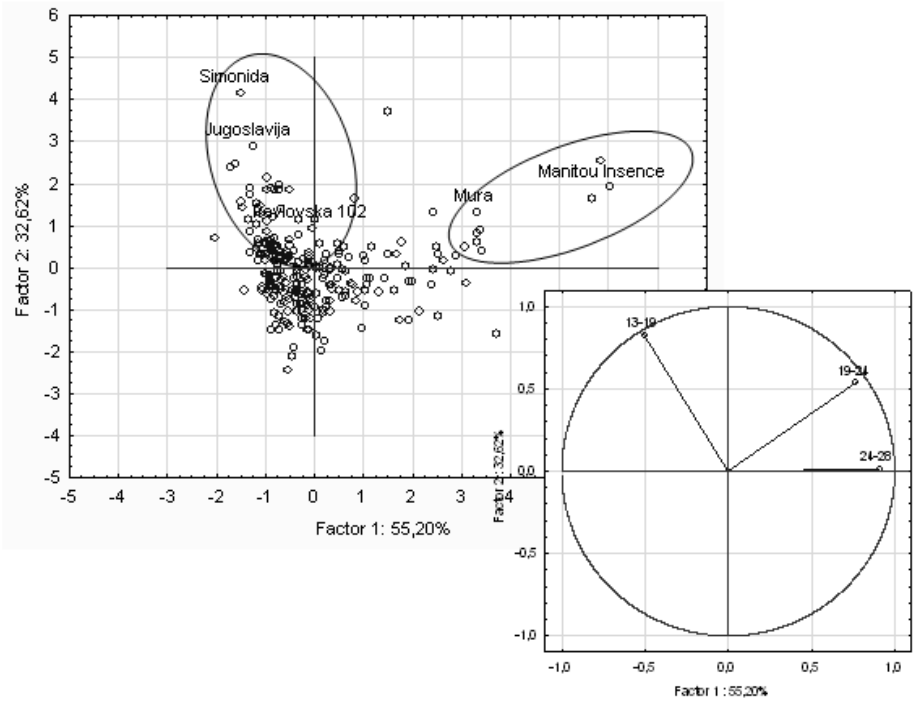

Figure 1. Principal component analysis of obtained data base for content of low molecular weight glutenins in intervals 13-19, 19-24 and 24-28 kDa

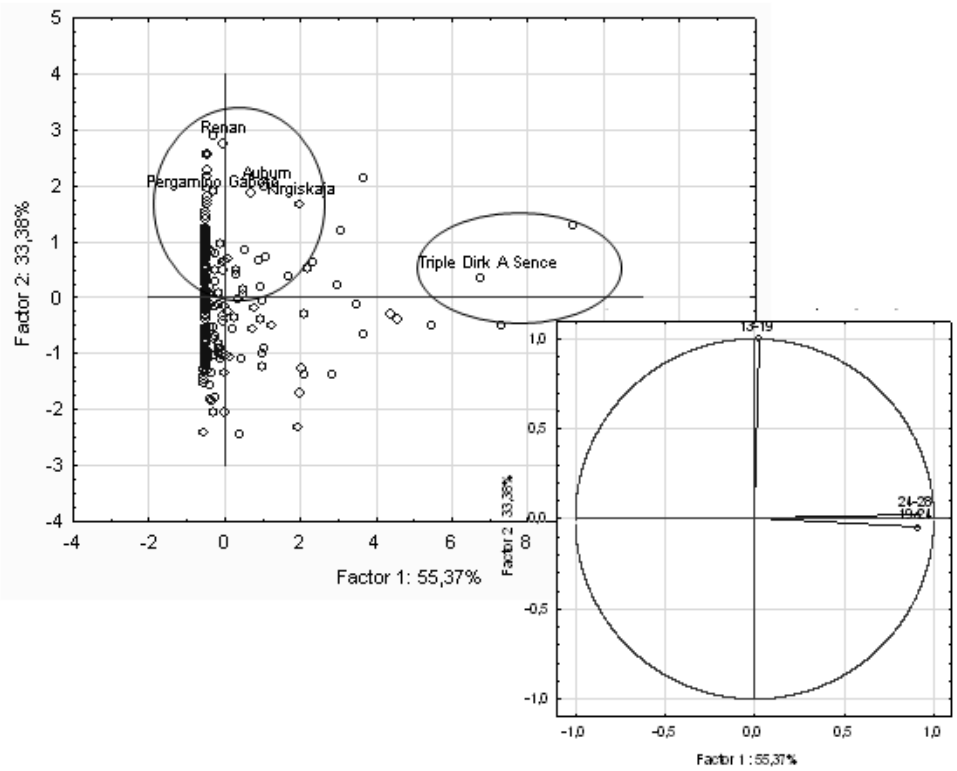

Figure 2. Principal component analysis of obtained data base for content of low molecular weight gliadins in intervals 13-19, 19-24 and 24-28 kDa

Five varieties for each type of wheat proteins were selected on the basis of principal component analysis. Their basic electrophoregramic data were analyzed and presented.

- For glutenins, varieties Jugoslavija, Simonida, Manitou Insence, Pavlovska 102, Mura;
- For gliadins, varieties Auburn, Renan, Pergamino Gaboto, Kirgiskaja, Triple Dirk A Sence.

Concenrning glutenins varieties Simonida, Jugoslavija and Pavlovska 102 were distinguished in interval of molecular weights from 13 to 19 kDa, variety Manitou Insence in both intervals from 19 to 24 kDa and 24 to 28 kDa and variety Mura in interval from 19 to 24 kDa.
Concerning glutenins variety Triple Dirk A Sence was distinguished in the intervals from 19 to 24 and 24 to 28 kDa. Varieties Pergamino Gaboto, Kirgiskaja, Auburn and Renan were distinguished in the interval from 13 to 19 kDa.
Content of low molecular weight glutenins and gliadins of varieties selected by distinguished intervals of molecular weights is presented in Tables 2 and 3, respectively.

Table 2. Low molecular weight glutenins content of selected varieties by identified molecular weight intervals

Variety	13-19 kDa		19-24 kDa		24-28 kDa	
	ppm	Number of peaks	ppm	Number of peaks	ppm	Number of peaks
Jugoslavija	3558.39$^{(a)}$	3	906.06$^{(c)}$	1	154.34$^{(c)}$	1
Simonida	3887.27$^{(a)}$	2	1059.32$^{(c)}$	1	0$^{(d)}$	0
Pavlovska 102	1514.53$^{(b)}$	1	835.00$^{(d)}$	1	225.65$^{(c)}$	1
Mura	926.50$^{(c)}$	3	2077.48$^{(b)}$	2	1420.58$^{(b)}$	1
Manitou Insence	800.24$^{(c)}$	2	2959.93$^{(a)}$	1	3845.62$^{(a)}$	1

(a), (b), (c), (d), (e) *Values with the same superscript within a column belong to the same homogenous group.*

Table 3.Low molecular weight gliadins content of selected varieties by identified molecular weight intervals

Variety	13-19 kDa		19-24 kDa		24-28 kDa	
	ppm	Number of peaks	ppm	Number of peaks	ppm	Number of peaks
Auburn	11313.72$^{(b)}$	2	0$^{(c)}$	0	3159.93$^{(c)}$	2
Renan	13495.89$^{(a)}$	2	0$^{(c)}$	0	780.27$^{(d)}$	1
Pergamino Gaboto	11006.67$^{(b)}$	3	0$^{(c)}$	0	0$^{(e)}$	0
Kirgiskaja	10458.63$^{(b)}$	2	1016.06$^{(b)}$	1	4022.82$^{(b)}$	1
Triple Dirk A Sence	7528.83$^{(c)}$	1	2105.73$^{(a)}$	1	8094.13$^{(a)}$	1

(a), (b), (c), (d), (e) *Values with the same superscript within a column belong to the same homogenous group.*

Appearance of electrophoregrams of selected varieties is presented on Figure 3.
Separated glutenin fractions (Figure 3) in investigated interval of molecular weights from 13 to 28 kDa confirm that the flour sample of variety Simonida was distinguished by interval of lower molecular weight, while Manitou Insence and Mura were distinguished by interval of higher molecular weights, with significant quantitative differences in mentioned range with regard to other varieties.
Separated gliadin fractions (Figure 3) in investigated interval of molecular weights from 13 to 28 kDa, confirm that the flour samples of varieties Kirgiskaja, Auburn and Renan were distinguished by interval of lower, while variety Triple Dirk A Sence was distinguished by interval of higher molecular weights. Variety Pergamino Gaboto had very characteristic appearance of electrophoregram, which was different from other investigated varieties.

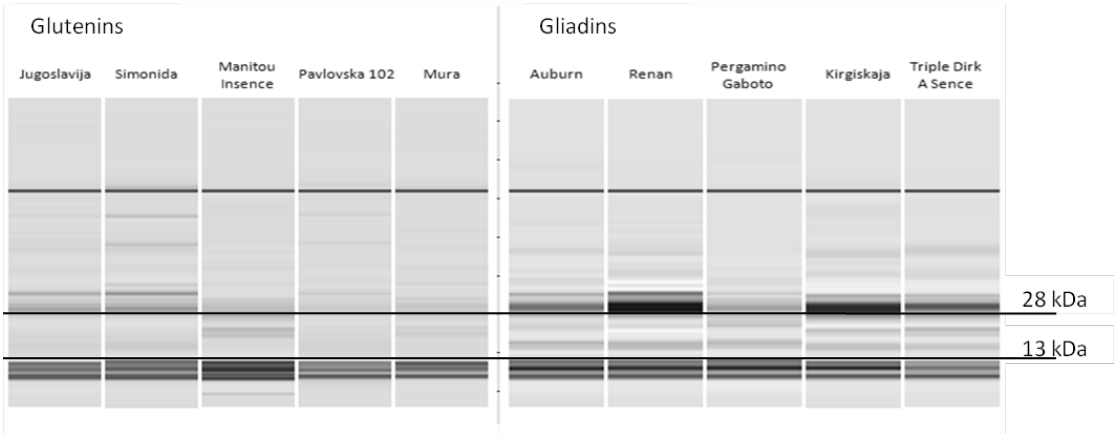

Figure 3. Appearance of electrophoregrams of selected wheat varieties

CONCLUSIONS

Wheat as a carrier of a number of biologically active compounds with preventive activity occupies a significant place as a carrier of functional ingredients in terms of frequency of consumption of bread and pastries in the diet. Cultivars originating from various parts of the world show differences in structure and proportion of both glutenin and gliadin fractions in the range of molecular weights for that literature data indicate the existence of fractions with bioactive properties. Generally, the range of lower molecular weights (13-28 kDa) in the structure of the wheat proteins, amounts of glutenin fractions are less that amounts of gliadin fractions.

ABSTRACT: Honey is regarded as a natural and safe product for human that free of any chemical contaminants. However, today some of honey is produced in an polluted environment by different sources of contamitants. These are present in air, water, soil and plants and are transported to beehives and bee products by bees. Pesticide is a general name of chemicals which consist of insecticides, acaricides, fungicides and herbicides. Nectar and pollen collected from pesticide-treated flowers can result in contaminated honey. The residues of pesticides detected in bee products are mostly organochlorines, organophosphates, carbamates and neonicotinoids. Plant-derived pesticides, called botanicals, have also been developing quickly. Consumers in Europe are concerned about pesticide residues in food. The small amounts of pesticide residues remain in the honey and other products constituting a potential risk for the human health. Pesticide use also raises a number of environmental concerns.
Key words: *pesticises, honey, pollen, honey bee, residue*

INTRODUCTION

We will be needed more food to feed world population predicted to be 9 billion by 2050. The development of public and private food safety standards has been driven by the numerous scandals like dioxin that occured during the last years (Willems et al., 2005). In recent years public concern about the safety of foods of animal origin has heightened due to residue problems originated from contaminants, dioxins and pesticide resistance. Residues are substances that can ocur in foods after using veterinary drugs and pesticides in beekeeping and in agriculture. Pesticide residues in foods are unwanted phytosanitary products or derivates. Pesticides are designed to control pests and disease-causing organisms. They are chemicals that control insects, weeds, fungi and other pests that destroy almost half of the world's food crops. However, pesticides are poisonous. Therefore they must be applied correctly to protect bees in pollination (Fraser, 2004). Many pesticides contain persistent organic pollutants, which persist in the environment and accumulate in the fatty tissue of animals, including humans. The accumulation of these chemicals in the body can pose a serious health risk to living organisms, and have been implicated in causing cancer, disease, hormonal imbalances and reproduction problems, including birth defects (Griffin, 2011). They can be also present in non fatty products, such as water, fruits and vegetables. Organochlorine pesticides (OCPs) can be present in honey by the means of treatment of some plants. Pesticides might be introduced into honey from nectar or pollen collected by honeybees from contaminated blossoms. They and their metabolites can accumulate in wax of the comb (Fernandez-Muino et al., 1995). However, for every one dolar that is sepent on pesticides for crops yields approximately four dollars in crop saved. Pesticides also reduce biodiversity, destroy habitat and cause pesticide resistance.
Pollination is an essential part of the ecology and bees are the most important pollinators (Martin, 2003). Honeybees are beneficial to human by producing honey, wax and pollen, besided pollination (Kolonkaya et al., 2002). They are biological indicators, picking up chemicals and other pollutions from their environment both external and internal to their hives (Wu et al., 2011). Bee products have the image of being natural, healthy and clean. Asia is the greatest honey producer. Total honey production in the world is approximately 1.3 million tones. However, today honey and other bee products such as pollen, wax and

propolis are produced in an environment polluted by different sources of contaminants (Chlebo, 2006). The contamination sources can be environmental and apicultural. Residue in honey (Piro and Mutinelli, 2003). There is a need to improve preventitive methods to reduce or avoid accumulation of contaminants in the apiary infrastructure in aim to produce clean honey and apiary products (Barel et al., 2011). Good Agricultural Practice (GAP) and Integrated Pesticide Management (IPM) can reduce risk to human, bees and the environment (McKee, 2003). The aim of this paper is to give information about pesticides, their action and effects on bees and bee products, human and the environment. It also aims to give preventition methods and legislations for pesticide residues in bee products.

PESTICIDES AND THEIR CHEMICAL STRUCTURE

Pesticides are used in agriculture and farming practices to eradicate insects, rodents, weeds and other forms of pests(Anonymous, 2012a). They can be divided to two classes, broad-spectrum and narrow-spectrum pesticides. Broad spectrum pesticides kill many kinds of pests, while narrow-spectrum pesticides do just the opposite. Narrow-spectrum pesticides are developed to kill specific organism types. However, systemic pesticides work differently. They penetrate to the inside of a plant travelling along its absorbtion path. These poisons work by poisoning the pollen and nectar of flowers and this can kill needed pollinators (Anonymous, 2012b). Pesticides include insecticides, fungicides, herbicides, acaricides, bactericides and nematodices. The residues of pesticides detected in bee products are mostly insecticides, acaricides, fungicides and herbicides. The total amount of pesticides applied worldwide is currently put at 2.5 million tonnes. Of this 50-60% is herbicides, 20-30% insecticides and 10-20% fungicides (Anonymous, 2012a). Pesticides used on various crops are divided to groups based on their chemical structure (Bogdanov et al., 2003; Anonymous, 2012a):

- Organochlorines pesticides (OCPs): They are hazardous because of their bioaccumulative action into the food chain, to remain stable for years and to move the environment. DDT, lindane, hexachlorocyclohexane, aldrin, dieldrin, endrin, heptachlor and endosulfan are in this group.
- Organophosphorus pesticides (OPPs): This specific class of pesticides is of relatively high toxic for humans. This includes dialiphos, trichlorophon, dichlorvos, parathion, malathion, ronnel, methoate and several others. These chemicals break down quickly when exposed to weather and very hazardous for mammals than the OCPs.
- Carbamates: They don't leave residue on foods. Their mode of action is similar to OCPs but their insecticidal activity is more selective.
- Pyrethroids: These chemicals are similar to pyrethrum but do not break down quickly as the natural products. These substances were proved toxic to bees but the concentrations of residues detected in honey were very low.

Beekeepers are frequently compelled to use varroacides to avaoid colony death from *Varroa* mites and residue (Johnson et al., 2010). The Varroacides can be divided into three categories: synthetic organic pesticides (pyrethroid, fluvalinate, amitraz and fenpyroximate), natural product pesticides (thymol, menthol and other herbal essential oils) and organic acid pesticides (formic acid and oxalic acid).

PESTICIDE RESIDUES IN HONEY AND OTHER BEE PRODUCTS

Effects of pesticides on honey bees

Honey bees make an important contribution to sustainable agriculture and the environment as the main pollinators (Anonymous, 2012c). Pesticides are responsible for disappearing of honey bees in recent years. Pesticides are stored in honey bee's body while they are harvesting nectar and pollen from flowers (Griffin, 2011; Kolankaya et al., 2002). Most of the time, accaricide treatments for *Varroa* lead to residues in hives (Chauzat and Faucon, 2007). The recent sequencing of the honey bee genome provides a possible explanation for the

sensitivity of bees to pesticides. The honey bee genome is markedly deficient, including cytochrome P450 monooxygenases, glutathione-s-transferaes, and carboxylesterases (Claudiones et al., 2006). Pesticide residues as ppb and occasionally ppm can be detected in hive matrices when bees forage in any conventional agricultural or urban settings (Johnson et al., 2010). Delayed development was observed in bees reared in containing high levels of pesticides (Wu et al., 2011).

Pesticide residues in bee products

Systemic pesticides are usually incorporated into the soil or onto seeds and more up into the stem, leaves, nectar, and pollen of plants. A systemic pesticide may incorporate into fruits, pollen and nectar of the treated plants (Anonymous, 2012d). However, bee products from natural vegetation contain lesser residues than agricultural fields. Most of the acaricides such as coumaphos, amitraz and fluvalinate leave residues in hives. In honey, residue levels are low, but accumulation of several pesticides in wax could lead to synergistic toxic effects on bees, also, the persistence of acaricides in wax favor the appearence of acaricide resistent mites (Barel et al., 2011). The medicines used in varroa treatment leave residue in honey, wax and propolis. Fluvalinate and flumethrin, fat soluble compounds, hazard with wax. They become the active ingredient and we do not get rid of it until the wax is burned. If these compounds are used several years in succession than the residues build up and some moment they become so large that there are traces to be found in the honey. Already after one year, there are such large traces in the wax. After one or two years the compounds can be found in honey. The compouns alternate to these chemicals (formic acid and lactic acid) are to be found naturally in honey. With the recommended dosages they do not produce a larger content in honey (Jorgensen, 2005). The relatively low concentrations of pesticides in honey seem to be due to a filtering effect of bees (Chlebo, 2006). Pesticides can baund strongly with propolis (Jorgensen, 2005). Bogdanov (2006) reported the main contamination risks for the different bee products. Antibiotics in honey and Royal jelly, persistent lipophylic acaricides in wax, persisitent lipophylic acaricides and lead in propolis and pesticides in pollen are the risk factors.

Results of experiments were conducted to determine the pesticide residues in bee products:

In Turkey, residues of OCPs and OPPs insecticides were detected in honey and pollen but not in propolis. The levels were below the level of toxicity (Kolankaya et al., 2002). In a Spain and Portugal study, 50 honey samples were analysed to determine 42 residues of pesticides. Most of the pesticides found in honey were OCPs (Blasco et al., 2003). In a Swiss study, 27 honey samples, produced between 1998 and 2001 were analysed. The results of this research showed that pesticides originating from agriculture and the environment are not a significant contamination source for honey and beewax (Bogdanov et al., 2003). In Switzerland, 27 samples of pesticide in wax have been analysed. All the samples contained at least one pesticide residue. The content was three to four times higher than that from the same year for fluvalinate, and for brompylate was twice as much, with contents of 3.7 mg and 1.3 mg per kg, respectively (Jorgensen, 2005). In a Danish study, 35 honey samples were tested for the present of 37 different pesticides including flumethrin. No measurable traces of pesticides were to found at all. However, traces of pesticide residue were found in fifteen of the samples of thirty two wax samples were collected from Danish market (Jorgensen, 2005). In Slovenia, monitoring of 20 honey samples for the presence of 14 insecticides showed no detectable residues of insecticides (Chlebo, 2006). A multiresidue analysis of 16 insecticides and acaricides and two fungicides showed that 14 of the searched for coumaphos and endosulfan residues were the most frequently (61.9, 52.2 and 23.4% of samples, respectively). Coumaphos was found in the highest average quantities (792,6 microgram^{-1}). Residues of cypermethrin, lindane and deltamethrin were found in 21.9, 4.3 and 2.4% of samples, respectively (Chauzat and Faucon, 2007). Martel et al. (2007) found varroacide in wax, pollen and bee bread include amitraz, bromopropylate, coumaphos, flumethrin and fluvalinate. In France, a 3-yr field survey was carried out from 2002 to 2005. Residues of imidacplorid and 6-chlorinicotinic acid were the most frequently detected in pollen, honey, and honey bee matrices (Chauzat et al., 2008). Amitraz residue was also

found in various levels in six out of 32 honey samples in Turkey (Çobanoğlu and Tüze, 2008). Choudhary and Sharma (2008) found DDT and its isomers in honey samples produced in India. Residues of OPPs were not detected. Johnson et al. (2010) analysed one hundred twenty one different pesticides and metabolites. Pesticides were found in 887 wax, pollen, bees and associated hives.

EFFECTS OF PESTICEIDES ON HUMAN HEALTH AND THE ENVIRONMENT

In the EU no plant protection substances can be used unless if they have been scientificly established that they have no harmful effects on consumers and farmers. However, the WHO estimates that each year, 3 million farmers in agriculture in the developing countries experience severe poisoning from pesticides. Pesticide residues may cause harmful health effects including skin irritations, delayed or altered development, lung problems, nervous system disorders, liver-kidney damage, reproductive damage, endocrine and immune damage, and cancer (Anonymous, 2012e). The dangers of pesticides can start as early as fetal stage of life and cause growth problem (Anonymous, 2012b). The health effects of pesticides depend on the type of pesticide. OPPs and carbamates affect the nervous system. Others may irritate the skin or eyes. Some pesticides are carciogens. Others may affect the hormone or endocrine system in the body (Anonymous, 2012f). OCPs hydrocarbons (e.g. DDT) operate by disrupting the sodium/potasium balance of the nevre fibre. OPPs and carbamates operate through inhibiting the enzyme acetylcholinesterase, causing a variety of symptoms such as weakness or paralysis (Anonymous, 2012g). OCPs pesticides transfer from blossom to honey and finally to the consumer. They have been restricted or banned in agriculture because of their persistence and bioaccumulation in the environment. However, these type pesticides are stil found in soil from which they continue to cycle through the environment. Compounds that are soluble in water are removed from the blood stream by the kidneys and excreted in the urine. Because DDT and its relatives are fat-soluble, they are not excreted in the urine. Modern pesticides are much less persistent than DDT and are not prone to bro-accumulation (Johnson and Jadon, 2010). The OCPs are banned in developed countries. However, they are stil widely used in developing countries because they are relatively cheap (Anonymous,2012a). More than 95% of insecticides and herbicides can reach non-target species, air, water and soil. They can be carried to other areas by wind. Pesticides also reduces biodiversity, damages habitat and decrease pollinators.

METHODS TO DECREASE PESTICICE RESIDUE IN BEE PRODUCTS

The beekeepers are the first subjects in the production chain to avoid honey contamination. They are mainly entered in the quality of bee product, but they needed more effective control tools (Piro and Mutinelli, 2003). Pesticide residue problem is on second of consumer perception list of possible risk. Food additives are on top of this list. Alll pesticides must be adequately tested, evaluated and authorised for potentionally adverse effects on foods, human health and the environment before they are licensed. Some pesticides are restricted. However, the restricted and not authorised pesticides carry a greater level of risk (Fraser, 2004). In the EU 0.01 mg/kg pesticide in honey is limit. To avoid pesticide residues should be used outside the bloom period or at least, not during the foraging time of bees. Beekeepers can also avoid residue by placing their hives more than 3 km from agricultural plants treated with pesticides (Chlebo, 2006). Farmers should do this application by using IPM. it is the best available pest control system. Farmers and beekeepers should also apply Push Pull strategy which uses a mixture of behaviour-modifying stimuli to manipulate the distribution and abundance of insects. The overuse, misuse and overuse of peticides must be controlled. Farmers should use cultivation practices including polyculture and crop rotation to manage the pest damage. Farmers must prefer biological pest control methods including natural predators or parasites of the pests. Beekeepers and farmers must be in good accordance during pesticide application period. It is beter to use new products have been produced in

recent years as alternative to hazardous pesticides. New pesticides include biological and botanical derivates and alternatives that are though to reduce health and environmental riks.

LEGISLATIONS FOR PESTICIDE RESIDUES IN BEE PRODUCTS

In Europe, recent EU legislation has been approved banning the use of carciogenic, mutagenic or toxic to reproduction. The EU approves the use of pesticides and sets tolerence levels. MRLs for pesticide residues permitted in or on a food are often 10 to 1,000 times less than the amount needed to pose a health risk. The amount of pesticides on fruits, vegetables and crops can be decreased by washing, peeling, blanching and cooking but people consume honey directly (Fraser, 2004). The substances for any type of animal or food that must be monitored were divided into two groups in EU legislations. The categories are shown in the table have to be monitored in bee products (Piro and Mutinelli, 2003):

- GROUP A- Substances having anabolic effect and outhori**z**ed substances:
  (6) Compounds included in Annex IV to Council Regulation (EEC) 2337/90
- GROUP B. Veterinary drugs and contaminants
  (1) Antibacterial substances icluding sulphanomides, quinolenes
  (2) Other veterinary drugs
  (c) Carbamates and pyrethroides
  (3) Other substances and environmental contaminants
  (a) Organochlorine compounds including PCBs, (b) Organophosphorus compounds (c) Chemical elements

However, in Europe, accaricide residues in wax are not regulated (Chauzat and Faucon, 2007). In Turkey, the same categories of substances also have to be monitored in bees and bee products. Turkey has been conducting an EU Leonardo da Vinci Transfer of Innovation project titled 'Beekeeping European Environmental Sustainability BEES' with Holland, Belgium, Italy, Poland and Hungary to produce learning materials for beekeepers for all about sustainable beekeeping (http//:www.beeseurope.eu). In 2008, the EU issued new and revised MRLs for the roughly 1,100 pesticides ever used in the world. The revision was intended to simplfy the previous system, under which certain pesticide residues were regulated by the Commission, other were regulated by the Member States, and others were not regulated at all (Anonymous, 2008). The new Regulation covers pesticides currently or formerly used in agriculture in or outside the EU. For crops grown outside the EU, MRLs are set on request of the exporting country. Developing country exports must meet importer's MRLs or perhaps in future the international recommendations under WTO rules.

In conclusion, the main contamination for bee products come from apicultural practices and agriculture. To avoid harmful effect of pesticides on environment, beekeepers, bee products, and human educational programs and projects should be developed by the public health organisations. Especially, developing countries need to assistance in establishing pesticide residue standards. Consumers in these countries must be also educated about health concerns associated with pesticides. It is also necessary for developed countries that importing bee products from third countries.

ABSTRACT: The aim of this study was to investigate microbiological, chemical and sensory properties of raw donkeys' milk from an autochthonous breed originated from Serbia. Changes in microbial flora during the six days of storage at 4 ºC were monitored by enumeration of total count of bacteria, yeasts and moulds, coagulase positive staphylococci, lactic acid bacteria, bacterial endospores, *E.coli*, *C. perfringens* and *Salmonella* spp. Descriptive method was used for determination of sensory properties. Descriptive terms were developed to describe appearance (colour), flavour, taste and aftertaste. Chemical analyses included determination of protein, milk fat, dry matter, lactose and vitamin C content. After five days of storage at 4 ºC microbiological quality of the raw Domestic Balkan donkeys' milk was in accordance with the requirements of European Regulation. The obtained results indicate strong antimicrobial activity of the tested milk and longer shelf-life in comparison to other raw milk sources. Sensory properties of the tested milk were in accordance with changes in microbial flora. High vitamin C content, low protein and milk fat content make the tested milk a valuable potential component of functional food.
Key words: *donkeys' milk, microbiological properties, sensory properties, chemical composition*

INTRODUCTION

The therapeutic effects of donkeys' milk have been known since ancient times, while nowadays the research is addressed towards its nutrient composition and health effects. Donkeys' milk has lower content of fat, protein and inorganic salts, and higher content of lactose in comparison to bovine milk. Low casein content, high percentage of essential amino acids, protein and lipid profiles similar to those of human milk (Fantuz et al., 2001; Salimei et al., 2004; Vincenzetti et al., 2008) favour donkeys' milk as a potential new dietetic food and a good alternative for infant nutrition in the case of cow's milk protein allergy (CMPA) (Iacono et al., 1992; Monti et al., 2007; Vita et al., 2007). Several studies reported potential anti-inflammatory effect (Ellinger et al., 2002; Jirillo et al., 2010) and positive effect of donkeys' milk on the prevention of atherosclerosis (Tafaro et al., 2007). Anti-proliferative and anti-tumor effects of some active compounds in donkeys' milk on human lung cancer cells have also been reported (Mao et al., 2009). High concentration of polyunsaturated fatty acids, vitamins A, B, C and low cholesterol level contribute to donkeys' milk functionality (Solaroli et al., 1993).

The Domestic Balkan donkey is an autochthonous breed primarily farmed in the Northern and Eastern regions of Serbia (Food and Agriculture Organization–Domestic Animal Diversity Information System, 2009; Kugler et al., 2008). The aim of this study was to investigate the chemical and sensory properties of Domestic Balkan donkeys' milk, as well as changes in microbial flora during the six days of storage at 4 ºC.

MATERIALS AND METHODS

Sample collection

Donkeys' milk samples were collected immediately after morning milking from "Zasavica" Special Nature Reserve. The milk obtained from eight manually milked donkeys was collected, mixed and kept in an ice box at 4 ºC during the transport. The milk sample was divided into three equal parts designated to study its microbiological, chemical and sensory properties. The milk sample assigned to microbiological examination was further divided into seven sub-samples of 50 mL each, intended to study the variability in microbial population during the six days of storage. One sub-sample was examined immediately, while the others were stored at 4 ºC and analysed on a daily basis. Donkeys' milk samples were collected three times following the same sampling procedure.

Determination of changes in microbial population during the storage

Changes in microbial flora during the six days of storage at 4 ºC were monitored by enumeration of total count of bacteria, yeasts and moulds, coagulase positive staphylococci, beta-glucuronidase-positive *Escherichia coli* and *Clostridium perfringens,* according to listed ISO methods: ISO 4833:2003, ISO 21527-1:2008, ISO 6888-1:1999/A1:2003, ISO 16649-2:2001, ISO 7937:2004, respectively. Enumeration of bacterial endospores was performed by incubation of previously heated (100 ºC, 5 min) milk samples on nutrient agar (Himedia, India) at 30 ºC for 72 h according to Serbian legislation (Sl. list SFRJ, no. 25, 1980). The lactic acid bacteria count was determined by incubation (30 ºC, 72 h) of inoculated Man, Rogosa and Sharpe (MRS) agar (LabM, United Kingdom). Coliform bacteria and *Enterobacteriaceae* were determined according to AOAC methods (AOAC Official method 996.02, 2002; AOAC Official Method 2003.01, 2003). Detection of *Salmonella* spp. was carried out according to the ISO 6579:2002/AC: 2006 method. All experiments were performed in triplicate.

Sensory analysis

Donkeys' milk samples were tempered at 15 ºC before analysis to allow the release of odors and flavors (Bandler et al., 1984). Approximately 25 mL of each sample was given to the assessors in 3-digits coded covered glasses. Sensory evaluation was performed during 6 days in order to test milk stability. Descriptive sensory analysis was performed by a trained eight-member panel. The panelists were selected according to SRPS ISO 8586-1(2002). Sensory evaluation was carried out in individual boxing in the laboratory according to SRPS ISO 8589 (1998).

Descriptive terms were developed for the assessment of sensory quality and intensity of colour, flavour, taste and aftertaste using terms from the lexicon of SRPS ISO 5492 (2000). The panelists used attributes, definitions and references from previous sensory studies of milk (Bandler et al., 1984). The following data scale was used: 1-typical, optimal quality; 2-neither good nor poor quality; 3-poor quality.

Chemical analysis

Protein, milk fat, lactose content and dry matter were determined by the IDF standard (Carić et al., 2000). The vitamin C content was determined by enzymatic method (Megazyme International Ireland 2011).

RESULTS AND DISCUSSION

The results of three independent experiments indicate that there was no significant difference ($P<0.05$) between total bacterial counts at the beginning (4.24 ± 0.90 – 4.79 ± 0.55) log cfu/mL and after five days of storage (4.59 ± 0.16–5.22 ± 0.76) log cfu/mL, whereas increase was observed on 6^{th} day (6.17 ± 0.40 – 6.57 ± 0.90) log cfu/mL. From the initial number of (2.08±0.03–2.10±0.90) log cfu/mL lactic acid bacteria count slightly increased to

(2.60 ± 0.31 – 2.95 ± 0.05) log cfu/mL after six days. Bacterial endospores remained at low level (<2 log cfu/mL) during the storage period. In the first experiment (milk collected in January 2011), *Enterobacteriaceae* and coliforms were not detected until the 2nd and 4th day, respectively, whereas in the milk samples collected in October and November 2011 these bacteria were not detected during all six days. The presence of *Salmonella* spp., *E. coli*, *C. perfringens*, coagulase positive staphylococci, yeasts and moulds were not observed in any of the analysed samples.

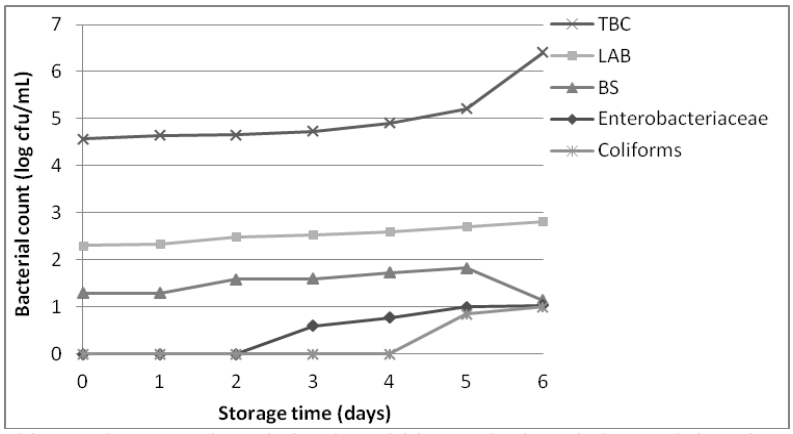

Fig. 1. Total bacteria count (TBC), lactic acid bacteria (LAB), bacterial endospores (BS) *Enterobacteriaceae* and coliforms counts in raw donkeys' milk during the six days of storage at 4 ºC (mean values of three independent experiments)

Typical milk colour did not change during all six days of assessment. Aroma was poorly expressed during the first three days, whereas on 4th day a milky-sweet flavour appeared and became more intense during the next two days leading to a lack of freshness. Panel members defined milk taste as a pleasant, with a slight sweetness originating from lactose. In terms of overall acceptability of taste, panellists did not observe any changes during the first three days of experiment. However, slightly bitter taste appeared on 4th day and intensified during the next days. For this reason, on 5th day milk was assessed as non specific according to its primary and residual bitter taste. Assessments of the sensory properties of the tested milk are shown in the Fig 2. The obtained results indicate that raw Domestic Balkan donkeys' milk is sensory acceptable during four days of storage at 4 ºC. This is in accordance with its microbiological quality.

Raw donkeys' milk has low protein and milk fat content and high lactose and vitamin C content (Table 2) which makes this milk optimal for new dietetic food formulation and human milk substituent in infant nutrition in the cases of bovine milk protein allergy.

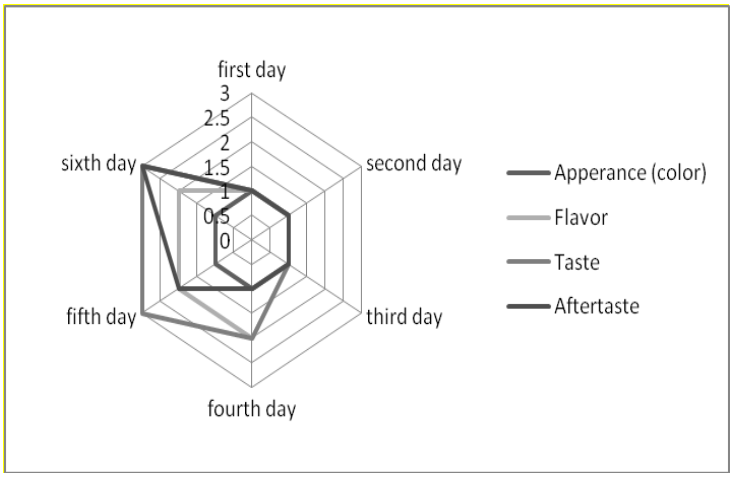

Fig. 2. Changes in the sensory properties of raw donkeys' milk during the six days of storage at 4 ºC

Table 2. Chemical composition of raw donkeys' milk

Chemical characteristics	(mean ± standard deviation)
Dry matter (%, w/w)	8.58±0.32
Protein content(%, w/w)	1.67±0.20
Milk fat content (%, w/w)	0.66±0.11
Lactose content (%, w/w)	7.07±0.14
Vitamin C (μg/mL)	32.95±1.38

CONCLUSIONS

Microbiological quality and changes in microflora during the six days of storage at 4 ºC indicate strong antimicrobial potential of raw Domestic Balkan donkeys' milk against the naturally occurring groups of microorganisms. After five days, microbiological quality of the tested milk was in accordance with the requirements of European Regulation, which indicates its longer shelf-life in comparison to other raw milk sources. Sensory properties of the tested raw milk were acceptable within four days of storage at 4 ºC. High vitamin C content, low protein and milk fat content make the tested milk a valuable potential component of functional food.

ABSTRACT: *Aeromonas hydrophila spp.* is commonly present in water and in certain incidences they might cause diseases in fish and amphibians. Humans are infected by ingestion of these bacteria with contaminated food or water. *Aeromonas hydrophila spp.* might cause gastro-intestinal disorders and poisoning in humans. One of the major issues associated with *Aeromonas hydrophila* and incidence of gastro-intestinal diseases is accurate identification of aeromonades at the species level. Therefore, there is a need for a clear phenotypic scheme and biochemical characterization of the mentioned species.
Objective of this paper was to study the presence of *Aeromas hydrophila* in trout samples and to test biochemical characteristics of isolated strains.
For isolation of *Aeromonas hydrophila* species, 120 samples of rainbow trout, commercially available, were studied. *Aeromonas hydrophila* was isolated from fish muscle tissue and skin according to "Microbiological Methods for the Meat Industry", second edition (1991) Biochemical studies were performed on Aeromonas hydrophila medium, followed by oxidase test (+), catalase test (+), staining according to Gram (-) and vibriostat test agar (0/129, vibriostatic), as well as biochemical tests API 20E and API 20NE.
From the 120 studied rainbow trout samples, 12 strains of *Aeromonas hydrophila* were isolated, out of which seven strains (58.3%) of *Aeromonas hydrophila* belonged to group 1, whereas five strains (41,6%) belonged to *Aeromonas hydrophila* group 2. Out of 12 isolated strains, 11 (91.7%) had β-galactosidase. They were citrate and indol positive, sorbitol negative, arabinose positive, NO_2 -producing and reducing it to N_2. Then (83.3%) of 12 twelve isolated strains were Voges-Proskauer positive and melibiose negative, whereas eight (66.7%) were amigdalin and lysine-decarboxylase positive. It was established that seven of 12 twelve strains (58.3%) ferment glucose.
The obtained results demonstrate the need to supplement phenotypic schemes for identification of *Aeromonas hydrophila* strains originating from fish at the species level.
Key words: *Aeromonas hydrophila, Rainbow teout (Oncorhynchus mykiss), biochemical characterization*

INTRODUCTION

Representatives of genus *Aeromonas hydrophila* are facultative anaerobes, oxidase positive and gram- negative bacteria, whose main reservoir in nature is water (Anon., 2006). Hence, *Aeromonas hydrophila* species are often isolated from samples of fish crustaceans and shellfish, but also can be found in fresh food stuffs such as fresh meat, packaged products ready for consumption, cheese and milk (Karabasil et al., 1999; Palumbo, 1996; Panin, 1993; Buchanan and Palumbo, 1985; Tsai and Chen, 1996). As a consequence of alimentary poisoning caused by these bacteria, gastroenteritis occurs in healthy persons, but usually these are individual cases of disease without large epidemics. Symptoms of the disease are nausea, vomiting, stomach cramps and diarrhea (Ashdown and Koehler, 1993; Janda and Abbot, 1998).
Main factors of *Aeromonas hydrophila spp.* virulence are: secretion of exotoxins and endotoxins (lipopolysaccharide, LPS), presence of S-layer and fimbria or adhesins (Merino et al., 1996). According to results of Karabasil et al. (2002), studied filtrates of strains

Aeromonas hydrophila (9) and *A.sobria* (3), had cytotoxic effect on tissue culture of Vero cells, but the intensity of chages differed depending on the filtrate. Changes on Vero cells in sense of cytotoxic effect were caused by thermo sensitive toxin component.
According to literature data, in patients suffering from diarrhea, *Aeromanas* species were isolated in rate from 0.6 to 10% and predominantly in small children *(Janda and Abot,* 2010; Essers et al., 2000). According to epidemiological data from Spain, *Aeromonas hydrophila spp.* are in fourth place of all microbiological causes of gastro-intestinal diseases that have been notified each year during the period 1997 - 2006. (Anon., 2007.). This is indication of the importance of *Aeromonas hydrophila spp.* as cause of gastro-intestinal disorders and poisonings in humans, especially small children and immune compromised persons. In scientific community, there is no common position on factors causing the poisoning. Association between introduction of *Aeromonas hydrophila* through drinking water, food and diarrhea, still hasn't been identified (Anon., 2006).
Herra et al. (2006) point out geographical differences in distribution of *Aeromonas hydrophila* species and strains belonging to *Aeromonas hydrophila* (*Aeromonas hydrophila, A.bestiarum, A.salmonicida*) and *A.caviae* (*A.caviae, A.mediji, A.eucrenophila*) which can be found in sea and fresh water fish, as well as fresh water environment.
Due to its nutritional value and availability, trout from aquaculture in Serbia is very appreciated fish and represents valuable and generally accepted source of animal proteins in human nutrition (Trbović et al., 2011; Vranić et al., 2011). Some literature data indicate that fish meat in nutrition (20 g/day) reduces the risk of cardio-vascular diseases with fatal outcome by 7% (He et al., 2004). According the data from American Heart Association it was established that cardio-vascular patients should eat fish more than twice per week. Daily intake of 1 g EPA (eicosapentaenoic acid, pentane-eicosenoic acid C20:5 n-3) and DHA (docasahexaenoic acid, hexanedioci acid, C22:6 n-3) is necessary, (Lichtenstein et al., 2006) since long chain n-3 PUFA PNMK influence reduction of mentioned risk (Dewailly et al., 2007) as well as risk of auto-immune diseases (Zamaria, 2004), also malignant diseases (Terry et al., 2004) and diabetes (Nettleton and Katz, 2005).
Given the large presence of *Aeromonas hydrophila spp*. in nature, its psychotrophe nature and increasing significance as potential alimentary pathogen, objective of our study was to investigate the diffusion/prevalence of *Aeromonas hydrophila* in trout, as well as biochemical properties of isolated *Aeromonas hydrophila* strains.

MATERIAL AND METHODS

For the purpose of isolation of *Aeromonas hydrophila* 120 samples of Rainbow trout from retail stores were collected. Samples were put in sterile Stomaher bags and in chilled condition transported to the laboratory. Samples were processed within two to four hours from the moment of sampling in the Laboratory for biotechnological research and control of food safety and quality of the Institute of Meat Hygiene and Technology in Belgrade. *Aeromonas hydrophila* was isolated from samples of muscle tissue and skin of rainbow trout.
Isolation was carried out according to Microbiological Methods for the Meat Industry, 1991, of the Research Institute of the meat Industry from New Zealand. According to recommendations of previously mentioned edition, isolates were obtained in the following way: sample was transferred into 9 times the amount of APW, Alkaline peptone water and incubated for 24 h at 28 °C. Culture which grew in APW, was superficially placed on selective-differential foundation – SAA, Starch ampicillin agar, incubated for 24 h at 28 °C. After incubation, SAA was topped with Lugol solution preparation and colonies of yellow colour (amylase positive) with zone of illumination were further subcultured on Aeromonas hydrophila medium (AHM), incubated for 24 h at 28 °C, and subsequently oxidase test (+), catalase test (+), staining according to Gram (-) and vibriostat test agar (0/129, vibriostatic), as well as biochemical tests API 20E and API 20NE were carried out.

RESULTS AND DISCUSSION

In 120 studied samples of rainbow trout, 12 strains of *Aeromonas hydrophila* were isolated (A, I, J, B, C, K, L, D, M, E, F and G).
Collection of mobile *Aeromonas hydrophila*, consisting of 12 isolates, of which seven strains (58.3%) were *Aeromonas hydrophila* group 1, whereas five strains (41.6%) *Aeromonas hydrophila* were group 2. Strains A, B, C, D, E, F and were identified as *Aeromonas hydrophila* group 1, whereas strains I, J, K, L and M were identified as *Aeromonas hydrophila* group 2. Biochemical properties of isolated strains are presented in table 1, for *Aeromonas hydrophila* group 1 and in table 2, for *Aeromonas hydrophila* group 2.

*Note: * Non-specific reactions for group 1*

One of the major issues in associating *Aeromonas hydrophila* originating from fish with gastro-intestinal disorders and diseases is accurate identification of aeromonades/Aeromonas hydrophila at the level of species (Euzeby, 2010; Figeras et al., 2010; Minana-Galbis et al., 2010). Because of the lack of clear phenotype scheme, biochemical characterization of described species is relatively complicated. Presently, phenotype identification scheme by Abot et al., (2003) is used, who suggested use of Moeller-decarboxylase and dihydrolase reactions for identification and grouping of

Aeromonas hydrophila species. In this way, five groups with set of biochemical tests defining the properties of each *Aeromonas hydrophila* species within the group were obtained.
In biochemical characterization of isolated strains it was established that they were oxidase positive, catalase positive, arginine positive, ornitin positive, H_2S negative, urease negative, tryptophan desaminase negative, gelatin negative, ferment manithol, inositol, rhamnose and saccharose, they are mobile, hemolytic and hydrolyze starch. In regard to other biochemical properties the following was determined: 11 (91.7%) of 12 studied strains of *Aeromonas hydrophila* have β-galactosidase, also they are citrate and indole positive, sorbitol negative, arabinose positive, produce NO_2 and reduce it to N_2, also that 10 (83.3%) of 12 studied strains were Voges-Proskauer positive and negative to melibiosis, whereas eight (66.7%) of 12 strains had lysine-decarboxilase positive reaction and were amygdalin positive. In 58.3% of strains (seven of 12 strains) it was established that they fermented glucose.

CONCLUSIONS

Obtained results in regard to biochemical properties of *Aeromonas hydrophila* isolates, isolated from trout tissues, show that phenotype identification schemes for identification of *Aeromonas hydrophila* strains originating from fish at the level of species, should be supplemented. Due to lack of clear phenotype scheme and poor biochemical

characterization of described strains originating from fish, further taxonomic research based on molecular methods are necessary.

ACKNOWLEDGEMENTS

Results were obtained during realization of the project No. TR31011, financed by the Ministry of Education and Science.

ABSTRACT: The utilization of agricultural waste products to produce food has recently received increased attention, not only to minimize waste disposal problems, but to help maximize potential resources and production of new and novel food products. The objective of this study was to characterize the pumpkin oil press-cake, a by-product of the pumpkin seed oil pressing process. The cakes were obtained by pressing the domestic variety of hull-less pumpkin seeds (*Cucurbita pepo* L.) „Olinka". Two pressing processes were applied: using a continual screw press in cold-pressed oil manufacturing and hydraulic press in the virgin pumpkin oil pressing process. In order to assess the suitability of this by-product, proximate analyses of the samples were conducted to determine the residual oil and water contents, as well as proteins, carbohydrates, crude fibers and ash using official methods of analysis. The residual oil was also analyzed in order to determine its nutritive quality. The obtained results showed that two kinds of oil press-cakes were significantly different in terms of oil and water contents. The press-cake obtained using a screw press had higher water content (8.30 ± 0.40%) and lower residual oil content (13.41 ± 1.48%), compared to the press-cake obtained using a hydraulic press (3.94 ± 0.65% water content and 18.18 ± 9.44% residual oil). In addition, the pumpkin press-cakes had a substantial amount of high quality proteins. The protein content of the press-cake obtained using a screw press was 67.09 ± 3.08 % d.m., while the protein content in the cake obtained using a hydraulic press was 59.20 ± 5.13% d.m. Results have also confirmed that the residual oil, regardless of the pressing method used, was of high quality, especially in terms of the high content of the essential omega-6 (linoleic fatty acid) and gamma tocopherols. The obtained results confirmed that both press-cakes can be used in different applications as value-added, functional ingredients for food manufacture.
Key words: *hull-less pumpkin seed, oil press-cake, chemical composition, nutritive value*

INTRODUCTION

There is a huge concern these days over technological processes of raw materials manufacturing that shall be employed in such a way which will provide protection of nutritional components from deterioration. The goal is to have these components in an unchanged form, so the by-products can be fully utilized as high quality ingredients.
The utilization of agricultural waste products to produce food has recently received increased attention, not only to minimize waste disposal problems, but to help maximize potential resources and production of new and novel food products. In this regard it is very important to utilize the oil seeds' press cake obtained using a pressing process, i.e. without using organic solvents, while the press-cake maintains desirable nutritional qualities of raw materials.
Recently reserachers have been paying much attention to nutritional qualities of proteins that originated from the pumpkin seeds, specifically family *Cucurbitaceae* (Ng et al., 2002; Tongyi et al., 2003; Wang and Ng, 2003). Pumpkin seed proteins have pharmacolgical activities such as antifungal (Wang and Ng, 2003), antibacterial and antiinflamatory (Caili et al., 2006), as well as ACE inhibitory and antioxidative properties (Nkosi et al., 2006). It has also been

demonstarted that the addition of pumpkin seed proteins improved the protein digestion of bread (El-Soukkary, 2001).
Due to their high nutritional quality and content of biologically active components, hull-less pumpkin seeds (*Cucurbita pepo* L. var Styriaca and Olinka) have been extensively used in the past decade for oil manufacturing using a pressing process. In some parts of Europe, such as Austria (Fruhwirt and Hermetter, 2008), Slovenia (Kreft et al., 2002), Croatia (Neđeral-Nakić et al., 2006), Germany and Hungary virgin pumpkin oil has been processed for decades, while cold pressed hull-less pumpkin seed oil has been recently manufactured in Serbia, especially Vojvodina. The main difference between the manufacturing processes of these two oils is that cold-pressed oil is obtained by pressing the oil seeds using a screw press at temperatures below 50^{o} C (Vujasinović et al., 2010), while virgin pumpkin seed oil is obtained by pressing thermally processed ground seeds (heated to temperatures of 100-120^{o} C) using hydraulic presses (Vujasinović et al., 2012).
Recent studies have demonstrated that the pumpkin oil press cake has superior nutritional qualities. It is very rich in proteins, essential amino acids, fatty acids (FAs), minerals such as potassium, magnesium, calcium, manganese, zinc, copper, iron, phsphorus, selenium, iodine as well as other bioactive components that are present in the residual press-cake oil (Radočaj et al., 2011).
The objective of this study was to compare the quality of oil press cakes, by-products that are obtained by pressing hull-less pumpkin seeds (*Cucurbita pepo* L.) using different methods for oil recovery.

MATERIAL AND METHODS

Hull-less pumpkin seed oil press-cake samples (domestic variety Olinka) were obtained from a small oil processing company (PANUNION OIL, Novi Sad, Serbia), where the seed pressing process is carried out using a common technology process. 10 press-cake samples obtained using borth, screw and hydraulic presses were investigated. Samples were kept in sealed PE bags until analyzed.
Using a continual screw press „Kern Kraft“ (capacity 40 kg of seeds per h, Germany), where cold-pressed oil was produced, a „*screw press“ oil cake* was obtained. When a hydraulic press (capacity 40 kg of seeds per h, ”Lešnik”, Slovenia) was used for a virgin oil production using ground roasted seeds, a “*hydraulic press” oil cake* was obtained.
Proximate analysis of press cakes was conducted using standard analytical methods: moisture (ISO 665, 2008), oil content (ISO 659, 2007) and crude proteins (SRPS ISO 1871, 1992). Crude fibres and ash were determined using standard methods (AOAC, 1997).
Carbohydrate content was determined by difference.
Oil content of press cakes was determined by Soxhlet extraction (solvent: hexane; 6 hrs.), after which a fatty acid profile and tocopherols content was determined.
Fatty Acid Composition. Fatty acid methyl esters (FAMEs) were prepared according to the standard method [ISO 5509, 2000]. The fatty acid profile was analysed by the gas chromatography method [ISO 5508,1990] on a Hewlett-Packard series II^{plus} GC analyzer equipped with automatic sampler HP 7673, splitless injector, flame-ionization detector and integrator. The gas chromatographic conditions were as follows: a capillary Supelco column SP-2560, 100 m length, injector and detector temperature 220 °C, oven temperature 175 °C, injection volume 1 μL. Helium was used as the carrier gas at a flow rate of 0.9 mL/min. Identification of the individual FAs was accomplished by comparing the GC retention time with that of the pure commercial standard.
Determination of *tocopherols* (Toc) was carried out using high performance liquid chromatography (Waters M600E, United States) on a reversed phase column Nucleosil 50-5 C18 with fluorescence detection (Vujasinović et al., 2012).
Statistical analysis. Data are reported as means ± SD (n = 3). Statistical analysis was performed using Statistica 8 software package. Statistical differences between samples were

estimated by applying one-way ANOVA and using the Tukey test at a significance level of 5% ($p < 0.05$).

RESULTS AND DISCUSSION

Oil and moisture content of samples obtained using a screw press and hydraulic press are presented in tables 1. Proximate analysis of press cakes is presented in table 2.

Table 1. Oil and moisture content of hull-less pumpkin seed oil press cakes obtained using screw and hydraulic presses

Sample	Oil press-cake *screw* press		Oil press-cake *hydraulic* press	
	Oil (%)	Moisture (%)	Oil (%)	Moisture (%)
1	12.1±0.20^{ab}	7.93±0.02^{a}	17.95±0.50^{abc}	5.38±0.03^{a}
2	12.1±0.30^{ab}	8.28±0.04^{b}	14.19±0.30^{de}	3.38±0.06^{b}
3	11.2±0.40^{b}	8.31±0.04^{b}	16.34±0.30^{cf}	3.99±0.04^{cd}
4	15.2±0.20^{cd}	7.63±0.03^{c}	12.69±0.20^{e}	2.99±0.05^{e}
5	16.2±0.50^{d}	8.84±0.05^{d}	18.47±0.40^{ab}	4.01±0.03^{cd}
6	14.8±0.30^{cd}	8.77±0.03^{d}	18.63±0.40^{af}	4.22±0.06 ^{cf}
7	13.5±0.20^{ac}	8.15±0.03^{be}	20.55±0.50^{f}	3.88±0.06^{dg}
8	13.8±0.20^{ac}	8.06±0.02^{ae}	15.01±0.30^{df}	3.68±0.03^{gh}
9	11.0±0.40^{b}	8.80±0.02^{d}	16.64±0.30^{bcf}	4.37±0.03^{f}
10	14.2±0.50^{c}	8.23±0.03^{be}	31.30±0.10^{g}	3.52±0.05^{bh}
Interval	11.0 – 16.2	7.63 – 8.84	12.69 – 31.30	2.99 – 5.38
Mean value	**13.41±1.48**§	**8.30±0.40**§	**18.18±9.44**$^{£}$	**3.94±0.65** $^{£}$

Means within the same column followed by different superscript letters ($^{a-h}$) are significantly different ($p < 0.05$).
Means within the same row followed by different superscript letters ($^{§, £}$) are significantly different ($p < 0.05$).

As it can be seen in table 1, press cake samples obtained using different oil pressing technologies are statistically different in terms of oil and moisture content. The mean value of oil content of the press cakes obtained using a screw press was 13.41 ± 1.48%, where the range of the moisture content of the samples is 11.0 to 16.2%. The mean value of the oil content of the press cakes obtained using a hydraulic press was higher (18.18 ± 9.44%), where the oil content of press cakes was distributed amongst samples in a much higher range (12.69 to 31.30%). The high range in values and differences amongst samples can be explained by the fact that the pressing is a batch process. Besides, the oil pressing process and a quantity of separated oil is dependant on the thermal process (roasting temperature and time) that is performed before the pressing step. Press cake samples are also significantly different (p<0.05) in terms of the moisture content, where the mean values of the press cakes obtanied using these two processes were 8.30 ± 0.40% for the screw press cake and 3.94 ± 0.65% for the hydraulic press cake. It shall be noted here that the moisture content of the screw press cake depends primarily on the moisture content of the raw seeds, while it depends on the thermal process before the pressing in the hydraulic press cake.
Proximate analysis of hull-less pumpkin oil press cakes (table 2) showed that they have very high nutritive values. Besides residual oil, a very high amount of crude proteins (67.09 ± 3.08% d.b.) was found in screw press cakes, as well as in hydraulic press cakes (59.20 ± 5.13%). The carbohydrate content in both types of press cakes was in the range of 9.14 ± 2.16 to 10.82 ± 0.4% (screw and hydraulic press, respectively). Ash content (approx. 6%) indicated a high content of minerals, which is in agreement with a published study (Radočaj et al., 2011). It can be seen that proximate analysis of press cakes obtained using different processes are statistically different, except the crude fibers content.

Table 2. Proximate analysis of hull-less pumpkin press cakes obtained using screw and hydraulic presses

Parameter	Oil press-cake *screw press* [§]	Oil press-cake hydraulic press [£]
Moisture content (%)	8,30±0,40	3,94±0.65
Oil content (% tel quel)	13,41±1,48	18,18±9,44
(% d.b.)	14,62±1,48	18,93±9,44
Crude protein (% tel quel)	61,52±3,08	56,87±5,13
(% d.b.)	67,09±3,08	59,20±5,13
Carbohydrates (%)	9,14±2,16	10,82±0,4
Crude fibers (%)	3,59±0,30*	3,51±0,03*
Ash (%)	5,80±0,50	6,64±0,11

Means within columns followed by different superscript letters ($^{§, £}$) are significantly different ($p < 0,05$) (between the press cakes obtained using screw press and hydraulic press).
**without statistically significant differences*

Nutritional quality of the residual press-cake oils is presented in table 3.

Table 3.Nutritive quality of residual press-cake oils

Parameter	Oil press-cake *screw press*	Oil press-cake *hydraulic press*
Fatty acid composition (% w/w)		
Palmitic acid (C16:0)	13,19±0,11	13,29±0,21
Stearic acid (C18:0)	6,40±0,08	6,74±0,11
Oleic acid (C18:1, ω-9)	26,89±0,62	27,05±0,93
Linoleic acid LA (C18:2, ω-6)	52,13±2,14	51,04±2,05
α-Linolenic acid (C18:3, ω-3)	0,21±0,05	0,23±0,03
Trans fatty acids	0,00	0,17±0,00
Tocopherols (mg/kg):		
α-	16,2±0,6	13,3±0,7
β-	3,4±0,5	4,3±0,5
γ-	777±12,3	704±10,0
δ-	7,84±0,8	1,97±0,5

Results presented in table 3 showed that hull-less pumpkin seed oil (domestic variety Olinka) is of the oleic-linoleic type, with a dominant oleic fatty acid (approx. 27%) and linoleic – omega-6 fatty acid (approx. 52%). In addition, although present in a very small quantity (approx. 0.2%), α-linolenic acid, i.e. omega-3 fatty acid was also detected.
Trans fatty acids were detected in a very small amount (0.17%), only in the hydraulic press cake, which is a cake obtained in the pumpkin virgin oil production process. Currently, there is a demand in the market for food products that are sources of omega-3 and omega-6 fatty acids.The omega-3 and omega-6 fatty acids are essential fatty acids, necessary from conception through pregnancy and infancy, and throughout life in the prevention of certain diseases (Connor, 2000). Omega-6 fatty acids are considered to increase lipid peroxidation, while the omega-3 FAs exert a chemo preventive effect (De Barros et al., 2011).
Tocopherols, as very important minor components of an oil with high antioxidant activity, were also found in significant amounts in the residual oil present in all cakes. The predominant type of tocopherols was the gamma tocopherol in the amount of 700 mg/kg oil. Both, fatty acid profile and tocopherol contents contribute significantly to the increase of the nutritive quality of the press cakes.
As it can be seen in table 3, residual press cake oils have a very similar fatty acid profile. However, their tocopherol profile is different and higher values were obtained using a screw press. In respect to such nutritive characteristics, hull-less pumpkin oil press cake can be used for the development of value-added, functional food products such as a fat based spread.

CONCLUSIONS

Obtained results have shown that the hull-less pumpkin seed oil press-cake which is a by-product of either the screw or hydraulic pressing process, has a very good chemical and nutritional quality, and is a suitable raw material for the manufacturing of different food products.

ACKNOWLEDGEMENTS

The authors would like to thank the Ministry of Education and Science, Republic of Serbia, for the grant (project: TR 31014, Development of the new functional confectionery products based on oil crops) and wish to thank Branislav Panić from the Oil mill plant PANUNION OIL Novi Sad for the supply of press-cake samples.

ABSTRACT: Bee pollen is promoted as a healthy food with a wide range of nutritional and therapeutic properties. The objective of the present study is to determine the chemical composition of multifloral bee pollen produced in Bulgaria. The study was carried out totally on fourteen bee pollen samples. The following parameters were determined: Moisture content – until constant weight, using oven at 105 ºC for two days; proteins by Kjeldahl method; lipids by Soxhlet procedure using diethyl ether as solvent; ash content – gravimetry using oven at 550 ^{o}C. Before testing the samples are stored in a refrigerator at -18 ºC. Ten commercial bee pollen samples were purchased from the market. It was found that bee pollen contains: moisture (8.92 – 14.60%), proteins (22.05 – 25.96%), lipids (3.81 – 9.32%) ash (2.30 – 2.80%). Four samples came from the experimental apiaries of Institute of Animal Science (IAS), Kostinbrod. For these samples the following results were obtained: moisture (11.39 – 16.48%), proteins (18.45 – 22.42 %), lipids (6.30 – 8.71%), ash (1.56 – 2.22%). The average values of moisture (13.81% ± 1.06), protein (19.80% ± 0.89), lipid (7.15% ± 0.54) and ash content (1.81% ± 0.14) of bee pollen samples collected at IAS are comparable with those of commercial samples – 11.51% ± 0.55; 23.48% ± 0.44; 6.38% ± 0.54; 2.58% ± 0.06, respectively. The variation between the samples can be explained by multifloral origin.
Key words: *pollen, chemical composition, moisture, proteins, lipids, ash.*

INTRODUCTION

Bee pollen is promoted as a healthy food with a wide range of nutritional and therapeutic properties. A high concentration of proteins, essential amino acids, sugars, unsaturated and saturated fatty acids, the presence of essential elements and vitamins (Almeida-Muradian et al., 2005; Villanueva et al., 2002) make bee pollen very important for human diets. These components depend on the botanical origin of pollen and variation in absolute amounts of the different compounds can be very high. Regardless of these proven benefits to human health, little attention has been paid to the development of methods for assessing the quality and composition of bee pollen.

Honey bees *Apis Mellifera* feed mainly on nectar and pollen. Pollen is the main source of protein for the bee colony. Pollen is produced in various countries as a feeding supplement for human nutrition.

The major components in bee pollen are proteins and amino acid, lipids (fats or their derivatives) and sugars.

Protein content is a standard determination of % N using the Kjedahl method, using a conversion factor of 6.25 (Rabie et al, 1983). The predominant amino acids are proline, glutamic and aspartic acids, lysine and leucine.

Analysis of pollens generally indicates that they are composed of about 50% polysaccharide, 4–10% simple sugars, 1–20% lipids, 6–28% protein, and 6% amino acids, accompanied by a variety of secondary plant products such as flavonoids, c arotenoids, terpenes (Tyler, 1993).

Protein contents of above 40% have been reported, but the typical range is 7.5 to 35%: sugar content ranges from 15 to 50% and starch content is very high (up to 18%) in some wind-pollinated grasses (Schmidt and Buchmann, 1992).

According to Campos et al. (2008) proteins are between 10 – 40%, lipids 1 – 13%, ash 2 – 6%.

The objective of the present study is to determine the chemical composition of multifloral bee pollen produced in Bulgaria, including moisture, proteins, lipids and ash content.

MATERIAL AND METHODS

The study was carried out at Institute of Animal Science (IAS), Kostinbrod, Bulgaria. Fourteen multifloral bee pollen samples were investigated. Four freshly bee-collected samples were harvested during two months (June and July) in 2010 from the experimental apiaries of IAS and ten samples were purchased from the market. Once collected, the samples from IAS were immediately dried at 30 °C. All pollen samples were kept frozen (-18 °C) in a refrigerator until analysis.
The proximate composition of the pollen was determined by using standard methods of food analysis:
Moisture content was made through gravimetry until constant weight, using oven at 60 ºC for three days and at 105 ºC for two days (sample of 5 g). Dry matter of the samples was obtained by subtracting the moisture content from 100.
Protein content was obtained using Kjeldahl method (sample of 2 g).
Lipid content was determined by Soxhlet extractor using diethyl ether as solvent (sample of 5 g).
Ash content was determined by gravimetry using oven at 550 ºC until constant weight (sample of 2 g).
All analyses were done in duplicate. Statistical analysis was performed using MS Excel 2007.

RESULTS AND DISCUSSION

The chemical composition of LRJ samples are presented in Table 1, Table 2 and Figure 1.

Table 1. Moisture, dry matter, proteins, lipids and ash of bee pollen from IAS

	Mean±S.E	**Min**	**Max**
Contents			
Moisture, %	13.81±1.06	11.39	16.48
Dry matter, %	86.19±1.06	83.52	88.61
Proteins, %	19.80±0.89	18.45	22.42
Lipids, %	7.15±0.54	6.30	8.71
Ash, %	1.81±0.14	1.56	2.22

Results are given as minimum, maximum, mean ± standard error (n = 4)

Table 2. Moisture, dry matter, proteins, lipids and ash of bee pollen purchased from the market

	Mean±S.E	**Min**	**Max**
Contents			
Moisture, %	11.51±0.55	8.92	14.60
Dry matter, %	88.49±0.55	85.40	91.08
Proteins, %	23.48±0.44	22.05	25.96
Lipids, %	6.38±0.54	3.81	9.32
Ash, %	2.58±0.06	2.30	2.80

Results are given as minimum, maximum, mean ± standard error (n = 10)

Moisture content of the tested samples ranged from 11.39 to 16.48% for the samples from IAS (Table 1) and from 8.92 to 14.60% for the samples from the market (Table 2). The average content of that constituent was also higher in the pollen samples from IAS – 13.81%. The product submitted to a drying out process in temperatures not higher than 30 °C. The higher temperature led to significant losses of vitamin and enzymes.
The content of pollen total protein in the samples from the market was higher (22.05 – 25.96%) than the other samples (18.45 – 22.42%). The protein content of pollen depends strongly on the botanical origin.
The comparison of the lipid values obtained in our samples with the samples from the market showed that the highest lipid concentration was predominant in the purchased samples

(3.81 – 9.32%). This fact could be explained with the high variation of this index and these values are comparable with the lipid levels reported in the literature (Campos et al., 2008).
As can be seen in Table 1 and Table 2 the ash content and the concentration of mineral elements do not exhibit a large range in the both groups of samples. There is considerable variation depending on the pollen type. According to Szczesna (2007) ash content is between 2.08 – 3.19%.

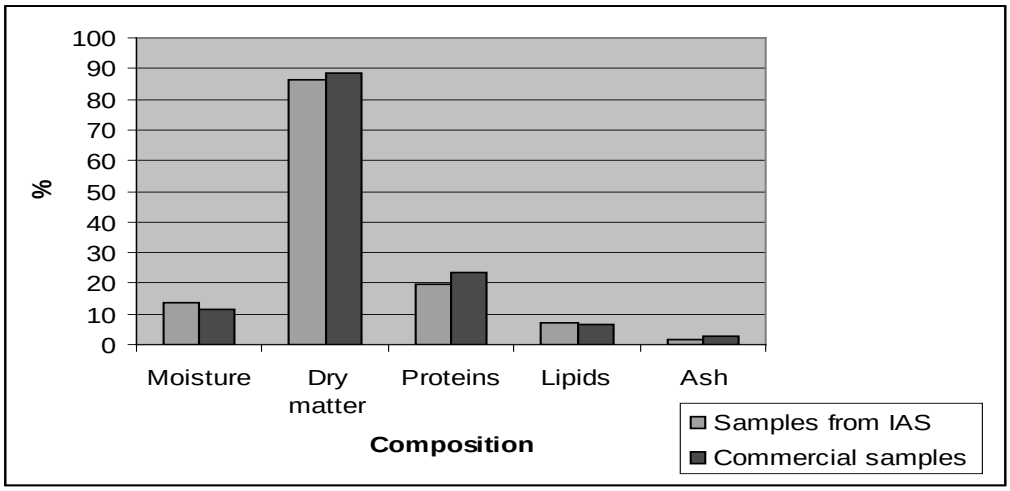

Figure 1. Chemical composition of bee pollen

CONCLUSIONS

The average values of moisture (13.81% ± 1.06), protein (19.80% ± 0.89), lipid (7.15% ± 0.54) and ash content (1.8 % ± 0.14) of bee pollen samples collected at IAS are comparable with those of commercial samples – 11.51% ± 0.55; 23.48% ± 0.44; 6.38% ± 0.54; 2.58% ± 0.06, respectively. Protein and ash contents were slightly higher in the purchased samples while the lipid content was lower. The variation between the samples can be explained by multifloral origin.

ABSTRACT: *Boletus edulis* is among the most popular and widely consumed wild macromycetes, being rich in minerals, dietary fiber, vitamins and having medical properties they have been used as antibacterial, anti-tumor, anti-cholesterol and antiviral agents. This research was conducted on 9 areas of SouthWest Serbia covering forests. Results of the research showed the main soil characteristics to be as follows: pH values ranging from 3.50 to 6.75, total organic carbon – 1.65-6.84%; and total humus range - 2.83-10.75%. Total content of heavy metals detected in all examined soil samples was under the permitted values, as well as in all the examined stone fungus samples, with the difference in Cd content ranging from 0.08 to 1.3 mg/kg. One of the tested localitites had exceeding permitted values of Cd content (>1mg/kg), as well as Hg content showing to be above the permitted values on 3 localities (0.58-0.71 mg/kg). These results indicate the absorption capacity of the wild mushroom to be higher for As and Pb, comparing to the present Cd from the soil. It is also interesting for Hg to be detectable in the mushroom samples deriving from the soils without Hg content, which indicates further invastigations regarding potential pollution sources.
Key words: *wild mushroom, heavy metals, absorption capacity*

INTRODUCTION

Mushrooms are important part of human diet. Furthermore, export of mushrooms is important part of total agricultural products that are being exported from Republic of Serbia to EU countries and Russian Federation. For all these reasons it is necessary to control the heavy metal content in mushrooms in order to provide safe food and environment protection. Mushrooms are considered to be healthy food with higher content of proteins and carbohydrates than vegetables.They present wide source of biologically active compounds and minerals (Mattila et al., 2001). Furthermore, mushrooms have certain medical properties, as well as antibacterial, anti cancer, antiviral influence and play important role in decreasing cholesterol content (Cochran, 1978; Chobot et al, 1997; Mattila et al 2000). Some researches showed that mushrooms have antiallergenic effect and can be used preventively against cholesterol, tumor and cancer (Visser, 1993).
The absorption and accumulation of heavy metals is dependent on mushroom species, growing substrate, age of mycelia and interval between mushroom appearance (Kalac and Svoboda, 2000).
Studies of heavy metal content in mushrooms showed a correlation between heavy metal concentration and point sources of contamination, as furnace and nearness of roads where the mushrooms are collected (Bargagli and Baldi, 1984; Isildak et al., 2004).
Considering the vast presence of mushrooms in forest ecosystems, metal content in forest soils is important parameter for mushrooms abundance, yield and biological value.
Some metals (Cd, Pb, Cr and Zn) are concentrated mostly in mushroom cap. Mushrooms collected near urban settlements have higher content of heavy metals (Cd, Cr, Ni, Pb) Therefore the determination of heavy metals in Boletus (and other edible mushrooms) is important parameter of safety and human health. For these reasons, determination of health

safety of Boletus (and other edible mushrooms) needs identification of potential sources of contamination on locations where mushrooms are collected.
Unlike As, Cd, Pb, which are present in all geological substrates and soil profiles, Hg is sporadically present in some location, but because of its high toxicity it is necessary to monitor its content. Highest level of some pollutants in foodstuffs, according to Board of European committee (EC 466/2001) is 0.2 and 0.3 mg/kg wet mass for Cd and Pb.
World Health Organization declares that weekly input of Cd and Pb for adults through food and agricultural products is between 0.42-0.49 and 1.5 mg, respectively. Content of 1.75 mg is considered to be highest level allowed (Leski and Rudawska, 2005).
The aim of this paper was to determine the relationship between heavy metals content in mushrooms and its content in substrate (forest soil).

MATERIAL AND METHODS

The wild edible mushroom *(Boletus edulis)* and soil samples (0-10 cm deeper) simultaneously were collected from nine, mostly forest location in SouthWest Serbia area following location and numbers (in tables): municipality of Priboj (Sjeverin, No. 1); Municipality Prijepolje (Jabuka-fagus forest, No.2., Jabuka-juniper bush, No.3.; Hisarđžik and i Kosatnica, No.5.; Prevoj and Drmanovići No. 6.; Aljinovići No. 7.), Brodarevo (No. 4.), Municipality Sjenica (Štavalj No. 8. Sugubine, No. 9.). Each location was divided in 3 sublocation, from which the mushroom samples were taken and analysed for heavy metal content. On the main mountain locations soil and *Boletus edulis* were paralely sampled.
The main soil characteristics (humus, pH values and organic C) have been analyzed using standard methods (electrochemicaly by nKCl, Kotzman method and CNS-analyzer), and the content of heavy metals As (detection limit 0.02), Cd (detection limit 0.1), Pb (detection limit 0.25) were determined using ICP technique. Atomic absorption spectroscopy (AAS) employing hydrid metod was used to determine the content of Hg in the examined soils (detection limit 0.02). In order to analyze the content of heavy metals in mushrooms, there has been used AAS method.

RESULTS AND DISCUSSION

Heavy metals have negative effects on all biological processes in plants as well as on mineral nutrition and biochemistry of wild mushrooms (Udosen et al., 2001). Generally metal absorptions in mushrooms (as well as in plants) depend on climate, rains, forest horizons, age of mycelium, time interval among mushrooms appearance and many other factors (Kalac and Svoboda, 2000). The main soil characteristics and content of heavy metals are presented in Table 1. Average pH values in soils were from 3.50 to 6.75. Content of organic C was ranging from 1.65 to 6.84%, and humus content was from 2.83 to10.75%. In most of the examined forest soils the pH was in acidic range, and only 1 sample had neutral pH values. For metal absorption these data are very important, since the acid soils had higher concentration of metal ions that can be readily absorbed by plants and mushrooms.
The content of As at investigated localities showed high degree of variation from 0.075 to 7.94 mg/kg. Pb content ranged from 14.06 to 69.85 mg/kg, although variation were not high at 8 investigated localities, ranging from 14.06 to 34.31 mg/kg. The Cd content in soil was found to be from 0.39 to 2.11 mg/kg. The Hg content in soil was not found in 7 localities except localities 4 (0.06) and 6 (0.018 mg/kg as presented in Table 1. According to limits allowed by Serbian law, contents of heavy metals in all the investigated samples were under the limits.

Table. 1. Heavy metal contents and soil characteristic of forest soil at Serbia Southwest area.

Location No.	Soil heavy metal contents (mg/kg)				Soil characteristics		
	As	**Pb**	**Cd**	**Hg**	**pH (nKCl)**	**Org.C %**	**Humus %**
1.	4.94	14.06	0.67	*	3.60	1.94	3.35
2.	7.94	17.88	1.03	*	4.30	1.65	2.83
3.	3.53	14.91	0.39	*	3.50	3.82	5.00
4.	6.07	69.85	2.11	0.06	6.75	6.53	10.75
5.	2.66	20.2	0.60	*	3.70	6.84	9.63
6.	3.35	34.31	0.71	0.018	3.65	2.90	4.98
7.	0.075	16.46	0.69	*	3.90	4.27	6.48
8.	4.32	22.47	0.46	*	3.80	3.54	5.69
9.	7.48	25.77	1.49	*	5.40	5.45	9.30

** - under detection limit*

Table 2. Heavy metals contents (mg/kg) in *Boletus edulis*

Location No.	Heavy metal contents in mushroom (interval)			
	As	Pb	Cd	Hg
1.	*	*	0.08-0.30	0.27-0.58
2.	*	*	0.26-0.40	0.42-0.71
3.	*	*	0.27-0.33	0.14-0.58
4.	*	*	0.14-0.18	0.10-0.37
5.	*	*	0.10-0.16	0.23-0.33
6.	*	*	0.70-1.30	0.14-0.45
7.	*	*	0.36-0.70	0.14-0.41
8.	*	*	0.20-0.48	0.10-0.20
9.	*	*	0.24-0.40	0.10-0.12

** - under detection limit*

According to the results from Table 2 only As and Pb were under detection limits. However content of Cd and Hg in most samples were higher than the limits given by Serbian law. The Cd content variation were from 0.08 to 1.30 mg/kg, and only in area No. 6 the content was higher than allowed (>1mg/kg). These results are similar to results from other research (Jilmaz et al., 1998; Turkekul et al., 2004). Opposite to low Hg content in forest soil (4 and 6 localities), the Hg contents in mushrooms were 0.10 to 0.71 mg/kg, and at 3 localities the Hg contents were higher that it allowed (>0.5 mg/kg). These results were similar to the results of Falandzysz et al. (2007).

CONCLUSIONS

The content of heavy metals in soils was found to be in most samples and localities under the allowed limits by Serbian law. The results showed also that As and Pb were not absorbed by mushrooms. However the Cd and Hg content in mushrooms were higher comparing to soil samples. However, the Hg was found in mushrooms grown on the soils where there are no genuine presences of Hg. This implies further research in this area, since the given results do not indicate the origin of Hg pollution.

ACKNOWLEDGEMENTS

This research was partially supported by Ministry of education and science of Serbia (grant number TR31080).

ABSTRACT: Since quince is a fruit relatively susceptible to browning, in the present work it was evaluated the colour of the quince over time of exposure to the atmospheric air. The colour of the fresh pulp was assessed using a handheld tristimulus colorimeter using the CIELab colour coordinates: L*a*b*. These Cartesian coordinates were then used to calculate the polar or cylindrical coordinates: value, hue angle (º) and chroma. At each instant, ten measurements of colour were made, and to evaluate the colour change, measurements were repeated in the same samples after every 5 minutes, over a period of two hours. The results obtained for the medium values of the cylindrical coordinates in the freshly cut quince were found to be: value = 7.80, chroma = 31.78 and Hue = 92.28º, being these values determined right after cutting. Total colour difference (TCD) was calculated having the values of the Cartesian coordinates of the freshly cut quince as reference. In relation to the colour change, the values for TCD were 0.00, 26.35, 30.41, 31.81 and 32.39, respectively for times 0, 30, 60, 90 and 120 minutes, indicating a faster rate initially and a tendency for stabilization towards the end of the period analyzed.
Key words: *quince, browning, colour, browning kinetics*

INTRODUCTION

The Quince (*Cydonia oblonga*) is a relatively small tree, the only member of the gender *Cydonia*, from the Rosaceae family. The fruit is called quince, and resembles a cross between an apple and a pear. Quince is rich in dietary fibre, vitamins, like vitamin C, and minerals, such as copper or potassium, while being low in saturated fat, cholesterol and sodium. In the raw form, the flesh is hard and unpalatable, with an astringent, acidulous taste. However, quince is rarely used in the raw form, being instead commonly made into preserves and jellies. Once cooked and sweetened, it turns red, with a pleasant taste and strong fragrance.

Colour is one of the most important appearance attributes of foods and it has a major influence on the reaction of the consumer, contributing to determine the acceptability or rejection of the food. However, the colour of food products is quite susceptible, and may be affected in a high extent by processing, in particular thermal processing. Nevertheless, some degradation also occurs during transportation and storage. Among the alterations that can occur are those resulting from pigment degradation, browning reactions like Maillard reactions, enzymatic browning or oxidation of ascorbic acid (Maskan, 2001, 2006; Suh et al., 2003).

Because colour is such an important attribute of food quality, it has been the object of study by many researchers, in many foods: pomegranate juice concentrate (Maskan, 2006), tofu (Baik and Mittal, 2003), kiwi (Maskan, 2001), spinach (Nisha et al., 2004), watercress (Cruz et al., 2007), carrots (Koca et al., 2007), bananas (Chua et al., 2001) or pears (Quevedo et al., 2009).

Tristimulus colorimetry has been widely accepted as a rapid and simple instrumental method for measuring the colour of food products, and CIELab Cartesian coordinates (L*, a*, b*) can be used to quantify that colour. There are other parameters derived from Hunter L*, a*, b* coordinates, such as the total colour difference (TCD), which aims at quantifying the overall colour difference between a sample and a reference material. Furthermore, the Cartesian coordinates can be used to calculate the cylindrical coordinates: value, chroma and Hue

angle (Maskan, 2001). Data about the kinetics of change in quality attributes in foods, like for example colour, provide valuable information for understanding and predicting changes that occur during processing and storage, and thus allow improving quality and minimizing losses (Kumar et al., 2006).
Although many studies can be found about the kinetics of colour change during processing of foods, studies about the kinetics of degradation of colour of quince just by exposure to the atmospheric air are lacking, and this is a product that is very susceptible to browning and quite rapidly too. In this way, the present study aimed at investigating the variation along time of colour of quince during exposure to atmospheric conditions.

MATERIAL AND METHODS

Sampling

The samples of quince (*Cydonia oblonga* Mill.) cultivar Gamboa were cut into slices and colour measurements were done right after cutting. After that, the slices were left exposed to atmospheric conditions, and colour measurements were made every five minutes until two hours.

Colour measurements

The colour was measured using a handheld tristimulus colorimeter (Chroma Meter - CR-400, Konica Minolta), calibrated with a CIE standard illuminant D65. The colour coordinates L*a*b* of the CIELab colour space were determined, where L* denotes lightness, and varies from zero (black) to 100 (white), a* varies from -60 (green) to +60 (red) and b* veries from -60 (blue) to +60 (yellow) (Kumar et al., 2006). From the Cartesian coordinates (L*a*b*) the total colour difference (TCD) was calculated by equation (1) (Chen and Ramaswamy, 2002):

$$\mathrm{TCD} = \sqrt{(\mathrm{L}^*_0 - \mathrm{L}^*)^2 + (\mathrm{a}^*_0 - \mathrm{a}^*)^2 + (\mathrm{b}^*_0 - \mathrm{b}^*)^2} \quad (1)$$

considering the colour of the freshly cut product as reference. The Cartesian colour coordinates were then used to calculate the cylindrical coordinates, value, chroma and hue angle, by the following equations (Maskan, 2001):

$$\mathrm{Value} = \mathrm{L}^*/10 \quad (2)$$

$$\mathrm{Chroma} = \sqrt{\mathrm{a}^{*2} + \mathrm{b}^{*2}} \quad (3)$$

$$\mathrm{Hue}\,(^{\circ}) = \tan^{-1}\left(\frac{\mathrm{b}^*}{\mathrm{a}^*}\right) \quad (4)$$

According to Maskan (2001) the browning index (BI) can be calculated from the Cartesian colour coordinates by the following equation:

$$\mathrm{BI} = \frac{\left[100\,(\mathrm{x} - 0.31)\right]}{0.17} \quad (5)$$

where

$$\mathrm{x} = \frac{(\mathrm{a}^* + 1.75\,\mathrm{L}^*)}{(5.645\,\mathrm{L}^* + \mathrm{a}^* - 3.012\,\mathrm{b}^*)} \quad (6)$$

For the colour determinations ten samples were analysed at each time instant and the mean values and standard deviations were calculated for each set.

Mathematical modelling

One of the many models cited in literature to describe the kinetics of change of a certain attribute, P, of a food product is the logistic model reported by Chen and Ramaswamy (2002) as:

$$\mathrm{P} = \mathrm{U}_0 + \frac{\mathrm{U}_e}{1 + \exp\left[\pm\,\mathrm{k}(\mathrm{t} - \mathrm{t}_0)\right]} \quad (7)$$

where k is the kinetic constant, U_0 and U_e are constants related to P_0 and P_e, respectively, and t_0 is the half-life time, i.e., the time at which the value of the property P

increases/decreases to half/double of the U value. P_0 represents the initial value of the property while P_e is the final equilibrium value, and the signs (+) or (-) indicate increase or degradation of the property P, depending on the case.

RESULTS AND DISCUSSION

Table 1 shows the results of the fittings made with the logistic model in Equation (7) to the experimental data of the different variables analysed (Cartesian colour coordinates, cylindrical coordinates, total colour difference and browning index). For the fittings, the software SigmaPlot V8.0 (SPSS, Inc.) was used. In Table 1 the values of all four parameters in the model are presented, along with the value of the correlation coefficient, R, which allows evaluating the quality of the fit, i.e., how good does the fit describe the experimental set of data for each case. The values for R in table 1 indicate that in all cases the model adjusts quite well the experimental data, being the fit for a* the best, with higher value of R, 0.9968, and the fit for b* the less good, with the lowest value, 0.9282. Still, since the value of R is quite close to 1, even in this case the fitting was quite successful. The values of the kinetic constant, k, are positive for L* and Hue and negative for all other cases, thus indicating that the variables L* and Hue decrease with time, whereas all other increase.

Table 1. Fitting of the experimental data with the kinetic model from Equation (7)

	L*	a*	b*	Chroma	Hue	TCD	BI
U_0	54.6055	-21.421	29.1377	27.3189	290.72	-36.138	15.2884
U_e	58.1742	39.1257	10.9047	16.27523	-1020.1	67.1939	124.178
t_0	-325.23	-25.239	317.35	402.94	-2328.8	-96.508	626.87
k (s^{-1})	1.04e-3	-1.29e-3	-3.55e-3	-2.34e-3	65.781	-1.25e-3	-1.58e-3
R	0.9918	0.9968	0.9282	0.9784	0.9963	0.9953	0.9920

To better understand how these different colour variables change along exposure time, Figures 1 to 4 show the experimental points of the variables along time, together with the corresponding fits obtained with SigmaPlot. In all cases, each point at a given instant results from the data measured in that instant, i.e., is the mean value between 10 measurements.

Figure 1 shows the different Cartesian colour coordinates, lightness (L*) and the two opposing colour coordinates (a* and b*). The graph evidences the decrease in L* along time, thus indicating that the quince samples become darker. As to the colour coordinate a* the freshly cut quince presents a value for a* lower than zero, thus indicating a slight prevalence of the green colour. However, very rapidly this vanishes giving place to positive values of a*, corresponding to the appearance of the reddish colour, as a result of the development of the brown compounds. As to b*, this is always positive, thus indicating that yellow prevails over blue (negative values of b*), and by increasing with time it shows that the yellowish colour is intensified, this also in result of browning. Furthermore, it is visible from all curves that colour change is faster at the initial moments (until 2000 sec, that is the first half hour), tending to stabilize thereafter.

Figure 2 shows the cylindrical colour coordinates as well as the corresponding fits obtained for each variable. Chroma, which indicates colour saturation, increases along exposure time, thus meaning that the colour is becoming more intense. The hue angle, which is used to characterise the colour of foods, diminishes from around 90º to about 70º. An angle of 0° or 360° represents red Hue, while angles of 90°, 180° and 270° represent yellow, green and blue Hue, respectively.

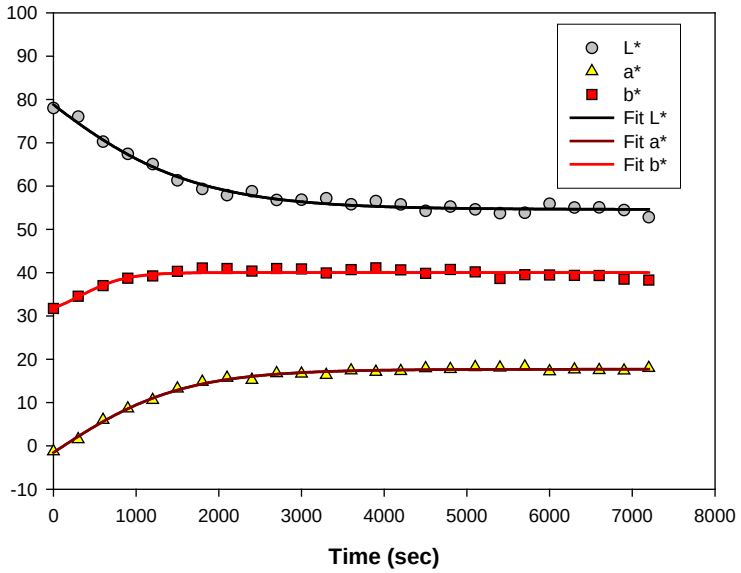

Figure 1. Variation along time of the Cartesian colour coordinates of quince

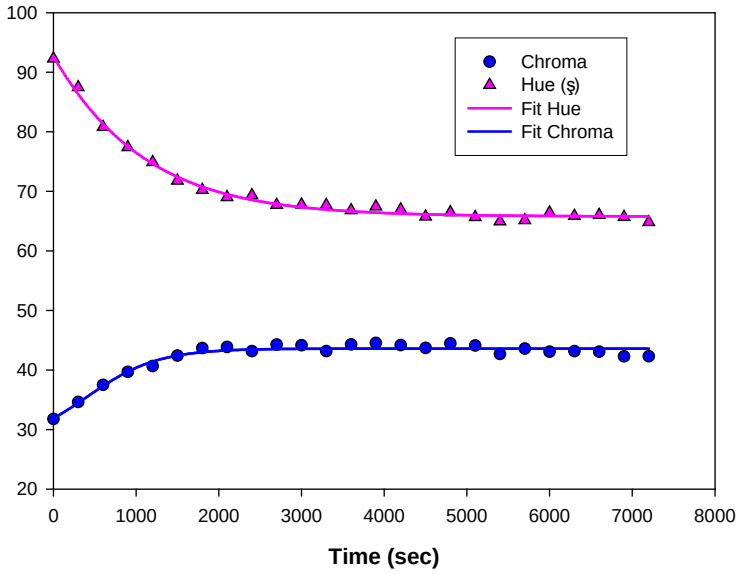

Figure 2. Variation along time of the polar colour coordinates of quince

Figure 3 shows the variation along exposure time of the total colour difference, which was calculated according to Equation (1), and that quantifies the deviation of colour in relation to the reference colour. In this case the freshly cut product was the reference and the corresponding Cartesian coordinates were: L* = 78.02(±0.86), a* = -1.27(±0.23) and b* = 31.75(±1.68). As the graph shows, the values of TCD increase along time, thus indicating a higher difference from the reference, i.e., from the freshly cut quince. This results, as previously said, from brown compounds formed during reactions that take place at the surface of the product that is exposed to the atmospheric air, and in particular oxygen.

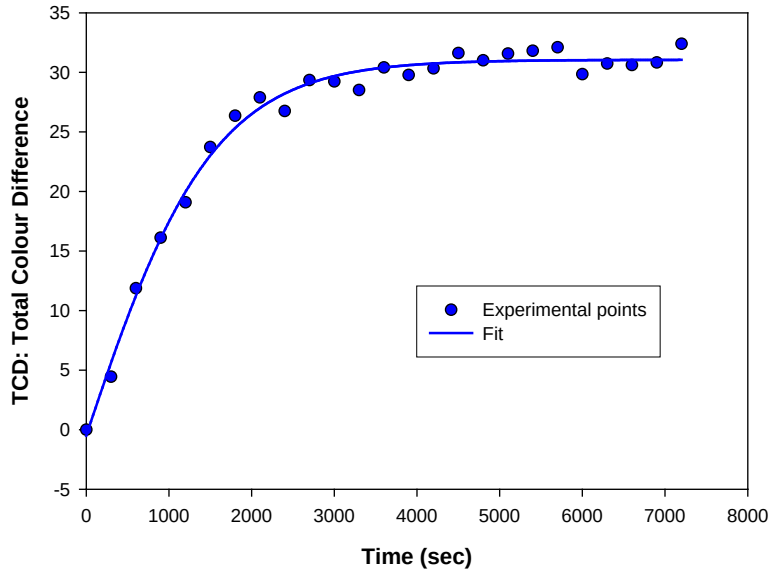

Figure 3. Variation along time of the total colour difference of quince

Figure 4, which represents the variation of the browning index along exposure time, shows a quite similar trend to that observed earlier in Figure 3. In fact, these two variables are different ways of quantifying the same type of phenomena, i.e., the development of darker colours as a result of browning. Once again is visible that the first half hour is critical for the darkening of the cut quince, and that in fact the degree of browning is quite important, given the high values of BI obtained towards the end reaching 140.

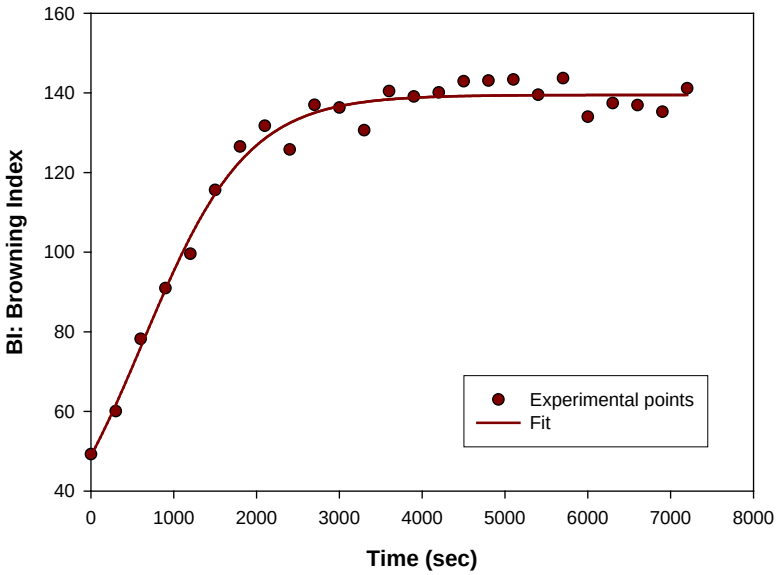

Figure 4. Variation along time of the browning index of quince

CONCLUSIONS

From the present work it was possible to confirm that quince is in fact very susceptible to the exposure to the atmospheric oxygen, which allows the development of an intense degree of browning. All the colour parameters analysed prove the appearance of brown compounds in result of the reactions undertaken at the surface of the quince. Furthermore, total colour difference and browning index were quantified and they revealed that the major colour

deterioration happens in the first half hour, and in the following 1 hour and a half the colour stays approximately constant. Furthermore, the experimental data were fitted to a kinetic model found in literature to describe browning in foods, the logistic model, and in all cases this proved to be very adequate to describe the kinetic behaviour of all variables along time, given the very high values of the regression coefficients.

ABSTRACT: Monitoring of PCBs in human colostrum in South Bačka started in 1982. The objective of this study was to determine concentrations of eight EPA PCB congeners (28, 52, 101, 118, 138, 153, 180 and 209) as typical representatives of persistent pollutants, in early human milk and commercial infant formulas, as a measure of exposure of breast fed newborn babies. Samples of 3rd day colostrum were collected in 2006 from mothers living in the region of Novi Sad, who had no known occupational or dietary exposure to chemicals, and analyzed on GC-ECD (HP 5890 supplied with a Quadrex fused silica column 5% Ph for PCBs). The age of mothers, donors of colostrum, was 28.73 ± 2.45 (25 – 32) years - nine were primiparous and thirteen multiparous. The weight of mothers before pregnancy was 61.5 ± 10.2 kg (median 62, range 51 – 87) and before delivery 77.9 ± 10.9 kg (median 80, range 67 – 102).
The sum of 8 PCB congeners was 1.06 ± 1.41 μg/kg wet weight (range 0.15 – 5.60). The highest values were of PCB 101. PCB congeners 28 and 118 were not detected in any of the samples analyzed. No correlation was found between PCBs concentrations and age of mothers. Birth weights also did not influence PCBs concentrations. Concentrations of PCBs in infant formulas were below average values in human colostrum. Formula manufactured in Serbia did not contain any of PCB congeners. In other four imported formulas, PCB congeners 153, 138 and 180 were detected in a concentration ranging from 0.05 to 0.07 ng/g wet weights. Although breast fed babies were more exposed to PCBs than formula fed babies, breastfeeding should be encouraged, since human milk is undoubtedly the best food for development and growth of infants.
Key words: *EPA congeners, human milk, infant formula*

INTRODUCTION

PCBs are persistent in the environment, and their high lipophilicity results in their bioaccumulation and bioconcentration into the biota and biomagnification through the food chain. Bioaccumulation factors of PCBs increase with higher chlorination and lower water solubility (Coristine et al., 1996). Bioconcentration factors (BCFs) for five chlorinated PCB 118 was measured to be 3.60 - 5.19, while for six chlorinated PCB 138 and PCB 153 were measured in range 4.79 - 5.96 and 3.31 - 5.57,respectively for dry weight of various marine species (Hope et al., 1998).
Depuration for less chlorinated PCBs (28, 52, 101) was presented with half time of 44 to 65 days in 30 d dietary exposure followed by 160 d depuration studies, while for highly chlorinated PCBs (101, 118, 138) elimination half time was from 56 to 224 d (Fisk et al., 1998). Less chlorinated PCBs (1–4 chlorines) are readily taken up by organisms, but are readily eliminated and metabolized. Thus, these homologs are not bioaccumulated to a great extent. The most highly chlorinated congeners (7–10 chlorines) occur in low concentrations in the environment, and are tightly bound with soil, sediment, and organic matter.
Most PCBs are slightly soluble in water and the solubility decreases with chorine content. Estimates of PCB solubility range from 2.7 to 15000 μg/l. PCBs have a high affinity for suspended solids, especially those higher in organic carbon. This is supported by their low

water solubility and high octanol/water partition coefficients (calculated Log Kow values range from 3.76 for biphenyl to 8.26 for decachlorobiphenyl).
PCBs, which have log Kow values >5, appear to enter biota through food-web transfer from sediment, which is less efficient. On the other hand, the penta-, hexa-, and hepta-PCBs are both bioavailable and resistant to degradation in organisms; and these PCB homologs bioaccumulate in organisms to the greatest extent (Willman et al., 1997). For example, the PCBs that dominate congener profiles in the tissues of mussels, crabs, and seals are hexa-PCB isomers 138 and 153 (Porte and Albaiges, 1993). Thus, these persistent lipophilic environmental contaminants accumulate in the human body. The elimination of such compounds and their lipophilic metabolites from body fat is very low. Due to the relatively high fat content of breast milk, the lipophilic compounds are transferred to the milk.
Breast milk is a convenient matrix for monitoring persistent organic pollutants (POPs) in human and for studies of time related trends in environmental contamination. The advantages include simple and non-invasive sample collection, suitability for determination of lipophilic POPs due to the relatively rich lipid content, and relevance with regard to the exposure of breastfeeding infants, who are at the early stage of development and vulnerable to toxic contaminants. However, due to the transfer of the mother’s body burden to the infant (Trapp et al., 2008), the contamination levels in female donors may vary with lactation time. Indeed, the levels of POPs in mother’s milk have been reported to decrease with the number of children (Kunisue et al., 2006; Sudaryanto et al., 2006).
Infant formula is a manufactured food designed and marketed for feeding to babies and infants under 12 months of age, usually prepared for bottle-feeding or cup-feeding from powder (mixed with water) or liquid (with or without additional water). The U.S. Federal Food, Drug, and Cosmetic Act (FFDCA) defines infant formula as "a food which purports to be or is represented for special dietary use solely as a food for infants by reason of its simulation of human milk or its suitability as a complete or partial substitute for human milk".
The composition of infant formula is designed to be roughly based on a mother's milk at approximately one to three through breastfeeding months postpartum, although there are still significant differences in the nutrient content of these products. The most commonly used infant formulas contain purified cow's milk whey and casein as a protein source, a blend of vegetable oils as a fat source, lactose as a carbohydrate source, a vitamin-mineral mix, and other ingredients depending on the manufacturer. In addition, there are infant formulas using soybean as a protein source in place of cow's milk (mostly in the United States and Great Britain) and formulas using protein reduced (hydrolyzed) into its component amino acids for infants who are allergic to other proteins. An upswing in breastfeeding in many countries has been accompanied by a deferment in the average age of introduction of baby foods (including cow's milk), resulting in increased use of both breastfeeding and infant formula between the ages of 3–12 months. Nonetheless, only limited information exists about the presence of PCBs and other POPs in commercial infant food (Loran et al., 2010, Weijs et al., 2006).
In humans a wide variety of health effects have been linked to high exposure to PCBs, including developmental defects, reproductive effects and chloracne, hormonal dysfunctions, reduced mental performance, endometriosis and cancer (Guo et al., 2000). Especially during the last two decades, it has been hypothesized that various human male reproductive disorders, such as testicular germ cell cancer, cryptorchidism, hypospadias and low sperm counts, have a common aetiology and may be related to increased PCBs exposure in utero or in early human life (Sharpe, 2003).
Among the other organochlorine pollutants, the authors analyzed residual quantities of PCBs in human milk samples in the Province of Vojvodina. This kind of research was initiated by the same group of authors more than a quarter of a century ago (Vukavic et al., 1986, 1997, 2003, 2008).

MATERIAL AND METHODS

Donors of colostrums were 22 healthy mothers from the city of Novi Sad and its surrounding. They filled in questionnaire contained data on food habits, age, weight, occupation and exposure to chemicals. Mothers expressed colostrum into specially prepared glass containers. Samples were frozen at -20 °C until analyzed. n- Hexane and concentrated sulfuric acid were added to milk samples and cooled. The hexane layer was separated and cleaned up twice with concentrated sulfuric acid and through the Florisil column, and the eluate evaporated and analysed by GC-ECD (HP 5890 supplied with a Quadrex fused silica column 5% Ph for PCBs).
In addition, five infant formulas were analyzed in 2006. in order to compare concentrations of POPs with the concentrations in human milk samples. Infant formulas were purchased in retail by the method of random choice. One was domestic and four were imported infant formulas. Results were statistically processed using IBM SPSS Statistics 15.0 (as $p<0.01$ the correlations were significant).

RESULTS AND DISCUSSION

The age of mothers, donors of colostrum on the 3rd day after delivery, as well as their weight before and after pregnancy were presented in Table 1. Nine of them were primiparous and thirteen multiparous. Mean birth weight of infants was 3351.8 g with mean height of 49.6 cm (Table 1).

Table 1. General demographic characteristics of mothers and infants, presented as mean standard deviation (SD) and range (min-max)

	Mean	SD	Range
Mothers			
Age (years)	28.73	2.45	25-32
Weight before pregnancy (kg)	61.5	10.2	51-87
Weight after pregnancy (kg)	77.9	10.9	67-102
Infants			
Birth weight (g)	3351.8	313.5	2930-3910
Birth height (cm)	49.6	1.7	47-53

Concentrations of 8 EPA PCB congeners were analysed in 22 human milk samples and in five infant formulas (one domestic and four imported). Six PCB congeners were detected in human milk samples, and four were detected in infant formulas. PCB 118 and PCB 28 were not found in any of analyzed samples. The highly chlorinated PCB 209 was found in only two milk samples. Average concentrations of PCB congeners varied from 0.09 (PCB 209) to 0.56 ng/g ww (PCB 101) in human milk samples. In all five samples of infant formulas concentrations were lower than in human milk samples. In domestic formula (manufactured in Serbia) no PCB congener was found. The most dominated congeners were PCB 153, 138 and 180 as it was found in earlier studies.
Comparison of mean concentrations of PCB congeners in human milk samples (n=22) and infant formulas (n=5) was presented in Figure 1.
Between the PCBs concentrations and age of mothers and birth weight of babies correlation was not found. Correlations between PCB 138, PCB 180 and sum of PCB congeners were significant at the 0.01 level (Table 2).

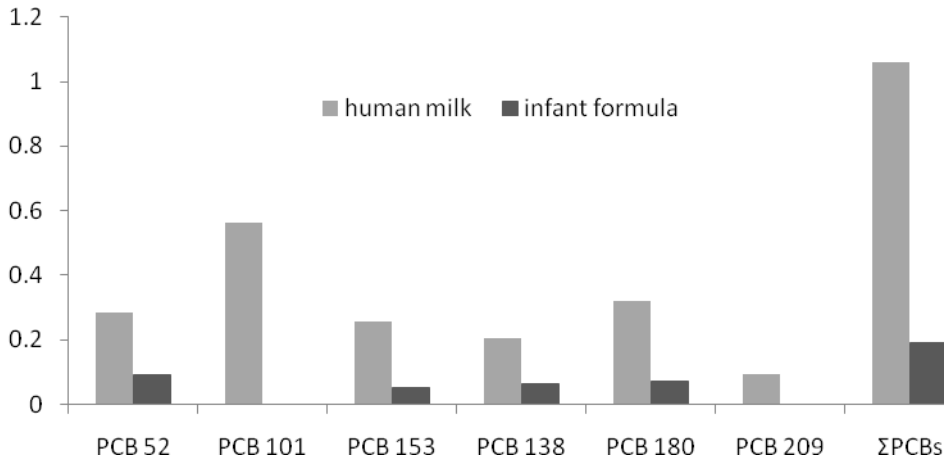

Figure 1. Average concentrations of PCBs (ng/g whole milk) in human milk (n=22) and infant formulas (n=5)

Table 2. Pearson correlations between PCB congeners, age of mothers and birth weight of babies

	PCB52	PCB153	PCB138	PCB180	∑PCBs	b.w.	a.m.

a.m.							1.000

*** the correlation is significant at the 0.01 level*
b.w. –birth weight of babies
a.m. – ages of mothers

CONCLUSIONS

22 samples of human milk from healthy mothers were analyzed for the presence of 8 PCB congeners and results were compared with results obtained for 5 analyzed infant milk formulas. No correlation was found between age of mothers and PCB congener levels. Higher exposure of babies to PCBs was estimated for human milk samples than for infant formulas of artificial milk. However, breastfeeding should be encouraged since human milk presents the indispensable food for infant's development and growth. This research of PCBs concentration levels in Serbia is very sensitive and scarce, and till now, performed only by this group of authors.

ABSTRACT: Development of new production technologies and quality improvement of traditional wheat products increase the competitiveness and food safety of these products both on domestic and international markets. Growers and users may differ widely in their estimates of wheat quality. Development of new genotypes, highly adapted to particular agroecological conditions, is crucial for obtaining high-quality end products. The aim of this study was to analyze the genotype-environment interactions (GEI) occurring under different agroecological conditions and to estimate their effects on two wheat quality parameters, farinograph quality number (FQN) and baking score (BS). These parameters serve as indicators of dough softening degree and elasticity and crumb structure in bread considered as the end product. The average values of FQN ranged from 43.6 to 72.1, the values of BS from 2.8 to 5.5. The analysis of variance of the genotypes grown in 15 environments showed that the effects of genotype, environment and GEI were highly significant for both analyzed traits. Stability of these parameters in 20 wheat genotypes differing in high molecular glutenin subunits (HMW GS) was studied in five locations for three years. The genotypes with a high FQN were more stable than the genotypes with a high average value of BS. The genotypes with different HMW GS values showed no significant difference in average values for FQN. Significant differences for BS, however, indicated that the final quality is affected by many factors. All these factors should be carefully analyzed in order to provide consumers with top quality products, which is a basic condition for their long-term positioning on the market.
Key words: w*heat, farinograph quality number, baking score, G × E interaction*

INTRODUCTION

Wheat, a major foodstuff and raw material for the milling and baking industries, takes an important place in the economies of many countries. Considering its complex nutritional value, it is important to produce the best possible raw material for human consumption. However, wheat quality is a debatable point, which depends on whether it is viewed from the aspect of growers or users, but in any case it calls for continual improvement (Hristov et al., 2010a).

Development of new production technologies and quality improvement of traditional wheat products are important for the competitiveness and food safety of these products both on domestic and international markets. Quality of wheat-based products is the key factor which secures their position on the market. In other words, it calls for continual development of high-yielding wheat varieties as a way of creating a brand name of high quality raw materials for the milling and baking industries (Kosanović, 2007).

Development of new genotypes, highly adapted to particular agroecological conditions, is crucial for obtaining high-quality end products (Hristov at al., 2010b). Success in breeding depends not only on the genotype but also on environmental factors. Successful wheat breeding of is based on the knowledge of characteristics of wheat genotypes, as well as their interactions with the environment (Zečević at al., 2009). Understanding these relationships may serve to determine the breeding strategy, to identify favorable conditions for testing, as well as to zone the new genotypes for the different agroecological conditions.

The aim of this study was to analyze the effect of the genotype-environment interaction (GEI) on two wheat quality parameters, farinograph quality number and baking score.

MATERIAL AND METHODS

Twenty winter wheat genotypes (G): Pobeda; NSR 5, Mina, Milica, Jarebica, Pesma, Renesansa, Tera, Nevesinjka, Evropa 90, Kremna, Prima, Zlatka, Prva, Tiha, Takovčanka, Toplica, Gruža, Bistrica and KG 100, which differed in the high molecular weight glutenin subunits (HMW GS), were studied at five locations (L): Novi Sad (1), Inđija (2), Sremska Mitrovica (3), Kragujevac (4) i Žitorađa (5), for three years (Y): from 2007 to 2009.
The experiment was set up in a randomized block design with three replications. Conventional agricultural practices used in the commercial production of wheat were applied in the experiment.
Two wheat quality parameters were analyzed: farinograph quality number (FQN) and bread crumb structure - baking score (BS). These parameters serve as indicators of dough softening degree and elasticity and crumb structure of bread considered as the end product. FQN shows the stability of dough consistency and it was determined by the ICC 115/1 method (ICC, 1995). BS (on the scale 0–7, where 7 is excellent) is a numerical expression for the organoleptic assessment of bread crumb structure, representing the sum of points for elasticity and crumb structure (Internal standards, 1976).
The analysis of variance for the three-factorial experiment (factors: genotype, location, year) and the AMMI analysis were calculated by GLM and IML procedures of SAS statistical program (SAS 1998).
Stability of the analyzed quality parameters was expressed as the coefficient of regression (b) (Eberhart and Russel, 1966).

RESULTS AND DISCUSSION

The analysis of variance showed that the effects of genotype, environment and GEI were highly significant for both quality parameters. The analysis of variance of the environment indicated that there existed highly significant effects of location and GEI, while the effect of the year was not significant. Dual interaction of the genotypes, with years and locations, showed no significance. In the triple interaction between the genotype, year and location, highly significant effects were noted on both parameters, with the location covering the largest part of the total variance (Table 1). High divergence of selected locations significantly affects the expression of quality indicators (Williams et al., 2008), accelerating the breeding process by shortening the test period and making it easier to spot differences between genotypes (Weikai and Hunt, 2001).
Genotypes with high FQN have gluten of superior quality, which affects the stability and causes a slower softening of dough (Erekula et al., 2009).
The genotype Kremna exhibited the highest FQN value (72.1), the genotype Takovčanka the lowest (43.6). The genotype Tera had the most stable reaction for this parameter (b = 1.01) (Table 2). According to the regression coefficient, genotypes are more stable if the deviation from b=1 is low. According to the LSD test, as many as 11 genotypes with high stability ($0.74 \leq b \geq 1.26$) showed no significant difference. The genotypes with high mean values (above the average for the study) exhibited different responses in terms of stability, from adequate adaptation to adverse environmental conditions (Milica), exceptional stability (Jarebica, Pesma, Tera, Prima), to better response to favorable environmental conditions (Kremna) (Table 2).This was an indication that each genotype had a specific adaptability to the ecological conditions in which it was grown (Mladenov et al., 2001; Marjanović et al., 2011), and that harmonious alignment between the various parameters is of great importance for high quality wheat varieties (Hristov et al., 2010b).

FQN - farinograph quality number, BS - baking score.

Regarding the BS value, the genotype Milica showed the highest and the genotype Prva the lowest average value, 5.5 and 2.8, respectively. Tronsmo et al. (2003) reported that in addition to environmental factors, protein quality significantly affects the texture and crumb structure in bread, which is directly correlated with BS. Pore structure also depends on rheological characteristics of dough, with flour quality affecting the intensity of intermolecular interactions (Rozyło et al., 2011) and thus the ratio of the small pores in bread. The genotypes Jarebica and Renesansa were most stable (b =0.98). However, except for the genotypes KG-100 and Kremna, the stability of the other genotypes was in the range $0.62 \leq b \geq 1{:}38$, with nonsignificant differences at the significance level of $P < 0.05$. The genotypes with high mean values (above the average for the study), were generally less responsive to changes in environmental conditions, which confirmed that high values of individual properties can be achieved in stable genotypes (Mut et al., 2010). The above-mentioned genotypes KG-100 and Kremna were exceptions, which were considerably responsive to favorable environmental conditions (Table 2).

Eleven genotypes with HMW GS 5+10 had a lower FQN value (59.4) than the general average (59.6), while eight genotypes with HMW GS 2+12 had a higher FQN value (60.4). However, there were no significant differences between the groups with different HMW GSs, which is consistent with the results of Hristov et al. (2010b). Regarding the BS value, the analysis showed an opposite reaction of the genotypes. The genotypes with HMW GS 5+10 had larger (4.6) and the genotypes with HMW GS 2+12 lower average value (3.9). Also, the analyzed groups differed significantly regarding this parameter (Table 2, Figure 1). It is well known that genotypes with HMW GS 5 +10 generally exhibit better quality compared with genotypes with HMW GS 2+12 (Tahir et al., 2011), with a possibility of deviations occurring in some genotypes (Saint Pierre et al., 2008). In this study, a single genotype (Tiha), with HMW GS 2 +10 at Glu-1D locus, was found to have the values of both parameters lower than the average. Similar situations were also observed in genotypes with HMW GS 5+10 (Nevesinjka, Takovčanka, Toplica) and those with HMW GS 2+12 (KG 100, Evropa 90, Prva), with only the genotype Takovčanka exhibiting a significant difference from the general average (Table 2).

Table 2. Mean values, regression coefficient (b) and HMW GS at Glu-1D for the analyzed genotypes

Genotype	FQN		BS		HMW GS at Glu-1D

FQN - farinograph quality number; BS - baking score; HMW GS - High molecular weight glutenin subunits.

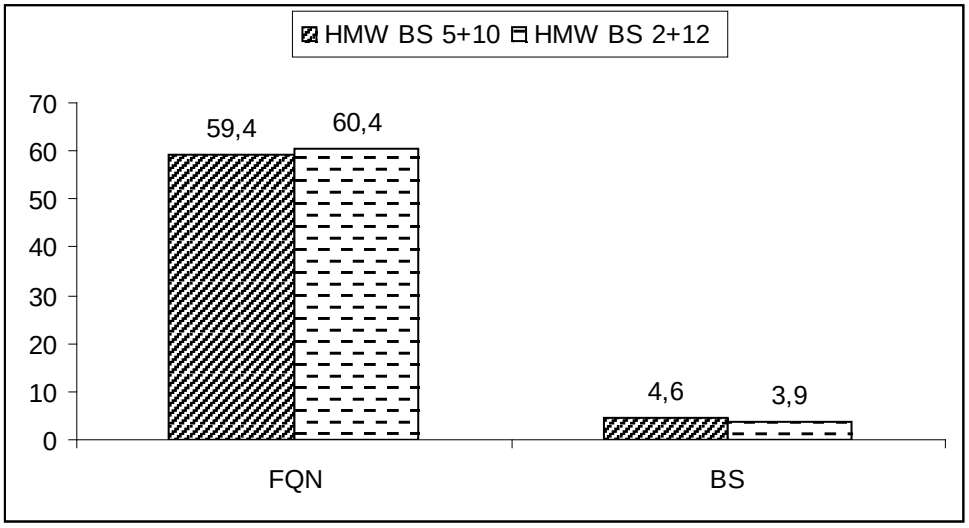

Figure 1. FQN and BS mean values for genotypes with different HMW GS

The year 2008 was most favorable for both parameters under study. On the other side, 2007 was the least favorable for FQN and 2009 for BS. Highest average values for FQN, in all three years, were achieved in the location ŽR. Regarding BS, the highest value was obtained in the location NS. The highest and the lowest FQN stability were established in 2008 in the location SM and in 2008 in the location KG, respectively. The stability of the genotypes studied in these two locations varied significantly (Table 3). Differences in agroecological conditions among locations significantly affect the reliability of the obtained data, which again directly contributes to a shorter test period.

Regarding BS, highest stability was expressed in different years and in different locations (2007 in KG and 2008 in IN). Lowest stability was exhibited in 2009 in the location IN, without significant differences being registered among the observed values of b (Table 3). For

breeders, the stability of quality parameters is important in terms of selection efficiency for individual properties, which directly affects the zoning and growing of certain genotypes in different regions. For milling and baking industries, continual quality of raw materials is crucial for further improvements of the technological process and production efficiency (Mut et al., 2010).

Regression coefficients and the values obtained for BS by AMMI analysis (PC1, PC2) indicated that the studied genotypes reacted similarly to environmental changes. Genotypes with high average values (above the average of the study) were mainly associated with the environments which ensured high BS levels (data not shown).

Table 3. Mean values and regression coefficient (b) for the analyzed environments

CONCLUSIONS

To ensure a high and stable production of quality raw materials for milling and baking industries, it is necessary to have wheat genotypes that combine superior performance with high technological quality. In addition to genotype, the quality of wheat is affected by production technology and environmental factors. It is crucial to have genotypes capable of maintaining continuity in the expression of quality indicators. It is known that rheological properties of dough affect baking characteristics, which can be taken into account in the breeding process. In this way, processors can get better idea about the different classes of wheat, the different wheat genotypes and the different growing conditions they require and how these parameters affect the mechanism of dough forming and improve the quality of flour and bread.

Since the final product quality is influenced by many factors, it is necessary to carefully analyze all of them in order to offer a steady supply of top quality products to consumers, as a way to secure the position of wheat-based products on the market in the long run.

ABSTRACT: Specific conclusions on wheat quality can be drawn from sedimentation value (SV) obtained by Zeleny test (mL). A shortcoming of this method is a reduction of SV during postharvest wheat storage. We studied the dynamics of SV reduction in 15 NS wheat cultivars differing in technological quality. A series of experiments was performed to establish changes in SV depending on the length of wheat storage at room temperature in laboratory. Wheat samples, taken at one-month intervals, were tested for SV (Zeleny test) for one year. The average SV ranged from 20 to 40 mL. The samples with high initial SV generally had a high intensity of SV decline, especially during the last three months of storage. Linear regression showed a significant linear decrease in SV of 0.7 mL per month during the one-year storage period.
Key words: *Wheat, storage, sedimentation value, Zeleny test*

INTRODUCTION

Classification of wheat on the basis of quality parameters is important for other users (food processing industry, human consumption, storage). Specific information on wheat quality can be promptly obtained on the basis of protein content and sedimentation value. The sedimentation value according to Zeleny (Zeleny, 1974) describes the degree of sedimentation of flour suspended in a lactic acid solution for a specified time interval and it is considered as a measure of baking quality. The sedimentation value of flour depends on wheat protein composition that is generally correlated with the protein content or grain hardness (Lasztity,1996). A shortcoming of Zeleny test is that the SV decreases during wheat storage (Ephrat and Sinmena.1976). Total protein content of examined wheat varieties remained unchanged during storage, while Zeleny sedimentation value indicate that quality parameter changes during storage could be highly dependent on cereal variety due to varietal differences in total protein content (Strelec et al.2010).
Wheats with a Zeleny volume (mL) between 22 and 30 are acceptable in EC but they require a machinability test. Wheats with a Zeleny volume (mL) of 30 or higher do not require a machinability test.
Zeleny test is used for preliminary quality testing in the early stages of wheat breeding. Qualitative differences between wheat varieties can be established on the basis of sedimentation value, while modified methods that render SV are needed for a more precise estimation of wheat quality (Kruger and Hatcher, 1995). The Zeleny and the sodium dodecyl sulphate (SDS) sedimentation tests (Axford *et al*., 1979) can be used to obtain a semi-quantitative estimation of the amount of glutenin (or indirectly, of general gluten strength).

Differences in the values of SDS and Zeleny sedimentation tests, which describe the quality of gluten proteins according to their ability to swell and settle in a slightly acidic medium, result from different composition and granulation of the tested components (Weegels *et al*. 1996).

MATERIAL AND METHODS

We studied the dynamics of the reduction of SV in samples of 15 NS wheat cultivars grown at Rimski Šančevi experiment field of Institute of Field and Vegetable Crops in Novi Sad in 2009. Each sample consisted of 5 kg of wheat grains taken after harvest. Grain moisture ranged from 12,8% to 13,5%, so that it was not necessary to dry the samples. Samples were kept in metal boxes at room temperature laboratory, so that the moisture remained unchanged. Samples were taken for analyses at one-month intervals for 12 months.
Grain protein content (GPC) and sedimentation value (SV) were monitored during a period of 12 months (from July 2009. to June 2010.).
GPC (N x 5.7 db) of the whole-grain meal was determined according to Kjeldahl, by ICC standard method 105/2 (ICC 1994). Sedimentation value (Zeleny, 1974) was determined according to ICC 116/1 (1994). All determinations were carried out in three replications.
Average values were used for the evaluation of wheat quality. Statistical evaluation involved the data processed by MS Excel. The effect of storage duration on wheat parameters was calculated by the regression equation.

RESULTS AND DISCUSSION

The effect of storage duration on the quality of wheat from the same harvest can be explained by variations in protein content which is correlated with the sedimentation value (Table 1).
The initial average GPC of the varieties analyzed in 2009. was lower (11.9%) than the long-term average GPC (12.5%) in quality NS wheat cultivars. GPC classification is a system that gives buyers and sellers a common language for grouping products in the same way, everywhere in the world.
The lower average protein content is the consequence of specific weather conditions during the period of protein formation (Hristov and MLadenov, 2005; Šeremešić et al., 2008; Đurić and Kobiljski, 2006).
One-year storage of the studied samples caused a slight reduction in the protein content (July 2009. –11.9% on average; June 2010. –11.7% on average). These results are consistent with findings of Mezei et al. (2007).

Table 1. Effect of storage period on sedimentation value and protein content in wheat grains from 2009.

No.	Storage period	Grain protein content (%/dm)	Max. SV (mL)	Min. SV (mL)	Average SV (mL)	(%) SV compared with 100% measured in July 2009.
1	July	11.9	38	20	31.3	100
2	August	12.4	40	20	32.3	103
3	September	11.6	36	24	30.9	98.7
4	October	11.7	34	23	29.8	95.2
5	November	11.6	33	21	28.8	92.0
6	December	11.6	33	21	27.6	88.2
7	January	11.7	30	21	27.4	87.5
8	February	11.5	30	20	26.5	84.6
9	March	11.7	30	21	26.7	85.3
10	April	11.5	30	21	26.2	83.7
11	May	11.5	29	20	24.5	78.3
12	June	11.7	28	20	24.2	77.3
	Average	11.7	28	21	28.0	89.4
	S.D.	0.25			2.62	
	CV (%)	2			9	

PC-protein content; SV-sedimentation value; S.D.–standard deviation; CV-Coefficient of variation

In agreement with GPC, the average initial SV values were lower (31,3 mL) than the long-term average SV (> 35 mL) in quality NS wheat cultivars. Zeleny sedimentation, however, proved to be a useful indicator of the effects of environmental conditions (Anneliese et al. 2005).
Sedimentation values were significantly different (38 mL on average in July 2009, 28 mL on average in June 2010). Average SV varied from max. 40 mL in the second month after storage, to the lowest value of 20 mL which was obtained several times during the analyzed year.
The rate of SV reduction was highest in the last three months, when the average SV were 83.7%, 78.3% and 77.3% compared with 100% measured in July 2009. The cultivars with high starting SV generally showed a greater rate of reduction than the cultivars with low starting values. This was consistent with the results and Ephrat and Sinmena (1976). After 15-month storage of two wheat cultivars, Lukow et al. (1995) found that SV decreased regardless of the temperature in storage boxes, which ranged from -4 °C to 25 °C.
The coefficient of variation (CV) was higher for SV (9%) than for GPC (2%), as well as the values of standard deviation (2.62 and 0.25, respectively). The deviation of wheat quality parameters from initial values was also observed by Brandolini et al. (2010).
Zeleny test values showed a strong variance in time and an evident trend of decline (Figure 1).

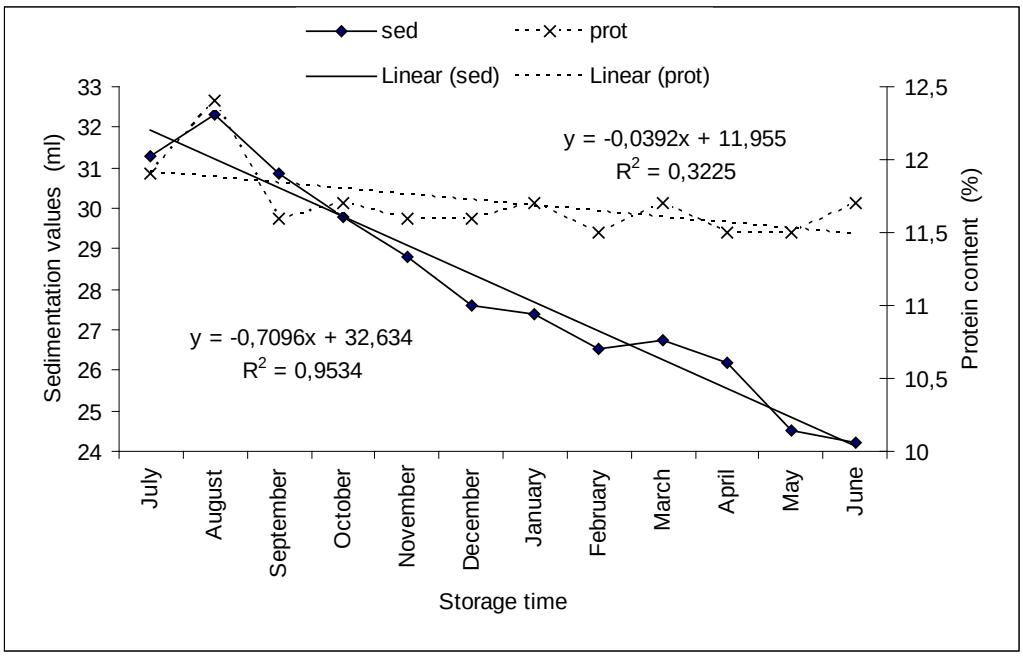

Figure 1. Sedimentation values and protein contents in wheat stored from July 2009. to June 2010. year

We found a slight linear decrease in GPC (0.039%) and a significant linear decrease in SV (0.7 mL per month). The different trends of impact of storage on wheat quality as compared with the results of other authors (Hrušková et al., 2004; Lukow et al., 1995) may be attributed to the production year, choice of cultivar, different conditions and length of storage of wheat samples. Hrušková et al. (2004) found that wheat quality differed from one year to another as well as that wheat quality did not decline inevitably each year.

CONCLUSIONS

After one year of storage of wheat grains under the described conditions, there were no significant changes in total grain protein content.

The vlues of Zeleny test showed a strong variance with time and an evident trend of decline (0.7 mL per month).
Predicting the wheat grain quality based on SV (Zeleny test) was not reliable, because the rate of variation in SV was not consistent among the cultivars which differed in quality and were storaged for different periods of time.

ABSTRACT: Wheat quality is a complex collection of traits affected by various loci on multiple chromosomes. This study was conducted in order to identify quantitative trait loci (QTLs) related to most commonly used quality parameters, protein content (PC) and sedimentation value (SED). For this purpose association analysis between SSR molecular markers and quality traits was performed on a selected sample of 94 diverse wheat genotypes. Quality parameters were determined during five years (2007-2011). Microsatellite markers located near targeted QTLs were carefully chosen in accordance with existing literature data. Genomic DNA was extracted from seedlings using CTAB method and PCR products were separated by capillary electrophoresis. The population structure was estimated in Structure v.2.0. software and association analysis was performed in the program Tassel. Significant marker-trait associations (MTAs) were found for the both quality parameters. The markers WMC31 and GWM18 showed significant and stabile associations with QTLs for PC and SED, respectively. Our results demonstrated that association analysis could complement and enhance previous QTL information and provide very useful information for marker-assisted selection.
Key words: bread wheat, protein content, sedimentation, QTLs.

INTRODUCTION

Wheat bread-making quality is highly heritable, controlled by multiple loci and influenced by a number of environmental, genetic and biochemical factors (Zheng et al., 2009). Breeding for improved quality of bread wheat is very difficult and this process can be accelerated by using molecular markers tightly linked to the genes of interest (Bekes et al., 2002; Chen et al., 2009).

Associations between molecular markers and wheat quality characteristics have been studied in two types of populations: structured populations, typically derived from biparental crosses and investigated via quantitative trait locus (QTL) analysis, and non-structured populations, usually collections of cultivars and breeding lines that are analyzed by association analysis methods (Zheng et al., 2009). Non-structured populations have several advantages, including the ability for simultaneous evaluation of different traits using the same genotypic data, more efficient use of resources, better genome coverage and use of multi-location and multi-year phenotypic data at no additional costs, because these data are collected routinely in many wheat-breeding programs (Breseghello and Sorrells, 2006). Due to these advantages, the largest number of marker-trait associations have been established in collections of wheat cultivars and advanced lines (He et al., 2005; Bekes et al., 2006; Chen et al., 2009; Bordes et al., 2011).

This study was conducted in order to identify QTLs related to wheat quality characteristics (protein content and sedimentation value) in a collection of 94 wheat varieties using association analysis.

MATERIAL AND METHODS

Determination of quality parameters

As the material for this study, 94 wheat cultivars were grown in a field conditions during five years (2007-2011). Conventional cultural practices for field experiments were applied as described in Hristov et al. (2010). In the material protein content (PC) was determined by Kjeldahl method ICC 105/2 (ICC 1994), while sedimentation value (SED) was obtained by Zeleny method ICC 116/1 (ICC 1994).

Molecular evaluation

A set of 94 genotypes was fingerprinted using four public available microsatellite markers (WMC31, WMC89, WMC420 and GWM18). Genomic DNA was extracted from approximately 10 young leaves for each variety using modified CTAB protocol (Doyle and Doyle, 1990). PCR amplification was done according to Röder et al. (1998) using fluorescently labeled primers. PCR products were denaturized with HI-DI formamide and fragment analysis was performed on ABI Genetic Analyzer 3130.

Data analysis

Phenotypic data were analyzed using STATISTICA 7 program. Molecular data analysis was performed using Microsoft Excel-Software, and the polymorphism information content (PIC) was calculated according to Anderson et al. (1993). Population structure was determined in software Structure (Pritchard et al., 2000). Q matrix obtained in this program was used for detection of marker-trait associations in Tassel1 (Bradbury et al., 2007). Markers with significant ($P<0.05$) association in the final general linera model (GLM) were declared as main effect QTLs.

RESULTS AND DISCUSSION

Quality parameters

The results have shown that protein content and sedimentation values significantly varied among the genotypes (Table 1). The basic statistic indicators have shown that SED is more variabile trait then PC.

Table 1. Descriptive statistics for protein content (PC) and sedimentation value (SED) in 94 wheat genotypes analysed in five years

Trait	Mean	Confidence -95.0%	Confidence +95.0%	Min	Max	Std. Dev.	Std. Error
PC	13.0	12.90	13.16	9.5	18.9	1.41	0.0648
SED	40.5	39.7	41.28	20.0	70.0	8.57	0.3938

Molecular evaluation

In addition to observed phenotypic variability, molecular evaluation also has shown a considerable level of genetic variability in the material. A total of 28 alleles were detected in the present study at four wheat microsatellite loci, with average allele number per marker of 7 (Table 2). The number of alleles for the individual markers ranged from five (*Xgwm513*) to nine (*Xgwm437*). In the three out of four microsatellite loci null alleles were detected. Polymorphism information content (PIC) ranged from 0.19 for WMC420 to 0.72 for GWM18. An average PIC value of 0.57 for all markers indicated the high level of detected polymorphism.

A similar number of allelic forms with the relatively high level of polymorphism per locus were also detected in other studies (Kobiljski et al., 2002, Maccaferri et al., 2008, Brbaklić et al., 2010), indicating a presence of significant genetic variability in tested materials.

Table 2. Number of detected alleles, product size and PIC-values of four microsatellite markers

Marker	No. of alleles	Product size	PIC
WMC31	6	126-138	0.71
WMC89	9	null, 122-138	0.68
WMC420	5	null, 118-124	0.19
GWM18	8	null, 178-196	0.72
Average	7		0.57

Association analysis

Prior the association analysis, the population structure of chosen genotypes was determined using the program Structure. The genotypes were clustered into three subpopulations according to admixture model used by software. After correction proposed by Evanno et al. (2005) the final number of subpopulations was two. An important prerequisite for association analysis is an existence of certain level of population structure in order to eliminate false positive associations (Prichard et al., 2000; Cockram et al., 2008).

The results of significant marker-trait associations in five analyzed years are shown in Table 3. The marker GWM18 showed significant (P<0.05%) associations with SED in three analyzed years and with PC in the year 2010. The marker WMC31 was significantly associated with PC in three out of five analysed years. The QTL located near to marker GWM18 explained from 15.2 to 26% of total variability for SED, while the QTL near marker WMC31 explained from 13.5 to 22.4% of total variability for PC.

Table 3. Associations between microsatelite markers and wheat quality prameters

Marker	Years	% Proteins		Sedimentation	
		P value	R^2 (%)	P value	R^2 (%)
GWM18	2007	0.7223	4.1	**2.35E+00****	**26**
	2008	0.9997	0.3	0,752	4
	2009	0.3001	8	**0.011***	**15.2**
	2010	**7.60E+00****	**23.6**	**0.0033****	**18.1**
	2011	0.5193	5.7	0.2121	8.4
WMC31	2007	0.096	9.1	0.8683	1.5
	2008	0.0625	10.4	0.3459	5.4
	2009	**0.0011****	**20**	0.5774	3.1

	2011	**0.0167***	**13.5**	0.819	1.7

**Significant at P<0.05*
***Significant at P<0.01*

Many QTLs for quality traits were identified in different regions of individual wheat chromosomes (Bekes et al., 2002; Chen et al., 2009; Zheng et al., 2009). In the present study, the detected QTLs for SED and PC were found in the regions on chromosome 1B near markers GWM18 and WMC31, respectively. These results are partly in agreement with the results of Wu et al. (2008). They detected three QTLs for kernel protein content on chromosomes 3A and 3B and three QTLs for Zeleny sedimentation value on chromosomes 1B, 1D and 3B. The QTLs on chromosome 1B and 1D were stabile across three environments, explaining 5.5%-17.6% of phenotypic variability. The QTLs controlling Zeleny

sedimentation value, and some other quality traits such as mixing time, eight minute width, peak viscosity and breakdown were mapped on the same region of chromosome 1B, with genetic distances of 0.1-0.8 cM from the nearest marker Glu-B3j, indicating the big influences of 1BL/1RS translocation on these traits. In addition, on chromosome 1D, one QTL was found to control the Zeleny sedimentation value, mixing time and eight minute width, with genetic distances of 2.5-3.3 cM from the nearest marker Dx5+Dy10, exhibiting a great effect of HMW glutenin subunits Dx5+Dy10 on these traits (Wu et al., 2008).
Macaferri et al. (2008) indicated that only stable QTLs expression in a wider range of agro meteorological conditions is one of the determining factors in successful application of candidate markers in MAS for high yield, quality and adaptability in wheat. The both QTLs detected in our study were significant in three of the five tested years, indicating significant environmental effect on these traits. Similar results were found in the study of Kumar et al. (2007), suggesting that the major part of genetic variation for grain protein content is due to environmental interactions. The results of Mann et al. (2009) also suggested the inconsistent genetic control of protein content across the test sites, with only two loci (3A and 7A) showing QTL at three of the five sites.

CONCLUSIONS

The results of the present study have shown significant phenotypic and molecular variability in the population of 94 wheat varieties, which makes it suitable for the detection of important QTLs. Significant associations were found between marker GWM18 and sedimentation value, and between marker WMC31 and protein content. The obtained marker-trait associations should be validated in other material and in more environments in order to check their applicability in MAS.

ACKNOWLEDGEMENT

The research is a part of the project 031066:"Modern breeding of small grains for current and future needs", funded by Ministry of Education and Science, Republic of Serbia.

ABSTRACT: Kefir is a traditional popular middle eastern drink originates from the Caucasus in central Asia. In this study kefir starter culture were used for production of beverages made from milk, whey and soymilk. The incubation time (24 h) and temperature (25 ºC) inoculation rate (5%) and mixing rate (90 rpm) were the same for the all products. Some chemical characteristics (carbohydrate, ethanol, dry matter, fat and pH value) were determined during 48 h of fermentation in 3 beverages. During the fermentation carbohydrate content (w/w) and pH decreased markedly, but dry matter and fat content of the beverages were not significantly different from dry matter and fat content of the substrates. Ethanol content in 3 beverages increased significantly during the fermentation.
Key words: *kefir starter culture, soymilk, fermented beverage*

INTRODUCTION

Kefir is a fermented milk product that has its origin in the Caucasian mountains, Tibet or Mongolia, many centuries ago (Cais-Sokolinska et al., 2008). Soymilk is a liquid extract from soaked and ground soybeans (Smith et al., 2009) which is widely recognized for its high nutritional value owing to its quality proteins. In addition, it is also recognized to contain isoflavones, the bioactive compound that has been extensively associated with the prevention of chronic diseases such as atherosclerosis, cancer, osteoporosis and menopausal disorders (Ewe et al., 2012).

The nutritive quality of soy bean protein is at the pinnacle of food sources available from the plant world. When soymilk compared with cow's milk, the high amounts of arginine and aspartate should be mentioned (Lee et al., 1990) .The polyunsaturated/saturated ratio of soymilk fatty acids is also high (1/1:0.3) along with its concentration of folate (Holland et al., 1991).

Many consumers find the taste of plain soymilk unappealing (Liu and Line, 2000). The distinct aroma of soymilk may be one factor for the low consumption of soymilk in western diets. The state of soymilk can be improved by decreasing the beany, grassy or soy flavor by lactic acid bacteria fermentation (Mital et al., 1974; Granata and Morr, 1996; Liu and Line, 2000).

Milk whey is a by-product of the cheese-making industry which presents about 85-95% of the milk volume and contains nutrients such as lactose, soluble proteins, lipids, minerals, vitamins and organic acids. Because of its high organic matter contents, milk whey can be a serious environmental problem with lactose being mainly responsible for its high BOD and COD values (Mawson, 1994).

Whey is the liquid effluent of the dairy industries and therefore it is produced in large capacities worldwide, creating serious environmental pollution problems (Koutinas et al., 2007). The dairy industry must therefore try to attain a position where handling the whey does not prevent the industry from meeting the market demand for its products. Using the whey for

the production of fermented beverage may reduce its pollution potential while results in the production of a value added product (Ben-Hassan et al., 1995).
In previous studies of Motaghi et al. (1997), the microorganisms from kefir grain were isolated and purified. In the present investigation, the starter cultures were prepared from native microbial strains. Various ratios of starter culture were made from the isolated microorganisms of kefir grain. Lactic acid bacteria, yeast and acetic acid bacteria were used for production of beverage and the products were examined and analyzed for protein, fat, sugar, alcohol, carbon dioxide, acidity, density and riboflavin content.
The aim of this study was to evaluate chemical changes during the fermentation of beverages made from milk, whey and soymilk using kefir starter cultures and mixed cultures consisting of certain species of kefir grain microorganisms in order to develop a procedure where lactic acid fermentation is followed by yeast fermentation.

MATERIAL AND METHODS

Stock cultures

Seven species of bacteria previously identified as *Lactobacillus kefir, L. brevis, L. casei, L. plantarum, Stereptococcus lactis, Leuconostoc mesenteroids and Acetobacter aceti* were combined to form a bacterial starter culture of kefir. Among the isolated yeast from Iranian kefir grain *Candida kefir, Saccharomyces lactis and S. fragilis* were previously isolated and identified by Motaghi et al. (1997). The stock cultures of these organisms were obtained from Persian Type Culture Collection (PTCC). Sterilized skim milk is suitable medium for kefir starter cultures and all cultures were maintained in this liquid.

Microbial enumeration

The preparation of the inoculum of the pure cultures was performed according to the method of Marshall and Cole (1985). Slants were incubated aerobically at 30 ºC for *Streptococci*, for *lactobacilli* under an atmosphere of 80% N_2, 10% H_2 at 30 ºC and *Acetobacter* slant was incubated aerobically at 26 ºC.
The turbidity of each microbial suspension was estimated by spectrophotometer at 550 nm according to the method of Kingra and Horikoshi (1988). Starter bacterial and yeast cultures were prepared in such a way that their concentration (cells/mL) was exactly equal to what they were in one gram of original kefir grain (Motaghi et al. (1997).

Beverage preparations

In the present study, preparation and fermentation of soymilk were performed according to the procedures described by Wang et al. (2002).Whole soybeans with Sahar variety were first washed and soaked overnight in distilled water, after decanting the water, the soaked soybeans were mixed with 10 times the weight of distilled water and comminuted in blender (National MJ-176NR model) for 3 min. The resultant slurry was then filtered through a double layered cheese cloth to yield soymilk. Soymilk was dispensed into containers and autoclaved for 15 min at 121 ºC. Soymilk was used as a growth medium with the following approximate composition: proteins 3.0%, lipids 2.5%, sugars 3.5%, ash 0.5% and water 90.5%. The sugar fraction comprised 2.8% sucrose and 0.7% stachyose. Prior to further use Soymilk was sterilized at 115 ºC.
Milk was homogenized and pasteurized at 85 ºC for 25 min and cheese whey was provided by Kalber S.A. which is a factory processing milk for cheese and other dairy products in the area of Arak that is situated in center of Iran.
The pasteurization technique for whey included heating to 60 ºC for 30 min, follow by cooling to 0 ºC for 30 min and letting stand at room temperature heating. Cooling and standing at room temperature was repeated three times to destroy any vegetative or spore cells present in the whey.
The plate count test (Messer et al., 1985) was performed to ensure the effectiveness of the pasteurization technique. The incubation time (24 h), temperature (25 ºC) and shaking speed

(90 rev/min) were kept constant. The procedures for making various beverages are as follows:
Beverage 1 (B_1): The pasteurized milk was inoculated with combined kefir grain bacteria with yeast inoculate was used (3% (v/v) bacterial strain and 2% (v/v) yeast kefir grains previously described by Mazaheri et al. (2000).
Beverage 2 (B_2): The pasteurized whey was inoculated with combined kefir grain bacteria with yeast inoculate was used (3% (v/v) bacterial strain and 2% (v/v) yeast kefir grains previously described by Mazaheri et al. (2000)
Beverage 3 (B_3): The sterilized soymilk was inoculated with combined kefir grain bacteria with yeast inoculate was used (3% (v/v) bacterial strain and 2% (v/v) yeast kefir grains previously described by Mazaheri et al. (2000).
From each batch of beverage, samples were taken at 0 h and after 24 and 48 h of fermentation (incubation).

Chemical analysis
Fat contents of individual sample were measured according to standard AOAC method 2000 18. AOAC, method 990. 19 was used to determine total solid in each sample. The pH was determined by inserting a pH probe (pH meter Micro pH 2002; Crison, Barcelona, Spain) directly into a well-mixed sample of the sample.
Carbohydrate was measured by HPLC (Waters, Mil ford, MA, USA) equipped with an Interaction ION 300 column (Phenomenex, Torrance, CA, USA), using H_2SO_4 (0.0064 N) as mobile phase at a flow rate of 0.4 ml min $^{-1}$ (2).
Ethanol was determined using a gas chromatograph. GC analysis was carried out on a Shimadzu Auto system gas chromatograph equipped with a flame ionization detector (FID). A CBP_{10} capillary column (L = 25 m, D = 0.33 mm, df = 0.5) was used. Helium was used as a carrier gas. The injector was heated to 100 ºC and the FID to 260 ºC and the column temperature program was isothermal at 90 ºC. The samples were injected in the split less mode (Wang et al., 2004).

Statistical analysis
All results presented in this study are the mean of three independent experiments with three replicates each. Data were analyzed by the general linear model procedures of the statistical analysis system (SAS, 1986); $p<0.05$ was considered significant. Means were compared by last significant difference.

RESULTS AND DISCUSSION

In present study by using the native microbial strains isolated from kefir grains starter culture, the following results were obtained.
Table 1 shows that mean changes in some chemical components during fermentation of milk in the manufacture of beverage 1. Table 2 shows that mean changes in some chemical components during fermentation of whey in the manufacture of beverage 2 and Table 3 shows that mean changes in some chemical components during fermentation of soymilk in the manufacture of beverage 3.

Table 1.Changes in some chemical components (%, w/w) during the 48h of fermentation of heat treated cow's milk.

	Fermentation time (h)		
	0	**24**	**48**
Carbohydrate	4.90 ± 0.22	4.02 ± 0.16	3.96 ± 0.18
Ethanol	0.002 ± 0.002	0.005 ± 0.003	0.008 ± 0.004
Dry matter	11.90 ± 0.52	11.70 ± 0.54	11.40 ± 0.50
Fat	3.71 ± 0.18	3.60 ± 0.12	3.47 ± 0.20
pH	6.30 ± 0.10	4.40 ± 0.20	4.30 ± 0.10

Table 2. Changes in some chemical components (%, w/w) during the 48h of fermentation of heat treated whey

	Fermentation time (h)		
	0	**24**	**48**
Carbohydrate	4.36 ± 0.26	3.89 ± 0.12	3.80 ± 0.28
Ethanol	0.002 ± 0.001	0.004 ± 0.004	0.006 ± 0.003
Dry matter	5.70 ± 0.32	5.60 ± 0.24	5.50 ± 0.40
Fat	0.57 ± 0.08	0.50 ± 0.10	0.41 ± 0.06
pH	5.50 ± 0.20	4.60 ± 0.1	4.50 ± 0.20

Table 3. Changes in some chemical components (%, w/w) during the 48h of fermentation of heat treated soymilk

	Fermentation time (h)		
	0	**24**	**48**
Carbohydrate	3.50 ± 0.18	3.20 ± 0.14	3.10 ± 0.18
Ethanol	0.002 ± 0.001	0.003 ± 0.004	0.004 ± 0.002
Dry matter	9.50 ± 0.44	9.35 ± 0.42	9.24 ± 0.46
Fat	2.50 ± 0.14	2.40 ± 0.10	2.32 ± 0.10
pH	6.70 ± 0.10	5.40 ± 0.10	5.00 ± 0.20

The Carbohydrate content decreased significantly ($P<0.05$) during the first 24 h, and then more slowly until the 48 h of fermentation.

Carbohydrate was consumed during the 24 h fermentation period, and carbohydrate levels decreased by 20–25% with respect to the initial carbohydrate levels present in the milk and whey. In milk substrate, the final carbohydrate contents were within the range of the values observed by other authors for Kefir produced from milk obtained from different species (Muir and Hunter, 1992; Muir, Tamine, and Wszolek, 1999). In soymilk carbohydrate levels decreased slowly. Alm (1982) did not detect galactose in the kefir samples, a finding repeated here in our study. This is because the galactose formed by hydrolysis of the lactose is employed by the kefir microflora to form the polymer kefiran characteristic of kefir, used to make the new granules formed during the fermentation process.

Assadi, Pourahmad, and Moazami (2000) manufactured kefir in the same conditions employed here using a 5% inoculate and reported lactose levels of around 1.4% after 24 h of fermentation, much lower than the levels recorded in the present experiment.

The ethanol content increased slightly, but significantly ($P<0.05$), during the period from 0 to 48 h, reaching a mean final value of 0.008% (w/w); this value is within the range of values observed by other authors for Kefir from different origins (Gu¨ zel-Seydim et al., 2000; Kurman, Rasic, and Kroger, 1992; Marshall and Cole, 1985; Wszolek, Tamine, and Muir, 2001). In whey the ethanol content increased slightly, but significantly ($P<0.05$), during the period from 0 to 48 h, reaching a mean final value of 0.006% (w/w); this value is within the range of values observed by other authors Mazaheri Assadi, Abdolmaleki, and Mokarram, (2008).

Dry matter in the three beverages did not significantly change after 48 h of fermentation .Dry matter values were similar to those recorded for other fermented milks (Gambelli et al., 1999) and to those reported by Ching-Yun and Ching-Wen (1999) for kefir made using a 5% inoculate. These values were not significantly different from the dry matter content of the source substrates. Accordingly, as was the case for the fat content, fermentation did not affect the dry matter content of the source substrate used. Ottogalli, Galli,Resmini, and Volonterio (1973) found that the dry matter in recently manufactured kefir differed according to the geographic origin of the granules, with variations in dry matter of between 9.4% and 11.1% in the milk substrate. The percentage of kefir grains inoculated did not significantly influence the dry matter in the samples.

The fat content of three beverages did not differ significantly ($p > 0.05$) from the fat content of the substrates (milk, whey and soymilk). This finding was consistent with reports by other researchers (Gambelli et al., 1999; Huerta-Gonzalez and Wilbey, 2001; Walstra and Jenness, 1987), who observed that in macro nutritional terms, the nutritional composition of

fermented milks, including the fat content, was the same as that of the source milk. In contrast, Ching-Yun and Ching-Wen (1999) observed the fat content of recently cultured kefir to be lower than that of the milk, a difference possibly ascribable to the lipases produced by the kefir grains during fermentation (Vujicic, Vulic, and Konyves, 1992).
There was a sharp decrease of around 2 pH units during fermentation in three beverages. As already related above, the lactic acid bacterial population declined with time, which is why the kefir did not become more acidic. Collar (1996) found that lactic acid bacteria multiply and produce lactic and acetic acids more slowly in mixture with yeasts than in pure culture (Collar, 1996). The percentage kefir grain inoculate added did significantly ($p < 0.05$) affect the pH values which reported by Irigoyen, Ortigosa, and Torrez (2003), who recorded significant differences during kefir manufacture according to the percentage kefir grain inoculate added.

CONCLUSIONS

In the manufacture of Kefir, by fermentation of heat treated cow's milk, whey and sterilized soymilk using kefir starter culture. During the fermentation carbohydrate content (w/w) and pH decreased markedly, but dry matter and fat content of the beverages were not significantly different from dry matter and fat content of the substrates. Ethanol content in 3 beverages increased significantly during the fermentation.

ABSTRACT: Since the technological quality of flour is directly influenced by protein content and quality, a great attention is paid to determination of its properties. For this purpose, a wide range of chemical, physical and rheological tests are commonly employed. The rheological properties of dough during baking processing and ultimately the quality of final product are influenced by the changes of the thiol/disulphide structure of gluten proteins. The aim of this study was to monitor the changes in the amount of thiol groups as a quality indicator of protein complex of three freshly harvested wheat samples from two localities characterized by different micro-climatic conditions in 2010/2011 production year. By modifying the method of Pérez et al. (2005), the content of thiol groups was spectrophotometrically determined in wet gluten of selected samples (λ = 412nm). Each sample was beforehand tempered at two different temperatures (30° and 37 °C) in order to imitate the flour processing conditions as well as to determine the impact of hydrolytic enzymes present. On the basis of obtained results, it was noticed that each variety manifested different trend in the amount of thiol groups over time when tempering at 30 °C, whilst tempering at 37 °C highlighted the dominant impact of selected localities on the amount of thiol groups.
Key words: *wheat, quality, gluten, thiol groups, micro-climatic conditions*

INTRODUCTION

Gluten proteins have a primary influence on the technological quality of wheat flour. In fact, the technological quality mainly depends on glutenin and gliadin fraction which account for 80% of total flour proteins (Shomer et al., 1998; Wieser, 2007). Both fractions influence rheological properties, with different role for wheat flour functionality. It is considered that glutenin fraction contributes visco-elastic properties of gluten and dough. On the other hand, gliadin fractions, by non-covalent interactions with one another and with glutenin polymers, act as plasticizers of gluten mass (Perez et al., 2005; Manu et al., 2008; Shewry et al., 1997). Therefore, the technological properties of flour depend on the structure of the protein fractions and their interactions as well as protein interactions with other components (Shewry et al., 1997).

Glutenin subunits form both intra- and inter-chain disulfide (-S-S) bonds, while the establishment of intermolecular disulfide bonds is characteristic for gliadins, resulting in smaller molecular weight of these proteins (Perez et al., 2005). During the mixing of dough, gluten network is formed as a direct consequence of the linking process by disulfide inter- and intramolecular bonds between monomeric gliadins and polymeric glutenins. Structure of gluten network is determined by the number of available thiol (-SH) groups, so the number of resulting inter-and intramolecular disulfide bonds influences various properties of gluten (Torbica, 2007).

Since the formation of gluten is related to the transformation of -SH groups to -S-S bonds, a great attention is given to examination of their contents because they are generally considered to be important indicator of rheological properties of dough and baking performance of wheat (Chen and Schofield, 1996; Ou et al., 2004).

Taking into account that in the processing of wheat flour dough, the proteins are undergoing certain biochemical changes that are followed by rearrangement or interchange of SH/SS

bonds, the aim of this study was to monitor the changes in the content of thiol groups as a quality indicator of protein complex of three freshly harvested wheat samples from two localities characterized by different micro-climatic conditions in 2010/2011 production year.

MATERIAL AND METHODS

Wheat samples of two Serbian varieties (Pobeda and Zvezdana) and one French variety (Apache) were collected from two localities in Northern Serbia (locality 1 and locality 2) in 2011.
The content of wheat-bug damaged kernels was determined by standard method (Pravilnik o kvalitetu poljoprivrednih proizvoda koji se skladište u javnom skladištu, 2010). Wheat samples were milled to flours using laboratory mill MLU 202 (Bühler, Switzerland) (flour extraction rate of 60%).
Gluten for determination of free thiol group content was washed according to ICC method 137/1, whilst determination of rheological behaviour of dough was performed by using Mixolab (Chopin Technologies, France) according to ICC method 173.
Each sample of wet gluten before examination was tempered at two different temperatures (30 °C and 37 °C) during 45, 90 and 135 min in order to imitate the flour processing conditions as well as to determine the impact of hydrolytic enzymes present.
Concentration of free thiol groups was examined as previously described by Prasada Rao et al (2002) and Perez et al (2005), with two modifications: after vortexing gluten was centrifuged at 14 500 rpm for 6 min and volume of Ellman's reagent was increased for 25%.

RESULTS AND DISCUSSION

Localities 1 and 2 for this study were selected due to the history of climatic conditions during the last decade, why wheat from locality 1 has been mainly characterized by poor technological quality (low values of extensograph energy), whereas wheat from locality 2 has been characterized by good technological quality (high values of extensograph energy) (http://www.fins.uns.ac.rs/index.php?page=studije-o-kvalitetu&hl=sr).
Figure 1 shows the results of determination of thiol groups of gluten samples previously tempered at 30 ^{o}C. According to obtained results, it is noticeable that the changes in thiol status were affected by the variety. The greatest changes occurred after incubation of gluten for 90 minutes. Variety Apache, regardless of geographic origin, did not show significant changes in the thiol groups' content, while the most dynamic changes were noticed in gluten of Zvezdana variety. Zvezdana manifested clearly visible difference in the thiol groups content depending on the growing locality. Gluten of Zvezdana variety from locality 1 tripled the thiol content compared to the untempered samples, indicating that gluten was hydrolised during the incubation, releasing polypeptides. Gluten of Pobeda variety showed the highest stability with regard to thiol groups content, while in relation to the all investigated samples it could be seen that the gluten sample from the locality 2 had the lowest content of -SH groups.

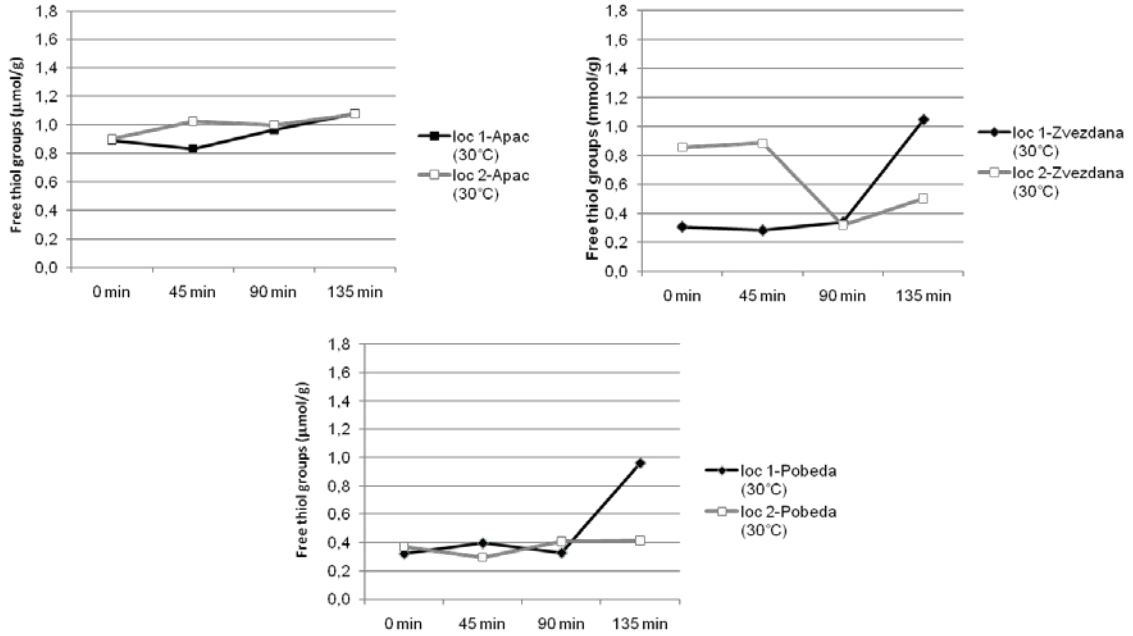

Figure 1. Concentration of free thiol groups of gluten during incubation at 30 ˚C

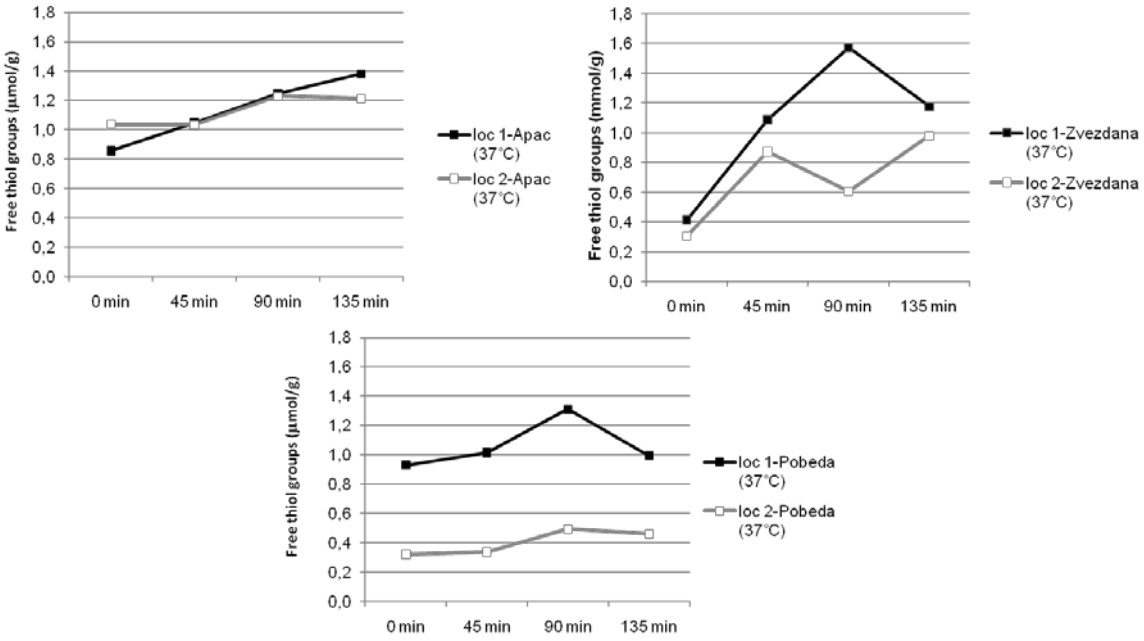

Figure 2. Concentration of free thiol groups of gluten during incubation at 37˚C

By tempering the gluten samples at 37 ^{o}C, different dynamic of changes in the content of thiol groups could be noticed, which could be primarily attributed to the inherent characteristics of the varieties. According to the values of thiol groups content observed from samples previously tempered at 30 ^{o}C, gluten of Zvezdana showed higher values. The changes for other samples were not significantly different. Gluten of Apache variety manifested negligible influence in relation to the locality. The samples of Zvezdana variety were similarly influenced after the incubation time of 45 minutes with an opposite trend in thiol groups content. Gluten samples of Pobeda variety showed nearly identical trend in change, with stronger influence of the locality in comparison to other samples.

Table 1. The selected indicators of technological quality of wheat flour samples

Locality	Sample	W.Abs (%)	Stability time (min)	Amp. (Nm)	Development time (min)	α	C2 (Nm)	Wheat-bug damaged kernels (%)
Locality 1	Pobeda	58.30	9.38	0.08	6.60	-0.026	0.51	0.40
Locality 1	Zvezdana	58.40	10.63	0.06	8.78	-0.086	0.53	0.42
Locality 1	Apache	53.30	10.53	0.09	1.63	-0.110	0.51	1.00
Locality 2	Pobeda	58.50	10.18	0.06	9.00	-0.026	0.51	0.30
Locality 2	Zvezdana	59.30	9.77	0.06	6.80	-0.084	0.49	0.41
Locality 2	Apache	53.30	10.90	0.09	1.40	-0.100	0.55	0.70

The values of selected rheological parameters of investigated wheat flour samples are shown in Table 1. By observing the values of parameters, which are related to the physical characteristics of the protein matrix, it could be seen that the examined samples had similar values of water absorption and dough stability. The dough elasticity, expressed by the value of amplitude (Nm), was slightly higher for flour samples of Apache variety. Dough development time, i.e. time required to reach the proper consistency of the dough, was also shorter for Apache samples, which could be attributed to the genetic origin of the variety. On the other hand, certain rheological parameters (α, C2, Stability time) indicated a better initial protein quality of the Apache samples despite the fact that this variety possessed the highest content of wheat-bug damaged kernel. The value of slope α showed that Apache variety was characterized by the lowest rate of weakening of the protein structure due to the effects of temperature increase and applied forces during dough mixing. Furthermore, it could be noticeable that the resistance of protein structure mainly depends on the characteristics of varieties, because the values of slope α for the observed varieties were very similar regardless the locality.

CONCLUSIONS

Based on the content of thiol groups, content of gluten samples of selected varieties from the two localities previously tempered at 30 °C and 37 °C, it could be concluded that the changes are primarily varietal characteristics. The most significant changes during incubation of gluten at 30 °C occured in 90 minutes. On the basis of selected rheological parameters on the Mixolab (α, C2, Stability time) it can be concluded that the resistance of protein structure mainly depends on the characteristics of variety. In order to achieve more reliable conclusions which can precisely explain how thiol groups influence the quality of wheat flour, further investigations should be conducted in the folowing harvest seasons on the greater numbers of wheat samples from the same locations.

ACKNOWLEDGEMENTS

ABSTRACT: Among cereal scientists it is widely accepted that rheological properties of dough, examined by different types of equipment, but also the structure of high molecular weight (HMW) glutenin subunits are highly related to wheat baking properties.
Farinograph, Extensigraph and Amilograph properties and lab-on-a-chip (LoaC) electrophoresis analysed composition of HMW glutenins of twenty different wheat varieties grown in three different years (2008, 2009 and 2010) were determined. Based on the occurrence of HMW glutetnin fraction of identified molecular weights (131, 133, 139, 148, 186 and 218 kDa) analyzed wheat varieties were, independently of the growing season divided in four groups under which varieties with the same HMW compositions were comprised. Rheological properties were compared among the groups of varieties with the same HMW glutenin compositions.
The group which differentiated in comparison to the other groups on the basis of presence of the fraction of HMW glutenin with the highest molecular weight of 218 kDa had statistically higher farinograph quality number than other groups. The group in which both HMW glutenin fractions with the lowest molecular weights of 131 and 133 kDa were present was characterized in comparison to other groups with statistically lower farinograph quality number and extensograph energy, and statistically higher farinograph softening degree. In the group which differentiated from the other groups based on presence of HMW fraction of 139 kDa amilograph peak viscosity was statistically higher than in other groups.
Key words*: wheat quality, rheology, HMW glutenin subunnits*

INTRODUCTION

Among cereal scientists it is widely accepted that rheological properties of dough from wheat flour, examined by different types of equipment are highly related to wheat baking properties. Brabender devices such as Farinograph, Extensigraph and Amilograph are well known in the last centuries as the standard methods for flour examinations (ICC 115/1, ICC 114/1 and ICC 126/1, respectively). Nowadays, scientist worldwide still use these techniques for predicting end-use quality for baking industry (Zhang et al., 2007; Hemalatha et al., 2010) and quality of different wheat lines and varieties (León et al, 2009; Rakszegi, et al, 2008).
Also, the structure of high molecular weight (HMW) glutenin subunits is highly related to wheat rheological properties. Hou et. al. (1996) confirmed that positive correlation exists between HMW glutenin subunits content and rheological properties of wheat flour, whereas Antes and Wiesser (2001) emphasize the great influence of HMW glutenin subunits amount in the prediction of the dough or the gluten strength.
During last decade new promising method for investigation of (HMW) glutenin subunits - microfluidic or Lab-on-a-Chip (LoaC) electrophoresis was developed. This technique can be used for fast identification of wheat varieties (Uthayakumaran et al., 2005) and separation, determination and quantitation of HMW glutenin subunits (Rhazi et al., 2009).

Aim of this study is to show how HMW glutenin composition determined by LoaC techinque is related to rheological properties of twenty different contemporary wheat varieties grown in three different years at the same location in Serbia.

MATERIAL AND METHODS

Sixteen different wheat varieties (Renesansa, NS Rana 5, Angelina, Simonida, Pobeda, NS 40S, Bastijana, Rapsodija, Dama, Etida, Arija, Evropa 90, Kantata, Ljiljana, Dragana and Vojvodina) were grown in three different years (2008, 2009 and 2010), whereas three wheat varieties (Nevesinjka, NS3-5299/2 and Zvezdana) were grown in two different years (Nevesinjka in 2008 and 2009; NS3-5299/2 and Zvezdana 2009 and 2010) and Astra wheat variety was grown only in 2008. These wheat varieties, supplied by Institute for field and vegetable crops from Novi Sad, Serbia, were milled by MLU 202 mill Bühler Switzerland to 60% flour yeald. Rheological properties of gained flour of examined wheat varieties were determined by Farinograph, Extensigraph and Amilograph Brabender Germany according to standard Serbian methods (Pravilnik o metodama fizičkih i hemijskih analiza za kontrolu kvaliteta žita, mlinskih i pekarskih proizvoda, testenina i brzo smrznutih testa, Regulation on physical and chemical methods for control of cereals, milling and bakery products, pasta nad fast frozen dough). Composition of HMW glutenin subunits was determined from flour samples (30 mg) which were first extracted once with 300 µl of deionisied water, once with 300 µl 2% salt solution and once with 70% ethanol solution to remove albumin, globulin and gliadin proteins (mixing each time on a vortex mixer for 10 s and centrifuging after 24 h for 20 min at 14500 r/min). The full range of glutenin subunits was then extracted at 100 °C for 5 min with 350 µl of 2% SDS solution containing 5% β-mercapto ethanol. Clarified extract (4 µl) of samples was mixed with 2 µl of Agilent sample buffer and 84 µl of deionisied water and gained mixture of each sample was added to one of the 10 sample wells of the chip. Then the chips with 10 samples were analysed in an Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA), in combination with the Protein 230 Plus LabChip kit and the dedicated Protein 230 software assay on 2100 expert software.
The data were statistically treated by analysis of variance (ANOVA) the means were compared by the Duncan test at significance level of 0.05 using the Statistical software StatSoft, Inc. (2011). STATISTICA (data analysis software system), version 10.0 www.statsoft.com.

RESULTS AND DISCUSSION

After separation of glutenin subunits of investigated wheat varieties by LoaC electrophoresis (Figure 1) region of HMW glutenin subunits was identified according to the results Uthayakumaran et al. (2006) who determined that apparent size of HMW glutenin subunits of wheat varieties identified by LoaC electrophoresis is ranged from 128 kDa. In this region six different glutenin subunits with average molecular weigth of 131, 133, 139, 148, 186 and 218 kDa were identified (Figure 1).
Based on the occurrence of certain HMW glutenin subunits, analyzed wheat varieties were, independently of the growing season divided in four groups with the same HMW compositions (Table 1):

- Group A: wheat varieties with HMW glutenin subunits of 131, 133 and 186 kDa,
- Group B: wheat varieties with HMW glutenin subunits of 133, 148 and 186 kDa,
- Group C: wheat varieties with HMW glutenin subunits with apparent size of 131, 139, 148 and 186 kDa and
- Group D: wheat varieties with HMW glutenin subunits with apparent size of 133, 148, 186 and 218 kDa.

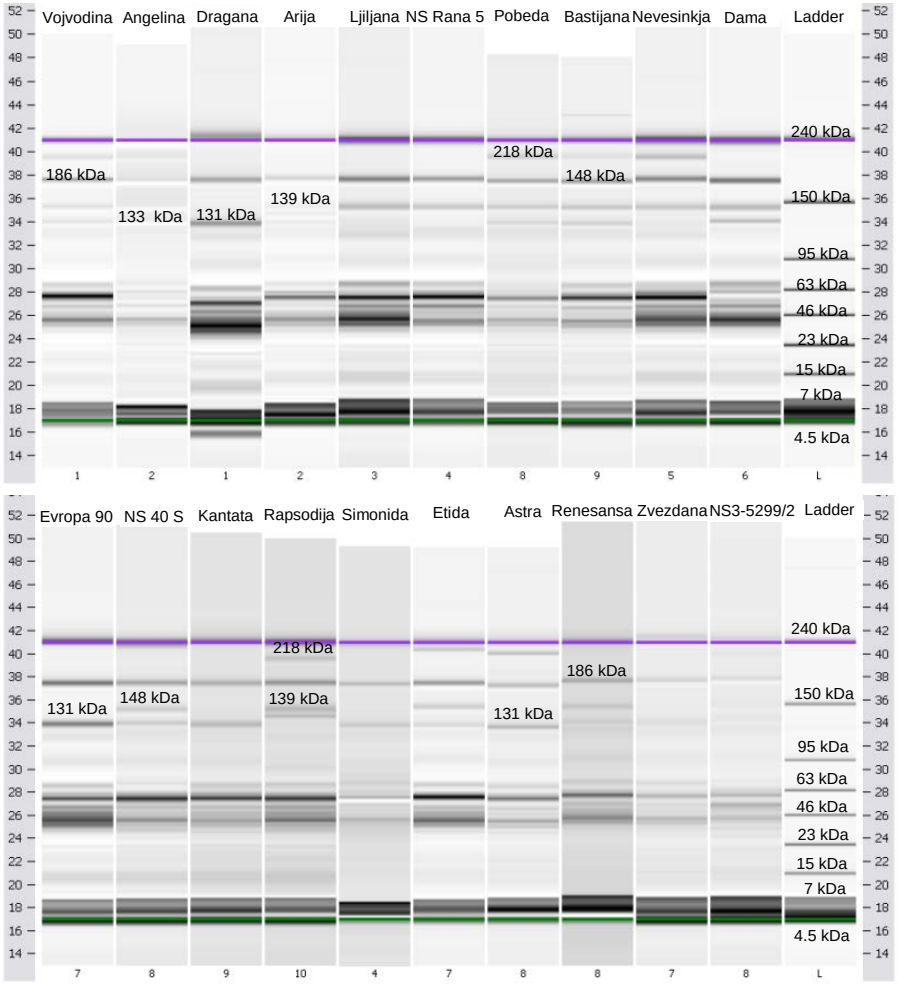

Figure 1. Gel like image of two chips representing glutenin subunits of twenty examined wheat varieties.

Table 1. Groups of wheat varieties with the same HMW compositions

Group A	**Group B**	**Group C**	**Group D**
131, 133 and 186 kDa	**133, 148 and 186 kDa**	**131, 139, 148 and 186 kDa**	**133, 148, 186 and 218 kDa**
Dragana, Evropa 90, Kantata, Simonida, Astra and Zvezdana	Ljiljana, NS Rana 5, Dama, NS 40 S, Etida and Renesansa	Arija, Nevesinjka and Rapsodija	Vojvodina, Pobeda, Angelina, Bastijana and NS3-5299/2

Rheological properties of flours samples of wheat varieties measured by Farinograph, Extensigraph and Amilograph were compared among the groups of varieties with the same HMW glutenin compositions (Table 2). The group D which differentiated in comparison to the other groups on the basis of presence of the fraction of HMW glutenin with the highest molecular weight of 218 kDa had statistically higher farinograph quality number than other groups. Group A in which both HMW glutenin fractions with the lowest molecular weights of 131 and 133 kDa were present was characterized in comparison to other groups with statistically lower farinograph quality number and extensigraph energy, and statistically higher farinograph softening degree, which is in agreement with well known results Payne et al. (1981) that HMW glutenin subunits 2+12 and 4+12 cause lack of dough strength. In the group C which differentiated from the other groups based on the presence of HMW fraction of 139 kDa amilograph peak viscosity was statistically higher than in other groups. However, in the group B was not noticed any statistical differentiation in rheological properties to the other groups of wheat varieties. Also, the groups of wheat varieties did not show statistical

differentiation in several rheological parameters such as water absorption, dough development, dough stability, resistance and extension, which can be explained by the fact that in this study was not included quantification of HMW glutenin subunits.

Table 2. Compared rheological parameters of four wheat varieties groups with the same HMW glutenin composition measured by Farinograph, Extensigraph and Amilograph,

Group	Water absorption (%)	Dough development (min)	Dough stability (min)	Degree of softening (FU)	Quality number	Peak viscosity (AU)	Energy (cm^2)	Resistance (EJ)	Extension (mm)	Resistance/Extension
Group A	61.9^{a}	3.1^{a}	1.7^{a}	88^{ab}	59.0^{a}	590^{a}	64.2^{a}	214^{a}	161^{a}	1.43^{a}
Group B	61.8^{a}	2.6^{a}	2.2^{a}	69^{ab}	64.5^{ab}	430^{a}	89.6^{b}	278^{a}	160^{a}	1.81^{a}
Group C	61.1^{a}	2.5^{a}	2.7^{a}	61^{a}	65.0^{ab}	1055^{b}	88.3^{b}	264^{a}	157^{a}	1.71^{a}
Group D	64.0^{a}	2.9^{a}	3.1^{a}	51^{a}	70.5^{b}	575^{a}	94.7^{b}	266^{a}	166^{a}	1.67^{a}

Mean values of examinated quality parameters calculated on dry matter labeled by the same letter in raw were not statistically significant difference ($p<0.05$).

CONCLUSIONS

It can be concluded that it is confirmed that relation among some rheological parameters such as farinograph degree of softening and quality number, amilographs peak viscosity and extensigraph energy, of flour of wheat varieties with different HMW glutenin structure exists. For better understanding of connections among examined groups of wheat varieties and composition of HMW glutenin subunits, it is probably needed to determine the quantity of determined HMW glutenin subunits.

ACKNOWLEDGEMENTS

This paper is a result of the research within the project TR 31007 “Vrednovanje kvaliteta i optimizacija prerade pšenice u svetlu klimatskih promena”, financed by the Ministry of Education and Science, Republic of Serbia.

ABSTRACT: This paper gives a rewiew of analytical methods for biotin determination in various mediums. Contemporary analytical methods provide fast biotin determination with low detection limits. Results of quantitative determination of biotin in sugar beet molasses obtained by various methods are presented.The following methods were applied: HPLC (High Pressure Liquid Chromatography), TLC (Thin Layer Chromatography), microbiological method by Danielsen and Eriksen (1968) for biotin activity determination in the raw materials for fermentation with active microorganism *Saccharomyces cerevisiae* and method for the microbiological analysis of selected nutrients given in AOAC International (1996) with active microorganism *Lactobacillus plantarum.* Microbiological method by Danielsen and Eriksen (1968) with active microorganism *Saccharomyces cerevisiae* for biotin determination in sugar beet molasses came out accurate, precise, with the detection limit of 0.0100 μg/cm^3 or 10 ppm, because it is the lowest concentacion of biotin which still shows linear response and fits into linear dependence of biotin concentrations - growth area of the yeast. For these reasons this method was accepted as the standard method for determination of biotin in sugar beet molasses by the Institute for Standardization of Serbia.
Key words: *biotin determination, sugar beet molasses, high pressure liquid chromatography, thin layer chromatography, Lactobacillus plantarum, Saccharomyces cerevisiae.*

INTRODUCTION

There are a number of analytical methods for biotin determination which were developed because of importance of biotin and its presence in various mediums (biological fluids, food, pharmaceuticals containing biotin, raw materials). Contemporary analytical methods provide fast biotin determination with low detection limits (Livaniou et al. 2000).
Already published analytical methods for biotin determination can be classified as: microbiological methods, biological methods (bioanalysis), physico-chemical methods and binding assays.
Microbiological methods are the oldest methods for biotin determination, its homologues and derivatives. For microbiological analysis of biotin a number of microorganisms are used: *Lactobacillus plantarum, Lactobacillus casei, Saccharomyces cerevisiae, Ochromonas dani, Micrococcus sodonen, Neurospora crasa, Rizobium trifolii, Escherichia coli 162 (*Livaniou et al., 2000). From the tested microorganisms the most widely used are *Lactobacillus plantarum* and *Saccharomyces cerevisiae*.
Method with active microorganism *Lactobacillus plantarum* even today is widely used for biotin determination in baby food (Watanabe i Fukui, 1996), as well as in molasses (Szopa, 1982, Lončar i sar., 2005, Došenović, 2004).
The yeasts are broadly used in microbiological methods for quantitative determination of "total biotin": biotin, biotin-d-sulphoxide, biocytin, dethiobiotin and pelargonic acid. In molasses it was determined by the yeast *Saccharomyces cerevisiae* (Szopa, 1982; Meledina et al., 1987; Danielsen and Eriksen, 1968; Došenović, 1993; Došenović et al., 1995 and 1995a; Pejin et al., 1996 and 1996a).
Microbiological determinations are easy, although requiring time, and are suitable for routine analysis. They belong to the group of the most sensitive methods for biotin because of their detection limit of 0.1 ng.

Biological methods (bioanalysis) are mostly used for determination of bio-available biotin present in food samples (Bonjour and Machlin, 1984). They are simple but less sensitive than microbiological methods (0.5 ng).
Physico-chemical methods for determination of biotin were developed in the mid- sixties of the 20th century. Application of these methods is limited by their sensitivity. They are mostly used for measuring vitamins in samples with high concentration of biotin, like pharmaceutical multivitamin preparations.
These methods include: spectrophotometry, colorimetry, polarography, thin layer chromatography, gas chromatography, liquid chromatography, high pressure liquid chromatography and capillary electrophoresis.
High pressure liquid chromatography (HPLC) is very important technique for biotin analyses in natural and pharmaceutical preparations. Several methods of HPLC for these determinations are described in the literature (Frappier and Gandry, 1985, Livaniou et al., 2000, Ekpe and Hazen, 1998).
Method RP-HPLC with post-column derivatization is used for biotin determination in food (beef liver, formulations for children, cereals, fruit juices, tomato, multivitamin tablets). The detection limit is about 0.004 mg of biotin without difficulties and with satisfactory reproducibility (Lahely et al., 1999).
Binding assays – the first developed binding assays for biotin determination were radioactive. Radioactive isotopes were used as markers. These methods were used for biotin determination in various samples, like nutrients, extracts of tissues and fluids, particularly human (Kneale and Hood, 1992).
Non-radioactive binding assays for biotin determiation were developed later and they represent progress, because these methods use non-radioactive markers like enzymes, chemiluminescents, bioluminescents, fluorescent substances, latex agglutinative particles, while maintaining high sensitivity (Livanion et al., 2000).
One of the binding assays, very popular and much used nowadays, is ELISA method (Enzyme-Linked Immunosorbent Assay) (Kynng et al., 1998).

Biotin determination in molasses

Sugar beet molasses, which is used in Serbia in the production of baker's yeast, is mainly deficient in biotin content, and that is the reason why in factories a routine and inexpensive method for determination of biotin in molasses is required. Knowing the content of biotin in molasses, the minimum amount of D-biotin or DL-destiobiotin which should be added to molasses to get the maximum yield of yeast and yeast optimum quality can be calculated.
Danielsen i Eriksen (1968) described a simple method for determination of biotin activity in molasses using their own productive yeast as a test organism. Solid substrate without biotin was inoculated with yeast and in the apertures, impressed in the substrate, a series of standard solutions of D-biotin and a series of diluted solutions of molasses were added. After incubation, the zones of growth of yeast were measured and from their diameters biotin content was calculated with a standard error of determining of 0.01µg/g of molasses.

MATERIAL AND METHODS

Biotin was determined in decadal samples of sugar beet molasses from four local sugar factories by method of high pressure liquid chromatography (HPLC), thin layer chromatography (TLC), microbiological method by Danielsen and Eriksen (1968) with active microorganism *Saccharomyces cerevisiae* (commercial baker’s yeast from two domestic producers) and microbiological method given in AOAC International (1996) with active microorganism *Lactobacillus plantarum* (ATCC 8014 from collection E. Merck, Darmstadt, Germany). Applied methods are described in detail in Došenović’s PhD thesis (2004).

RESULTS AND DISCUSSION

Determination of biotin by HPLC method

Strong base ion exchanger LEWATIT MP 500A is very efficient in purification of "raw biotin". Eluates are light yellow and it is confirmed by RP-HPLC analysis of standard solution of biotin (B_k) that there is no biotin retention. Nevertheless, the retention periods of biotin transmitted only trough column (B_k) and of biotin treated with various types of active coal (B_A, B_{A1}, B_{A2}) are to some extent shorter from the retention period of standard of biotin (B) – solution of biotin which is directly injected in column of chromatograph (Table 1). Probably some changes with biotin are made during transmission trough ion exchanger. Although the peaks of the different biotin samples have similar intensity on wavelength of 230 nm and 220 nm (Figure 1), there are some differences in their retention periods (Table 1)

Table 1. Retention periods of various samples of biotin on different wavelenght

Biotin sample*	Retention period T (sec)	
	λ=220nm	λ=230nm
B	313	308
B_k	251	248
B_A	306	248
B_{A1}	306	306
B_{A2}	306	306

**B-basic solution of biotin; B_K-biotin transmited trough column; B_A, B_{A1}, B_{A2}-sequentially biotin treated with powder, spiked and granulated active coal*

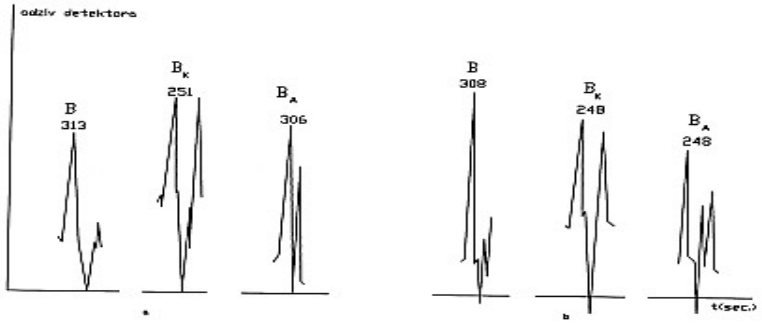

Figure 1. HPLC chromatogtam of various samples of biotin with UV detection on 220nm (a) and 230nm (b); Marks are like in Table 1.

From eluates of molasses, only the sample M_4 was analysed with RP-HPLC method, and it was the brightest. Chromatogram has the shape of stretched peak with retention period of about 15 minutes. That shows that the eluate of molasses, even prepared by complex process and visually acceptable, is not sufficiently pure for analysis with the applied method.

Determination of biotin by TLC method

Since the HPLC method was not able to identify biotin in molasses, further examinations were continued with the thin layer chromatography (TLC) with silica gel layer and water as mobile phase. The retention values of different samples of biotin and biotin from molasses (M_4) are shown in Table 2.

Biotin from molasses can be extracted on granulated active coal with granule size of 2.5 mm and be identified on thin layer of silica gel. Extraction and determination of biotin from molasses by the applied procedure is very complicated. Adsorption and desorption of biotin, evaporating the solution after desorption and after passing through a column last very long. Neither is adsorption selective enough, nor is the extraction of "raw biotin" on strong base ion exchanger efficient enough for the quantitative analysis of biotin. The final solution is not sufficiently clear, which disables the determination of biotin in molasses by liquid

chromatographic methods. In addition, chlorine-tolidine reagent, although with a detection limit of 0.2µg of biotin (Frappier and Gaudry, 1985) it is not specific only for biotin.

Table 2. R_f values of different samples of biotin and biotin from molasses

Sample	R_f x 100
B	65
B_k	83
B_{A2}	82
M_4	81

M_4-sample of molasses 1 from granulated active coal and electric vibrator; other marks are like in Table 1.

Determination of biotin by microbiological method – with active microorganism *Saccharomyces cerevisiae*

The precision and accuracy of method are examined and deviation results, expressed as % of utilization or recovery in relation to additional real value of biotin, are given in Table 3.

Table 3. Results of deviation from the true value of biotin content

Biotin added µg/cm^3	Biotin detected µg/cm^3	Utilization %
0.0400	0.0385	96.25
0.0800	0.0795	99.38
0.1200	0.1190	99.17

As seen from Table 3 the efficiencies are above 95% biotin indicating that the applied microbiological method for determination of biotin in molasses commercial yeast *Saccharomyces cerevisiae* is a very accurate analytical method.

Figure 3 shows linear dependence of diameter of growth zone of yeast on biotin concentration in standard solutions added into substrate.

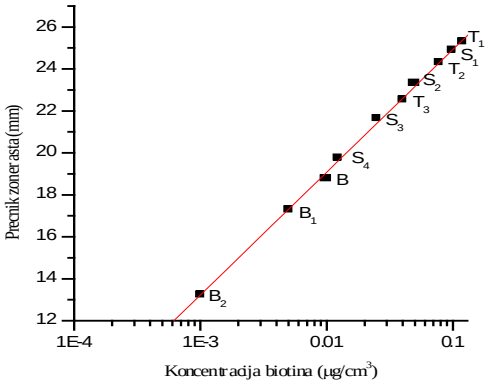

Figure 3. Dependence of diameter of growth zone of yeast on the concentration of biotin in the substrate (marks are like in Table 1 and 3)

From figure 3 it is obvious that the linearity is excellent in the concentration range of biotin 0.001-0.1200 µg/cm^3. The correlation coefficient of linear dependence is 0.99943. This range is sufficient for our analyses since the biotin content in the tested molasses is from 0.02951µg/g to 0.08465 µg/g of molasses.

For determination of the detection limit the following solutions of D (+)-biotin are prepared: B-10ng/cm^3. B_1-5 ng/cm^3. B_2-1 ng/cm^3. B_3-0.5 ng/cm^3. S_3-25 ng/cm^3. S_4-12.5 ng/cm^3.

The results of the entire experiment are shown in Table 4.

Table 4. Zone diameters of growth of yeast depending on the concentration of biotin in biotin standard solutions

R - zone diametar of growth of yeast

The presented results indicate that the detection limit of biotin is 0.5 ng/cm^3. At that concentration of biotin, observed with the naked eye, a very weak whitish irregular zone of yeast growth was hardly noticed and the diameter was not possible to measure. In Table 4 the presence of yeast growth at this concentration of biotin is marked with plus (+).
According to the results the concentration of biotin of 0.0100µg/cm^3 or 10 ppm could be used for the limit of determination because this is the lowest concentration of biotin which still shows linear response and fits into linear dependence of biotin concentrations - growth area of the yeast.

Determination of biotin by microbiological method – with active microorganism *Lactobacillus plantarum*

In comparison with biotin content in molasses 2 and 3 determined by the yeast *Saccharomyces cerevisiae* (Table 5 and 6) significantly higher content of biotin is obtained with *Lactobacillus plantarum* (Table 7). This is not expected since the growth of *Lactobacillus plantarum* is stimulated only by the D (+)-biotin and the growth of *Saccharomyces cerevisiae* besides biotin also by some of its analogues. The colour of solution certainly had influence on the results as at nephelometric measurement (intensity of scattered radiation (IRZ) and transparency (%T)). Furthermore, no research on the presence of other stimulating substances for growth of *Lactobacillus plantarum,* such as niacin and tryptophan, was made (AOAC. 1996).

CONCLUSIONS

In this paper the advantages and disadvantages of applied analitical methods for determination of biotin in sugar beet molasses are shown. in order to point the importance of use of microbiological method with active microorganism *Saccharomyces cerevisiae*.
The applied method for determination of biotin with *Saccharomyces cerevisiae* is accurate. precise. with the limit of quantitative detection of 0.0100 µg/cm^3 or 10ppm.
Therefore it can be recommended for operational control of the quality of molasses used in the production of baker's yeast or for the determination of biotin - a growth factor for this yeast - in molasses.
This method was accepted by the Institute for Standardization of Serbia as Serbian standard SRPS E. L8. 021: 2006. under the name Molasses – Determination of Biotine content.

ABSTRACT: *Campylobacter jejuni* has become the leading cause of human inflammatory enteritis and of the most important zoonosis worldwide. Despite of its high prevalence, extraintestinal survival mechanisms and virulence properties are still poorly understood, also due to the lack of useful models for such studies. We confirmed previously bacterial environmental stresses to be implicated in the adhesion, invasion and intraepithelial survival of *C. jejuni* in Caco-2 cells, J774 murine macrophages and PSI cell lines in *in vitro* cell models. In this work BALB/c mice were experimentally infected with stressed *C. jejuni* cells to mimic the infection *in vivo*. After bacterial spreading and tissue invasion we followed the survival of stressed campylobacters (exposed to starvation or short-term oxidative stress) at 1, 3 and 8 days post infection in the organs (liver, spleen) of infected animals. Colonization of untreated as well as stressed campylobacters can occur in the livers and spleens of BALB/c mice. Starvation impaired the ability of *Campylobacter* to persist in organs, however, short term exposure to oxygen enhanced its survival and duration of infection. Thus we confirmed in *in vitro* and *in vivo* model that adaptive stress response is crucial for *Campylobacter* survival during host-pathogen interaction and its pathogenicity.
Key words: *Campylobacter jejuni, environmental stress, bacterial virulence, cell monolayers.*

INTRODUCTION

Campylobacter jejuni is the most common bacterial cause of food-borne disease and the leading cause of diarrheal disease in humans (Allos, 2001). This microaerophilic, highly motile, gram-negative rod-like bacterium with an optimal growth temperature at 42 °C is part of the normal intestinal flora of many domestic and wild animals, with poultry as a major source of human infection. It is highly infectious and infective doses as low as 500 to 800 CFU have been reported. The clinical symptoms vary significantly from mild watery diarrhea to severe enteritis with bloody diarrhea, abdominal cramps, fever, and nausea (Janssen et al., 2008). In majority the disease is mild and self-limiting, but extra-intestinal post-infection complications, e.g. Guillain-Barre´ syndrome (GBS) and reactive arthritis can occur (Zilbauer et al., 2008).
Although *C. jejuni* is very susceptible to environmental stress conditions due to the lack of stress-adaptive response factors such as RpoS, CspA, OxyR, and SoxRS it has developed survival mechanisms, both inside and outside the host. Exposure to unfavorable environmental conditions may trigger conversion of *C. jejuni* into a viable but nonculturable (VBNC) state (Klančnik et al., 2009). Despite the significant health burden caused by the organism, the mechanisms of pathogenesis and host immunity response during the course of disease are not yet well understood. Following the passage through the acidic environment of the stomach, surviving bacteria adhere to intestinal epithelial cells or to the mucus overlying these cells and replicate in both small and large intestine. Motility and adhesion of

C. jejuni are essential steps for human disease and colonization in animals. Disease development involves a multifactorial process requiring bacterial adherence to host cells, epithelial cell invasion and replication, secretion of virulence proteins, and bacterial translocation across the epithelial cell barrier of the intestine (Konkel et al., 2001; Park, 2002). Once, reaching the underlying tissues *C. jejuni* is no longer exposed to peristaltics, interacts with professional phagocytic cells and can cause systemic infection, which is reflected in occasional recovery from spleen and liver of infected host. Colonic biopsies from infected patients show an acute inflammatory response with infiltration of the epithelium and lamina propria with neutrophils and mononuclear cells, crypt abscesses, focal ulcerations, and plasma cell proliferation (Parathasarathy and Mansfield, 2009, Berreswill et al, 2011). Furthermore, the ability of bacteria to survive within phagocytic cells represents a strategy to evade the host defences and migrate to other areas of the body. Previously, we have demonstrated that despite being efficiently internalized, *Campylobacter* was eliminated from murine macrophages within 24h to 30h post infection (Šikić Pogačar et al, 2009). This can explain why bacteremia occurs very rarely (Allos, 2001).

Various models to study the pathogenesis of *Campylobacter* were established. Polarized or nonpolarized epithelial cell culture as well as animal models can be used to study mechanisms of *C. jejuni* infection. Cell culture models have shown the ability to adhere, invade and translocate across intestinal epithelial cells. Large animal models and ferrets enabled early progress in studies of pathogenesis, transmission, and vaccines. Chickens, ferrets, dogs, primates, rabbits, mice, and pigs have been inoculated experimentally by various routes to mimic the course of infection in humans (Mansfield et al., 2008). Even, larvae of Galleria mellonella (Greater Wax Moth) have been recently shown to be susceptible to *C.jejuni* infection and were used as infection model (Senior et al., 2011). Monkeys are the best model, but expensive and not available to most institutions. An optimal animal model should assure: symptoms similar to those observed in human cases following oral administration of bacteria, availability, ease of manipulation, repeatability, inexpensive, and also known immune status of animal (Mansfield et al., 2008). However, animals are generally silent carriers and thus symptoms do not always appear. In addition, animal should have a sufficient life span to complete the entire study (Haddad et al., 2010). ‘‘Complete’’ models, which reproduce intestinal disease induced by *Campylobacter* (particularly diarrhea), must be distinguished from ‘‘partial’’ models, in which only one or a few aspects of virulence (e.g., colonization, adhesion, internalization, or toxigenesis) are reproduced (Haddad et al., 2010).

In humans, disease symptoms and course of infection can vary dramatically and the outcome depends on many factors, such as the dose and virulence of *C. jejuni* strain, the immune status of host, the composition of patient’s entric microflora etc. Despite the difficulties, pathophysiological findings from *in vivo* studies using animal models complement *in vitro* studies and provide a deeper insight in the course of human infection. For this reason the present article focuses on confirmation of the results from *in vitro* cell culture models with *in vivo* BALB/c mouse model study used to investigate colonization and survival of bacterial cells during infection.

MATERIAL AND METHODS

Bacterial strain, culture media, growth and stress conditions

A poultry meat isolate *C. jejuni* K49/4 was previously identified, stored at -80 °C and subcultured prior to subjecting to test conditions as described previously (Klančnik et al., 2009). For starvation, the cells were harvested by centrifugation (12000xg, 5 min, 4 °C), washed, resuspended in Ringer solution (KH2PO4, 5 mM, Kemika), and incubated 24 h microaerobically at 42 °C. For oxidative stress, the cells were exposed to oxygen at atmospheric concentration for 5 hours. Untreated *C. jejuni*, taken from culture at the same time as the stressed organisms, were used as controls.

In vitro cell lines and growth conditions

Caco-2 cells and J774 macrophages were grown in Dulbecco's minimum essential medium (DMEM) and RPMI 1640 medium as described previously (Šikić Pogačar et al., 2009, Rubeša Mihaljević et al., 2007)

Adhesion, invasion and intracellular survival

For all assays, 24-well tissue culture trays were seeded with approximately 5.0 $x10^5$ cells per mL and incubated for 24 h. The bacterial number was determined spectrophotometrically (absorbance mode at a wavelength of 600 nm). Infection was carried out by inoculating *C. jejuni* at an approximate MOI of 100. Infected monolayers were incubated for 2 h to allow adhesion and invasion as described previously (Šikić Pogačar et al, 2009). The monolayers were washed with medium without antibiotic to remove unbound bacteria and medium containing 100 mg per mL of gentamicin for enumeration of intracellular bacteria. The monolayers were lysed with cold distilled water and released intracellular bacteria were enumerated by the culturability assay 24, 72 and 96 h post infection. The total number of adherent and internalized bacteria in macrophages was determined simultaneously by performing an invasion assay without gentamicin treatment. The difference between the total and intracellular bacteria was calculated to obtain adherent *C. jejuni* cells. Results are expressed as the mean of the log10 CFU/mL of adherent or internalized bacteria for three independent measurements.

Polarized epithelial cell model of PSI cl.1 cells

To obtain polarized epithelial cell monolayers, we seeded PSI cl 1 cells onto Transwell® filter inserts and infected them with *C. jejuni* to allow adhesion and invasion as described previously (Šikić Pogačar et al, 2010).

In vivo experiments

Male BALB/c (H-2d) mice 8- to 12-weeks-old were used in all experiments and infected intravenously with a single dose of 0.5-1$x10^9$ CFU/mL starved or untreated *C. jejuni* cells. After 24, 72 and 96 h post infection the number of *C. jejuni* CFU in livers and spleens was determined as previously described (Vučković et al., 1998). The experiments were repeated 3-5 times. Data are presented as the $\log_{10}$ of the mean ± SD bacterial CFU per organ.

Statistical analysis

Data on bacterial counts from different experimental groups were compared using the One-way ANOVA and Tukey-b test for post hoc analysis. All statistical values were considered significant at the P level of 0.05. Statistical analysis was performed using Statistica for Windows version 6.1 (Statsoft Inc., Tulsa, OK, USA).

RESULTS AND DISCUSSION

Influence of enviromental stresses on virulence properties of *Campylobacter jejuni* in *in vitro* cell culture model

The virulence of the *C. jejuni* K 49/4 as indicated by the ability of bacteria to adhere to, invade, and replicate within different cell lines was investigated. Intestinal epithelial cells: colon adenocarcinoma human cells Caco-2, mature small intestinal pig cells PSI and murine macrophages J774 were used in the study as *in vitro* models of infection. We examined the influence of 5 h starvation and 5 h oxygen exposure on the ability of *C. jejuni* to adhere, invade, and replicate (survive) within cell cultures measured by plate-count assay and compared to a non-stressed control. Our results showed that starvation reduced *C. jejuni* ability to adhere to the surface of eucaryotic cells and invade these cells (Figure 1). On the other hand, short oxidative stress lasting for 5 h improved *C. jejuni* virulence properties, improved bacterial ability to adhere and invade cell cultures (Figure 1).

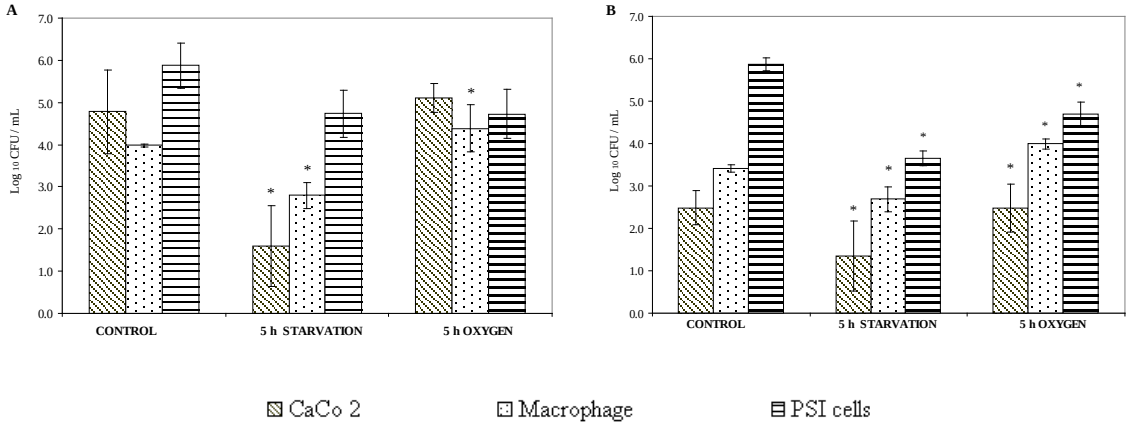

Figure 1: Adhesion (A) and invasion (B) ability of control, 5-h-starved and 5-h-oxygen exposed *C. jejuni* in Caco-2, macrophage and PSI cell lines.

Starvation also reduced *C. jejuni* ability to survive within cell cultures. Even though, both, control and starved *C. jejuni* survived intracellularly during the entire observation period in Caco-2 cells and PSI cl.1 cells. The number of recovered starved cells remained high throughout the entire experimental period, but did not reach the control level. A significant proportion of starved bacterial cells persisted within Caco-2 cells even after 5 days. In addition, the number of non-stressed (control) bacteria within Caco-2 cells started to decrease 72 h post infection, 48 h post infection in case of 5 h starvation, while on the other hand, the number of bacteria exposed to atmospheric oxygen prior to infection increased until 72 h post infection, when it slowly started to decline (Figure 2A).

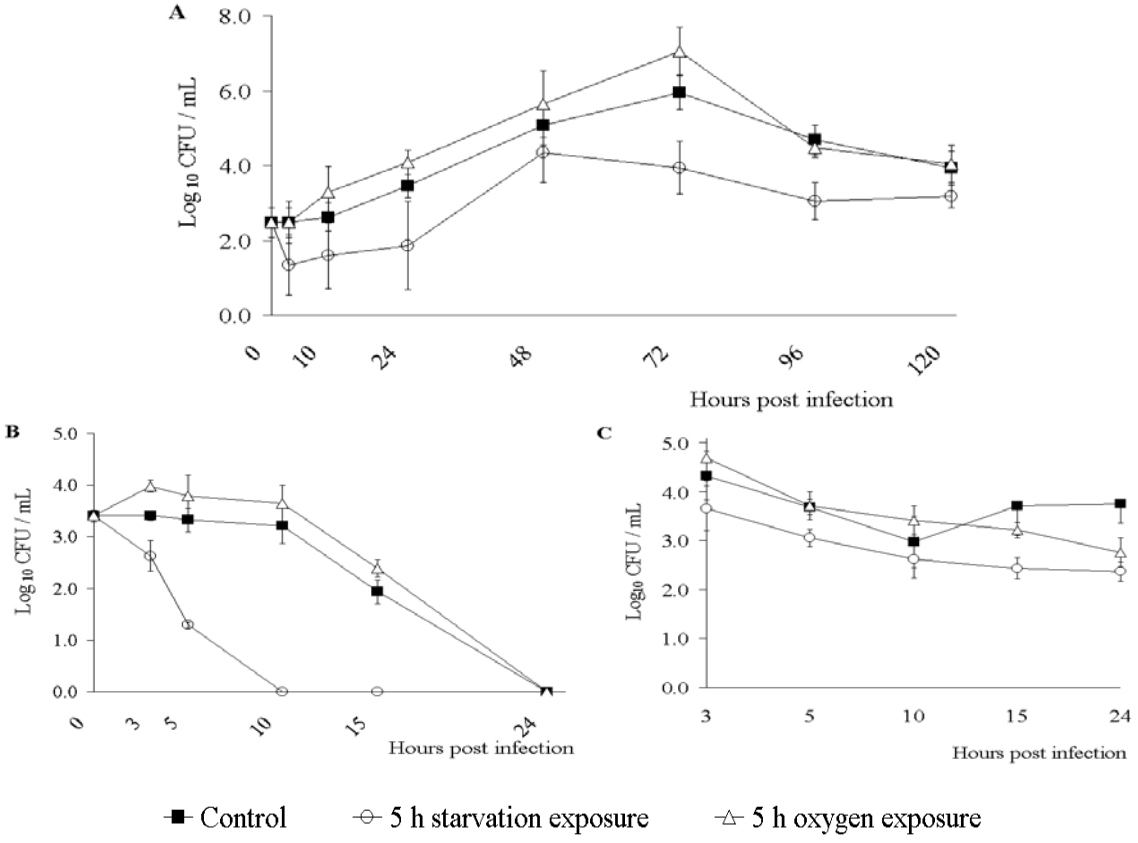

Figure 2: Intracelullar survival of control, 5-h-starved and 5-h-oxygen exposed *C. jejuni* in Caco-2 (A), macrophage (B) and PSI (C) cell lines.

Survival pattern of *C. jejuni* within murine phagocytes J774 exhibited similar survival characteristics, and already 5 h post-infection showed a progressive decrease in the number of intracellular bacteria. No intracellular bacteria were recovered 29 h post infection, indicating extensive killing by the macrophages. However, considerable differences in the number of intracellular bacteria were observed. Bacterial starvation once again significantly decreased the survival period of bacteria within J774 macrophages while 5 h pre-exposure to atmospheric oxygen enhanced its intracellular survival (Figure 2B).
The decrease in the number of survived bacteria within polarized PSI cl. 1 cells was observed 5 h post- infection in case of 5 h starvation. On the other hand, bacteria exposed to 5 h oxygen stress were recovered in the same number as control 5 h-post infection. Furthermore, 10 h post-infection bacterial count exceeded the number of control, thereafter the number of bacteria exposed to oxygen prior to infection began to decrease gradually and remained below control level (Figure 2C).
Our results are consistent with the study by Day et al. (2000), confirming the ability of *C. jejuni* to survive intracellularly for relatively long periods both in phagocytes (72 h) and in intestinal epithelial cells (96 h), persuading some investigators to classify this organism as a facultative intracellular pathogen. The role of macrophages in development *C. jejuni* enteritis is still unclear. There exist contradictory reports regarding the ability of *C. jejuni* to survive within macrophages, which may be the consequence of the use of phagocytic cells of different origin and various bacterial isolates showing different virulence potential. However, any prolongation of survival in macrophages may increase the probability of transmission of bacteria in the host organism and have further implications in the pathogenesis of campylobacteriosis.
Although the results obtained from cell cultures provide information on survival of *C. jejuni* under stress conditions and influence of stress on its virulence properties, they might not truly reflect the situation *in vivo*. For that reason, we used animal model of BALB/c mice to validate *in vitro* cell model of testing virulence properties of *C. jejuni.*

Influence of enviromental stresses on virulence properties of *Campylobacter jejuni* in *in vivo* BALB/c mice model

Different patterns of bacterial growth were observed in spleens and liver of BALB/c mice. The results of *in vivo* experiments in mice confirmed impairment of *C. jejuni* virulence properties upon starvation (Fig 3A and B).

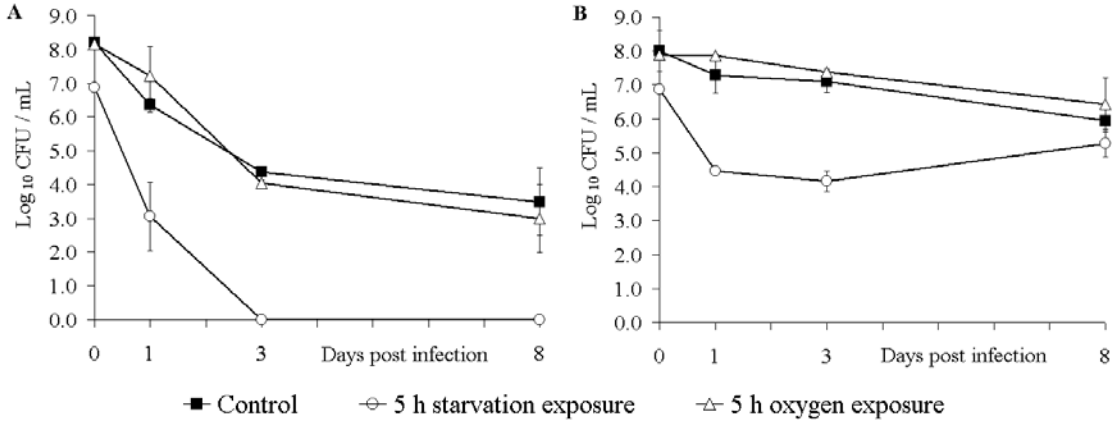

Figure 3: Intracelullar survival of control, 5-h-starved and 5-h-oxygen exposed *C. jejuni* in spleen (A) and liver (B) of mice.

The number of isolated bacteria from spleens was significantly lower and the infection was resolved as early as three days post infection (Figure 3A). In the livers, a marked difference in the number of isolated bacteria was seen, but the duration of infection was similar regardless of starvation (Figure 3B). 5h-atmospheric oxygen exposure improved the ability of *C. jejuni* to persist in liver and showed better survival pattern than non-stressed *C. jejuni.*

CONCLUSIONS

Since *C. jejuni* is mainly a food-borne pathogen, stress factors in the food chain may have an impact on its viability in the product and are important risk for human health. This study demonstrated that cell culture-based virulence of *C. jejuni* was generally equivalent to the infectivity in a BALB/c mouse model. The results showed that starvation reduces the ability of *C. jej*uni to survive within polarized and non-polarized cell cultures lines as well as in mouse model of infection. Like in cell culture based assays, short exposure of *C. jejuni* to atmospheric oxygen concentration enhanced its ability to survive and persist within animal host.

ABSTRACT: The most important oil and protein plant crops belong to different families. Constant increase in demand for plant oils used as food or for processing industry inspired evaluation of other, insufficiently used plant species for breeding and commercial production. Fifteen plant species were grown during 2010 on a quarantine plot of the Institute of Field and Vegetable Crops in Novi Sad. Oil and protein content was determined in the seeds accordingly. The highest oil content was found in castor oil plant (52.28%), and the lowest in chard (4.58%). Protein content was highest in white mustard (39.54%), and lowest in castor (13.12%), while the largest total content of oil and protein was found in oil gourd (82.62%), and the lowest in chard (21.94%). Selected species will be included in further research as a source of oil and protein for various purposes.
Key words: *protein content, oil content, alternative crops*

INTRODUCTION

The demand for plant oils used for food and feed or for processing industry is in constant increase (Popović et al., 2010). In order to make plant oil production profitable, cultivated plants should have high oil content in the plant parts used for its extraction. The residues remaining after pressing are commonly used as a source of plant protein used in animal nutrition, but also in the food industry. The high protein content and their quality ensure nutritional value, and thus the market value of these nutrients.
Changes in the global oil market, demand for oil of specific quality, growing requirements of cultivated plants and their exposure to different biotic and abiotic stresses, require more research on under-used cultivated plant species.
Unlike the cultivated cereals, oilseed plant species belong to different and often phylogenetically very distant families and genera. This origin also requires diversity in the study methods of qualitative and quantitative characteristics and application of plant breeding methods.
In order to investigate quality of under-grown oil-protein plant species from the collection of the Institute of Field and Vegetable Crops in Novi Sad, oil and protein content in 15 plant species was analysed.

MATERIAL AND METHODS

The Department of Oil Crops of the Institute of Field and Vegetable Crops in Novi Sad holds a collection of 15 oil plant species represented with different number of accessions. The collection includes: flax (*Linum usitatissimum* L.), false flax (*Camelina sativa* Crtz.), castor oil plant (*Ricinus communis*), safflower (*Carthamus tinctorius* L.), sesame (*Sesamum indicum* L.), mary thistle (*Silybum marianum* syn. Carduus Marianus), caper spurge (*Euphorbia lathyris* L.), coriander (*Coriandrum sativum* L.), dill (*Anethum graveolens* L.) and okra (*Hibiscus esculentus*).
The collected species were of different geographical origin and the collection was formed through a long period by exchange with other scientific research organizations.

Optimal agro-technical practices were applied for the cultivation of each plant species (Todorovic et al., 2003). Harvesting was carried out when the seed was at the technological maturity. Seeds were used for the analysis of oil content in all tested species, except for the caper spurge where tubers were analyzed.
Oil content was analyzed by classical Soxhlet method according to the ISO standard 659:1994, involving gravimetric determination of oil using light petroleum extract from oilseeds. The petroleum extract is called “oil content”. Protein quantity was determined using classical micro-Kjeldahl method, on VAP-50, Gerhardt apparatus, in the Chemical Laboratory of the Department of Oil Crops of the Institute of Field and Vegetable Crops in Novi Sad.

RESULTS AND DISCUSSION

The tested plant species differed widely in oil content. Species with high contents were allocated to one group: castor oil plant (52.28%), caper spurge (50.08%), oil gourd (47.87%), flax (39.95%) and false flax (35.69%) (Figure 1).

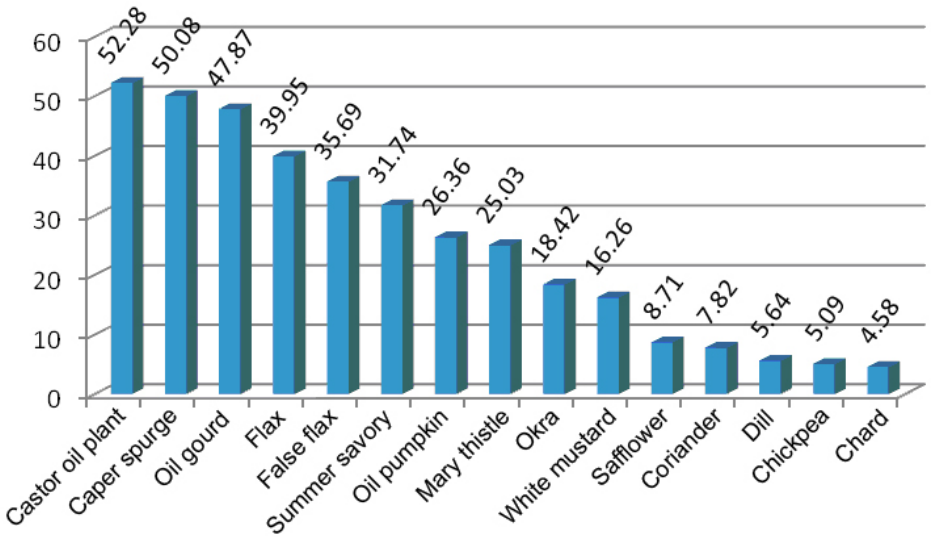

Figure 1. Oil content of alternative oil plant species (%)

Toxic compounds in the oil of castor oil plant and caper spurge present a problem for its use (Knights et al., 2001), therefore the oils obtained from these species can only be used as raw materials for industrial processing.
The group with medium oil content consisted of savory (31.74%), oil pumpkin (26.36%), mary thistle (25.03%), okra (18.42%) and white mustard (16.26%). Although these species hadslightly lower oil content, they hadgood prospects for the production of high quality oil (Knights et al. 2001). It can be used for human consumption, mostly as cold pressed oil, or in the food and pharmaceutical industries.
Due to its low boiling point, pumpkin oil is not suitable for frying, but is used as salad oil, and because of healing powers it is applied in pharmaceutical industry (Berenji, 2011).
Mary thistle oil is extremely rich in tocopherols, which is why it is recommended for human consumption (El-Mallah et al., 2003). White mustard contains oil high in erucic acid and as such is used for industrial purposes (Zheljazkov et al., 2012).
Low oil content group is formed of safflower (8.71%), coriander (7.82%), dill (5.64%), chickpea (5.09%) and chard (4.58%). The low oil content found in safflower is different from the values given by other authors (Beaulieu et al., 2009), which can be explained as a result of the used testing method. In our research we analyzed the entire fruit-seed, not just the core. The high content of shell significantly reduced the value of the resulting oil content. In addition, safflower is a plant species of arid climate and of soil below the natural fertility, while conditions in our experiment were not fully optimal for this plant species.

Based on the protein content, plants species were also divided into three groups. The highest protein content was found in white mustard (39.54%), oil gourd (34.75%) and false flax (28.78%). The mean content had flax (24.17%), savory (23.59%), chickpea (23.19), oil pumpkin (22.98%) and okra (22.73%) (Figure 2).

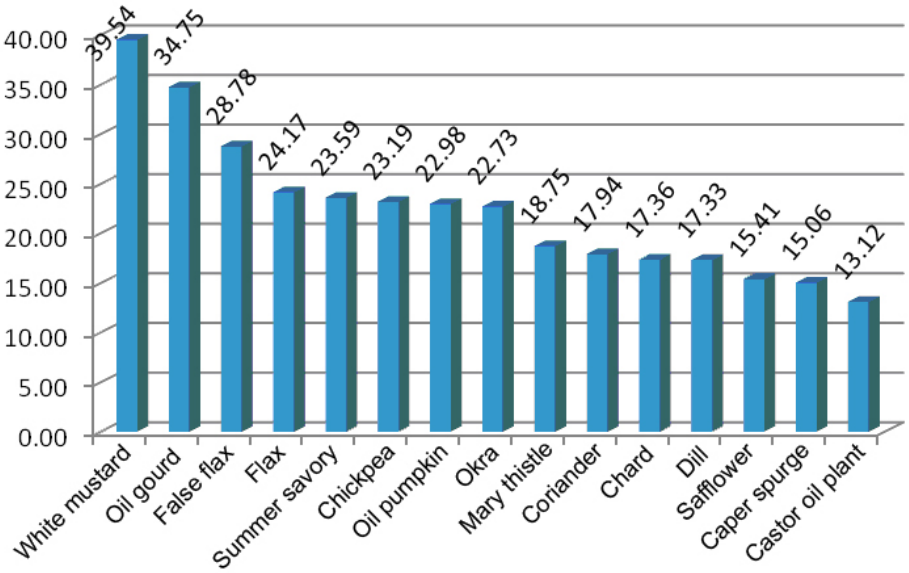

Figure 2. Protein content of alternative oil plant species (%)

The lowest contents were found in mary thistle (18.75%), coriander (17.94%), chard (17.36%), dill (17.33%), safflower (15.41%), caper spurge (15.06%) and castor oil (13.12%).
The low protein content of castor oil plant and caper spurge is expected due to the high oil content. A large number of authors found a negative correlation between these two properties with other oil crops (Chung et al., 2003; Zhao et al., 2006).
Oil gourd (82.62%), false flax (64.47%) and flax (64.12%) have a high content of both components in the seeds (Figure 3).

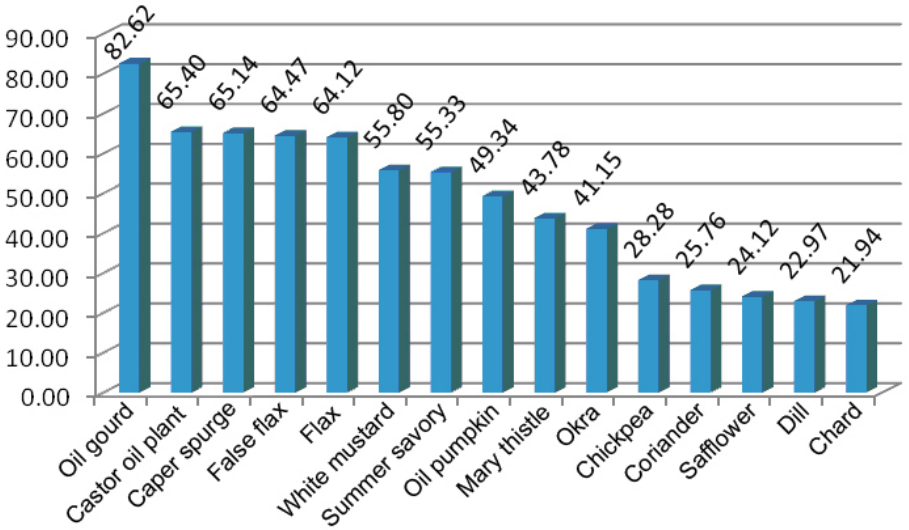

Figure 3. Combined oil and protein content of alternative oil plant species (%)

This allows their use as oil and protein crops. Despite the high total content in castor oil plant (65.40%) and caper spurge (65.14%), using proteins from their seed is not possible because toxic substances are present in large percentage (Griffiths et al., 1987; Fuller and McClintock 1986).

In addition to use as a feedstock for the production of oil or proteins, some species are used in the production of food for domestic animals, especially birds. The total oil and protein content in flax (64.12%), white mustard (55.80%) and safflower (24.12%) are important traits that determine their share in the feeding mixtures as high-energy components.
Commercialization of the studied species requires determination of seed yield, i.e. tubers, to determine the profitability of production.

CONCLUSIONS

Fifteen tested oil-protein species from the collection of the Institute of Field and Vegetable Crops differ in oil and protein content, as well as in total content of both components. Plant species which have great potential to be used as oil plants (castor oil plant, flax, oil pumpkin), protein plants (white mustard, false flax), or protein-oil plants (oil pumpkin, flax, false flax) were selected. Further studies of these species will be focused on requirements of processing industry and the market.

ABSTRACT: Among human enteric viruses, the noroviruses (NoVs) are of a major epidemiological significance as a common cause of both epidemic and sporadic non-bacterial gastroenteritis in humans. According to the recent CDC data, NoVs caused most illnesses (58%) through consumed contaminated food especially soft fruits, vegetables and RTE foods. The most effective methods for virus detection in food samples are those based on nucleic acid amplification. However, two major obstacles that influence routine virus detection in foods include the low efficiency of concentration and nucleic acid extraction procedures and the presence of inhibitors from food matrix to the molecular reactions. Most false negatives are consequence of inefficient virus and/or nucleic acid extraction and of inhibition of the RT-PCR reaction. To verify whether amplification reactions have functioned correctly, implementation of internal amplification controls (IACs) is essential. For this purpose, previously constructed IACs for application with highly reactive degenerate primers (COG) for the detection of human NoVs genogroups GI and GII by real-time RT-PCR were tested. Twenty-five grams of raspberries, lettuce, cherry tomatoes, green onions and deli meat have been artificially inoculated with norovirus GI and GII positive stool samples. IACs were incorporated in all real-time RT-PCR assays, and simultaneous amplification of both target and RNA IAC was achieved after optimization without decreasing detection levels of virus. In this study it has been shown that IACs amplification was unaffected by the viral RNA extraction procedure from different food items, which could potentially be a source of diverse inhibitors.
Key words: *noroviruses, detection, food, internal amplification control, real-time RT-PCR*

INTRODUCTION

Enteric viral transmission due to the consumption of contaminated foods is clearly recognized as a significant public health concern. Recent estimation revealed that in the US, most foodborne illnesses were caused by noroviruses (NoVs), 58% out of 9.4 million episodes caused by 31 major pathogens (Scallan et al., 2011). In Europe, human NoVs are also the principal cause of foodborne illness (Phillips et al., 2010). Food is a common vehicle for human NoVs transmission due to the contamination with human fecal material, poor personal hygiene of food workers and virus long survival in the environment (Atmar, 2010). Therefore, it is not surprising that the detection of NoVs in food, especially salad vegetables, soft fruits, and ready-to-eat (RTE) has become very important. These food items have been implicated in numerous viral outbreaks (Le Guyader and Atmar, 2008).
Virus detection from food includes diverse challenges, such as typically low viral load, extremely genetic heterogeneity, and presence of food components (e.g., organic and phenolic compounds, glycogen, fats, and Ca^{2+}) that are able to inhibit molecular assays. Although detection of NoV relies on molecular methods, with (real-time) reverse transcription (RT)-PCR considered as the gold standard due to high sensitivity and specificity, it is well known that PCR reactions are susceptible to inhibitors (e.g., humics, complex polysaccharides, microorganisms debris, metal ions, organics, and nucleases) ubiquitous in environmental samples (Julian and Schwab, 2012). Though the identities and biochemical mechanisms of action of many inhibitors remain unclear, bile salts and complex polysaccharides in feces, heme in blood, and urea in urine have all been shown to inhibit

PCR, probably through interference with binding and/or polymerization activity of DNA polymerases (Nolte, 2004). Carryover of reagents used for isolation of nucleic acids from samples can also inhibit amplification reactions. Generally, inhibitory factors that have been identified in PCR reactions included organic and inorganic chemicals, detergents, antibiotics, buffers, enzymes, polysaccharides, fats, and proteins (Wilson, 1997).
The vast number of PCR inhibitors can lead to unacceptable high number of false negatives in real-time PCR detection of NoV contamination in food. Other causes of false-negative results include target nucleic acid degradation, sample processing errors, thermal cycler malfunction, and in reverse transcription-PCR, failure of the reverse transcription step. To eliminate the risk of false negative results it is recommended that all PCR assays should include internal amplification control (IAC) which is typically co-amplified along with the target amplicon (Hoorfar et al., 2004). IAC is to be applied specifically in the amplification step to verify whether amplification reactions have functioned correctly, and identify those which have failed (D'Agostino et al., 2011). Although, an IAC is nucleic acid sequence present in every reaction, which can be co-amplified with the target sequence, it is distinguishable from the target sequence in conventional nucleic acid amplification by band size, and in real-time amplification by different melting temperatures of the amplicons or through detection by IAC-specific probe.
The aim of this paper was to reexamine and determine stability, suitability and significance of previously constructed IACs (Radin and D'Souza, 2011a) for use with earlier published specific COG primers (Kageyama et al., 2003) for the detection of human NoVs genogroups GI and GII from fresh produce and RTE items by real-time RT-PCR assay based on SYBR Green-I chemistry. Here we were interested to investigate the influence of possible contamination of real-time RT-PCR NoV detection assays with inhibitors. These inhibitors could be carried over from RNA extraction from artificially contaminated food items (lettuce, green onions, cherry tomatoes, raspberries, and deli meat). The premise in this work was that if the same concentration of IACs were used in all detections of NoVs and if there is no interference from some food compounds, C_t values obtained for IACs should be the same, or very close. This assumes that the PCR is operating at 100% efficiency, which is ideal or theoretical value. Experimental factors such as the length, secondary structure, and GC content of the amplicon can influence efficiency. Therefore, some slight differences could be expected. If there is significant difference for C_t values it has to represent the influence of diverse inhibitory factors from food, nucleic acid extraction procedures, etc. Inhibition in real-time PCR can be measured as the increase in threshold cycle (C_t) relative to an uninhibited control (Bustin et al., 2005).

MATERIAL AND METHODS

Internal amplification controls (IACs)

Previously constructed RNA IACs for COG set of primers (Radin and D'Souza, 2011a) were used in detection of NoVs genogroups GI and GII from the food samples. IACs could be co-amplified under the same conditions and in the same PCR tube, with the same sets of primers as used for target NoV amplification. IACs are the non-target RNA templates of about 155 bp, with the shiga toxin region of *E. coli* O157:H7 flanked by NoV sequences, containing COG primer binding sites. Due to the RNA nature of IACs they can also be used as a positive control for reverse transcription reaction. The optimal amounts of IACs (0.5 fg of RNA / approximately 5.750 copies of RNA molecules per reaction) were used in real-time RT-PCR assay for the detection of human NoV from food (Radin and D'Souza, 2011a). The optimal concentration considered to be the one that did not decrease the detection sensitivity of the assay (detection of the target product), in the presence of the visible IAC product.

Viral inoculation onto food

All food items (fresh produce: lettuce, green onion, cherry tomatoes; frozen raspberry and sliced fat free turkey breast) obtained from local retail stores were washed with sterile DDI H_2O and 5% tri-sodium phosphate (TSP) prior to inoculation. Additionally, deli meat was kept

under UV light for 3 min prior to inoculation. Food samples (25 g) were artificially contaminated with 100 µl of tenfold serial dilutions of the stool samples (in phosphate-buffer) containing approximately 10^5 and 10^4 RT-PCR units per ml for NoV GI and GII, respectively. After an incubation period of 10 min at room temperature (RT), the food items were processed for viral RNA extraction. Experiment included the samples that were spiked with phosphate-buffer to serve as a negative control during the entire viral detection procedures. All procedures were repeated four times.

Viral RNA extraction

Viral RNA extraction was performed directly from all food items; except from raspberry for which elution/concentration and polyethylene glycol (PEG) precipitation method was used (Baert et al., 2008, Stals et al., 2012). Briefly, treated and untreated food samples were rinsed with 1 ml of TRIzol™ reagent (Invitrogen, Carlsbad, CA). The viral RNA-containing aqueous layer was extracted after the addition of 0.2 ml of chloroform, incubation for 3 min at RT, and centrifugation for 15 min at 10.000 × g and 4 °C. The viral RNA was precipitated in 0.5 ml of isopropanol at RT for 10 min, after centrifugation for 10 min at 10.000 × g and 4 °C. The resulting RNA pellet was washed with 70% ethanol and centrifuged for 5 min at 7.500 × g and 4 °C, air dried, and resuspended in 40 µl of RNase-free water. Following heat treatment at 55 °C an additional purification was done using QIAShredder Mini Spin Column (QIAGEN, Valencia, CA). Extracted RNA was stored at -80 °C. To determine nucleic acid purity optical density measurements were made using Nano Drop® ND-1000 spectrophotometer. Samples of extracted RNA were analyzed by real-time RT-PCR with previously published NoV highly specific degenerate primers COG1F-COG1R (COG1F: 5' CGY TGG ATG CGN TTY CAT GA 3' COG1R: 5' CTT AGA CGC CAT CAT CAT TYA C 3') and COG2F-COG2R (COG2F: 5' CAR GAR BCN ATG TTY AGR TGG ATG AG 3' COG2R: 5' TCG ACG CCA TCT TCA TTC ACA 3') (Kageyama et al. 2003). Primers were obtained from Sigma-GenoSys (St. Louis, MO).

Real-time RT-PCR

Invitrogen SuperScript™ III Platinum® SYBR® Green One-Step qRT-PCR Kit was used according to manufactures instruction. Separate mixes for detection of GI and GII were prepared. To chilled PCR tubes 22 µl of cold reaction mix was added followed by 0.5 µl of appropriate IAC and 2.5 µl of the serially diluted extracted viral RNA. The tubes were fast spin and immediately placed into a Bio-Rad iCycler iQ (Hercules, CA). Protocol for COG primers was as follows: reverse transcription at 50 °C/60 min, denaturation at 94 °C/3 min, followed by 50 × cycles at 94 °C/45 s, annealing at 56 °C/50 s and extension at 58/50 s and final extension at 72 °C/7 min. Post-amplification melt temperatures (*Tm*) were obtained after completion of the PCR by plotting the fluorescence intensity against temperature as the temperature was increased from 50 to 95 °C increasing set point after each cycle by 0.5 °C. The threshold cycle (C_t - the cycle number at which the fluorescent signal of the reaction crosses the threshold) was determined by the software. For confirmation of amplicon presence and purity, the real-time RT-PCR product was run on a 2% agarose gel in 1× TAE buffer. A 100 bp DNA molecular weight marker (Promega, Madison, WI) was included to determine size of the RT-PCR product.

Statistics

For comparisons of C_t values Student's T-test from Microsoft Excel was used.

RESULTS AND DISCUSSION

The objective of this research was to assess the influence of the some food types (lettuce, green onion, cherry tomatoes, frozen raspberry, sliced fat free turkey breast) as a possible source for PCR inhibitors. Influence of these inhibitors was determined by addition of IACs to all PCR reactions for amplification of NoV RNA extracted from contaminated food items. This

influence was evaluated as increase in threshold cycle (C_t) relative to an uninhibited control (water). Only PCR reactions positive for IACs but not for NoV RNA, were considered in this study. Mean values for threshold cycle for each food product with respective standard deviation (SD) obtained solely for IACs throughout all the experiments are shown in Table 1.

Table 1.Threshold cycle (C_t) obtained for IACs in the real-time RT-PCR assays based on SYBRGreen-I chemistry in detection of human noriviruses GI and GII with COG primers

Food	Norovirus GI		Norovirus GII	
	Average C_t	SD	Average C_t	SD
Lettuce	25.3	1.3	25.3	1.5
Green onion	28.5	0.4	26.3	0.1
Cherry tomatoes	27.2	1.2	25.9	0.8
Raspberry	25.8	1.4	26.0	1.4
Deli meat	26.6	0.9	25.6	1.3
Control - water	25.9	0.6	25.8	0.7

Inhibition can be assessed by comparing the C_t of the control reaction to which RNAse/DNase-free water had been added with the C_t of the reaction to which NoVs RNA extracted from food had been added. Comparison of C_t values was done with Student's T-test and $P<0.05$ was reconsidered as statistically significant. Reaction to which NoVs RNA extracted from different food showed statistically insignificant difference in values for IACs C_t compared to control. In the case of green onion both for NoVs GI and GII genogroups statistical analysis was not performed as a limited number of data points was available.
After each real-time RT-PCR all reaction products have been run on the agarose gel and the size of IACs amplicons was determined. In Figure 1 it can be seen that in all PCR reaction amplicons of the appropriate size (155 bp) were obtained.

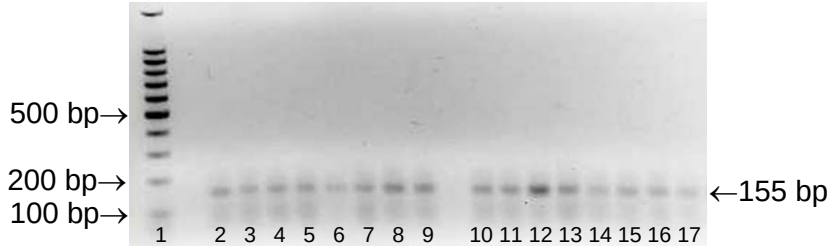

Figure 1. Analysis of IAC real-time RT-PCR amplicon size by gel electrophoresis. *Lane 1* contains 100 bp marker, *lanes 2-6* (NoV GI) and *lanes 10-14* (NoV GII) showing the expected size of 155 bp IACs amplicon in detection of NoV GI and GII RNA extracted from lettuce, green onion, cherry tomatoes, raspberry and deli meat, respectively. *Lanes 7-9* and *lanes 15-17* represent controls, IACs in water.

It was expected that RNA extraction from tested food matrixes would lead to carryover of different compounds and inhibitors for PCR reactions. This would cause PCR reaction inhibitions, which could be observed ether as total PCR failure or increased C_t values for IACs. Surprisingly, we observed no statistically significant change of C_t values for IACs, indicating that PCR reactions weren't affected by the starting material for viral RNA extraction. This could mean that used protocols were effective in reducing the carryover of inhibitory compounds, as seen by unchanged C_t values for IACs. Our results have clearly showed that use of IACs as PCR control is justified. Therefore, IACs provides an accurate way to assess the integrity of all the steps in nucleic acid amplification assays (Nolte, 2004). In general, controls provide evidence that a laboratory assay is meaningful within the environmental system studied (Julian and Schwab, 2012).
Throughout all the experiments, same equipment, reagents and materials have been used, in order to avoid additional sources of results variation, since it is known that for example, microcentrufuge tubes from different manufactures can contribute to the variation of the

results (Hughes et al., 1994). As well, parameters and condition of real-time RT-PCR assays and primers were identical, because different PCR reactions are not equally susceptible to same inhibition by substances co-purified in nucleic acid extracts (Huggett et al., 2008). Furthermore, phenolic compounds from the sample or carried over from nucleic acid purification procedures can inhibit the reaction by binding to or denaturing the polymerase (Young et al., 1993). Since bovine serum albumin proved to be the most effective in overcoming inhibition (McGregor et al., 1996), it was used in these investigations.
Other researchers have had a similar approach like developed SYBR Green RT-PCR assay to detect human and bovine noroviruses and control for inhibition (Scipioni et al., 2008) or the use of single-stranded oligonucleotides of ~ 120 nucleotides as IAC in real-time PCR assays (Burggraf and Olgemoller, 2004) described for *Mycobacterium tuberculosis* complex, hepatitis B virus, herpes simplex virus, and varicella zoster virus. Use of the IAC did not change the detection limits neither of these, nor of ours assays (Radin and D'Souza, 2010; 2011b).

CONCLUSIONS

It is of vital importance to recognize failed NoV RNA amplification in detection assays as it may lead to a false negative interpretation of the results. An internal amplification control can identify failed reactions. Desirable characteristics of IAC to be used in real-time RT-PCR assay are reliability which is reflected in consistent show of a signal in the absence of a target or in the presence of low target concentrations; performance at concentrations, that won't decrease the detection sensitivity of the assay (detection of the target product). This work has shown that IACs amplification was unaffected by the viral RNA extraction procedure from different food items (lettuce, green onion, cherry tomatoes, raspberry, deli meat), indicating that presented protocols are adequate for use in the detection of HuNoVs.

MICROBIAL IMMOBILISATION TREATMENTS OF CATTLE HIDES - A NOVEL APPROACH TO HIDE INTERVENTION STRATEGY

ABSTRACT: Cattle hide decontamination treatments have been recognized as an effective way to reduce microbial contamination of beef carcasses during slaughter and dressing in abattoirs. A range of related techniques – aimed at killing and/or removing pathogens on hides – have been considered in previously published studies. However, reported microbial reductions achievable were relatively limited: around 2-3 logs on decontaminated hides or about 1 log on resulting dressed carcasses. Consequently, to improve the effectiveness of hide treatments, a new approach – treatment to immobilize microbiota on cattle hide rather than to kill it – has been proposed. An insect-produced, natural, food-grade resin (Shellac) was evaluated as an on-hide microbiota-immobilizing agent in a laboratory models system using a sponge-swabbing microbiological sampling method. On hides spray-treated with a Shellac-in-ethanol solution, recoveries of general microbiota (total viable count of bacteria-TVC, *Enterobacteriaceae* counts and generic *E. coli* counts) were greatly reduced: up to 6.6 $\log_{10}$ CFU/cm^2 reductions. The effects of the Shellac treatment were mainly due to immobilization of bacteria on hair by the resin, and to lesser extent due to bactericidal action of the ethanol. Furthermore, post-slaughter but pre-skinning treatment of hides with Shellac-in-ethanol solution, under practical conditions of small commercial abattoir operation, significantly reduced (up to 1.7 log) levels of general microbiota found on final beef carcasses. Overall, in both laboratory- and abattoir-based experiments, microbial reductions achievable by the Shellac-treatment of hides were superior - on both hides and beef - to those achievable by a control hide treatment using rinse-vacuum with sanitizer. Therefore, the Shellac treatment of hides can be considered as an effective alternative approach to hide decontamination strategies to improve beef safety.
Key words: *cattle hides, hide microbiota, Shellac, microbial immobilisation*

INTRODUCTION

It is well known that the main sources of microbiological contamination of beef carcasses are the alimentary tract and hide of slaughtered cattle. However, in modern abattoirs leakage/spillage of intestinal contents onto the meat occurs rarely, whilst contamination from the hides is a key and inevitable event (Bell 1997, Elder et al., 2000, Vivas Alegre and Buncic 2004, Antic et al., 2010a, Blagojevic et al., 2011). It was found that cattle hide can carry not only up to 11 $\log_{10}$ colony-forming units (cfu)/cm^2 of aerobic bacteria (Antic et al., 2010b), but also some of currently the most important foodborne pathogens, such as *Escherichia coli* O157, *Salmonella* species and *Campylobacter* species, which consequently can contaminate carcass meat (Bell 1997, Elder et al., 2000, Avery et al., 2002, Reid et al., 2002). Therefore, reduction of hide contamination contributes to the reduction of transmission of microorganisms from hide onto carcass and improves the microbial status of dressed carcasses (Nou et al., 2003, Bosilevac et. al., 2005, Antic et al., 2010b). Consequently, studies of various pre-skinning decontamination treatments of hides, aimed at reduction of microbiota levels on hides and subsequent improvements of microbial status of carcasses, have been published (Koohmaraie et al., 2005; Small et al., 2005). The USA regulatory authorities acknowledge that, even with the best hygiene practices, some microbial contamination of the carcass including with foodborne pathogens, is inevitable. Decontamination interventions are therefore perceived as an adjunct to HACCP in meeting pathogen reduction performance standards (Smulders and Greer, 1998). In contrast, until

very recently, the EU regulatory authorities considered that strict hygienic processing should be sufficient to ensure product beef carcass safety, and that introduction of carcass decontamination treatments could carry a risk of producers relying too much on these interventions, so reducing their process hygiene efforts. For carcass decontamination, interventions with substances other than potable water are not used presently although are permissible in the European Union (Regulation (EC) No. 853/2004), but subject to regulatory authorisation and following a risk assessment by the European Food Safety Authority (EFSA).

Published studies on hide decontamination were primarily focused on killing of microbiota on hides, alone or in combination with their physical removal from hides, through use of a range of techniques based on heat (up to 80 ^{o}C) or chemicals (Bosilevac et. al., 2005; Koohmaraie et al., 2005). However, reported microbial reductions achievable under practical conditions in abattoirs were relatively limited: around 2-3 logs on decontaminated hides or around 1 log on resulting dressed carcasses. In principle, to reduce carcass contamination from the hide, it is sufficient to reduce the detachment of bacteria from the hide hair and their subsequent transfer onto the carcass meat - so to kill the bacteria on the hide is not a must. Accordingly, a novel alternative approach to improve the effectiveness of hide treatments in reducing microbial transfer from hides on carcasses has been proposed recently: treatment of hides with Shellac, an on-hide microbiota-immobilizing, natural, food-grade resin (Antic et al., 2010b; Antic et al., 2011).

MATERIAL AND METHODS

Comparison of the Shellac treatment with a hide decontamination treatment in a laboratory model

Shellac (Zinsser Co. Inc., USA) is a food-grade, insect-produced natural resin widely used as a glazing agent in the food (e.g. confectionary and fruit) industry. Pieces of clean and dry hides were treated with the Shellac solution (23% in 99.09% ethanol) by uniform spraying using a commercial sprayer. To evaluate the overall effects of the Shellac hide treatment (based on microbial immobilisation) not only through comparison with untreated hide control, but also through comparison with the effects of a “comparative treatment” (based on killing-removing of microbiota), some of the hide pieces were subjected to decontamination treatment with a sanitizer using rinse-vacuum technique. The sanitizer comprised quaternary ammonium-based surface disinfectant preparation (Fink-Antisept G, FINKTEC GmbH). The preparation was dissolved in warm water (50 °C) and filled into a rinse-vacuum spray extraction cleaning machine (Puzzi 200, Karcher). The hide pieces were treated with the machine in the hair growth direction and subsequently left to dry. Hides were sampled using swabbing technique, because it reflects the way of transfer of bacteria from hides onto carcass meat. After sampling, swabs were processed in laboratory using standard microbiological techniques and Total Viable Count of aerobic bacteria, count of *Enterobacteriaceae* and generic *E. coli* count determined on Petrifilms. Colony counts (CFU/cm^2 of hide) of target microorganisms were converted to $\log_{10}$ CFU/cm^2 before calculation of mean values, standard deviation values and significance of differences between means (T-test).

Evaluation of the effects of hide treatment with Shellac solution on microbial status of beef carcasses in abattoir

The study was conducted in a small commercial abattoir in Serbia, with a total of 57 cattle randomly selected for the trials. The large majority of animals presented for slaughter at the abattoir were visually categorized as dirty: either cleanliness category 3 (dirty; dry or damp, with significant contamination of dirt or faeces) or category 4 (very dirty; dry or damp, with heavy contamination of dirt or faeces). The Shellac or the sanitizer hide treatments were applied after slaughter and bleeding of animals, but before the start of the skinning operation. Hide of each of 18 slaughtered bovines was uniformly sprayed with the Shellac solution using a hand-held commercial sprayer, over the longitudinal area where initial skin-opening

cuts are routinely made during the skinning operation: along the hock (both hind legs)–rump–perianal region–flank–belly–brisket line. In addition, hide of 18 other slaughtered bovines was rinsed-vacuumed with a solution of sanitizer (quaternary ammonium-based surface disinfectant Fink-Antisept G) using a rinse-vacuum spray extraction cleaning machine (Puzzi 200, Karcher) along hide area identically as with the Shellac treatment. Twenty one slaughtered bovines that were not subjected to any pre-skinning hide treatment served as untreated controls. Skinned carcasses of bovines whose hides had been previously subjected to the Shellac solution- or sanitizer rinse-vacuum treatment, as well as of untreated-hide bovines, were surface swab-sampled immediately on completion of the skinning, and microbiological examinations conducted as described for the laboratory model system experiment. The efficacies of each of the Shellac solution- and the sanitizer rinse-vacuum hide treatment in reducing the hide-to-meat microbial transfer (expressed as microbial reductions achieved) were calculated *via* differences between microbial levels found on skinned carcasses of bovines that were previously hide-treated or hide-untreated.

RESULTS AND DISCUSSION

Remarkable reductions of TVC swab-recoveries (average 6.6 log reduction) from natural (uninoculated) hides were achieved by the 23% Shellac solution treatment (Table 1), that were significantly larger (by 1.7 log/cm^2) than those obtained by the sanitizer rinse-vacuum treatment (4.9 log). Overall, the results from this part of the present study demonstrated that the hide treatment combining microbial killing and immobilisation on hair (i.e. Shellac solution in ethanol) is superior to a hide decontamination treatment involving microbial killing and removal from hair (i.e. sanitizer rinse-vacuum treatment), in terms of reduction of general microbiota swab-recovery from treated hides.

Table 1. Comparison of reductions of microbial recoveries from cattle hides achieved by the Shellac treatment and by the sanitizer-based decontamination

	Rinse-vacuum with sanitizer solution (Antisept G) [a]			Spraying with 23% Shellac in ethanol solution [a]		
Microorganisms	Untreated hide	Treated hide	Microbial reduction [b]	Untreated hide	Treated hide	Microbial reduction [b]
Total count of bacteria (log_{10} CFU/cm^2) [c]	9.9±0.3	5.0±0.3	-4.9±0.4^A	10.8±0.2	4.2±0.7	-6.6±0.8^B
Enterobacteriaceae count (log_{10} CFU/cm^2) [c]	5.9±1.2	2.5±0.7	-3.4±1.1^A	4.8±2.4	0.0	-4.8±2.4^B
Generic *E. coli* count (log_{10} CFU/cm^2) [c]	3.9±0.4	1.2±0.4	-2.8±0.7^B	2.9±0.8	0.0	-2.9±0.8^B

[b] *Difference between mean values (± standard deviation) of correlated untreated and treated hide samples. Within each row, the values marked by different capital letters are significantly different; B>A (P<0.05)*
[c] *Mean value ± Standard deviation*

In other part of the study, the Shellac hide treatment was further evaluated in a commercial abattoir, to assess its potential to improve microbial status of carcasses in a real-life situation. In abattoir trials, after the Shellac treatment of hides of slaughtered bovines (pre-skinning), the total viable count of bacteria (TVC), *Enterobacteriaceae* counts (EC) and generic *E. coli* counts (GEC) on corresponding beef carcasses (after skinning) were significantly reduced compared to control beef carcasses from untreated-hide bovines - the reductions were 1.7 log_{10} CFU/cm^2, 1.4 log_{10} CFU/cm^2 and 1.3 log_{10} CFU/cm^2, respectively (Table 2). On the other hand, after the pre-skinning sanitizer treatment of hides, TVC, EC and GEC on the skinned beef carcasses were also significantly reduced compared with

control carcasses from untreated-hide bovines – the reductions were 1.0 $\log_{10}$ CFU/cm^2, 1.3 $\log_{10}$ CFU/cm^2 and 1.2 $\log_{10}$ CFU/cm^2, respectively (Table 2). The on-carcass microbial reducing effect of the Shellac hide treatment was significantly better that of the sanitizer hide treatment in case of TVC levels.

Table 2. Reductions of microbial loads on skinned beef carcasses after the Shellac and the sanitizer treatments of hides in small commercial abattoir

Pre-skinning treatments of hides on slaughtered bovines	Parameters	Microorganisms ($\log_{10}$ CFU/cm^2) [a]		
		Total count of bacteria (TVC) on carcasses after skinning	*Enterobacteriaceae* count (EC) on carcasses after skinning	Generic *E. coli* count (GEC) on carcasses after skinning
Untreated hides (control; n=21)	Microbial levels on control carcasses	4.9±0.8 ^{A}	0.8±0.7 ^{A}	0.7±0.8 ^{A}
Hides treated by the Shellac solution (n=18)	Microbial levels on carcasses	3.2±0.7 ^{C}	-0.6±1.1 ^{B}	-0.6±1.0 ^{B}

CONCLUSIONS

Overall, the present study clearly demonstrated that this novel microbial-immobilisation treatment of hides with Shellac-in-ethanol solution greatly reduced “bacterial transferability” as measured through recoveries of microbiota from the treated hides by swabbing and also markedly reduced microbial loads on beef carcasses after Shellac treatment of hides before skinning.

ABSTRACT: Solid phase microextraction (SPME) followed by comprehensive gas chromatography coupled to time of flight mass spectrometer (GCxGC-TOF-MS) was used to characterise volatile organic compounds present in acacia flowers (*Robinia pseudoacacia)* and acacia honey in order to identify volatile compounds that come to honey directly from acacia plant. Acacia honey as well as acacia flowers were collected in Komarno-Komarom district at Slovak-Hungary border. Up to 500 volatile organic compounds were detected in acacia honey at given signal to noise ratio 200, while only 216 were identified. They belong to various chemical classes (hydrocarbons, alcohols, aldehydes and ketones, terpens, benzene derivatives and compounds containing heteroatom). On the contrary, acacia flower scent was characteristic by presence 680 volatile organic compounds.
Key words: *honey, VOC, CGxGC, comprehensive gas chromatography*

INTRODUCTION

Honey belongs to the one of the oldest known food, dating back to ancient times, where it is mentioned in old Sumerian, Babylonian and Egyptian scared texts and writings. Over history, it becomes valuable product that was used as a currency or a special form of tribute. One can distinguish between monofloral and polyfloral honey. Monofloral honey is usually more appreciated, since it primarily originates from the nectar of one type of flower. Monofloral honeys differ in taste, flavor as well as in color depending on properties of primary nectar sources. Up to these days, various analytical methods have been used for determination of botanical origin of monofloral honeys (Kaškoniene et al., 2010) e.g. analysis of pollen (melissopalynology) (Sabo et al., 2011) or monitoring of various analytical parameters, like sugar content (Kukurova et al., 2008), profile of phenolic compounds and flavonoids (Escrich et al., 2011), conductivity, mineral content, pH and colour (Vanhanen et al., 2011), stable isotopes (Rossmann, 2001) etc., but often a correct determination of honey origin requires a detailed knowledge about its physical properties and chemical composition. In the past decade, it was shown that composition of volatile organic compounds (VOC) has to be considered as a perspective tools in the assessment of honey origin. Honey VOCs represents a complex mixture of various low molecular weight organic compounds. Some of them originate from flowers and another are formed during conversion processes of nectar into honey. Thus, VOC in honey could serve as an indicator of botanical origin. Indeed, many papers published within last 10 years deal with characterization of VOC profile of honeys with different botanical origin with special attention to identify their possible markers (Radovič et al., 2001; Castro-Vazquez et al., 2003; Baronni et al., 2006).
Considering fact, that VOC in honey is a complex mixture of different components containing various chemical functional groups with relatively low molecular weight that are present at low concentration levels, their extraction requires utilization of effective sample treatment methods. There are several ways how to extract VOC from honey in order to reach required sensitivity, recovery and reliability. The most frequently used is solid phase microextraction (SPME). This solventless technique can be easily automated, but requires a bit time

consuming optimization of working conditions like type of SPME fibres, sorption temperature, sorption time and desorption temperature. As was mentioned above, honey is a very complicated matrix that contains sometimes several hundreds of different organic compounds with various chemical properties. Thus an application of GC coupled to the universal and specific detector such as mass spectrometer is prerequisite for precise and accurate determination of many chemical compounds in a single run. In spite of considerable developments in chromatography, even high-resolution separations with optimized selectivity may not be sufficient to handle such complex mixtures as honey undoubtedly is. One possibility how to solve problems of overlapped peaks is use multidimensional chromatographic systems with much higher separation efficiency, such as comprehensive gas chromatography (GCxGC). In GC×GC, the entire sample is separated on two different columns, and no information gained during the first separation is lost during the second one. The final chromatogram, except of identification of compounds based on their mass spectra allows also provisionally classify unknown compounds based on the presence of ordered structures for classes of structurally related compounds. Additionally, comprehensive gas chromatography provides two complete sets of retention data for all constituents of a sample, which yields an additional tool for their identification.
The aim of the study presented in this work was to compare VOC profile of acacia honey and acacia flowers from which honey was made in order to identify volatile compounds that come to honey directly from acacia plant.

MATERIAL AND METHODS

Samples of acacia flowers were obtained from acacia trees near village Marcelova at Slovak-Hungarian border. Similarly, studied honeys were collected in 2010 and originate from the same place as collected flowers. In this work 2 samples of collected flowers and 6 samples of acacia honey in different stages of its processing (2 samples from opened honey combs, two samples from sealed honey combs and two samples of stored honeys) were studied in details.
VOCs from flowers and honey samples were extracted by SPME procedure using Gerstel MPS2 autosampler. A 5 g of honey together with a 0.5 g of NaCl were dissolved in DI water in a 20 ml clear glass vials. In case of flowers, a 10 g of flowers were closed in 20 ml clear glass vials. A sample in vials (in case of honey a stirred solution at 450 rpm) was heated at 60 °C for 30 min. VOCs were extracted by SPME fiber for autosampler coated with PDMS/CAR/DVB (50/30 µm thickness) obtained from Supelco (Bellefonte, PA, USA). The fiber was conditioned prior use by heating in the injection port of GC under the conditions recommended by the manufacturer. The adsorption of VOCs from honey samples on SPME fiber took 30 min at 60 °C. Desorption was performed in GC injector in splitless mode at 220 °C for 2 min.
LECO Pegasus 4D (LECO Corporation, St. Joseph, MI, USA) consisting of an Agilent 6890 gas chromatograph and Gerstel MPS 2 autosampler equipped with a CIS injector, dual-stage thermal modulator and secondary oven connected to a Time-Of-Flight Mass Spectrometer. The VOC from honey samples was injected into GC by desorption in GC injector in splitless mode at 220 °C for 2 min. In case of standards, 1 l of solution was injected directly into CIS injector in split mode 1:50. Stored mass range m/z from 29 to 600 with an acquisition rate of 100 spectra/second was used. Helium was used as a carrier gas in constant flows mode 1.0 ml/min. DB-FFAP (30 m × 0.25 mm I.D. coated with 0.25 µm film thickness of nitroterephthalic acid modified polyethylene glycol phase, Agilent, Agilent J &W Column, Agilent Technologies, Palo Alto, CA, USA) was used as 1D column. This column was coupled to 2D column BPX-50 (1.5 m × 0.1 mm I.D. coated with 0104 µm film thickness of 50%-diphenyl-50%-dimethyl polysilphenylene-siloxane), Supelco, Belefonte, PA, USA). Primary oven was programmed from 40 °C (1 min) to 220 °C (5 min) with 2.0 °C/min rate. The temperature offset between secondary and primary oven was 10 °C, 8 seconds modulation period, hot pulse duration 1.5 second, temperature offset of modulation 30 °C, temperature of transfer line 240 °C, temperature of ion source 230 °C, electron impact

ionization energy 70 eV. LECO ChromaTof software was used for instrument control and data evaluation. Data was processed at S/N ratio 200.
Anhydrous NaCl used in sample treatment procedure was obtained from Mikrochem (Pezinok, Slovakia). DI water was prepared in laboratory using NANOpure device from Wilkem Werner Gmbh. Standard solution of chemicals with concentration 1 ppm was prepared in hexane or methanol (Merck, Darmstad, Germany).

RESULTS AND DISCUSSION

All studied honey samples were analysed under these optimized separation conditions. The chromatograms obtained for acacia flower and honey are shown in Figure 1. The chromatograms were evaluated in order to identify compounds present in honey. The compound was considered as identified only if its retention characteristics in both dimensions, as well as, recorded mass spectra were in agreement with those recorded for standard. If the standard was not available, the identification was performed by comparison of recorded mass spectra with NIST 2008 mass spectra library. However in this case, the compound was consider only as tentatively identified if spectral match higher than 800 was achieved. Homologous series of alkanes starting from pentane up to heptadecane (except of hexadecane), while nonane was present at highest concentration levels, primary, secondary (C4-C10) and tertiary (C5-C8) alcohols, aldehydes (C6-C12), ketonones (except of C4 and C10), organic acids (C1-C16) and their methyl esters have been found in honey.
In total, 509 compounds were found in acacia honey, while only 216 was identified. Benzene derivatives, 2-butanone, alkanes (C6-C9), nonanal, cis-linalool oxide, methyl ester of hexanoic and octanoic acid were present at highest concentration level. Carboxylic acids were found in very low concentration, which could be characteristic for this type of honey. The methyl esters of carboxylic acids were present in relatively high concentration. The presence of all aldehydes from hexanal to decanal is characteristic for this honey. 1-methylpyrrolidinone, 2,4-decadienal (trans isomer), 2-hexen-1-ol, (trans isomer), 3,4-dimethyl-3-hexanol, 3-ethyl-3-heptanol, 3-heptanone, dihydrolinalool were also found in acacia honey. Some aldehydes and terpenes come to honey from primary nectar source, thus those can be used to differentiate honeys based on their botanical origin. A homologous serie of alkanes starting from pentane up to heptadecane (except of hexadecane) with nonane present at highest concentration level were found only in honey samples. On the contrary, VOC profile of acacia flower was characteristic by presence of 2,3-octadiene, 2,4-hetadienal, bicycle [4.2.0] octa-1,3,5-triene, decane, 3-methyl and dodecanoic acid, 2-methyl. Nonen-1-ol, 1-nonen-4-ol, 1-penten-3-ol, 2-octen-1-ol and 2-penten-1-ol were present at highest concentration level. 1,3-octadiene, cyclopentanol, 2,6-octadien-1-ol, 3,7-dimethyl and methyl salicylate were present at lower concentration level.

CONCLUSIONS

In this study, SPME-GCxGC-TOF-MS was used to characterise VOC fraction of acacia honeys in different processing stage as well as corresponding acacia flowers taken from the same geographical area. From all present compounds two important groups were identified. The first group contains compounds that were found either in flowers or only in honey samples. Such example is alkanes identified only in honey samples. Only in acacia flowers were identified example compounds pinene, 4-carene, azulene and eucalyptol. On the other hand, some aldehydes or terpenes come to honey from primary nectar source, thus some of them can be used to differentiate honeys based on their botanical origin.

ABSTRACT: The prevalence of antibiotic and biocide resistance among *Campylobacter jejuni* and *Campylobacter coli*, the involvement of active efflux to these resistances and the potential for adaptive resistance after step-wise exposure to increasing sub-inhibitory concentrations of biocides were studied. The antimicrobial resistances were examined with broth microdilution method. The presence of active efflux was studied on the basis of restored sensitivity in the presence of the efflux pump inhibitors (EPIs) and inactivation of the *cmeB, cmeF* and *cmeR* efflux genes. Changes in outer membrane protein profiles (OMPs) and morphological changes were studied in adapted and their parent strains. Among 42 *Campylobacter* strains studied, different antibiotic and biocide resistance levels as well as multidrug resistance were seen, but no correlation between biocide and antibiotic resistance was confirmed. EPIs partially reversed the resistance to all antimicrobials tested. The antimicrobial resistances were reduced in *cmeB* and *cmeF* and increased in the *cmeR* mutant. Repeated exposure to biocides resulted in the partial increased resistance and acquisition of cross-resistance to biocides and antibiotics, which was partially stable. More than one type of active efflux was identified in adapted strains. Different alterations in OMP profiles and morphological changes were also observed. This data suggest that active efflux is a crucial mechanism involved in antibiotic and biocide resistance in *C. jejuni* and *C. coli*. More than one type of efflux is employed. The same is true for adaptation to biocides. However, these adaptations were strains specific; no species specific mechanisms were recognized.
Key words: *Campylobacter, biocide, antibiotic, multidrug resistance, efflux, adaptation*

INTRODUCTION

The thermotolerant *Campylobacter* spp., and especially *C. coli* and *C. jejuni*, have become the most commonly reported bacterial cause of food-borne gastroenteritis in humans worldwide (Moore et al., 2006). Beside this widespread occurrence, they have become increasingly resistant to antibiotics (Engberg et al., 2001).
Biocides are widely used to prevent bacterial contamination in food-processing and in clinical environments (McDonnell and Russell, 1999). In comparison to antibiotic resistance, mechanisms of bacterial resistance to biocides has only been described more recently, and has been less studied overall. A potential concern is the possibility that mechanisms providing resistance to biocides may also provide cross-protection to the activity of antibiotics (Ng et al., 2002). A possible link between biocide and antibiotic resistances in bacteria has been reported in several studies (Copitch et al., 2010; Russel, 2002). However, contrary evidence has appeared in the literature to suggest that this phenomenon does not cause a real problem in practice (Lear et al., 2006; Avrain et al., 2003).
Bacterial resistance to biocides can result from changes in the cell envelope permeability or enhanced biocide efflux (Russell, 2002; Li and Nikaido, 2004). The presence of the efflux pumps CmeABC (Lin et al., 2002; Martinez and Lin, 2006) and CmeDEF (Akiba et al., 2006) belong to the resistance-nodulation cell division family of transporters has been demonstrated to contribute to the antimicrobial resistance in *C. jejuni*. The CmeABC is regulated through the transcriptional repressor CmeR (Lin et al., 2005).
Adaptation to biocides by serial passage in increasing sub-inhibitory concentrations of biocides has been documented for some bacterial species. The development of adaptive

resistance and cross-resistance to dissimilar biocides and increased resistance to antibiotics has occurred after step-wise exposures to biocides (Braoudaki and Hilton, 2005; Tattawasart et al., 1999). Active efflux is one of the mechanisms involved in this resistance (Braoudaki and Hilton, 2005; Thomas et al., 2000). It has also been suggested that alterations in the outer membrane are involved, including for the content of lipopolysaccharide and outer membrane proteins (OMPs) (Tattawasart et al, 2000). This adaptive resistance is also associated with morphological changes (Tattawasart et al, 2000a).
In this study, we examined the prevalence of resistance among 15 *C. jejuni* and 27 *C. coli* isolates from food, animal, human and environmental water sources to five biocides: triclosan (TLN), benzalkonium chloride (BC), cetylpyridinium chloride (CPC), chlorhexidine diacetate (CHA) and trisodium phosphate (TSP), two antibiotics: erythromycin (ERY) and ciprofloxacin (CIP) and sodium dodecyl sulphate (SDS). The involvement of active efflux to these resistances was determined on the basis of restored sensitivity in the presence of the efflux pump inhibitors (EPIs). To investigate the contributions of the CmeABC and CmeDEF efflux pumps to these resistances, *cmeB, cmeF* and *cmeR* mutants of *C. jejuni* strain NCTC 11168 were screened for susceptibility in the presence and absence of EPIs. The potential for adaptive resistance of *C. jeuni* and *C. coli* after step-wise exposure to increasing sub-inhibitory concentrations of these five biocides was investigated to identify the mechanisms underlying resistance.

MATERIALS AND METHODS

Bacterial strains and growth conditions

Fifteen *C. jejuni* and 27 *C. coli* strains isolated from animals (poultry, pig), humans and environmental water were used in this study. Three *C. jejuni* (NCTC1168, ATCC33560, and the K49/4 poultry isolate) and two *C. coli* (ATCC33559, and the 137 poultry isolate) strains were used in the adaptation experiments. The cultures were stored at –80 °C in Brain Heart Infusion broth (Biolife) with 20% horse blood (Oxoid) and 20% glycerol (Kemika). The isolates were cultivated at 42 °C under microaerophilic conditions (3% O_2, 10% CO_2 and 87% N_2) in gas-tight containers on Columbia agar with 5% horse blood (Oxoid).

Mutant strains

Purified DNA from *cmeB* (Lin et al., 2002), *cmeF* (Akiba et al., 2006) and *cmeR* (Lin et al., 2005) mutants (obtained from Prof. Zhang, Iowa State University, USA) was used to transform *C. jejuni* NCTC 11168 using standard biphasic methods for natural transformation and construction of *cmeB, cmeF* and *cmeR* mutants (Wang and Taylor, 1990). The transformants were confirmed by PCR using specific primers as desribed previously (Lin et al., 2005).

Antimicrobial susceptibility testing

The minimal inhibitory concentrations (MICs) of TLN (Merck) BC, CHA, CPC, TSP (Sigma-Aldrich, St. Louis, USA), SDS (Invitrogen), ERY (Sigma-Aldrich) and CIP (Fluka) were determined with broth microdilution method in Muller Hinton broth (MHB, Oxoid) as described previously (Mavri et al., 2012). The MICs were defined as the lowest concentration where no viable cells were present, determined on the basis of fluorescent signals measured using a microplate reader (Tecan) after adding CellTiter-Blue® Reagent (Promega) to the culture media, following the manufacture instructions. The assays were repeated twice in duplicate, to confirm the reproducibility of the MIC data.

Involvement of efflux pump activity

The involvement of active efflux to resistance to five biocides, two antibiotics and SDS were determined using the broth microdilution method as described above in the presence of EPIs phenylalanine-arginine beta-naphthylamide (PAN) (10 mg/ml) and 1-(1-naphthylmethyl)-piperazine (NMP) (60 mg/ml).

Adaptation to biocides
Adapted strains were prepared by step-wise exposure to gradually increasing concentrations of biocides over 15 days. Overnight bacterial cultures (100 l) in MHB were inoculated into fresh MHB containing sub-lethal concentrations of the biocides and incubated for 24 h at 42 °C under microaerophilic conditions. One millilitre aliquots of the 24 h bacterial cultures from the samples with the highest biocide concentrations that permitting growth were transferred into a second series of biocide concentrations in MHB, and incubated as before. This step was repeated every 24 h for a total of 15 passages. The concentrations of the biocides were subsequently increased and ranged as follows: TLN from 1 to 3 mg/l; BC and CHA from 0.063 to 0.35 mg/l; CPC from 0.125 to 0.5 mg/l; and TSP from 2 to 5 g/l, depending upon the growth of the adapted microorganism. The concentrations of the cultures were assessed by measuring the optical density at 600 nm on a UV-visible spectrophotometer (Hewlett Packard) and its purities by streaking them onto selective Karmali agar (Oxoid), after 5, 10 and 15 passages.

Determination of adaptive resistance, cross-resistance and stability of adaptive resistance
The adaptive resistance and cross-resistance were determined for each strain after 5-, 10- and 15-day exposure to gradually increasing concentrations of biocides in MHB. The stability of the adaptive resistance was determined for each adapted strain by subculturing in biocide-free MHB every 24 h, for 10 days. The concentration and purity of cultures were assessed at each stage.

Determination of efflux pump activity: Efflux pump activity was determined for each pre-adapted and adapted strain after 5, 10 and 15 passages on the basis of restored sensitivity in the presence of five EPIs: PAN (20 mg/l), NMP, verapamil, reserpine (100 mg/l) and cyanide 3-chlorophenylhydrazone (CCCP) (0.25 mg/l).

SDS-PAGE analysis of outer membrane proteins (OMPs)
OMPs from adapted strains were isolated after 5, 10 and 15 passages from the cell pellets with ProteoExtract® Transmembrane Protein Extraction kits (Novagen).The concentrations were determined using Protein Assay (Bio-Rad). The absorbance was measured at 595 nm using a microplate reader (Tecan). The proteins were analysed with a NuPAGE® electrophoresis system (Invitrogen) in 12% acrylamide NuPAGE® Novex Bis-Tris gels. The gels were stained with the fluorescent stain ruthenium II tris-bathophenantroline disulfonate (RuBP) (B*iotium)* according to the published protocol (Lamanda et al., 2004) and documented using the G: BOX-HR gel documentation system (Syngene). Protein bands were then quantified with Bionumerics v6.6 software (Applied Maths NV). The concentrations of the sample proteins in the protein bands were calculated as described previously (Zupan et al., 2009).

Transmission electron microscopy (TEM)
The cell morphology was assessed for each pre-adapted and adapted strain after 5, 10 and 15 passages using TEM as described previously (Klančnik et al., 2008). Negatively stained cultures were examined with a CM100 electron microscope (Philips Electronics N.V) with the magnification ranging from 13,500× to 34,000×.

Statistical analysis
Statistical analyses were performed with IBM® SPSS® software v17.0 (T-test and Pearson χ^2 test). Results were considered significant when $p \leq 0.05$.

RESULTS AND DISCUSSION

Antimicrobial susceptibility testing

In total, 42 *C. jejuni* and *C. coli* isolates were tested for their susceptibilities to ERY, CIP, five biocides (TLN, BC, CHA, CPC and TSP) and SDS. The range of concentrations for antibiotics and biocides (in two-fold increases) and the breakpoints for antibiotics were used according to CLSI (2007). With regard to antibiotic resistances, 33 out of the 42 strains tested (78.6%) were susceptible and 9 out of 42 (21.4%) were resistant to ERY, and a half of these strains tested (51.4%) were resistant to CIP. The resistance to both antibiotics tested was observed in 16.2% of tested strains. A significant difference in ERY resistance was observed between *C. jejuni* (6.7%) and *C. coli* (29.6%). A higher rate of multi-resistance was also found in *C. coli* (20.8%) than *C. jejuni* (6.7%). Higher rates of ERY resistance among *C. coli* than among *C. jejuni* have been reported previously (Kurinčič et al., 2005). A similar situation was observed for the triclosan resistance. *C. coli* strains were in general more resistant than *C. jejuni* strains. Conversely, the level of BC resistance was higher in *C. jejuni* than in *C. coli*. The overall level of biocide resistance was not significantly different in strains with different antibiotic resistance level. No statistically significant correlation was observed between antibiotic and biocide MICs.

Involvement of efflux pump activity

The efficiencies of EPIs PAN and NMP were determined for each strain, in terms of the resistance to all 8 antimicrobials. Table 1 gives the effects of both EPIs in *C. jejuni* and *C. coli.*

Table 1. The effect of PAN and NMP to MIC reduction in *C. jejuni* and *C. coli*

Species	**PAN** (10 mg/l)			**NMP** (60 mg/l)

**The number of strains / the number of tested C. jejun or C. coli strains*

Both of the EPIs can partially reverse the resistances to all antimicrobials tested and expressed different target preferences. PAN was less effective in reversing the susceptibilities in *C. jejuni* than in *C. coli*, which can explain the lower occurrence of antimicrobial resistance among *C. jejuni* than *C. coli.* The effects of the *cmeB, cmeF* and

cmeR gene inactivation on antimicrobial resistance in the *C. jejuni* NCTC 11168 strain and the effects of PAN and NMP addition are given in Table 2. The MICs of the antimicrobials were reduced in *cmeB* and *cmeF* mutants and increased in the *cmeR* mutant, with few exceptions. Both of these putative EPIs further decreased the MICs of the antimicrobials in these mutant strains.

Table 2. The antimicrobial MICs in the absence and presence of PAN (10 mg/l) and NMP (60 mg/l) in C. jejuni NCTC 11168 reference and mutant strains. Changes of at least 4-fold are indicated in bold

Strain	MICs							
	TNL (mg/l)	BC (mg/l)	CPC (mg/l)	CHA (mg/l)	TSP (mg/l)	SDS (mg/l)	ERY (mg/l)	CIP (mg/l)

Adaptation to biocides

Repeated exposure of *C. jejuni* and *C. coli* to biocides resulted in partially increased resistance and acquisition of cross-resistance to dissimilar biocides and antibiotics (data not shown). The developed resistances were partially stable. Active efflux is one of the mechanisms involved in this adaptive resistance. More than one type of efflux pumps was identified on the basis of restored sensitivity in the presence of five different EPIs that block different types of efflux pump systems (data not shown). According to the noted changes in the OMP profiles and their content in the adapted strains, this could be an additional mechanism involved in adaptation. However, each of the adapted strains had different alterations in their OMP profile. Electron micrographs revealed several morphological changes after adaptation, which differ between the different biocides, as well as between the individual strains.

CONCLUSIONS

Among 42 *Campylobacter* strains studied, different antibiotic and biocide resistance levels were seen. The multidrug resistance was also observed, but no correlation between biocide and antibiotic resistance was confirmed. Active efflux is a crucial mechanism involved in antibiotic and biocide resistance in *C. jejuni* and *C. coli*, wherein more than one type of active efflux is employed. Repeated exposure to biocides resulted in the partial increased resistance and acquisition of cross-resistance to biocides and antibiotics. Developed resistance was partially stable. More than one type of active efflux was identified in adapted strains, which expressed also different alterations in OMP profiles and morphological changes. However, these adaptations were strains specific; no species specific mechanisms were recognized.

ACKNOWLEDGEMENTS

The authors are grateful to the Ministry of Higher Education, Science and Technology of the Republic of Slovenia for financial support for this project, and especially for a PhD grant to A.M. that enabled this study on *Campylobacter* spp.

ABSTRACT: An objective of this study was to evaluate the behavior of three domestic sunflower hybrid fruits on compressive loading considering seed moisture content. Those were Bačvanin, Krajišnik and Šumadinac hybrids. The mean bio yield force, deformation, work and bio yield modulus are presented, as a result of quasi-static fracture measurements of fruits. A sample of 15 seeds was randomly selected from the bulk of each hybrid at four different seeds moisture content range from 5.9 to 36.8% w. b. The fruits of Šumadinac and Krajišnik demonstrate low values of bio yield force from 29.3 to 45.2 N at low moisture content of fruit (between 3.7 and 5.9% w. b.). Opposite result was measured for Bačvanin hybrids (76.2 N) within the same moisture content of seeds. The machine head displacement has increasing tendency as the seeds moisture content increase for all hybrids. The linear model shows a decreasing trend of bio yield modulus for all hybrids as the moisture content of seeds increased, with high values of the coefficient of regression.

INTRODUCTION

The sunflower is the most important oil crop in the Republic of Serbia. According to data from the Statistical Office of the Republic of Serbia (www.webrzs.staserb.sr.gov.rs), over the last decade, cultivable sunflower land comprised approximately 170000 hectares, with the gross production of 380000 tonnes of grain per year. Approximately 92% of this production occurred in Vojvodina Province. Sunflower farming has a long tradition in the Balkan Peninsula. Sunflower fruit is the raw material used for sunflower oil production for human consumption, and its defatted meal, as a feed for livestock, has advantages over other oilseed farm crops.

By botanical definition, the sunflower is a fruit or seed consisting of two main parts. The hull or pericarp is a visible outer component that protects the inner kernel. Information about sunflower seed and kernel physical and mechanical properties are necessary for seeding, harvesting, handling, drying, storage and further processing. The quality of sunflower kernels is not evaluated solely by the physical traits like three perpendicular dimensions, surface area, sphericity, thousand kernels weight, bulk and true density, porosity and static coefficient of friction. The behaviour of the sunflower fruit during compressive loading is one of its textual properties. The processing of sunflower for food and feed requires various types of mechanical treatment that depend on external forces, for instance the compression loading behaviour affects milling process or hullability, therefore is necessary data for every new hybrid. The intensity of the external force necessary to crush the fruit depends on the composition of the kernel and the arrangement of its structural elements. The study of the behaviour of the non-homogeneous organic structure of sunflower kernels on compression loading offers a basis for general conclusions regarding how this type of change might be achieved. Furthermore, because compression behaviour is important in sunflower processing, studies that measure such behaviour over a wide spectrum of kernel moisture content are desirable.

The compression loading test shows the response of biomaterials to an applied external force that deforms the body and induces a change in dimension, shape or volume. This test provides important information about elastic or plastic behaviour. The stress-strain uniaxial compression test shows the response of biomaterials to an applied external force. The

stress-strain curve is a graphical measure of the mechanical properties of a biomaterial. The stress-strain biomaterial behaviour should be differentiated from hardness, which defines the resistance of metal to deformation, usually by indentation. This term may also refer to resistance to stiffness or temper, or resistance to scratching, abrasion, or cutting.

The stress is an external force (F) upon a cross section area (A_o) of the specimen. An important aspect is not the quantity of force, but rather that it is applied to a cross section area (Mohsenin, 1980). This is the reason the specimen is a regular shape such as a cylinder or cube. The stress is identified as compressive, tensile or shearing according to the straining action and it is referred to using the Greek letter σ. The unit of stress is (N m^{-2}) and its equation (Đorđević, 1999) is:

$$\sigma = F/A_o \quad (1)$$

Compressed biomaterial changes in length (L). The ratio between displacement (δ) and initial specimen length (Lo) is strain (ε). The unit of strain is nondimensional (-) and the equation is:

$$\varepsilon = \delta/L_o = (L-L_o)/L_o \quad (2)$$

where displacement is $\delta = (L-L_o)$. The strain is an internal reaction of the biomaterial particles induced by the external force. The stress-strain diagram is a graphical presentation of the values simultaneously recorded for stress and strain. The graph indicates biomaterial properties associated with elastic and inelastic behaviour. The typical shape of this curve is presented in Figure 1. Point P in the figure is known as the proportional limit. Stress and strain are linearly correlated. Therefore, the slope of the straight line section is termed the modulus of elasticity, E, or Young's modulus

$$E = \sigma/\varepsilon \text{ or } \sigma = E\,\varepsilon \quad (3)$$

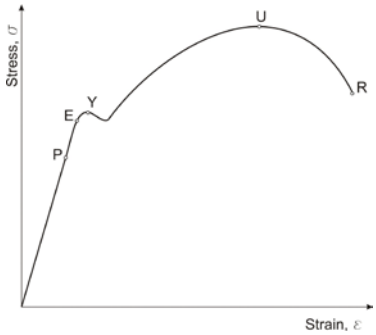

Figure 1. Stress-strain curve

The unit of Young's modulus is (N m^{-2}). The equation (3) is the well-known Hooke's law. The point E in Figure 1 represents the maximum stress that can be applied without resulting in permanent deformation when the specimen is unloaded, whereas point Y is the elastic limit or bio yield point force. After the yield point, the resistance of the material to stress decreases. Therefore, after the peak of the curve, the "yield of displacement" is observed.

Previous studies have described the physical and mechanical properties of sunflower seeds. Jafari et al. (2011) and Santalla and Maschroni (2003) determined sunflower seed properties as a function of moisture content, while Perey et al. (2007) reported similar results for wild sunflower seeds. The compressive load behaviour of sunflower fruits is tested by applying an external force F (N), upon the specimen. The stress-strain diagram represents simultaneous values of force and head displacement (stress) recorded during testing. Within the biomaterials, such as sunflower fruits, the bio yield point force is marked (Mohsenin, 1980). From an engineering point of view, information about the value of the bio yield point force F (N), and head displacement or deformation δ_H (mm), for different hybrids is interesting and relevant. The behaviour of sunflower seeds during compressive loading was reported by Gupta and Das (2000), and the results emphasised the differences of seed orientation (horizontal and vertical) at different seed and kernel moisture contents and the corresponding effects on rapture force, deformation and energy absorbed. The authors concluded that compressive rapture force for unhulled seeds and kernels decreases as the moisture content increases, and higher force values were observed for seeds in the vertical orientation.

Khodabakhian et al. (2011) conducted similar research with three sunflower hybrids, as Voća at al. (2008). Similar to the sunflower, the physical and mechanical properties of other biomaterials are available, like for wheat (Babić et al., 2011; Dobraszczyk et al., 2002), vetch seed (Taser et al., 2005), for soybean kernels (Babić et al., 2001), popcorn seed (Karababa, 2006), chick seed (Konak et al., 2002), barley (Ozturk and Esen, 2008), oats (Gates, 2004) and legume seeds (Kaskowski et al., 1999).
The objectives of this study were to provide new information describing the compression loading behaviour of three domestic sunflower hybrids at different moisture contents. The results of the study were statistically processed using Statistica (www.statsoft.com) version 9.0 and Microsoft Office Excel.

MATERIALS AND METHODS

Seed samples

Three sunflower hybrids from the 2010 harvest season (Krajišnik, Šumadinac and Bačvanin) were tested. The samples (5 kg) were obtained from experimental fields of the Institute of Field and Vegetable Crops, Novi Sad. The seeds were manually cleaned to remove all foreign matter. Each sample was divided into four groups that were adjusted to different moisture contents for testing compression loading. The seeds were kept in sealed plastic bags and stored in a refrigerator at 4 °C. Before each compression test, the sample was removed from the refrigerator and allowed to equilibrate to room temperature. The moisture content was determined according to Regulations about agricultural crops quality (1987) and expressed as Mc (%) on wet basis.

Mechanical properties

Tests of sunflower seed compression in this study were conducted using whole non-grade fruits. Compression tests were applied to fruits in the horizontal orientation. Fifteen replicate tests were conducted for each hybrid, and four different moisture contents of each hybrid. The testing equipment consisted of a loading cell and a computer running the TMS-PRO Texture measurement system (Food Technology Corporation); a trigger load from 0.5 to 450 N was used. The constant deformation rate was 60 mm/min before contact with the specimen and 30 mm/min during compression. The bio yield modulus of elasticity, Ey (N/mm), is the ratio of bio yield force F and machine head displacement or deformation mean value, δ_H (mm), for certain hybrids and moisture contents (Mohsenin, 1980).

RESULTS AND DISCUSSION

The mechanical behaviour of the sunflower fruit under uniaxial loading is a function of its moisture content and genotype. The presence of a larger amount of water in the hull and kernel increases the volume. The water molecules enter the polymeric chain and force it to rearrange, which effects on the compressive behaviour of the whole fruit. The bio yield point force-moisture content curves for three sunflower hybrids are shown in Figure 2. The hybrid Bačvanin attains maximum bio yield forces of 69.7 N with a moisture content of 12.8%. Further increasing the seed moisture content causes a decreasing of bio yield forces. A similar trend was observed by Gupta and Das (2000) during the sunflower seed compression test with horizontal orientation of seed. The same authors emphasised that the hull is fragile at lower seed moisture contents. Therefore, the initiation of its rapture occurs at lower bio yield force values. The results of this study confirm data findings for Šumadinac and Krajišnik hybrids. The low value of bio yield force (34.78 N) was measured with Šumadinac at seed moisture content of 12.5%, while Krajišnik demonstrated the force of 47.6% at 12.7% of seed moisture content. The compressive load behaviour of these two hybrids is quite different as the moisture content increase compare to Bačvanin hybrid. This different behaviour probably results from the histological architecture of the hull.

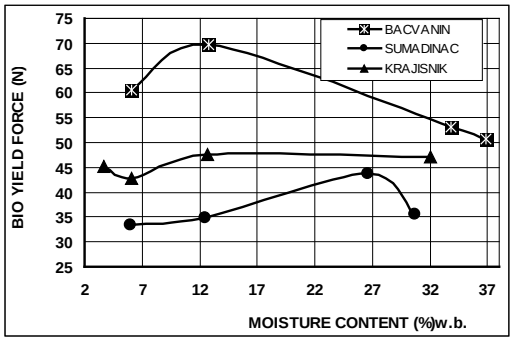

Figure 2. Bio yield force versus seeds moisture content of sunflower hybrids

The two main components of the hull are the sclerenchyma and parenchyma (Hernandez and Belles, 2007), which occupy 20-27% d. b. of the entire fruit. The scerenchyma consists of lignin (20-25% d. b.). The pericarp is arranged in several layers that differ between the cells structure and mechanical properties. The outside of the epidermis is composed of cells that are rectangular in shape. The hypodermis has cells with thin walls. Sclerenchyma cells are polygonal and insert with parenchyma cells at regular spaced intervals in the shape of rays. Such a biochemical construction differs significantly of sunflower genotype and agroecological condition of production, which is the only explanation of the different behaviour. The relationship between bio yield force and the moisture of seed for those hybrids is expressed by the following equations:

For Bačvanin $F=-0.4561Mc+68.742$ $R^2=0.6534$

For Krajišnik $F=-0.0113Mc^2+0.5194\ Mc+42.126$ $R^2=0.5448$

For Šumadinac $F=-0.0066Mc^3+0.3172Mc^2-3.9179Mc+47.016$ $R^2=1$

Deformation (machine head displacement) of the sunflower fruits at bio yield force is plotted in Figure 3. The values of head displacement are a narrow range for all hybrids at lower moisture content because the hull and kernel are both brittle.

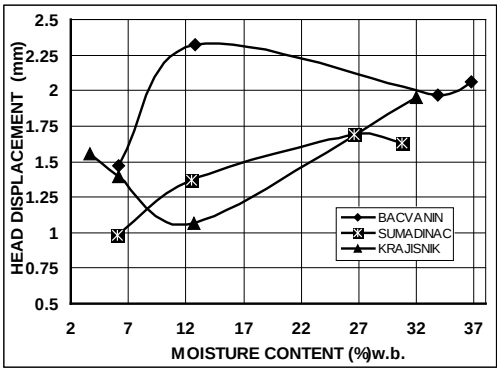

Figure 3. Relationship between head displacement at the bio yield point

The hybrids Šumadinac and Krajišnik expressed an increasing trend of deformation as the seed moisture content increases. The same observation was previously reported by Gupta and Das (2000) and Jafari et al. (2011). The results of this study statistically confirm the linear relationship among the head displacement and seeds moisture content. The equations for these relationships are:

For Šumadinac $\delta_H = 0.025\ Mc + 0.9248$ $R^2=0.8765$

For Krajišnik $\delta_H = 0.0182\ Mc + 1.2426$ $R^2=0.4031$

Bavčanin hybrid exhibited a maximum deformation of 2.43 mm at a seed moisture content of 13.5% w.b. As the seed moisture content of these hybrids increases, the maximum deformation values decrease, according to following equation:

For Bačvanin $\delta_H = -0.0002\ Mc^3 - 0.0175\ Mc^2 - 0.3935\ Mc - 0.3329$ $R^2=1$

The work of bio yield forces at different seed moisture content is presented in Figure 4. The increasing work values occur when the seed moisture content increases (similar to

increasing trends for deformation) for hybrids Šumadinac and Krajišnik. These results are in agreement with the report by Gupta and Das (2000) on absorbed energy of sunflower seed and kernel, for moisture content ranging from 4.21 to 10.65% d. b. Bačvanin hybrid has a decreasing bio yield work tendency as a function of the seed moisture content.

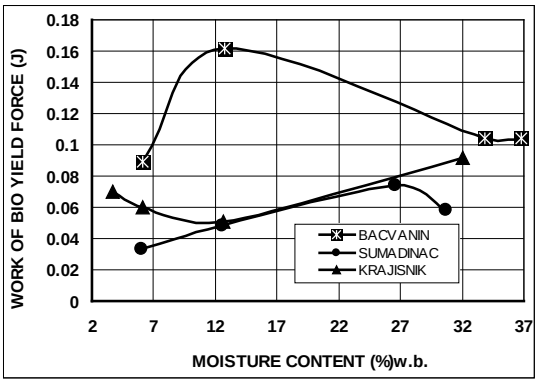

Figure 4. The work of bio yield forces for tested hybrids

Šumadinac, Krajišnik and Bačvanin hybrids demonstrate a decreasing trend of bio yield modulus of elasticity as the fruit moisture content increases. These results statistically confirm the linear relationship between the bio yield modulus of elasticity and the seed moisture content (Figure 5). The equations that express these relationships are:

For Šumadinac	Ey= -0.375 Mc + 33.936	R^2=0.6945
For Krajišnik	Ey= -0.2044 Mc + 30.112	R^2=0.6953
For Bačvanin	Ey= -0.4282 Mc + 40.316	R^2=0.7732

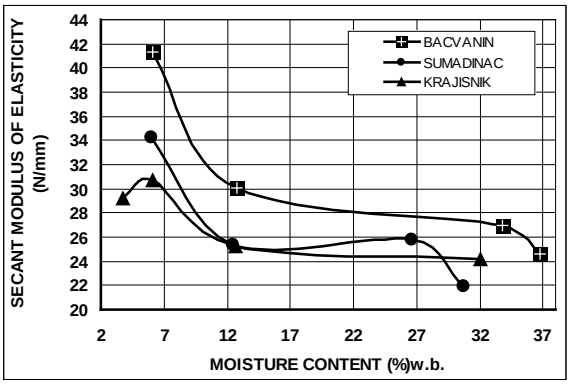

Figure 5. Bio yield modulus of elasticity of tested hybrids versus seed moisture content

The sunflower kernel occupies the inner space only partially, there is intermediate space between kernel and hull filled with spongy and elastic tissue. Those tissues are not a barrier to external force, so after the cracking of the hull, the stress is generated in the kernel. Such stress is not generated in tested hybrids because the hollow inside of the seed is filled with the kernel, which produces some extra resistance to external force. The second important issue that affects the differences in compressive behaviour of these hybrids is the arrangement of pericarp tissues (Hernandez and Belles, 2007), which is characteristic of the genotype.

CONCLUSION

For hybrids Šumadinac and Krajišnik, the increase of bio yield force work values occurs when the seed moisture content increases. The Bačvanin hybrid has a decreasing bio yield work tendency as a function of the seed moisture content. Šumadinac, Krajišnik and

Bačvanin demonstrate a decreasing trend of bio yield modulus of elasticity as the seed moisture content increases.

ACKNOWLEDGEMENT

The study has been granted by Ministry of Education and Science, Republic of Serbia, project No TR-03105.

ABSTRACT: Production of sugar beet and granulated sugar in environmental conditions of the Province of Vojvodina is possible but to have a successful production optimal technology must be applied. Production of sugar beet and granulated sugar is virtually impossible without the use of modern cultivars with triple tolerance to the most important diseases: *Cercospora beticola*, rhizomania and *Rhizoctonia solani*. Field microtrials involving cultivars with various levels of tolerance towards the most important diseases of sugar beet were set in 2009, 2010 and 2011, in four replicates. The root yields were determined on the site whereas the chemical analyses were conducted in the laboratory of the Institute of Food Technology in Novi Sad. In 2009, sugar beet showed the best processing quality, followed by those harvested in 2011 and 2010. All seven indicators of processing features were best in sugar beet harvested in 2009. But, the mean root yield was the highest in 2011, reaching the value of 100.02 t/ha whereas it was the lowest in 2009, 88.77 t/ha. The yields of granulated sugar were significantly dependent on cultivar, year and locality. The highest yield of granulated sugar, averaged over cultivars and years, was obtained in 2011 (14.246 t/ha) with Prestige as the best performing cultivar. In contrast, the lowest granulated sugar yield was registered in 2010 with a mean value of 10.566 t/ha, averaged over cultivars and localities. The poorest performance regarding this parameter was shown by cultivar Kontrola I (9.539 t/ha).
Key words: *sugar beet, processing quality, yield, root, granulated sugar*.

INTRODUCTION

The importance of cultivar in the estimation of sugar beet productivity under the agro ecological conditions of the Province of Vojvodina is rather high (Radivojević et al., 1999).
During the last decades, overlapping the period of transitional economy, narrow crop rotation of sugar beet (growing in 2-year rotation or even monoculture) prevailed in large percentage in our country, driven by a desire for quick profit. Hence, it is very important to carefully choose the sugar beet cultivar especially in respect to their tolerance against the main diseases (Märländer, 1991; Uphoff, 2011). The most important diseases occurring under our agro ecological conditions are: *Rhizomania, Rhizoctonia solani*, *Cercospora beticola*, etc.
Taking into consideration the aforementioned, it is important to know the quality of field and level of infestation i.e. the status of inoculums in the field. It is important to note that sugar beet cultivation on certain smaller percentage of fields in the Province of Vojvodina is not considered cost-effective (Radivojević et al., 1999; Radivojević et al., 2008). On these fields, inoculums of different sugar beet diseases have been accumulated causing significantly lower taproot yields with poor processing performances and marginally low granulated sugar yields.
The major growing regions in the Province of Vojvodina differ widely regarding soil fertility and climatic conditions. The four localities included in the field trials are positioned in the regions most favourable for sugar beet cultivation. The years during which the trials were conducted were prominently differing regarding climatic factors.

MATERIAL AND METHODS

Experiments were sown for 3 successive years (2009, 2010 and 2011) and included seven sugar beet cultivars. The trials were settled at four locations across the most important sugar beet growing regions in Vojvodina: Pančevo, Bečej, Sombor and Stara Pazova. Sugar beet genotypes were planted in a randomized block design with four replications at each location and each cultivar was plotted in six rows. The trials were optimally sown in the third decade of March. The microtrial plots were optimally treated regarding fertilization, pest and weed control with respect to conditions characteristic for the growing region. After growing shoots, appropriate weed control was applied including manual weed control which was repeated three times. Besides that, sugar beet crop was protected against *Cercospora beticola*. In 2010, four treatments were applied. Additional fertilization of crops was omitted, only major fertilization as a part of basic cultivation was applied. Taproots were harvested in optimal period, in the middle of October from harvesting plots of 9.80 m^2. The sugar beet cultivars sown in the trials were highly tolerant to *Cercospora beticola* and *Rhisomania*, some of which even to *Rhizoctonia solani*. The studied cultivars are all registered and approved and belonged to the following types: Tibor, Markus, Elmo, Sandor and Elvis were "Z" type whereas Victor and Prestige belonged to „N/Z“ type.
The sugarbeet processing was carried out in the beet laboratory of the Institute for Food Technology in Novi Sad. The analyses of beet composition were performed from fresh beet brei clarified by lead acetate according to the methods published in the Handbook. Sucrose content was determined polarimetrically by a digital automatic saccharometer (Saccharomat IV, Schmidt + Haensch, Germany). Potassium and sodium contents were analyzed by atomic absorption spectrophotometry (Carl Zeiss, Germany). α-amino-N was determined by the Blue number method (spectrophotometer Specord M40, Carl Zeiss, Germany).
The calculation of most important parameters was according to standard formulas (Milić et al., 1992).
The obtained results were analyzed using ANOVA procedure for 3-factorial experiment (Software GenStat v.9., Rothamsted Experimental Station). The factors were cultivars, localities and years.

RESULTS AND DISCUSSION

Taproot yields

Mean taproot yield, depending on cultivar and year was 87.77 t/ha in 2009, 91.43 t/ha in 2010 and 100.10 t/ha in 2011 (Table 1). Maximal variation in taproot yield, averaged over three years was 14.75 t/ha and individual variations by years were significant and ranged from 15.93 t/ha in 2010 to 17.17 t/ha in 2011. Cultivars rang varied due to year among Prestige, Elmo and Victor.
Analysis of variance of the data set showed that the highest influence on taproot yield can be attributed to the interactive effect of year x locality (38.40%), then to the effect of locality (16%) and year (9.69%). Variation due to year was not high which harmonizes with the findings of Webster et al. (1977). The aforementioned effects and their interaction were statistically significant. The influence of cultivar was statistically significant (8.08%) as was the interaction effect between year and cultivar (2.04%). Cultivar-locality interaction was not significant (2.44%). Significant year-cultivar-locality interaction was found (7.76%). The variance of total experimental error was 15.30%.

Table 1. Variations in taproot yield due to cultivar and year

Cultivar	Cultivar type	2009		2010		2011		Mean 2009-2011

Sugar content

Mean sugar content in root depending on cultivar and year was 17.59% in 2009, 14.23% in 2010 and 16.56% in 2011 (Table 2). Maximal deviation in the sugar content was 1.02%, averaged over three years and individual deviations by year spanned over the range 1.04% (in 2011)-1.42% (in 2009). Individual variations in this parameter within the cultivars were statistically significant. Over years, cultivars rang varied between cv. Tibor and Markus.

Table 2: Sugar content in root averaged over cultivars and year

Cultivar	Cultivar type	2009		2010		2011		Mean 2009-2011	
		%	rang	%	rang	%	rang	%	rang
Tibor	Z	17.99	3	14.74	1	16.88	2	16.54	1
Victor	N/Z	17.60	4	14.31	4	16.26	5	16.06	5
Markus	Z	18.21	1	14.42	3	16.81	3	16.48	2
Prestige	N/Z	16.79	7	13.61	7	16.14	6	15.51	7
Elmo	Z	16.95	6	13.91	6	16.04	7	15.63	6
Sandor	Z	17.45	5	14.10	5	17.08	1	16.21	4
Elvis	Z	18.13	2	14.56	2	16.71	4	16.47	3
Annual mean		17.59		14.23		16.56		16.13	
Max deviation		1.42		1.13		1.04		1.02	

LSD (0.05) Year 0.10
Cultivar 0.15
Year x Cultivar 0.28

The highest variation in the sugar content was due to the effect of year (51.28%), followed by the interaction of year and locality (32.79%) and locality (7.33%). Similar findings were reported by Glattkowski and Märländer (1994). These effects and their interactions were statistically significant. The influence of cultivar on this parameter was 3.88%. The interaction between year and cultivar was statistically significant. Locality by cultivar interaction was 0.55% and year x cultivar x locality interaction was 1.08%, both of them reaching statistical significance. The variance of total experimental error was 2.23%.

Granulated sugar yield

The yield of granulated sugar content, averaged over cultivars and years, was 13.759 t/ha in 2009, 10.642 t/ha in 2010, 14.389 t/ha in 2011 (Table 3). Average maximal variation in this parameter over the three-year trial was 0.980 t/ha and individual variations ranged from 1.155 t/ha in 2010 to 1.655 t/ha in 2011. Individually, the differences within the tested cultivars were statistically significant. Cultivars rang depended on growing season and varied among Tibor, Prestige and Elmo.

Table 3: Granulated sugar yield averaged over cultivars and years

Cultivar	Cultivar type	2009		2010		2011		Mean 2009-2011	
		t/ha	rang	t/ha	rang	t/ha	rang	t/ha	rang
Tibor	Z	14.302	2	11.304	2	14.552	2	13.386	1
Victor	N/Z	13.070	7	10.846	3	14.472	3	12.796	5
Markus	Z	14.594	1	10.243	5	13.912	6	12.916	4

Annual mean		13.759		10.642		14.389		12.930	
Max deviation		1.524		1.155		1.655		0.980	

LSD (0.05) Year 0.36
Cultivar 0.55
Year x Cultivar 0.95

According to analysis of variance, major factor affecting the granulated sugar yield was year explaining 34.40% of total variance, followed by year x locality interaction (30.99%) and locality (11.60%). This is in concordance with data reported by Märländer et al., 1994. The influence of cultivar was much lower in relation to the influence of year and locality and their interactions and amounted to 1.28% of total variance. Cultivar by year interaction was also low (2.05%). All these influences were statistically significant. Cultivar by locality interaction was low and did not have statistical significance (accounted for 2% of total variance). But, cultivar x year x locality interaction was 6% and was very significant. The variance of total experimental error was 11.68 %.

Influence of cultivar on the granulated sugar yield was low, accounting to barely 1.28% of total variance. Similar results were reported in several other studies (Märländer, 1991; Wolf and Märländer, 1994; Glattkowski and Märländer, 1995).

Cultivar by year interaction had low impact on the granulated sugar yield (2.05%) but was statistically significant. Much lower influence of cultivar x year interaction on granulated sugar yield was observed by Wolf and Märländer, 1994.

CONCLUSIONS

In this study, the highest influence on the yield of taproots could be attributed to the year by locality interaction (explaining 38.40% of total variance), locality (16.29%) and year (9.69%). The effect of cultivar accounted for 8.08%. The magnitude of other influences was as follows: year by cultivar interaction 2.04%, cultivar by locality 2.44%, and year x cultivar x locality 7.76%. The variance of total experimental error was 15.30%.

Consistently the most important influence on the sugar content in root was exerted by the growing season accounting for 51.28% of total variance, followed by year x locality interaction (32.79%) and locality (7.33%). The effect of cultivar was 3.88%. Other

components of variance were: year x cultivar interaction 0.86%, cultivar x locality interaction 0.55% and year x cultivar x locality interaction 1.08% and total error (2.23%).
The results showed that the granulated sugar yield was most affected by the effect of year (34.40%), locality (11.60%) and cultivar (1.28%). Regarding interactive effects, the highest influence was due to year by locality interaction (30.99%). Other interactions were much less influential. Year by cultivar interaction was 2.05%, cultivar x year x locality interaction was 6% and the lowest was cultivar by locality interaction (2%).

ACKNOWLEDGEMENTS

The authors would like to express their gratitude to the Ministry of Science and Education of the Republic of Serbia for the financial support in the frame of Projects 20066 and III 46001.
The authors are also thankful to all farm communities for enabling the settlement of sugar beet micro trials.

ABSTRACT: The quality of wheat-based products is highly dependent on the quality of the used flour, where the quality of starch and protein fractions has the most dominant role. The degree of protein hydrolysis, which indicates the level of protein quality as well as the end-use flour quality, is determined by different methods (chemical, physical and rheological). The aim of this study was to determine the biochemical status of freshly harvested wheat in terms of the amount of free amino groups as an indicator of the protein hydrolysis degree. Determination of free amino groups was carried out from wet gluten by using modified method of Nielsen at al. (2001), where each sample was beforehand tempered at two different temperatures (30 and 37 °C). The temperature of 30 °C corresponds to the real baking conditions as well as it is commonly used in rheological measurements. Moreover, the temperature of 37 °C provides optimal conditions for the activity of hydrolytic enzymes present. Three wheat varieties were collected from two localities in northern Serbia in 2010/2011 production year. The selected localities were characterized with different micro-climatic conditions during grain filling and maturing. The obtained results indicated that the amount of free amino groups from the samples tempered at 30 °C to a greater extent depends on the locality, whilst the amount of free amino groups from the samples tempered at 37 °C to a greater extent depends on the variety. The further research should be carried out in different stages of post-harvest maturation of wheat as well as in optimal stage of flour maturation.
Key words: *wheat, quality, gluten, free amino groups, micro-climatic conditions*

INTRODUCTION

It is known that protein molecules are linear polymers of amino acids. There are 20 different amino acids, each of them having the combination of a carboxyl group (-COOH) and an amino group (-NH_2) with a side chain that provides the essential difference between all of them. The amino acids are linked together by peptide bonds to form a polypeptide chain (). The sequence and specificity of amino acids are contained exactly in the generic code of the genes, thereby ensuring that the protein will be made in the same manner each time in the specific species and tissue. Amino acids that are considered to be direct products of hydrolysis of proteins are divided into neutral (with equal number of -NH_2 and –COOH groups), basic (with more -NH_2 over –COOH groups) and acidic (with more –COOH over -NH_2 groups) amino acids. The processing properties of a wheat cultivar can significantly vary as a result of climate and cultivation factors (Prieto et al., 1992; Weegels et al., 1988). Recent researches have implicated interference from high temperatures (over 35 °C) during the ripening of the grain. Evidence has been provided that these extreme weather conditions may cause a redirection of protein synthesis, thereby changing the protein quality and thus the dough properties (Wrigley et al., 2004).
The aim of this study was to determine the biochemical status of freshly harvested wheat in terms of the amount of free amino groups as an indicator of the protein hydrolysis degree. The ninhydrin, trinitrobenzenesulforic acid hydrate (TNBS), and fluorescamine reactions and the formol titration technique are commonly used to evaluate the free amino groups. The pH-stat technique is used to evaluate the free α-amino groups (Navarrete del Toro, García-Carreño, 2002).

MATERIAL AND METHODS

Three wheat varieties (Pobeda, Apache and Zvezdana) were collected from two localities in northern Serbia in 2010/2011 production year (Locality 1 and 2).
The localities were selected on the basis of the results of monitoring of microclimatic conditions and the results of commercial and technological quality of the selected wheat varieties during the last decade. Unstable climatic condition during May was suitable for *Fusarium* development, so it was necessary to apply appropriate agro-technical measures. A weather condition in the Locality 1 was characterized by moderate drought, whilst a severe drought was recorded in the Locality 2. Locality 1 was characterized with absolute maximum air temperature ranged from 29 to 30 °C, absolute minimum temperature (1-2 °C), weak and moderate ground frost, as well as short-term poor frost on 2 m height, which did not cause serious damage. Total rainfall ranged from 39 mm (Locality 1) to 46 mm (Locality 2). June 2011 was characterized by variable and moderately warm weather with rainfall deficits. The absolute maximum air temperature in the Locality 1 ranged from 30 to 33 °C, whilst in the Locality 2 ranged from 31 to 34 °C. In July, a period of dry and warm weather allowed the wheat harvest by mid-month to an end. The absolute maximum air temperature in the first week of July stood at 36 °C in the Locality 1 and 38 °C in the Locality 2 (http://www.hidmet.gov.rs).
Wet gluten and protein contents of wheat were determined using near-infrared grain analyzer Infratec 1241 (Foss Analytical AB, Denmark), Besatz content and structure were determined according to Pravilnik o kvalitetu poljoprivrednih proizvoda koji se skladište u javnom skladištu (2010). Wheat samples were milled to flours using laboratory mill MLU 202 (Bühler, Switzerland) (flour extraction rate of 60%). Determination of rheological properties of wheat flour dough was done using the Mixolab (Chopin Technologies, France) according to the standard ICC method 173.

Samples preparation

Wet gluten balls of investigated three wheat varieties were obtained using the method ICC standard No.106/2, and each wet gluten sample was beforehand tempered at two different temperatures (30 °C and 37 °C) during different time intervals (0 min; 90 min; 135 min). The temperature of 30 °C corresponds to the real baking conditions and it is commonly used in rheological measurements. Moreover, the temperature of 37 °C provides optimal conditions for the activity of hydrolytic enzymes present.

Standard preparation

10 mg serine (Art. A0288902) was diluted in 100 ml deionized water to obtain the standard solution, which was used for preparing following dilutions: 0 µg/l; 620.031 µg/l; 1313.625 µg/l; 2774.376 µg/l; 4413.780 µg/l; 6252.855 µg/l; 8333.637 µg/l; 16667.274 µg/l; 33334.548 µg/l; 50001.822 µg/l; 66669.096 µg/l; 83336.37 µg/l and 100003.644 µg/l.

Standard measuring

100 µl serine standard was added to a test tube containing 500 µl o-phtalaldehyde (OPA) reagent and mixed for 5 s. The mixture was left to stand for exactly 2 min and the absorbance was measured at 340 nm (GBC CINTRA 303UV/VIS). This measuring was used to choose the dilution range for calibration curve. Standard calibration curve was constructed each day after setting spectrophotometer at 340 nm.

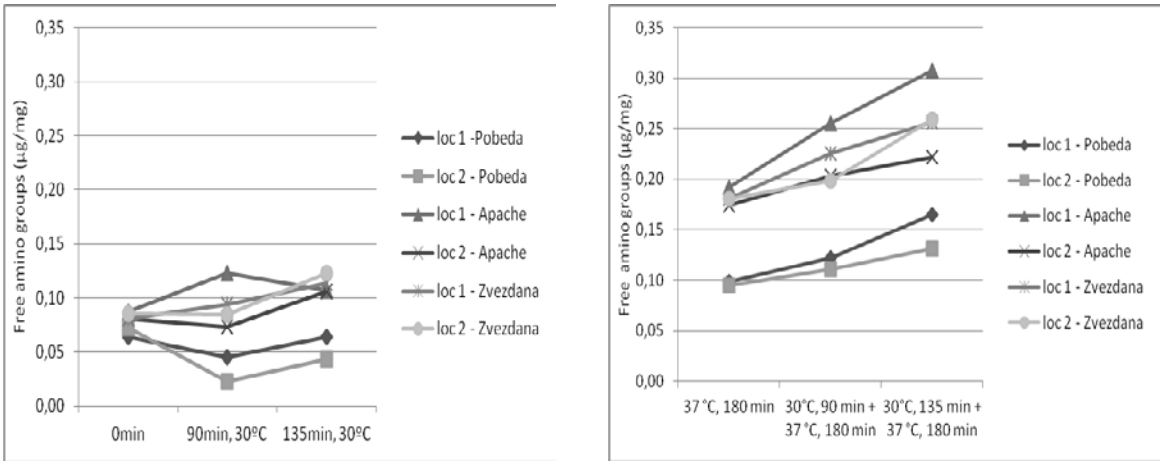
Quantification of amino groups

Changes in amount of free amino groups were determined by spectrophotometric assay using the modified OPA method of Nielsen at al. (2001). All spectrophotometric readings were performed at 340 nm (fixed before measuring with blank reagent (100 µl 1.0 ml KCl solution pH 1.0 and 500 µl OPA reagent containing mercaptoethanol (ME).
Wet gluten (100 mg) was suspended in 1.0 ml KCl solution pH 1.0, vortexed (Vortex V1 plus, BOECO) for 5 min and centrifuged (Centrifuge Minispin + Eppendorf) at 14500 x g for 6 min.

After that, 100 µl of clear supernatant was added to 500 µl OPA reagent containing ME, vortexed for 5 s, and transferred to test tubes (0.7 ml). As absorbance changes somewhat with time, it is important to leave the samples for exactly the same time (2 min) before measuring. Four replicates were made for each determination.

RESULTS AND DISCUSSION

The results obtained after incubation of wet gluten at 30 °C for 2 hours indicated that there were not significant changes in the content of free amino groups (Figure 1).



a) at 30 °C b) 30 °C plus 37 °C

Figure 1. Effect of wheat damage on the concentration of free amino groups of gluten during incubation at a) 30 °C and b) 37 °C and 30 °C plus 37 °C

The content of free amino groups of selected cultivars from two localities was approximately on the same level at 0 minutes, while incubation during 90 and 135 minutes led to differentiation in the content of free amino groups depending on the locality. After incubation of 135 minutes, the content of free amino groups of tested varieties was approximately on the same level as in the 0 minute.

The content of free amino groups in the tested flours (wet gluten) from physiological immature wheat increased with time during incubation at 37 °C, which provided optimal conditions for hydrolytic enzymes activity.

At the incubation temperature of 37 °C, the examined varieties manifested significant differences in the content of free amino groups. The increased content of free amino groups over time was noticed for all samples. Pobeda had the lowest content of free amino groups, with slightly influence of the locality, noticeable after 315 minutes (at 30 °C 135, and then at 37 °C 180 min) of incubation. The varieties Apache and Zvezdana had higher content of free amino groups compared to variety Pobeda. On the basis of free amino groups' content, variety Apache from both localities was characterized by poor technological quality due to the damage occurred during the grain formation. This was confirmed by the shape of the curve, which was in accordance with the results of Pérez et al. (2005).

Table 1 shows the selected indicators of physico-chemical and rheological parameters of the examined wheat varieties from two selected localities.

The highest content of free amino groups and the lowest protein and wet gluten content of variety Apache could be result of higher amount of wheat-bug damaged kernels. The present proteolytic enzymes influenced the release of certain free amino groups which were hidden in a structure of the protein polymer chain (Aja et al., 2004; Pérez et al., 2005). The variety Zvezdana from both localities showed the similar behavior.

Moreover, another possible reason for the increased content of free amino groups could be the influence of maximum temperatures in June from both localities that were very near the critical temperature for the protein synthesis. These influences affected rheological properties

of dough determined by Mixolab, such as the lowest water absorption and the shortest development time of dough.

Table 1. The selected indicators of physico-chemical and rheological characteristics of wheat

		physico-chemical characteristics of wheat						rheological parameters by Mixolab			
locality	varieties	wheat-bug damaged kernels (%)	spoiled and *Fusarium* infested kernels (%)	kernels with black point (%)	protein content (% dmb)	gluten content (%)	protein content in flour (% dmb)	water Absorption (%)	development time C1 (min)	C2 (Nm)	stability time (min)
1	Pobeda	0.40	0.48	0.86	12.7	26.6	11.5	58.3	6.60	0.51	9.38
	Zvezdana	0.42	0.68	0.46	13.2	27.6	12.2	58.4	8.78	0.53	10.63
	Apache	1.00	0.94	0.28	12.4	25.2	11.0	53.3	1.63	0.51	10.53
2	Pobeda	0.30	0.46	6.16	14.0	30.1	12.7	58.5	9.00	0.51	10.18
	Zvezdana	0.41	1.18	2.84	13.2	27.9	12.3	59.3	6.80	0.49	9.77
	Apache	0.70	0.28	2.54	12.6	25.6	10.9	53.3	1.40	0.55	10.90

dmb - dry matter basis

The variety Pobeda exhibited the least pronounced change in the amount of free amino groups, which was confirmed by the shape of the curve that corresponded to the good wheat protein quality. The presence of spoiled, *Fusarium*-damaged and black point kernels could be the additional cause of technological quality deterioration, due to their adverse effect on kernel protein fraction.
It was demonstrated that simply comparison of technological quality indicators of diverse varieties could be inappropriate if they are of different genetic origin, as Apache.

CONCLUSIONS

The obtained results indicated that the amount of free amino groups of the samples incubated at 30 °C to a greater extent depends on the locality, whilst the amount of free amino groups of the samples incubated at 37 °C to a greater extent depends on the variety. The further research should be carried out in different stages of post-harvest maturation of wheat as well as in optimal stage of flour maturation.

ABSTRACT: Essential oils are well known antimicrobials that may be used as alternative to synthetic preservatives in foods. The objective of the study was to evaluate the efficacy of different essential oils and their components on fungal growth and mycotoxins production. Minimal inhibitory concentrations (MICs) of essential oils of oregano, thyme, mint, fennel, pine needles and pinecones, and carvacrol, thymol, menthol and anisaldehyde were determined with broth microdilution method for *Aspergillus westerdijkiae*, *A. ochraceus*, *A. flavus* and *Penicillium nordicum*. Thymol, carvacrol and oregano, thyme and menthol essential oils were most efficient antifungals with growth inhibition of all strains already at concentrations 1/4 or even 1/8 of MICs in solid and liquid medium. Among tested fungi only *A. westerdijkiae* produced ochratoxin A, although growth was inhibited when antifungals were added to tested media. The study provides useful information of the potential application of essential oils as very efficient fungal growth inhibitors, but also of the risk of mycotoxin accumulation irrespective to fungal growth inhibition.
Key words: *Aspergillus*, *Penicillium*, *essential oil, antifungal*

INTRODUCTION

Moulds are natural food, raw material and feed contaminants. Moulds are the reason for food spoilage and thus great economics losses worldwide. Next to the moulds potential to cause yield losses and food decay, many species represent a serious health risk for consumers because of their dangerous secondary metabolites–mycotoxins (Fung and Clark, 2004; Kumar et al., 2008). The majority of mycotoxin-producing moulds can be found in genera of *Aspergillus*, *Penicillium*, *Fusarium*, and *Alternaria* which are also the most abundant contaminants of food and feed. The most important mycotoxins in terms of food safety are aflatoxins, ochratoxin A, patulin, fumonisins, zearalenone and trichothecenes (García-Cela et al., 2012).
The growth of fungi in foods is inhibited with application of different technological processes and various chemical additives. The consumers demand less use of synthetic preservatives but still they expect food to be free from microbial growth, toxins and other quality deteriorating factors). Additionally, resistance of moulds to chemical additives has led certain fungicides to become ineffective. There is a great need for new antifungal agents with alternative modes of action (Kabak et al., 2006). Research in recent years have shown that different essential oils can be very effective antifungal agents (Cheng et al., 2006; Bajpai Vivek et al., 2008; Kukić et al., 2008; Ahmadi et al., 2010). Effectiveness of essential oils as antifungal agents may, at least partly, be compared with the MIC (minimum inhibitory concentration) values that are in range from some µg/mL to several mg/mL. The comparison of MIC values is problematic because different essential oils are obtained with different procedures, different methods of testing antifungal efficacy, and different types of fungi, different media, and different conditions of cultivation. Determination of MIC values is not sufficient to define whether the production of mycotoxins is reduced or even increased.

Garcia et al. (2011) showed that in some cases, the inhibition of growth with plant extracts also caused reduced mycotoxin production (*Aspergillus westerdijkiae* produced ochratoxin A only in the control samples without addition of plant extracts), but in others it may be that inhibition of growth leads to stimulation of toxin production (ochratoxin A production by *Aspergillus carbonarius* was in presence of plant extracts higher than in the control for 7 and 21 incubation days). Another study showed that MIC of *Caesulia axillaris* Roxb essential oil for growth inhibition for toxigenic strain of *Aspergillus flavus* was higher (1.0 µg/mL) than for the inhibition of aflatoxin B1 production (0.8 µg/mL) (Mishra et al., 2012). Tian et al. (2011) showed that essential oil extracted from the fruits of *Cicuta virosa* L. var. *latisecta* Celak completely inhibited mycelial production of *Aspergillus flavus* at concentration of 5 µL/mL. Mycelial growth was observed at 4 µL/mL, but aflatoxin B1 production was completely inhibited. At lower concentration of essential oil (2 µL/mL) both growth and the aflatoxin B1 production was reduced to about half that of the control.
The aim of our work was to evaluate the effect of selected essential oils and their components on growth of mycotoxigenic moulds and their mycotoxins production.

MATERIALS AND METHODS

Fungal strains, culture media and conditions

The strains *Aspergillus westerdijkiae* ŽMJ26, *A. ochraceus* ŽMJ28, *A. flavus* ŽMJ30 and *Penicillium nordicum* ŽMJ31 were reference strains or isolated and reported previously to produce mycotoxins (Sonjak et al., 2011), They were incubated on Malt Extract agar (MEA) at 25 °C and on Yeast Extract Sucrose agar (YES) at 28 °C from 10 to 14 days for inocula preparation in concentrations of 10^4 and 10^6 spores/mL.

Essential oils, their components and other chemicals

Essential oils of oregano (*Origanum vulgare* L.), thyme (*Thymus vulgaris* L.) (Lakić et al., 2012), mint (*Mentha ×piperita* L.), fennel (*Foeniculum vulgare* Mill.), pine needles (*Abies alba* Mill.) and pinecones (*Abies alba* Mill.), and their pure components carvacrol, thymol, menthol and anisaldehyde (Sigma-Aldrich) were used for antifungal testing. Dimethyl sulfoxide (DMSO) (Merck, Darmstadt, Germany), 96% ethanol, toluene, ethyl acetate, 90% formic acid, chloroform and acetone (all obtained from Kemika, Zagreb, Croatia) were used as solvents while reagent p-iodonitrotetrazolium violet (INT) (Sigma-Aldrich) as indicator of fungal growth by microdilution method.

Minimal inhibitory concentration (MIC) determination by broth microdilution method

For the broth microdilution test 50 µL of spore suspension (10^4 spores/mL) in Tween solution was added to the wells of a sterile 96-well microtitre plate already containing 50 µl of two-fold serially diluted stock solutions of essential oils or pure components in RPMI-1640 medium. Control wells were prepared with RPMI-1640 medium, essential oils only, spore suspension only and DMSO solvent. Plates were put in a microplate shaker (Eppendorf, Hamburg, Germany) for 1 min and then incubated at 25 °C for 48 h for all tested strains except for *A. flavus*, which was grown at 35 °C for 24 h. To indicate metabolic activity the presence of colour was determined after adding 10 µl/well of INT dissolved in distilled water (2 mg/mL) and incubation under appropriate growth conditions in the dark. The MIC value was determined as the lowest concentration of an essential oil or pure component where no colour was observed. All measurements of MICs were repeated twice. According to the MICs, the most efficient oils were selected for further analysis.

Evaluation of the kinetics of growth inhibition

Stock solutions of the selected oils were added in Czapek Yeast Autolysate agar (CYA) to obtain the final concentrations of ½ MIC and ¼ MIC values. Spore suspension (10^6 spores/mL.) was inoculated on solid growth media containing desired concentrations of oils or components. Control samples without oil were also prepared. The growth inhibition was followed by measuring radial growth in 2-4 days intervals at 25 °C. It was also followed by

broth macrodilution test where stock solutions of essential oils were added in YES medium to give final concentration of ½ MIC values obtained in YES medium. 0.5 ml of spore suspension was added in medium in order to obtain final concentration 10^6 spores/mL. After 7, 14 and 21 days of incubation at 28 °C, fungal biomass was gravimetrically measured after chloroform extraction, filtration and drying to constant mass. Growth inhibition rate was calculated from the proportion of dried biomass in the sample containing essential oil comparing to control samples, both prepared in two replicates.

Detection of mycotoxins production by thin layer-chromatography (TLC)
Analysis was performed after 7, 14, 17 and 21 days of culture growth on CYA with silica gel TLC plates (Merck, Darmstadt, Germany) in solvent systems toluene-ethyl acetate, formic acid (5:4:1; TEF) for ochratoxin A (OTA) and chloroform-acetone (9:1; KAC) for aflatoxin B1 (AFB1). Identification of the mycotoxins with agar plug method was performed by comparison of spots from moulds chromatogram with standards (Samson et al., 2000).

RESULTS AND DISCUSSION

Selection of antifungal agents of the basis of MICs
The antifungal effect of 6 essential oils and 4 pure components was examined against mycotoxigenic fungi *A. westerdijkiae*, *A. ochraceus*, *A. flavus* and *P. nordicum.* According to MIC values determined with microdilution method (Table 1), thymol, carvacrol, oregano, thyme and for *P. nordicum* also menthol, were chosen for further analysis as most efficient essential oils. Thymol among the pure components and thyme essential oil showed the lowest MIC values for all tested strains. Obtained MIC values of essential oils were the basis for further testing.

Table 1. Antifungal activity of essential oils and their components expressed as MIC values

	Strain and MIC value			
Antifungal agent	***A. westerdijkiae***	***A. ochraceus***	***A. flavus***	***P. nordicum***
Thymol (mg/ml)	**0.13**	**0.13**	**0.10**	**0.05**
Carvacrol (µl/ml)	**0.20**	**0.39**	**0.78**	**0.07**
Menthol (mg/ml)	0.43	0.75	0.56	**0.06**

Fungal growth inhibition on solid media
The results of fungal growth on CYA agar plates are shown on Figure 1 (A-F).
Essential oils or their components determined with microdillution method and added in CYA in concentrations ½ or ¼ MICs, delayed or completely inhibited growth of all tested fungal strains. These results are in consistence with other literature data about thymol and carvacrol antifungal activity against different phytopatogenic fungi (Kordali et al., 2008). Inhibitory effect of essential oils or their components was proportional to their concentration, which was shown in the earlier study where essential oils of 12 medicinal plants including thyme, anise, fennel and mint demonstrate inhibitory activity against *Aspergillus* and *Fusarium* fungi (Soliman and Badea, 2002).

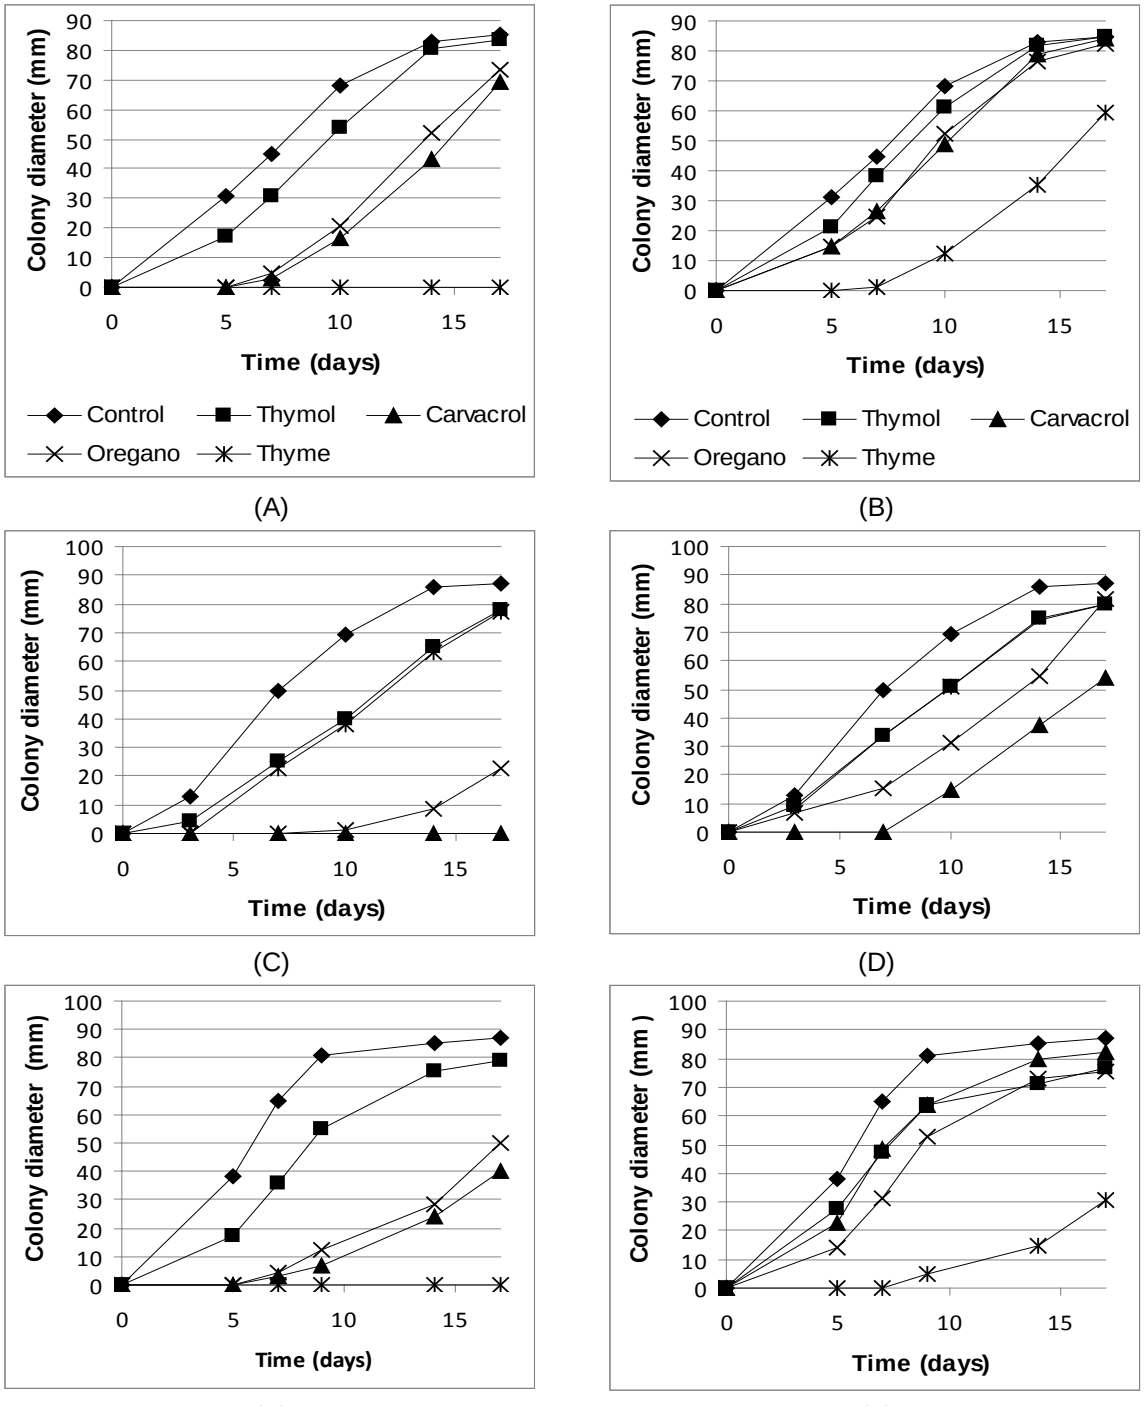

Figure 1. Fungal growth inhibition on CYA with addition of essential oils or their components in concentrations of ½ MIC (left) and ¼ MIC (right) for *A. westerdijkiae* (A, B); *A. ochraceus* (C, D) and *A. flavus* (E, F), respectively.

Fungal growth inhibition in liquid medium:

Thymol and carvacrol as well as thyme and oregano essential oils were the most efficient fungal growth inhibitors on agar plates, so they were tested for their inhibitory effect on *A. westerdijkiae* also in YES liquid medium. Concentrations in range from 1/8 to 1/2 of MICs were tested. These results also indicated antifungal effect of thymol, carvacrol, oregano and thyme essential oils against all tested strains but the efficiency depended on the selected agent and the strain. After 21 days the most efficient agents were oregano essential oil, thymol and carvacrol. Still, there are no reports of essential oils effect against *A. westerdijkiae*, however numerous studies indicate inhibitory effect of thyme, oregano and

thymol essential oils against *A. ochraceus* (Basilico and Basilico, 1999; Soliman and Badeaa, 2002; Nguefack et al., 2009). Until recently these two *Aspergillus* genera were classified as the same *A. ochraceus*, yet however, taxonomical diversity has been recognized (Frisvad et al., 2004). In case *of A. flavus,* growth inhibition in liquid medium was most efficient, including complete inhibition after adding ½ MICs of carvacrol or thyme essential oil.

Detection of mycotoxins production:
The results of determining the formation of mycotoxins by TLC showed that only *A. westerdijkiae* produced OTA in our experimental conditions. When thymol, carvacrol, oregano and thyme in concentrations of ½ MIC and 1/8 of MIC were added to solid and liquid media, the production of OTA was detected by TLC. Quantitative analysis is currently under study to highlight the possibility that mycotoxin production is even induced, when fungal growth is exposed to antifungal components of essential oils and not completely inhibited in growth, as it was reported recently for different *Aspergillus* mycotoxigenic species (Garcia et al., 2011; Mishra et al., 2012).

CONCLUSIONS

The study provides useful information on very effective fungal growth inhibition with plant essential oils and/or their components, especially thymol and thyme essential oils, but also the evidence of the potential risk of mycotoxin accumulation irrespective to fungal growth inhibition. Effective natural alternatives need to be evaluated as the inhibitors of growth and microbial secondary metabolite synthesis, before they can be effectively used in foods.

ACKNOWLEDGEMENTS

The authors are grateful to ARRS for financial support of the project V4-1079 and the Serbian Ministry of Science and Technological Development and ARRS to finance the bilateral project BI-SR-SLO-0034-10/11as well as for CEEPUS grant for M.A. that enabled this study. We are grateful also to Nina Hostnik and Saša Piskernik, who also contributed to this work.

ABSTRACT: The objective of this study was to assess the chemical and fatty acid composition of representative fish (common carp, silver carp, bighead carp, grass carp, tench, catfish and zander) which were collected from retail stores in area of Novi Sad. Chemical analysis and fatty acid determinations were carried out in the Institute of Meat Hygiene and Technology, Belgrade. The amount of protein was the highest in zander fillets (19.27%) and the lowest percentage of protein was found in grass carp fillets (14.73). Percentage of fat ranged from 1.8, in the muscles of zander, to 10.07 in the meat of carp. The total cholesterol content was the highest in Chinese carps fillets (around 65.38mg/100g), and the lowest in catfish (33.14mg/100g). The amount of saturated fatty acids (SFA) was the lowest in zander (28.6). Tench contained the highest percentage of polyunsaturated fatty acids (PUFA) 34.78% and the lowest percentage was detected in common carp (20.1%). PUFA/SFA, which is an indicator of the quality of lipids was the most favourable in zender 1.17. Also, significant is the ratio of unsaturated (UFA) to saturated (SFA) fatty acids in fish lipids and it was the best in the fat of zender 2.53, but no significance difference among species was not observed (p>0,01). The chemical and fatty acid composition of fish varies greatly between different species and within the same species. Quality of fish meat in our retail stores is quite good but it should be improved by using completed formulated feed mixtures on fish ponds.
Key words*: fresh water fish species, fatty acid, chemical composition, retail stores*

INTRODUCTION

Consumption of fish is increasing based on the recommendations of healthy nutrition (Komprda et al., 2003) and because of the knowledge about fat, protein and cholesterol content, and also quality of fat in fish meat. Ingredients of fish meat are very important in the prevention of cancer (Connor, 2000), brain aging and Alzheimer disease (Kyle, 1999), in the development and sustention of the nervous system, eyes and skin (Lauritzen et al., 2001). Fresh water fish species meat has been assumed to reduce the risk of heart disease, because of low levels of saturated fatty acids (Guler et al., 2008). Further, polyunsaturated fatty acids (PUFA) are often present at high levels in fish meat, especially those of the n-3 series which have particularly beneficial effects on health (Connor and Connor, 2010). The chemical composition of fish varies greatly from one species to another and one individual to another depending on the diet, age, sex, environment and season (Buchtová et al., 2010; Ćirković et al., 2011; Steffens and Wirth, 2007; Celik et al.,. 2005; Guler et al., 2008). Fatty acid composition also varies largely in dependence on the fish species, if they are wild fish or farm-raised, on the age of fish and on origin of diets and its composition (Steffens et al., 2005; Ćirković et al., 2010). Recently, several investigations about meat quality and safety of fish from our fishponds were carried out (Trbović et al., 2009, 2011; Ćirković et al., 2010, 2011, 2011a), but no data is available concerning fatty acids and chemical composition of warm water fish species in our market. The objective of this study was therefore to assess the chemical and fatty acid composition of commercial important fish (common carp, silver

carp, bighead carp, grass carp, tench, catfish and zander) which were collected from retail stores in area of Novi Sad.

MATERIAL AND METHODS

Meat quality of common carp, silver carp, bighead carp, grass carp, tench, catfish and zander which were obtained from retail stores in Novi Sad was analyzed in this study. Eight samples of each fish species were taken from different retail stores and stored at –18ºC prior toanalyses. The meat from dorsal muscles without skin was used for chemical analyses. Chemical composition of fish muscle tissue and feeds was determined by standard SRPS ISO methods. Fatty acids determination was performed according to Spirić et al. (2009) by capillary gas chromatography. Cholesterol determination in carp fillets (from direct saponification) was performed by using HPLC/PDA system (Waters 2695 Separation module/Waters photodiode array detector, USA) on a Phenomenex Luna C18 (2) reverse/phase column, according to Maraschiello et al. (1996). In quantification of cholesterol, external standardization was used, along with Empower Pro software to control the HPLC system for data acquisition and data processing as described (Spirić et al., 2009). Group effect was determined using one-way ANOVA (Statistica 10.0, StatSoft Inc.). Inter-group differences were attained by the Tukey HSD test at $p \leq 0.01$. The results were presented as means ± standard deviation.

RESULTS AND DISCUSSION

Regarding chemical and fatty acid composition of muscle tissue, it was expected to find some major differences within the same species and among different species in percentages of the nutrients monitored between tested fish species because the fish were from the different environment, they were of the different species and age, and were fed with different feed. The results of the chemical composition are shown in Table 1. It was observed that fat content varies the most in common carp (6.3-15%), bighead carp (3-10%), silver carp (4-8%), and the least in zander (1.5-2.2%). Protein content also varied but less than fat content, and variation was also the greatest in common carp (14.1-16.9%) and the lowest in silver carp (17.6-18.6%). Fauconneau et al. (1995) and Romvári et al. (2002) also reported that lipid content of common carp's fillet shows high variance (1–13%) in commercial size of fish depending mainly on previous nutrition. High average values of fat content observed in fillets of Cyprinids, especially in common carp, showed that the energy-protein ratio was not balanced in the feed of these fish in the great number of ponds. Variation within the same species was noted in the amount of total cholesterol, which was the biggest in common carp (43.2-65mg/100g). The total cholesterol content in fillets of carps is in agreement with the data of Wheeler et al., (1987); Vácha and Tvrzická (1995) and Bieniarz et al. (2000), who reported slightly higher cholesterol content in the most analyzed fish species (49-92 mg/100 g) in comparison with meats (45-84 mg/100 g) and it was lower for catfish, zander and tench (33, 42, 45, respectively), which is in agreement with our previous results (Ćirković et al., 2011). The total cholesterol content of the animal tissues can be influenced by the composition of the feed (Komprda, et al., 2003), that could be explanation of variations in cholesterol content because examined fish were from different ponds and fed different feed.
Significant variations in distribution of various fatty acids were noted between and within species. Fatty acid compositions, which are shown in Table 2, were in the wide range especially in fillets of common carp, so C16:0 was in range 17.3-33.4%. The amount of saturated fatty acids was notably constant in all examined species at around 30 %and palmitic acid was the dominant saturated fatty acid and no significance difference between species was not observed (P>0,01). The amount of C18:1c was in wide range in common carp fillets and the least value was observed in silver carp fillets (12.5%). C22:6n-3 varied between species and within the same species, it was the lowest in fillets of common carp and the most favourable in fillets of zander. The greatest deviation of total SFA was observed in

common carp and of content of MUFA and PUFA in catfish and zander. The lowest n-3/n6 ratio was found in one sample of common carp (0.12), and the greatest in one sample of bighead carp (3.7). Obtained results are in agreement with previous reported results referred to studied fish species (Jankowska et al., 2004; Celik et al., 2005; Steffans and Wirth, 2005; Ćirković et al., 2011). All species of analyzed warm water fish contained significant quantities of the n6 series, particularly C18:2 and C20:4. The presence of these and the other polyunsaturated fatty acids emphasizes the potential of freshwater fish for use in special low fat diets.

Table 1. Chemical composition of seven fish species obtained from retail stores

Parameters	Common carp	Silver carp	Bighead carp	Grass carp	Wels catfish	Zander	Tench
Moisture content (%)	73.16±2.81^{a}	74.68±1.49^{a}	74.48±2.44^{a}	76.17±1.67^{ab}	77.74±0.89^{b}	77.89±0.45^{b}	76.13±1.44^{ab}
Protein content (%)	15.64±0.98^{a}	18.01±0.32^{b}	18.03±0.34^{b}	14.73±0.70^{a}	17.34±0.53^{b}	19.27±0.39^{c}	15.71±0.4^{a}
Fat content (%)	10.07±3.18^{a}	6.1±1.59^{bc}	6.29±2.42^{bc}	8.02±1.61^{ac}	3.96±0.69^{bd}	1.8±0.0.23^{d}	6.16±1.14^{bc}
Ash content (%)	1.14±0.09^{ab}	1.21±0.05^{ac}	1.2±0.0.3^{ae}	1.07±0.16^{ad}	0.96±0.12^{d}	1.04±0.02^{bde}	2.00±0.03^{f}
Total cholesterol (mg/100g)	56.38±6.48^{a}	65.38±3.29^{b}	65.2±2.19^{b}	65.29±2.56^{b}	33.14±1.58^{c}	42.34±1.33^{d}	44.97±2.55^{d}

Values are means ± SD (n = 8); Values in the same row with different letter notation statistically significantly differ at p < 0.01/

The reason for the least favourable composition of fatty acid profile in lipids of common carp can be accounted to the type of food dominating in the diet. The traditional approach to the rearing of common carp in the Republic of Serbia is based on foods naturally occurring in ponds (zooplankton, benthos). The energy-producing component of their diet is supplemented with untreated cereals (corn and wheat) (Ćirković et al., 2002). The feed rich in saccharides leads to an increase in the percentage of the oleic acid (C18:1n-9) in body lipids of the fish. At the same time, there is a decrease in the percentage of PUFA n-3 (Fajmonová et al. 2003; Buchtová et al. 2007). According to research conducted by Buchtová et al. (2010) and Ćirković et al. (2010), carp grown on natural food had a high content of both n-6 and n-3 fatty acids and Ćirković et al. (2011) observed that PUFA/SFA ratio was the most favourable in carp fed complete food, and the least in carp fed with maize and wheat. UFA/SFA ratio was also the best in carp fed a complete feed mixture.

Wood et al (2008) have suggested that ratio of PUFA/SFA should be above 0.4 and according that all examined fish species have had favourable (from 0.66 to 1.17) PUFA/SFA ratio. Scollan et al., (2006) have advised that n-6/n-3 ratio should not exceed 4. All studied species meet this suggestion.

The elementary prerequisite for sustainable carp and other fresh water fish production, with favourable chemical and fatty acid compositions should be seen in the development of better feeding procedures. Completed formulated feed mixtures are necessary in modern fish farming because it improves growth performance and chemical and fatty acid composition in fish (Ćirković et al., 2011). Supplemental feeding should contain more vegetable oils that will help to increase PUFA content in muscle lipids of the fish (Steffens and Wirth 2007).

CONCLUSIONS

The meat of warm water fish from our market represents valuable source of healthy nutrition for the consumer. Chemical and fatty acid composition varied between different species and among the same species. The variations were the greatest in common carp which is the most important species in our country and it was probably because different rearing systems on our fish ponds. All examined species have had PUFA/SFA ratio higher than 0.4, andn–6/n–3 ratio was lower than 4 which are the prescribed values recommended from WHO/FAO organization. Components of fish meat, especially common carp can be improved by improvement rearing procedures. Completed formulated feed mixtures which should contain more vegetable oils are necessary in modern fish farming.

ABSTRACT: The content of iron (Fe) was investigated in *M. longissimus dorsi* and *M. semimembranosus* for five purebred pigs (Large White – LW, n = 6; Landrace – L, n = 6; Duroc – D, n = 6; Hampshire – H, n = 6 and Pietrain – P, n = 6), produced in Vojvodina. Fe was determined by flame atomic absorption spectrometry after mineralization by dry ashing. The difference in the Fe content among the five purebred pigs was not significant in the analysed longissimus dorsi (F = 1.517; P= 0.228) and semimembranosus (F = 0.480; P= 0.750) muscles tissues. Muscles type had no significant effect on the Fe content (F = 2.839; P= 0.097). The order of the purebred pigs regarding Fe content in the longissimus dorsi muscle samples expressed as mg/100g was as follows: LW (1.41–1.81, on average 1.55) > P (1.16–1.77, on average 1.37) > H (1.06–1.62, on average 1.31) > L (1.04–1.65, on average 1.29) > D (1.07–1.57, on average 1.28). The average Fe content in all investigated longissimus dorsi muscle samples was 1.36 mg/100g. The order of the purebred pigs regarding Fe content in the semimembranosus muscle samples expressed as mg/100g was as follows: LW (1.00–2.79, on average 1.57) > P (1.17–1.93, on average 1.52) > D (1.13–1.83, on average 1.47) > L (1.16–1.99, on average 1.46) > H (1.19–1.60, on average 1.37). The average Fe content in all investigated semimembranosus muscle samples was 1.48 mg/100g. The Vojvodian pig meat analysed in this study, showed slightly higher Fe content compared with the values found in other countries.
Key words: *pigs, M. longissimus dorsi, M. semimembranosus, iron*

INTRODUCTION

Meat quality is the sum of all sensoric, nutritive, hygienic-toxicological and technological factors of meat. The nutritive factors of meat quality include proteins and their composition, fats and their composition, vitamins, minerals, utilisation, digestibility and biological value (Olsson and Pickova, 2005; Honikel, 1999; Hofmann, 1990). Red meat (beef, veal, pork and lamb) contains high biological value protein and important micronutrients, including iron, zinc and vitamin B12, all of which are essential for good health throughout life (McAfee et al., 2010; Lombardi-Boccia et al., 2005; Williamson et al., 2005; Higgs, 2000).
The nutrient levels in foods are variable. The major sources of variability in nutrient composition are the wide diversity of soil and climatic conditions (geographical origin), seasonal variations, physiological state and maturity, as well as cultivar and breed (Greenfield and Southgate, 2003). The continuous innovations in the breeding systems, rearing practices, feeds composition, changes in slaughtering methods and ageing, largely contribute to induced changes in the concentration of some micronutrients (Greenfield et al., 2009; Lombardi-Boccia et al., 2005). According to Hermida et al. (2006), the average macrominerals and trace elements concentrations in tissues depend, in part, on the type of cuts, the age of the animals, and various other factors, which are often not reported. Greenfield and Southgate (2003) concluded that the major sources of variation in animal products are the proportion of lean to fat tissue, and the proportion of edible to inedible materials (bone and gristle). Variations in the lean-fat ratio affect the levels of most other nutrients, which are distributed differently in the two fractions.

Dietary sources rich in iron include liver, meat, beans, nuts, dried fruits, poultry, fish, whole grains or enriched cereals, soybean flour and most dark green leafy vegetables. Iron in foods occurs in two main forms: haem and non-haem iron. The major sources of haem iron in the diet are haemoglobin and myoglobin from meat, poultry and fish. Non-haem iron consists mainly of iron salts, derived from plant and dairy products. Most of the non-haem iron present as foods is in the ferric form. Fortification of food with iron is common in developing countries, where deficiency of the element is widespread. In some countries fortification of white and brown flour is mandatory at a level not less than 16.5 mg iron/kg flour. Many breakfast cereals are fortified on a voluntary basis; levels vary but are typically within the range of 70 to 120 mg/kg. Inorganic dietary iron supplements are generally available as ferrous salts (chloride, fumarate, gluconate, glycerophosphate, succinate, sulphate), which are more readily absorbed than ferric salts. Ferrous sulphate and succinate are the most commonly available. Also, water is a potential source of iron (EVM, 2003).

Estimated average daily iron requirements in the UK are 8.7 and 6.7 mg for males aged 11-18 and 19+ years, respectively. For women in the 11-50 years age group the estimated average daily iron requirement is 11.4 mg, whilst that for postmenopausal (50+ years) women is 6.7 mg. Estimated average daily requirements for children are 1.3 mg (0-3 months), 3.3 mg (4-6 months), 6.0 mg (7-12 months), 5.3 mg (1-3 years), 4.7 mg (4-6 years) and 6.7 mg (7-10 years). It has been estimated that the total amounts of iron required for a full gestation is 680 mg. Existing body iron stores should provide this requirement, assuming adequate iron stores at conception, cessation of menstruation and increased intestinal absorption throughout gestation (COMA, 1991). According to FDA (2009), the Recommended Dietary Allowance (RDA) for iron is 18 mg for adults and children four or more years of age.

The majority of functional iron within the body is present in haem proteins, such as haemoglobin, myoglobin and cytochromes, which are involved in oxygen transport or mitochondrial electron transfer. Many other enzymes also contain or require iron for their biological function. Iron deficiency generally develops slowly, and may not be clinically apparent until iron stores are exhausted and the supply of iron to the tissues is compromised, resulting in iron-deficiency anaemia. Groups that are vulnerable to iron deficiency include: infants over 6 months, toddlers, adolescents and pregnant women (due to high requirements); older people and people consuming foods high in iron absorption inhibitors (due to poor absorption); menstruating women or individuals with pathological blood loss (due to high blood losses) (EVM, 2003).

Pig meat is the most widely consumed meat in the EU (Williamson et al., 2005), as well as in Serbia, and the consumption has been steadily increasing. The Autonomous Province of Vojvodina (the northern part of the Republic of Serbia) is a region where the number of animals of the porcine species and the production of pork meat are of high economic importance. Over 30 percent of the total number of pigs slaughtered annually in Serbia comes from Vojvodina. Five purebred pigs (Large White, Landrace, Duroc, Hampshire and Pietrain) and their crosses are used for commercial pork production. In (cross) breeding programme Large White and Landrace are used as female lines and Duroc, Hampshire and Pietrain are used as male lines.

The aims of this study were: (i) to obtain the iron levels of *M. longissimus dorsi* and *M. semimembranosus* from pigs in Vojvodina; (ii) to investigate the potential differences in iron levels of *M. longissimus dorsi* and *M. semimembranosus* among five purebred pigs, used nowadays in Vojvodina for pork production; (iii) to compare the results of our study with results found in other studies, i.e. other countries, for *M. longissimus dorsi* and *M. semimembranosus*; (iv) to calculate the average daily intake of iron through consumption of one serving of 100 g of pork compared to the Recommended Dietary Allowance (RDA). The overall objective is to produce high quality pork to ensure the competitiveness of Vojvodian pork in the international meat markets.

MATERIALS AND METHODS

Animals, sampling and preparing

In this study five purebred pigs (castrates males and females) were used: Large White (LW), n = 6; Landrace (L), n = 6; Duroc (D), n = 6; Hampshire (H), n = 6; and Pietrain (P), n = 6.
The pigs were fattened at the production farms in the northern part of the Republic of Serbia (Autonomous Province of Vojvodina). The pig fattening involved the following phases: starting period (from 15 to 25 kg), growing period (from 25 to 60 kg) and finishing period (from 60 to 110 kg). The diets were based on locally produced corn and soybean meals, and were formulated to meet the nutrient requirements (National Research Council, 1998) for the different growth phases. The finishers were housed in pens with fully slatted floor and 0.80 m^2 space allocation per pig. Each pen contained 10 animals. The environmental temperature in the building was 22°C. All pigs had ad libitum access to a diet and water.
The pigs were randomly selected at an individual live weight between 95 and 110 kg, and were about 6 months old. One pig from each purebred was taken at every six mounts from the same farm. The pigs were slaughtered in the two biggest Vojvodian slaughterhouses according to routine procedure. Carcasses were conventionally chilled for 24 h in a chiller at 2–4°C. After chilling, *M. longissimus dorsi* (LD) and *M. semimembranosus* (SM) were removed from the right hind leg of each carcass. LD and SM muscles were taken from the same animal. The meat samples were trimmed of visible adipose and connective tissue. The samples for chemical analysis (approximately 250 g) taken after the homogenisation of the LD and SM muscle, were vacuum packaged in polyethylene bags and stored at –40°C until analysis.

Analytical methods and quality control

The iron (Fe) content was determined after dry ashing mineralization (Tomović et al., 2011; Gorsuch, 1970). Fe content was measured in the ash solution by flame atomic absorption spectroscopy according to the manufacturer's instructions (Varian Spectra AA 10, Varian Techtron Pty Limited, Mulgvare Victoria, Australia, 1989).
The analysis of the certified reference material (SMRD 2000 – Matrix meat reference material, National Food Administration, Uppsala, Sweden) was used for analytical quality control programme. The results of the analytical quality control programme are presented in Table 1. All analyses were performed in duplicate.

Table 1. The results of the analytical quality control programme (n = 8) used in the determination of the iron in *M. longissimus dorsi* and *M. Semimembranosus*

Element	Fe
Certified concentration (mg/kg)	6.3 ± 3.9
Recovery (%)	101.6 ± 2.51
Limit of detection (mg/100g)	0.50
Limit of quantitation (mg/100g)	0.75

Statistical analysis

All data are presented as average, standard deviation (SD) and range (Min, Max). Independent t-test and analysis of variance (one-way ANOVA) were used to test the hypothesis about differences between two or more average values. The software package STATISTICA (2008) was used for analysis.

RESULTS AND DISCUSSION

Average concentrations, standard deviations and ranges of iron in the *M. longissiumus dorsi* and *M. semimembranosus* tissue samples from five different purebred pigs are presented in Table 2. The minimum Fe content found in all samples was greater than the detection limit.
The order of the purebred pigs according to average iron content in the *M. longissiumus dorsi* samples in mg/100g was: LW (1.41–1.81, on average 1.55) > P (1.16–1.77, on average

1.37) > H (1.06–1.62, on average 1.31) > L (1.04–1.65, on average 1.29) > D (1.07–1.57, on average 1.28). Iron levels found in the present study did not differ significantly (F = 1.517; *P* = 0.228) among *M. longissiumus dorsi* for the different purebred pigs. The average iron content in all investigated longissimus dorsi muscle samples was 1.36 mg/100g.
The order of the purebred pigs according to average iron content in the *M. semimembranosus* samples in mg/100g was: LW (1.00–2.79, on average 1.57) > P (1.17–1.93, on average 1.52) > D (1.13–1.83, on average 1.47) > L (1.16–1.99, on average 1.46) > H (1.19–1.60, on average 1.37). Iron levels found in the present study did not differ significantly (F = 0.480; *P* = 0.750) among *M. semimembranosus* for the different purebred pigs. The average iron content in all investigated semimembranosus muscle samples was 1.48 mg/100g. Muscles had no significant effect on the iron content (*F* = 2.839; *P* = 0.097).

Table 2. Iron levels (mg/100g wet weight) in the *M. longissiumus dorsi* and *M. semimembranosus* of various purebred pigs from Vojvodina

Muscle	Purebred	LW	L	D	H	P	F value	*P* value[1]	All animals

The average iron contents in the *M. longissimus dorsi* and *M. semimembranosus* found in this study were slightly higher compared to the data presented in the food composition tables of other countries (loin: 0.54 mg/100g and ham: 0.73 mg/100g, Australia – Greenfield et al., 2009; loin: 0.71 mg/100g and SM: 0.7 mg/100g, Denmark – National Food Institute, 2009; ham: 0.6 mg/100g, Finland – National Institute for Health and Welfare, 2009; loin: 1.3 mg/100g and ham: 1.6 mg/100g, Italy – INRAN, 2007; loin: 0.7 mg/100g and ham: 0.8 mg/100g, Norway – The Norwegian Food Safety Authority, 2006; loin: 0.84 mg/100g and ham: 1.01 mg/100g, USA – Romans et al., 1994, The US Department of Agriculture's, 2009).

Table 3. Contribution of *M. longissimus dorsi* and *M. semimembranosus* to RDA* for iron in human nutrition (adult and children four or more years of age**; values for the consumption of one serving of 100 g of meat)

Muscle		LD	SM
% RDA (18 mg/day)	Average	7.5	8.2
	Min	5.8	5.6
	Max	10.1	15.5

* *RDA – Recommended* Dietary Allowance
** *Daily values based on a caloric intake of 2.000 calories (FDA, 2009)*

According to obtained results (Table 3), the iron content in 100 g of *M. longissimus dorsi* and *M. semimembranosus* of pigs produced in Vojvodina contributes minimally 5.6% (up to 15.5%) of the RDA value.

CONCLUSION

The results of the present study show that the levels of iron in the *M. longissimus dorsi* and *M. semimembranosus* were not influenced by purebred or muscle. The Vojvodian pig meat showed slightly higher Fe content compared with the values found in other countries.

ACKNOWLEDGEMENTS

These results are part of the project No 114-451-2091/2011 (Improvement of meat quality from indigenous and modern pig breeds produced in Vojvodina for the production of traditional dry fermented sausages and dry cured meat products), which is financially supported by the Provincial Secretariat for Science and Technological Development, Autonomous Province of Vojvodina, Republic of Serbia.

ABSTRACT: High Resolution NMR Spectroscopy offers unique screening capabilities for food quality and safety by combining untargeted and targeted screening in one analysis.
The objective of this contribution is to demonstrate, that due to its extreme reproducibility NMR can detect smallest changes in concentrations of many components in a mixture, which is best monitored by statistical evaluation however also delivers reliable quantification results.
The methodology typically uses a 400 MHz high resolution instrument under full automation after minimized sample preparation, which in the case of aqueous solution just needs buffering to adjust pH and in case of cloudy samples centrifugation. For example one fruit juice analysis in a push button operation takes at maximum 15 minutes and delivers a multitude of results, which are automatically summarized in a PDF report.
The method has been proven on fruit juices, where so far unknown frauds could be detected. In addition conventional targeted parameters are obtained in the same analysis. This technology has the advantage that NMR is completely quantitative and concentration calibration only has to be done once for all compounds. Since NMR is so reproducible, it is also transferable between different instruments of the same field strength and different laboratories. Based on strict SOP`s, statistical models developed once can be used on multiple instruments and strategies for compound identification and quantification are applicable as well across labs.
Key words*: High Resolution NMR, Targeted Screening, Quantification, Untargeted Screening*

INTRODUCTION

A new approach, based on ^{1}H-NMR-technology combined with advanced statistical evaluation was developed to supplement conventional analysis (Hofsommer, 1999; Koswig, 2006) with the intention to pre-screen all samples with regard to as many parameters as possible and sort out suspicious ones for confirmation by conventional analysis in order to avoid unnecessarily spent cost for full analysis. The resulting SGF-Profiling (Spin Generated Fingerprint Profiling) for fruit juices (Rinke et al., 2007) can answer this request by using chemo metric comparison of spectrum fingerprints for authenticity control using non-targeted screening procedures. The method is especially successful when used in routine control. It provides additional benefit without creating further costs, delivering targeted analysis of multiple relevant compounds, e.g. indicators for microbiological spoiling or deviations during process or storage. In addition, the structure analysis capability of the NMR technique helps to identify problems caused by unknown compounds. In addition an overview will be presented on further possibilities for food material screening beyond fruit juice. This covers wine, edible oils, cheese and milk powder. It is shown, how the untargeted part of the NMR approach could have immediately resolved the melamine problem, if applied to baby milk powder.

MATERIALS AND METHODS

The SGF-Profiling is providing a full ^{1}H-NMR-spectrum for each sample. In principle, all NMR spectrometers are suitable for this analysis. A 400 MHz spectrometer with proton optimized

detection and automatic sample changing was defined as the basis of the procedure. Strict SOP`s have been established for sample preparation, storage, measurement and processing.
For sample preparation only a predefined buffer (1M KH_2PO_4) has to be added. For cloudy sample a centrifugation has to be done prior buffer addition. Concentrates are diluted to reach a predefined Brix value. 540µl of sample material is mixed with 60 µl buffer (containing phosphate buffer in D_2O) to obtain a final sample pH of 3 (e.g. for fruit juice and wine).
The ^{1}H-NMR spectral acquisitions are carried out by using a modified version of the NOESYGPPRID pulse sequence, with standardized continuous wave pre-saturation of the water resonance (25Hz field), during the relaxation delay.
For fruit juice time domain data were collected into 64K data points. A recycle time of ~8 sec was covering a sweep width (SW) =20 ppm. An exponential window function, with line broadening (LB) = 0.3 Hz, was used prior to Fourier transformation of the data with zero filling into 64K frequency domain points.
Data processing with standard Bruker spectrometer software TopSpin was performed.
Baseline and phase correction were carried out using an automated processing program. Measurement procedure runs under complete control of a laboratory management system using barcodes for every sample.
For wine, acquisition conditions only vary in the solvent suppression mode, using a shaped pulse with 8 suppression frequencies on each individual solvent line with a presaturation field of 3 Hz per frequency.
Per registered spectrum, different interpretation routines are performed. Each interpretation of data is carried out by uni- and multivariate statistical analysis to reference models based on authentic samples (untargeted mode). The system is calibrated with a reference database containing spectra of representative samples covering the natural variability of the examined sample type. The quality of interpretation depends on representativeness and the number of reference spectra. The databases for the food analysis are built up using certified authentic samples of juices from the industrial process. All spectra have to be acquired under identical conditions to ensure comparability. For each sample a fully signed documentation including origin and condition of processed fruits, as well as the applied technology is available to guarantee traceability.
From the large range of available multivariate statistical methods applied in context of metabonomics data analysis (Vandeginste et al., 1998; Hastie et al., 2001), different possibilities of comparison can be used. A multitude of NMR spectral parameters can be entered into mathematical models. The combination of methods can improve sample characterisation and in some cases final judgement. Individual components are identified and quantified using information from a reference compound NMR spectral base (targeted mode).
Besides in-house developed scripts for MatLab, data analysis was performed mainly with the Bruker software package AMIX. For chemo metrical data analysis, spectra are segmented into equidistant chemical shift regions, the so-called buckets. Respective segment integrals are calculated in order to set up so called bucket tables for input into Principal Component Analysis, combined with discriminant analysis. Bucketing parameters were adjusted to the specific aspects investigated.

RESULTS AND DISCUSSION

The SGF Profiling for fruit juice represents a heterogeneous collection of cascading statistical models which can be applied consecutively to one single spectrum , see figure 1, such as specific models for multi fruit type separation, fruit type differentiation between citrus varieties (e.g. citrus sinensis and citrus reticulata), differentiation of product categories (e.g. orange juice and orange juice made from concentrate), or characterisation of compositional differences for two groups of similar products (e.g. apple juice concentrates from Poland and

China). Different answers presented as graphical or numerical results can be compiled in an analytical report by suitable software.
Only an exemplary extract of the possibilities can be presented here. In a cloud representation of PCA output as well as in classification, the position of the examined sample spectrum is indicated by a star.

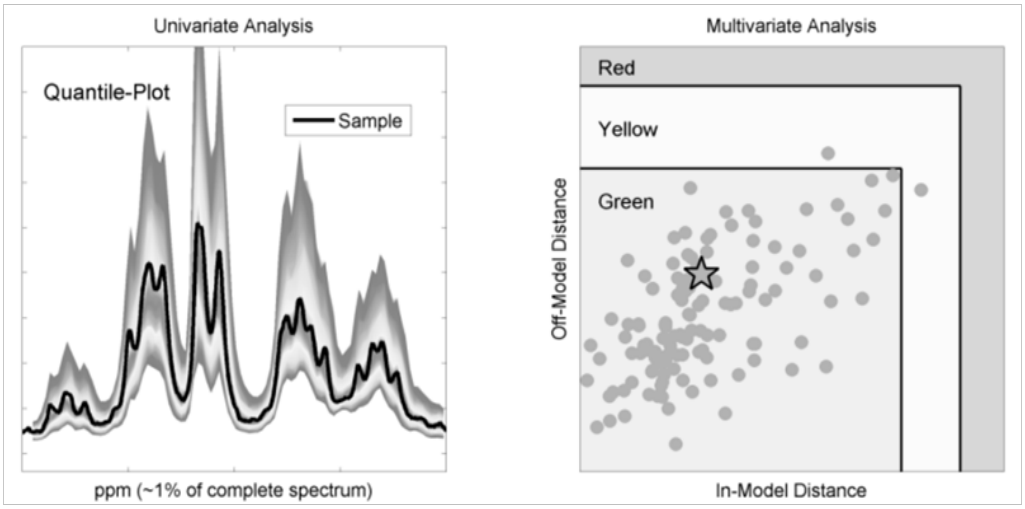

Figure 1. Univariate Analysis vs. Multivariate Analysis in NMR based Food Screening shown on orange juice sample. The univariate model is represented by the colour-coded quantile plot. The yellow and the red limits on the multivariate analysiswere calculated by Monte-Carlo/Cross-Validation analysis and represent the 95% and 99% confidence limit respectively.

An orange juice concentrate is from a Brazilian producer has been allocated to the common group, Orange/Mandarin and has been separated from other fruit types.

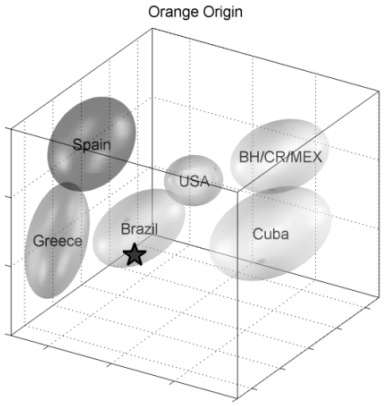

Figure 2. Orange Juice Origin as determined by rapid NMR screening

The same sample is projected to differentiation of geographic origin, which is a relevant commercial aspect with regard to price and quality. The control of product type is important in some cases, to detect economic frauds, e.g. if a label says direct juice, however in reality rediluted concentrate was used. Therefore a special model was developed to solve such question.
All models comparing different groups apply similarity calculations in order to classify any sample. Such models are mainly used to check declared specificities of any product in comparison with defined alternative possibilities. The Soft Independent Modelling of Class Analogy is comparing a spectrum only with one specific reference spectra set, in order to determine if spectral sequences with low variability in the reference group. This can indicate a deviation from the target population, without comparing to any defined alternative. The same spectrum, as per previous figures, is calculated here.

An addition of citrus reticulata (mandarin, clementine) in orange juice is not allowed in Europe. Such an addition is considered as an adulteration. A Ridge Regression curve is calculated based on pure orange and mandarin juice samples, for which spectra have been combined mathematically with different proportions. Value 0 corresponds to 100% pure citrus sinensis, value 1 to 100% pure citrus reticulata. In the laboratory, different mixtures of juices used for modelling, were prepared and measured with the calibration system. The share of reticulata is given on the x-coordinate. The results close to the linearity curve indicate good prediction and are in line with verification by DNA-testing and conventional analysis.
Similar models, as shown for orange juice products are developed for other juice products as well as for wine, honey and edible oil, too.
Furthermore, using the same spectra again, quantification can be carried out. Considering that analytical errors for both methods could be added when comparing NMR results and conventional analysis by enzyme test kit and/or HPLC, the NMR precision is more than sufficient for a pre-screening prior to conventional analysis.
Quantification of multiple compounds can be performed with one calibration and reference database to finished goods (bottled consumer goods). Furthermore, other models are transferable like the control of fruit content in products, with less than 100% fruit content such as drinks and nectars.
For better performance of compound identification, in case of signal overlap, a rapid 2D J-Resolved spectrum (Braun et al., 1998) is recorded as part of the standard routine.

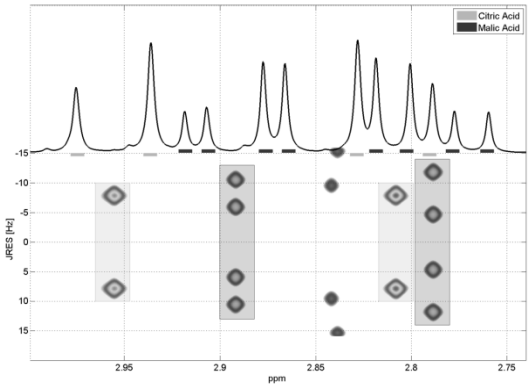

Figure 3. Rapid 2D J-Resolved spectrum recorded during the automatic measurement procedure. Upper part shows sub-region of 1D spectrum of pear juice sample mainly displaying overlap of peaks from malic and citric acid. Lower part shows subregion of JRES where coupling information and multiplicity information of malic acid peaks and citric acid peaks can be obtained from F1-dimension.

Figure 3 shows a region of the ID (NOESY) and 2D (JRES) spectra of a pear juice. Signals of Citric Acid (light grey) and Malic Acid (dark grey) are separated in the 2D-spectrum. With the information of JRES correct peak assignment it is possible in the 1D spectrum, however quantification from 1D is assisted by JRES.

Extension to food and drink materials other than fruit juice

Having established the statistical and quantification methodology, it is possible to expose the technology described for fruit juices to other food material by exchanging the underlying spectral database from juice for example to wine. The knowledge base for quantification in this case has to be modified as well to represent chemical shift variation of the compounds to be quantified, as they are observed in a different matrix, which can also produce different signal overlay problems. Applying the statistical technology to a set of about 800 German wines allows e.g. to differentiate variety, geographical origin and vintage year.
Figure 4 shows the analysis of the vintage year on a set of Riesling Wines from Rhineland-Palatinate in Germany. On the left side a 2-dimensional projection of the 4-dimensional space is shown for the years 2004 to 2008. On the right side the respective confusion matrix is shown, indicating the very low rate of false assignment even keeping in mind the still small sample cohort used (184 wines).

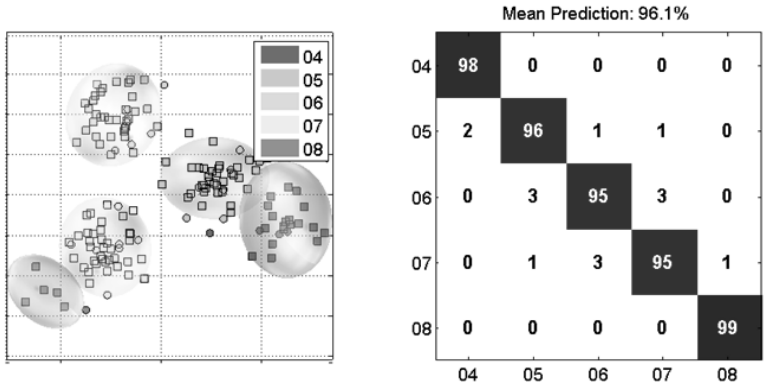

Figure 4: Statistical Analysis of the vintage year on 184 Riesling wines from Rhineland-Palatinate (Germany)

Melamine addition to baby milk powder was and still is a threat to the health of babies especially in China.
Added to pretend higher protein content, melamine was not detected for long time due to the targeted nature of food control methods used. Applying the NMR approach readily leads to the detection of melamine comparing to authentic baby milk powders from China (Lachenmeier et al., 2009). Figure 5 shows a quantile plot of the authentic model of milk powders dissolved in DMSO. The quantile plot can be interpreted as a superposition of all authentic sample spectra, the red colour indicates the average intensity at each point in the spectrum, while the dark blue colour indicates rare intensities in the dataset at the upper and lower limit. It can be seen, that the melamine signals clearly falls outside the range described by the normal model. When the same sample set was dissolved in H2O it could be shown, that sucrose was added to compensate the deviating sugar/nitrogen ratio.

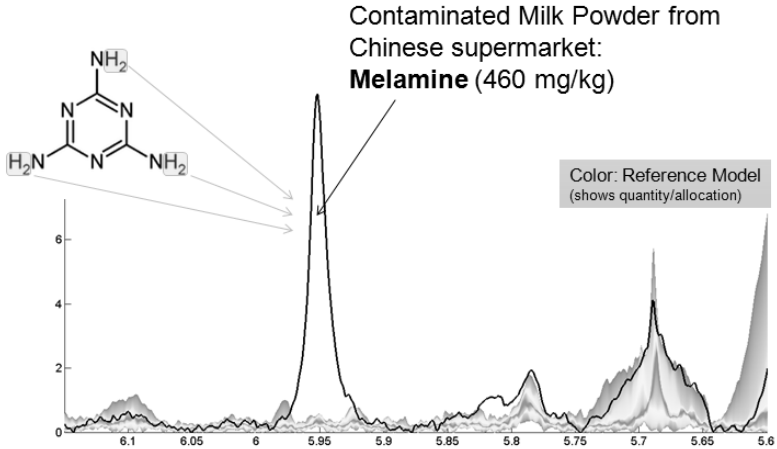

Figure 5: Comparison of contaminated milk powder NMR spectrum in DMSO to quantile plot of an authentic sample set

The two examples given indicate the potential of NMR in food quality and safety, being transferable from one material to another applying the corresponding normal sets. Investigations have also been made on olive and other edible oils as well as honey and mozzarella cheese.

CONCLUSIONS

SGF-Profiling is a NMR-based high throughput screening for fruit juices. The combination of chemo metric modelling with molecule specific signal treatment makes it a powerful tool for fruit juice quality assessment. Specific quality aspects and adulterations can be identified by applying a number of statistical tests on the same spectrum. Fruit and product type differentiation, adulteration by sugar or acid addition, geographical origin and fruit mixtures are predictable. Moreover, a list of substances being present in fruit juice is quantifiable. The application of SGF-Profiling in routine controls is enhancing the control density and the amount of detected quality deviations. The pre-selection carried out allows choosing well targeted conventional analysis for a sample. In many cases, it can save higher analytical costs. Therefore the SGF-Profiling is useful and extremely economic in cases where samples need a very fast analytical answer and where a large number of samples should be tested and can be transferred to other food materials as shown.

ACKNOWLEDGEMENTS

The Riesling Sample Set was obtained from Prof.Fischer from DLR Neustadt Germany

ABSTRACT: In this paper the composition and content of fatty acids and acylglycerols of lipids from chickpea flour were examined. The chickpea flour was obtained by milling seeds to an average particle size of 0.3 mm. The lipids are obtained by trichlorethylene duplicate extraction and by using reflux at solvent boiling temperature. For the content and composition of chickpea flour fatty acids and acylglycerols analysis, the GC and HPLC method, respectively, were performed. In order to obtained the fatty acids methyl esters, the lipids were alkaline hydrolyzed and methylated. The content of lipid was 3.11 g per 100 g of chickpea flour and fatty acids composition was palmitic 12.18%, stearic 2.47%, arachidonic 1.10%, behenic 0.52%, oleic 37.77% and linoleic 42.14%. The result showed the chickpea flour contained 16.27% of total saturated fatty acids, 38.28% of total monounsaturated fatty acids and 42.14 % g of polyunsaturated fatty acids, so the total unsaturated fatty acids was 80.14%. The ratio of total unsaturated to saturated fatty acids content was 4.93, and as this ratio is higher than ratio previously obtained for wheat flour, it can be concluded that chickpea flour addition to the wheat flour in dough, as well as in final product, will change this ratio in benefit to unsaturated fatty acids. By HPLC analysis it was obtained that the lipids had the highest content of triacylglycerols (57.48%), while the content of diacylglycerols was 36.66% and monoacylglycerols, 5.51%.
Key words: *fatty acids, acylglycerols, chickpea flour*

INTRODUCTION

The chickpea (*Cicer arietinum* L.) known also as ceci bean, garbanzo bean, chana, sanagalu Indian pea and Bengal gram, is alegume plant of the family *Fabaceae.* It is one of the earliest cultivated vegetables and there are the remains found in the Middle East, 7,500 year old. The chickpea seed is an excellent source of protein ranging between 12 and 30% and healthy carbohydrate known as dietary fiber (Sotelo et. al., 1987; Saleh and Tarek, 2006). Due to these components it is a great food especially for diabetics and insulin-resistant individuals. Chickpea also can help in lowering cholesterol and improving the blood sugar levels (Marray et al., 2005). Much work has been done to improve protein quality and amino acid composition in several crops (Mosse and Baudet, 1983; Monti and Grillo, 1983). The chickpeas provide an excellent source of folic acid and minerals such as iron, copper, zinc and magnesium, as well as phenolic compounds (Segev, et al., 2010).
Oil content, including essential fatty acids is the third important organic component of chickpea. According to genotype and environmental factors, oil content had wide range between 3.8 and 10% (Nikolopoulou et al., 2006). Linolenic, oleic and palmitic acids are the major fatty acids of chickpea oil (Ling and Robinson 1976). The previous research indicated that cultivation method, growing conditions, environmental factors and planting time (Nikolopoulou et al., 2006; Gül et al. 2011), affect on yield and fatty acid composition in chickpea seeds. Recently there are increasing interests for fatty acids and acylglycerols composition since there are reports about fatty acid influence, especially of n-3 and n-6 fatty acids and their ratio, on human health (Simopolous, 2002; Simopolous, 2008). The influence

includes benefits related to cancer, inflammatory bowel disease, rheumatoid arthritis, and psoriasis (Rose et al., 1999; Connor, 2000).
In general, the lipids content in seed of leguminous plant is considerably and the lipids have an important physiological role in food quality, such as dough rheology (Dobraszczyk and Morgenstern, 2003). The addition of flour of leguminous plant seeds (Nikolić and Lazić, 2011,) or other plant to wheat flour, changes the dough rheology and lipid composition (Nikolic, et al., 2011). In order to investigate the effect of chickpea flour addition to the wheat flour on dough rheology and its lipid composition, these results are needed. They represent the first step to thataim and are important for predicting the potential benefits for nutrition value of final product.
The aim of the study presented in this paper was to investigate fatty acid composition and acylglycerols of lipids from chickpea flour with the emphasis on total unsaturated and saturated fatty acids content and their ratio.

MATERIAL AND METHODS

Plant material

The decorticated and fried chickpea seeds, originated from Iran, grown in 2009 year, and were bought from the local market in Leskovac, Serbia. The chickpea flour was obtained by milling of chickpea seeds and sieving through a 0.25 mm riddle.

Lipids content determination and isolation

The lipids content was determined by trichlorethylene duplicate extraction, for the same sample, by using reflux (1:20 w/v at boiling temperature, 60 minutes). The extracts were combined and 3 ml were dried at 110 ^{o}C to a constant weight and the dry residue content was read out on the analyzer display (Scaltec SMO 01, Scaltec instruments, Germany). For lipids isolation, the rest of combined n-hexane extracts was evaporated under vacuum.

Fatty acid composition determination by GC analysis

For GC analysis, fatty acids methyl esters were prepared. The lipids were alkaline hydrolyzed and methylated by methanol and BF_3 as catalysts. The final fatty acids methyl esters concentration was about 8 mg/ml in heptane. For obtaining a methyl esters GC spectra, the HP 5890 SERIES II GAS-CHROMATOGRAPH, HP with FID detector and 3396 A HP integrator was used. Column was ULTRA 2 (25m x 0.32mm x 0.52 μm) (Agilent Technologies, Wilmington, USA), injector temperature of 320 ^{o}C, and injector volume of 0.4 μl. The carrier gas was He at a constant flow rate of 1 ml/min. The flame ionization detector was at 350 ^{o}C and split ratio was 1:20. Oven temperature was initially 120 ^{o}C and was maintained at 120 ^{o}C, for 1 min, then increased by 15 ^{o}C/min until 200 ^{o}C, increased by 3 ^{o}C/min until 240 ^{o}C, increased by 8 ^{o}C/min until 300 ^{o}C and maintained at 300 ^{o}C for 15min. The fatty acids were identified by comparison of retention times of the lipids components with those of standards.

Acylglycerols composition determination by HPLC analysis

For HPLC analysis, Holčapek et al. (1999) modified HPLC method and the Agilent 1100 High Performance Liquid Chromatograph, a Zorbax Eclipse XDB-C18 column: 4.4 m x 150 mm x 5 μm (Agilent Technologies, Wilmington, USA), and an UV/ViS detector were used. The samples of the reaction mixture were dissolved into a mixture of 2-propanol: *n*-hexane, 5:4 v/v and filtered through 0.45 μm Millipore filters. The flow rate of binary solvent mixture (methanol, solvent A, and 2-propanol/*n*-hexane, 5:4 by volume, solvent B) was 1 ml/min with a linear gradient (from 100% A to 40% A+ 60% B in 15 min). The column temperature was held constant at 40 ^{o}C. The components were detected at 205 nm. The monoacylglycerols (MAG), diacylglycerols (DAG) and triacylglycerols (TAG) were identified by comparing the retention times of the lipids components with those of standards.

Statistical analysis

STATISTICA, version 5.0 software was used to perform the statistical analysis: the means and standard deviations and cluster analysis. The means and standard deviations were obtained by Descriptive Statistics, marking the Median & Quartiles and Confirm Limits for Means. For cluster analysis the Euclidean method with the complete linkage was used.

RESULTS AND DISCUSSION

The lipids content in investigated flour from chickpea seeds was 3.11 g per 100 g of chickpea flour and it is lower than those found in literature data (Nikolopoulou et al., 2006). The results of lipid profile analysis, the free fatty acids, total saturated fatty acids (TS), total monounsaturated fatty acids (TMU), total polyunsaturated fatty acids (TPUS), total unsaturated fatty acids (TUS), monoacylglycerols (MAG), diacilglycerols (DA) and triacylglycerols (TAG) are presented in Table 1. The HPLC chromatogram of acylglycerols is presented in figure 2. The content of acylglycerols was determined by measuring the peak area from 3.445 to 4.580 min, for MAG, peaks area from 5.276 to 8.677 min, for DAG and peaks area from 10.907 to 15.815 min, for TAG.

Table 1. Fatty acid and acylglycerol composition (% w/w) of chickpea seed flour

Fatty acid composition obtained by GC analysis	
Fatty acid	**Content (%)**
Palmitic acid (16:0)	12.18± 0.1
Stearic acid (18:0)	2.47± 0.09
Arachidic acid (20:0)	1.10± 0.09
Behenic acid (22:0)	0.52± 0.06
Palmitoleic acid 16:1)	0.51± 0.06
Oleic acid (18:1)	37.77±1.32
Linoleinic acid (18:2)	42.14±2.32
TS (%)	16.27±0.2
TMUS (%)	38.28±1.56
TPUS (%)	42.14±1.75
TUS (%)	80.14±2.37
Ratio TUS toTS	4.93
Acylglycerol composition obtained by HPLC analysis	
Acylglycerol	**Content (%)**
MAG	5.51±0.09
DAG	36.66±1.69
TAG	57.84±2.78

Results are given as mean ± standard deviation (n = 3);
TS –total saturated fatty acids;TMU – total monounsaturated fatty acids; TPUS –total polyunsaturated fatty acids;TUS – total unsaturated fatty acids; MAG-monoacylglycerols, DAG-diacilglycerols; TAG-triacylglycerols

Fatty acids composition was: palmitic 12.18%, stearic 2.47%, arachidonic 1.10%, behenic 0.52, oleic 37.77% and linoleic 42.14%. The result showed the chickpea flour contained 16.27% of total saturated fatty acids, 38.28% of total monounsaturated fatty acids, 42.14% of polyunsaturated fatty acids, so the total unsaturated fatty acids was 80.14%, and ratio of total unsaturated to saturated fatty acids was 4.93. The previously obtained data of GC analysis (Nikolić, et al., 2011) showed this ratio was 3.71. Based on these data, it can be concluded that chickpea flour addition to the wheat flour in dough will change unsaturated to saturated fatty acids ratio in benefit to unsaturated fatty acids.

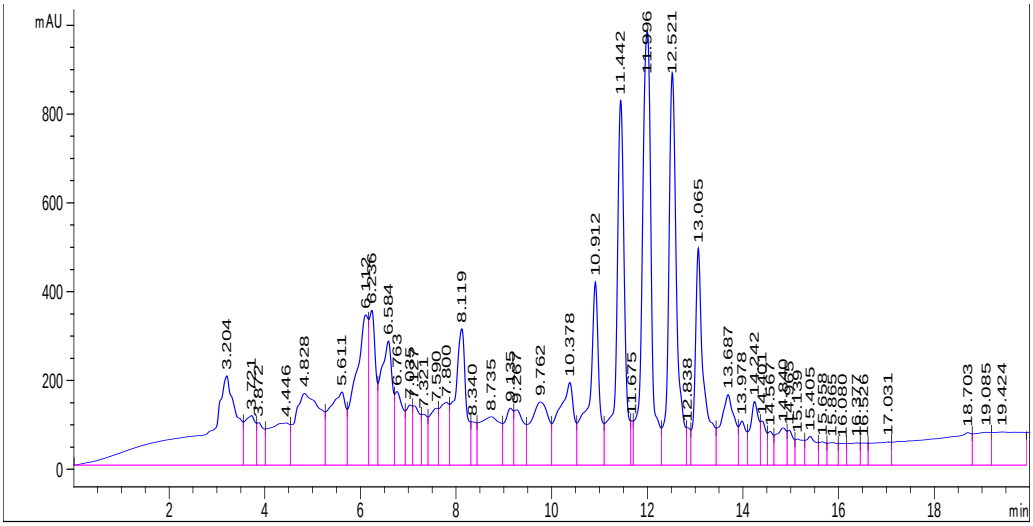

Figure 1. The HPLC chromatogram of acylglycerols of lipids from flour of chickpea seeds

By HPLC analysis, in lipids from chickpea flour, the highest content had triacylglycerols (57.48%), while the content of diacylglycerols was 36.66% and monoacylglycerols, 5.51%.
The diagram of Euclidean distances based on eight variables (palmitic-PAL, oleic -OLE and linolenic -LIN fatty acid content, total saturated-TS and total unsaturated fatty acids -TUS content and content of mono- (MAG), di- (DAG) and triacylglycerols (TAG)) are shown in figure 2. Results of cluster analysis indicate, in total saturated fatty acids the palmitic acid had the main part, the oleic acid in diacylglycerols, while in total unsaturated fatty acids it was the linolenic acid.

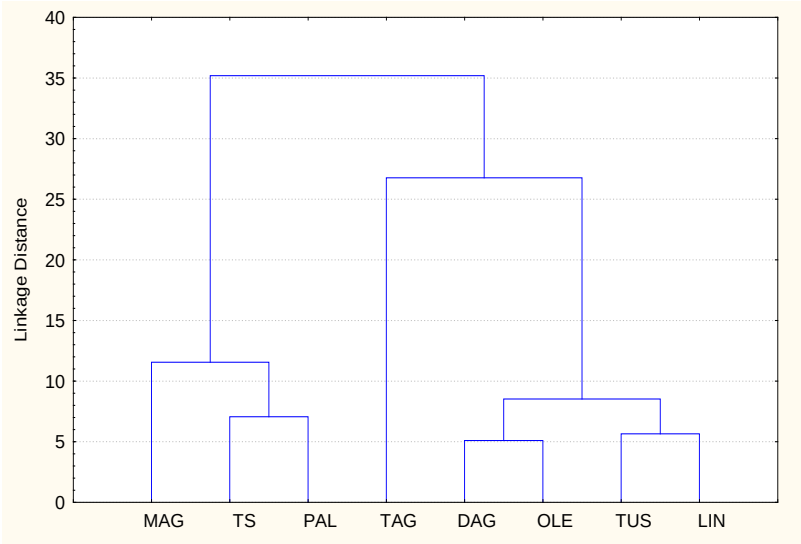

Figure 2. The Euclidean distances for components of lipids from flour of chickpea seeds

In investigated sample of flour from chickpea seeds, the content of lipid was 3.11%. The fatty acids profile composed from palmitic (12.18%), stearic (2.47%), arachidonic (1.10%), behenic (0.52%), oleic (37.77%) and linoleic (42.14%) acid. The ratio of total unsaturated to total saturated fatty acids content was 4.93. As this ratio is higher than ratio previously obtained for wheat flour, it can be concluded that chickpea flour addition to the wheat flour will change unsaturated to saturated fatty acids ratio in dough, in benefit to unsaturated fatty acids. The analysis of acylglycerols content showed the highest content had triacylglycerols (57.48%), while the content of diacylglycerols was 36.66% and monoacylglycerols, 5.51%.

SUITABILITY OF THIOBARBITURIC ACID METHOD FOR ASSESSING LIPID OXIDATION IN PORK, OSMOTICALLY DEHYDRATED IN SUGAR BEET MOLASSES

ABSTRACT: Thiobarbituric acid (TBA) reaction for measuring secondary lipid oxidation products, was evaluated for interferences by ingredients of sugar beet molasses, used for osmotic dehydration. Pork meat was dehydrated in molasses solution and stored for 105 days at 4^{o}C, under the modified atmosphere conditions, or under the atmospheric conditions at 4^{o}C and 20^{o}C for 30 days. The effectiveness of different TBA methods was measured by aqueous acid extraction method (EM) under different conditions of incubation: 1) boiling or 2) room temperature, with 20 mM TBA, and 3) at 40^{o}C, with 80 mM TBA. The distillation TBA method (DM) was employed to evaluate the interferences found in EM, and low TBA values were obtained in all TBA method procedures. Primary lipid oxidation products were, also, low, except for microbiologically contaminated samples with increased water activity value, where elevated peroxide values, but low TBA values were obtained. The data are suggestive of oxidative stability of osmotically dehydrated pork meat under storage in modified atmosphere and refrigerated conditions. TBA EM may be the inadequate method for the analysis of oxidative deterioration of meat samples dehydrated in sugar beet molasses, due to interferences which cause erroneously high value of TBA, detected as absorption at: max. 350 nm and 450-460 nm, present in dehydrated meat and sugar beet molasses itself, which are overlapping the pink peak (max. 532 nm), characteristic for malondialdehyde. TBA EM procedure at low incubation temperature (40^{o}C), and elevated TBA concentration (80 mM), was the most sensitive of analyzed TBA methods.

INTRODUCTION

Osmotic dehydration (OD) is one of the most relevant methods of food dehydration based on partial removal of water from the food material by direct contact of product with hypertonic solutions of salts, sugar, acids, etc., (Raoult-Wack, 1994). Reduction in moisture and water activity of the food matrix lead to the reduction in microbial growth (Rastogi et al., 2002) and differences in lipid oxidation status (Singhal et *al.*, 1997). Lipid oxidation involves the degradation of polyunsaturated fatty acids (PUFA) and the production of primary (hydroperoxides) and secondary lipid decomposition products (Claxson et al., 1994). Free fatty acids (FFA), peroxyde values (PV) and thiobarbituric acid-reactive substances (TBA-RS) have been most commonly used determinants of the degree of lipid oxidation. Brining and drying of meat generally increase FFA, PV and TBA-RS (Khuntia et al., 1994). The assessment of primary lipid oxidation products, using PV, is limited because peroxides are unstable intermediate products in the formation of carbonyl compounds. The thiobarbituric acid (TBA) test is widely used to evaluate secondary lipid oxidation products in meat. Malondialdehyde (MDA), a secondary oxidation product of PUFA with three or more double bonds, reacts with TBA to form a stable pink chromophore with maximal absorbance at 532 nm (TBA-RS_{532}). Aqueus acid extraction method (EM) and the distilation method (DM) are the most frequently applied TBA tests in meat research. The EM may be considered as more suitable method for estimating the MDA, because the meat itself is not exposed to heat treatment. Certain compounds interfere with the reaction between TBA and MDA: sugars, water-soluble proteins and peptides, DNA, volatile aldehydes different to MDA, pigments,

amino acids, nitrites, metals and compounds with similar spectral properties to that of the TBA–MDA adduct. Numerous method modifications were developed to reduce these interfering reactions (Ganhao et al., 2007) (Fernandez et al., 1997) (Wang et al., 2002).
Recent research has shown that usage of sugar beet molasses as hypertonic solution improves osmotic dehydration processes (Koprivica et al., 2009). Molasses is an excellent medium for osmotic dehydration, due to the high dry matter (65-80%) and enrichment of the food material in minerals and antioxidants (Koprivica et al., 2009) (Guimaraes et al., 2007). High level of sucrose (44-54%), other sugars and their degradation products in molasses (El-Geweley, 1997), used in osmotic dehydration of meat, could generate interfering yellow chromagen (max. 450-460 nm) overlapping the pink peak (max. 530-537 nm) of TBA-MDA aduct. Yellow chromagen is formed by a variety of aldehydic compounds reacting with TBA (Fernandez et al., 1997). The reaction between TBA and MDA is more specific at room temperature than at boiling temperature. Hence, the interfering colorings can be reduced by incubating TBA and MDA at lower temperatures, while the reaction time can be reduced by increasing the concentration of TBA concentrations from 20 mM to 80 mM. The modified method can be used to measure MDA in the presence of high concentrations of interfering sucrose (higher than 4%), or other similar interfering agents (Wang et al., 2002).
The objective of this study was to choose the appropriate method for TBA-RS measurement in pork meat, osmotically dehydrated in sugar beet molasses which contained 4-13% of sucrose. The difficulty to determine the optimal conditions for the release of MDA from its bound forms in muscles without using strong acidic conditions and heating, which, could destabilize the MDA-TBA complex (Fernandez et al., 1997), was suggestive of combining mild extraction procedure (Wang et al., 2002) with different incubation temperatures and TBA concentrations in EM. The effectiveness of different EM-TBA was evaluated by applying the DM-TBA (Tarladgis et al.,1964).

MATERIALS AND METHODS

Osmotic dehydration

Fresh pork (Musculus brachii) of normal pH (6.05), was cut into approximately 1x1x1 cm ($1cm^3$) cubes and dehydrated in solutions of sugar beet molasses (81,95 ^{0}Brix) at 22°C for 5 hours.

Modified atmosphere packaging (MAP)

Osmotically dehydrated meat (100g/sample) were put in packaging molds under modified atmosphere (30% CO_2 : 70% N_2. Packaged meat samples were stored at 4 ± 0.5 ^{o}C for 105 days and at 4 ± 0.5 ^{o}C or 20±1 ^{o}C for 30 days.

Water content

Water content of the osmotic dehydrated samples was determined by the ISO 1442:1997.

Water activity (a_w)

a_w of the osmotic dehydrated samples was measured using a water activity measurement device (TESTO 650, Germany) with an accuracy of ±0.001 at 25ºC.

pH measurements

Was determined by ISO 11289:1993.

Acid value (free fatty acids, FFA)

Was measured after cold lipid extraction of samples (using chloroform), according to ISO standard method for determination of acid value and acidity in oils and fats of vegetable and animal origin, (ISO 660:1996). Acidity was expressed as acid value (mg KOH/g of sample) or as % FFA (% of oleic acid).

Peroxide value
Was measured after cold lipid extraction of samples (using chloroform), according to ISO standard method for determination of peroxide value in oils and fats of vegetable and animal origin (ISO 3960/1998). Peroxide value was expressed as mmol O_2/kg of sample.

TBA test
Secondary lipid oxidation products were determined using both aqueous acid extraction TBA method (EM), (Wang et al., 2002), and a distilation method (DM) Tarladgis et al. (1964). The incubation conditions in EM for TBA-reactive substances **(**TBA-RS) were: A) boiling temperature/25 min with 20 mM TBA, B) 40^{o}C/70 min, with 80 mM TBA and C) 20 ^{o}C/20 h with 20 mM TBA. D) The steam distillation TBA method (DM) was employed to evaluate the interferences with the spectrophotometric measurement at around 532 nm found in EM. TBA-RS values were calculated by multiplying the absorbance values at 532 nm by a constant coefficient K_{med}. K_{med} value was from standard curves and known dilutions of MDA standard (1, 1, 3, 3 tetrametoxypropane, TMP), and expressed as mg MDA/kg of sample.

Statistical analysis
MicroSoft Excel software (MicroSoft Office 2003) was used for statistical analyses. All measurements were performed in triplicate.

RESULTS AND DISCUSSION

Water content, water activity and pH in pork meat after osmotic dehydration
Dehydration in sugar beet molasses solution caused a significant moisture loss in meat samples, from initial water content of 75.957±0.045%, before osmotic dehydration, to 40.433±0.244%-47.13±0.030, after osmotic dehydration, during 105 days of observation.
The water activity (a_w) values decreased with the osmotic treatment from 0.938±0.002 to 0.872±0.00, which resulted in the microbiologically more stable product (Šuput, personal communication). After approximately 60 days, the a_w values raised to the final values of 0.894±0.001 (Fig.1). The enhancement of the a_w values coincided with the increase in total bacterial count after 60 days of observation (Šuput, personal communication).

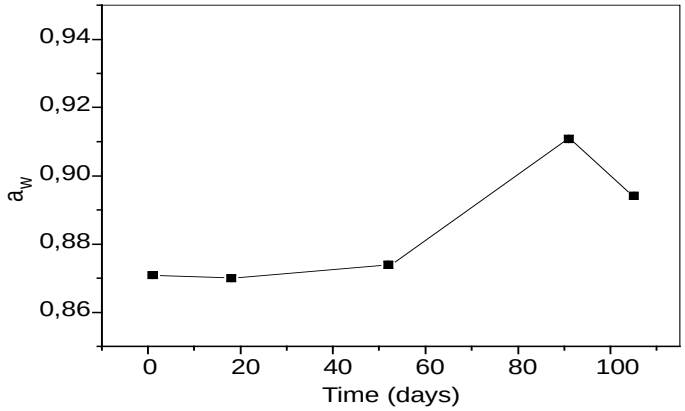

Figure 1. Water activity (a_w) kinetics during storage of pork meat, dehydrated in sugar beet molasses and stored in MAP at 4^{o}C.

pH values of osmotically dehydrated meat decreased during first 60 days of observation from 6.693±0.11 to 6.387±0.006. pH decreases in MAP more that in any other packaging, as common gases used in MAP are carbon dioxide (to inhibit bacterial growth), and nitrogen (to avoid oxidation of fats and pack collapse). Final increase of pH to 6.98±0.004 was probably caused by modified atmosphere changes.

Acid value (free fatty acids) and peroxide value

At refrigeration temperatures, free fatty acids are enzymatically released from neutral lipids and phospholipids. FFA in pork meat at 2°C are caused by lipases, produced by spoilage bacteria (Chung-Wang et al., 1997). In our study, the concentration of free fatty acids remained low, in the range of 17.64±0.5 to 22.3±0.54 mgKOH/g of sampe (0.049-0.63 % FFA). Primary lipid oxidation products were, also, low (peroxide value=0), except for microbiologically contaminated samples with increased water activity values, where elevated peroxide values (more than 12 mg O_2/kg were obtained).

TBA analysis

The effectiveness of different TBA tests in minimizing the interferences of sugar molasses, used as osmotic solution, was measured by aqueous acid extraction method (EM) under different conditions of incubation (A, B and C). Interferences, which cause erroneously high value of TBA-RS in meat samples dehydrated in molasses, were detected as absorption at 350 nm, 450-460 nm, and 532 nm. These spectrophotometric interferences, found also in diluted molasses solution, are overlapping the pink peak (532 nm), characteristic for MDA, (Fig. 2 and Fig. 3). The reaction of molasses with TBA was dependent on concentration and maximal at 100°C, (Fig. 2, scan 2 and 4), and than slowed when the incubation temperature was decreased, (Fig. 3, scan 2 and 4). It is known that sucrose reacts with TBA, generating a yellow adduct with maximum absorbance at 450 nm, when the incubation temperature is above 50 °C (Fig. 3, scan 5) and interfering reaction stopped when the incubation temperature was decreased to 40°C (Fig. 3, scan 5) (Wang et al., 2002). Since interferences in 20% molasses solution (with approximately 50% sucrose) was diminished, but not completely reduced, as in 10% sucrose, when the incubation temperature was decreased to 40°C (Fig. 3, scan 4 vs. scan 5), it is evident that some other TBA-reactive compounds, possibly antioxidants, (Guimaraes et al., 2007) may be present in the sugar molasses, which can lead to interferences with the spectrophotometric measurement and hence, cause an overestimation of the results. For such problematic samples, the DM TBA method may be a reliable option to assess TBA-RS values. The oscillations in TBA-RS values, obtained in DM method, (Fig. 4. D), are, however, suggestive of interferences from molasses. Molasses contain more than 40 volatile products, mainly aldehydes (El-Geweley, 1997), which could be released in DM procedure.

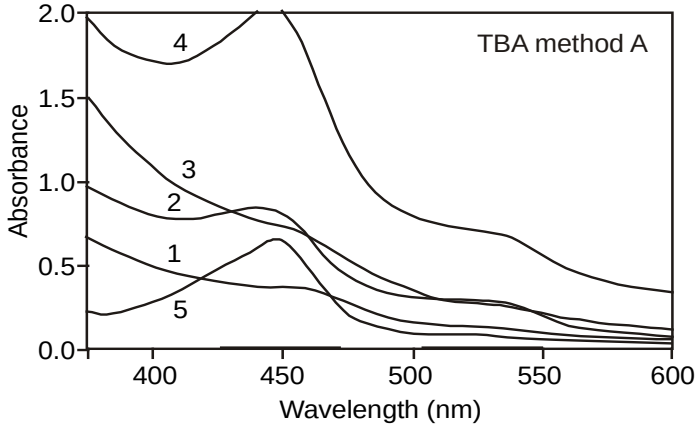

Figure 2. Scans of sugar beet molasses and sucrose absorbance in TBA method A (EM, 100°C/25 min, 20 mM TBA). Scans: 1) 10% molasses, before TBA reaction; 2) 10% molasses, after TBA reaction; 3) 20% molasses, before TBA reaction; 4) 20% molasses, after TBA reaction, 5) 10% sucrose after TBA reaction.

TBA-RS values were low in all analyzed methods, which are indicative of oxidative stability of osmotically dehydrated pork meat under storage in modified atmosphere and refrigerated conditions. Under storage at atmospheric conditions, in TBA method B, the most significant increase in TBA-RS values was found in meat samples stored 30 days at 20°C, (Fig. 5). It must be, however, taken into consideration that in dehydrated meat, mayor part of MDA may

be in volatilized form, which can cause difficulties in MDA detection (Fernandez et al., 1997). TBA values of microbiologically contaminated samples with increased water activity and peroxide values, were low in DM TBA method, in accordance with possible lipolytic effect of bacteria (Fig. 5, D) (Chung-Wang et al., 1997).

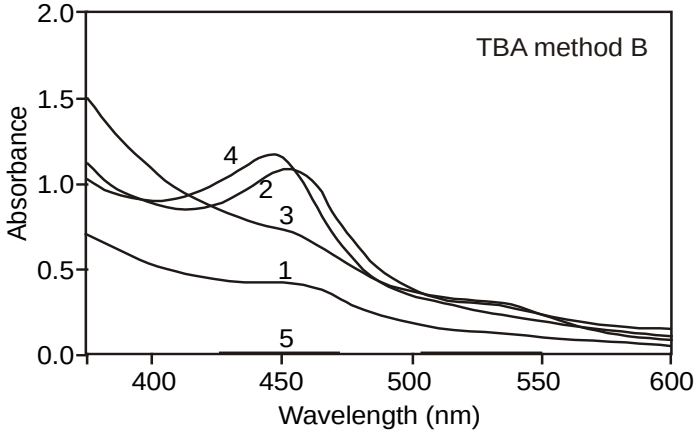

Figure 3. Scans of sugar beet molasses and sucrose absorbance in TBA method B (EM, 40°C/70 min, 80 mM TBA). Scans: 1) 10% molasses, before TBA reaction; 2) 10% molasses, after TBA reaction; 3) 20% molasses, before TBA reaction; 4) 20% molasses, after TBA reaction, 5) 10% sucrose after TBA reaction

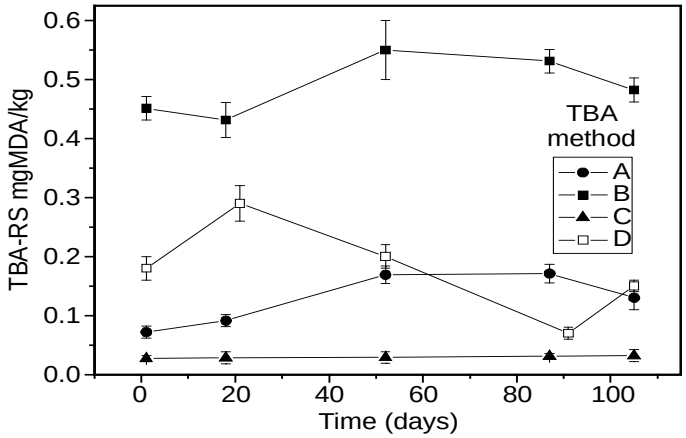

Figure 4. Thiobarbituric acid reactive substances (TBA-RS) kinetics during storage of pork meat, dehydrated in sugar beet molasses and stored in MAP at 4°C. TBA method*:

A) EM,100°C/25 min, 20 mM TBA
B) EM, 40°C/70 min, 80 mM TBA
C) EM, 20°C/20 h, 20 mM TBA.
D) DM, steam distillation

**Absobance values at 532 nm before TBA reaction was substracted.*

CONCLUSION

Pork meat was osmotically dehydrated in sugar beet molasses and stored for 105 days, at 4°C, under the modified atmosphere (MAP), or under atmospheric conditions at 4°C or 20°C for 30 days. The interferences of ingredients of sugar beet molasses, presumably sugars and sugar degradation products, are evaluated in TBA reaction for measuring secondary lipid oxidation products. The effectiveness of three TBA tests in minimizing the interferences of molasses ingredients was measured by aqueous acid extraction method (EM) under different conditions of incubation. The distillation TBA method (DM) was employed to evaluate the interferences found in EM, and low TBA values were obtained in all TBA procedures. Primary lipid oxidation products were, also, low, except in microbiologically contaminated samples with increased water activity values, where elevated peroxide values, but low TBA values

were obtained. TBA-EM may be the inadequate method for the analysis of oxidative deterioration of meat samples dehydrated in molasses, due to interferences which cause erroneously high values of TBA, detected as absorption at: 350 nm and 450-460 nm, present in dehydrated meat and sugar beet molasses itself, which are overlapping the pink peak (max. 532 nm), characteristic for MDA. TBA-EM procedure at low incubation temperature (40^oC) and elevated TBA concentration (80 mM) was the most sensitive of analyzed TBA methods. Low PV and TBA values in all analyzed methods are indicative of low lipid oxidation in osmotically dehydrated pork meat under storage in modified atmosphere at 4^oC.

ABSTRACT: The content of cadmium (Cd) was investigated in liver and kidney for five purebred pigs (Large White – LW, n = 48; Landrace – L, n = 48; Duroc – D, n = 48; Hampshire – H, n = 48 and Pietrain – P, n = 48), produced in Vojvodina. This element was determined by flame atomic absorption spectrometry after mineralization by dry ashing. The difference in the Cd content among the five purebred pigs was not significant in the analysed liver (F = 1.191; P = 0.315) and kidney (F = 0.867; P = 0.484) tissues. Pigs kidney Cd content was significantly higher (F = 461.650; P = 0.000) than liver. The order of the purebred pigs regarding Cd content in the liver samples in mg/kg was: H (0.057–0.261, on average 0.146) > LW (0.052–0.268, on average 0.138) > D (0.031–0.252, on average 0.133) > L and P (0.029–0.270 and 0.039–0.227, on average 0.124). The average Cd content in all investigated liver samples was 0.133 mg/kg. The order of the purebred pigs regarding Cd content in the kidney samples in mg/kg was: L (0.173–1.160, on average 0.412) > D (0.178–1.060, on average 0.398) > P (0.180–1.012, on average 0.367) > H (0.203–0.649, on average 0.366) > LW (0.168–0.654, on average 0.361). The average Cd content in all investigated kidney samples was 0.381 mg/kg. The maximum Cd content found in the liver samples was significantly below maximum level (0.5 mg/kg), while only 2.1% (n = 5) of kidney samples slightly exceeded the maximum level (1.0 mg/kg) set by EU and Serbian legislation. Obtained Cd contents in analysed liver and kidney tissues indicate Cd availability in the local agricultural environment in Vojvodina.

INTRODUCTION

Cadmium is a heavy metal found as an environmental contaminant, both through natural occurrence and from industrial and agriculture sources. The metal has been reviewed by the International Register of Potentially Toxic Chemicals of the United Nations Environment Programme. As a result, it has been included on the list of chemical substances and processes considered to be potentially dangerous at the global level (IRPTC, 1987). It is toxic, teratogenic, mutagenic and carcinogenic to most organisms (Robards and Worsfold, 1991).

Food is the most important source of cadmium exposure in the general non-smoking population in most countries (Andrée et al., 2010; Järup and Åkesson, 2009; Järup, 2003; Robards and Worsfold, 1991; Doyle and Spaulding, 1978). Cadmium is likely to accumulate in the food chain (Dave Oomah et al., 2007; Oskarsson et al., 2004; Lindén et al, 2003; Sharma et al., 1982). In mammals, cadmium is virtually absent at birth but accumulates with time, especially in the liver and kidney (Andrée et al., 2010; Järup and Åkesson, 2009; Sapunar-Postružnik et al., 2001; Lindén et al., 1999; Robards and Worsfold, 1991; Henke et al., 1970). Cadmium is efficiently retained in liver and kidney with a very long biological half life ranging from 10 to 30 years (Andrée et al., 2010; Järup and Åkesson, 2009; Friberg et al., 1974).

The World Health Organisation (1992) has recommended that the provisional tolerable weekly intake (PTWI) of cadmium not exceed 0.4–0.5 mg per person or 0.007 mg/kg body weight.

The cadmium maximum levels in food have been regulated in Republic of Serbia by national legislation (Serbian Regulation, 1992a, 1992b, 2002), which is in accordance with legislation of European Union (Commission Regulation (EC) No 1881/2006). The maximum levels are 0.05, 0.5 and 1.0 mg/kg (wet weight) for pig meat, liver and kidney, respectively.
Pig meat is the most widely consumed meat in the EU (Williamson et al., 2005), as well as in Serbia, and the consumption has been steadily increasing. The Autonomous Province of Vojvodina (the northern part of the Republic of Serbia) is a region where the number of animals of the porcine species and the production of pork meat are of high economic importance. Over 30 percent of the total number of pigs slaughtered annually in Serbia comes from Vojvodina. Five purebred pigs (Large White, Landrace, Duroc, Hampshire and Pietrain) and their crosess are used for commercial pork production. In (cross)breeding programme Large White and Landrace are used as female lines and Duroc, Hampshire and Pietrain are used as male lines.
The aims of this study were: (i) to obtained the cadmium levels of liver and kidney from pigs in Vojvodina; (ii) to investigate the potential differences in cadmium levels of liver and kidney among five purebred pigs, used nowadays in Vojvodina for pork production; (iii) to compare the obtained values with the maximum levels set by European Commission, i.e. by national legislation. The overall objective is to produce high quality pork to ensure the competitiveness of Vojvodian pork in the international meat markets.

MATERIALS AND METHODS

Animals, sampling and preparing

In this study five purebred pigs (castrates males and females) were used: Large White (LW), n = 48; Landrace (L), n = 48; Duroc (D), n = 48; Hampshire (H), n = 48; and Pietrain (P), n = 48.
The pigs were fattened at the production farms in the northern part of the Republic of Serbia (Autonomous Province of Vojvodina). The pig fattening involved the following phases: starting period (from 15 to 25 kg), growing period (from 25 to 60 kg) and finishing period (from 60 to 110 kg). The diets were based on locally produced corn and soybean meals, and were formulated to meet the nutrient requirements (National Research Council, 1998) for the different growth phases. The finishers were housed in pens with fully slatted floor and 0.80 m^2 space allocation per pig. Each pen contained 10 animals. The environmental temperature in the building was 22°C. All pigs had ad libitum access to a diet and water.
Animals were randomly selected during one year period. The pigs were slaughtered at a live weight between 95 and 110 kg and about six months old in the two biggest Vojvodian slaughterhouses according to routine procedure. Liver and kidney were conventionally chilled for 24 h in a chiller at 2-4°C. The samples for chemical analysis (approximately 250 g) taken after the homogenization of the whole liver and both kidney, were vacuum packaged in polyethylene bags and stored at –40°C until analysis.

Analytical methods and quality control

The cadmium (Cd) content was determined after dry ashing mineralization (Tomović et al., 2011; Gorsuch, 1970). Cd was measured in the ash solution by flame atomic absorption spectroscopy according to the manufacturer's instructions (Varian Spectra AA 10, Varian Techtron Pty Limited, Mulgvare Victoria, Australia, 1989).
The analysis of the certified reference material (ERM - CE278, Mussel tissue, IRMM, Geel, Belgium) was used for analytical quality control programme. The results of the analytical quality control programme are presented in Table 1. All analyses were performed in duplicate.

Table 1.The results of the analytical quality control programme (n = 8) used in the determination of the cadmium in liver and kidney

Element	Cd
Certified concentration (mg/kg)	0.348 ± 0.007
Recovery (%)	98.3 ± 6.22
Limit of detection (mg/kg)	0.050
Limit of quantitation (mg/kg)	0.075

Statistical analysis

All data are presented as average, standard deviation (SD) and range (Min, Max). Independent t-test and analysis of variance (one-way ANOVA) were used to test the hypothesis about differences between two or more average values. The software package STATISTICA (2008) was used for analysis.

RESULTS AND DISCUSSION

Average concentrations, standard deviations and ranges of cadmium in the liver and kidney tissue samples from five different purebred pigs are presented in Table 2. Only 3.75% of liver samples were below, while all kidney samples were above the detection limit. The minimum Cd content found in liver samples was greater than half the detection limit; therefore, all measured values were used for calculating the average (Miranda et al. 2001).

Table 2.Cadmium levels (mg/kg wet weight) in the liver and kidney of various purebred pigs from Vojvodina

	Purebred	LW	L	D	H	P	F value	*P* value[1]	Total
Liver	X	0.138	0.124	0.133	0.146	0.124	1.191	0.315	0.133
	Sd	0.060	0.072	0.050	0.059	0.049			0.059
	Min	0.052	0.029	0.031	0.057	0.039			0.029
	Max	0.268	0.270	0.252	0.261	0.227			0.270
Kidney	X	0.361	0.412	0.398	0.366	0.367	0.867	0.484	0.381
	Sd	0.121	0.249	0.184	0.117	0.137			0.169
	Min	0.168	0.173	0.178	0.203	0.180			0.168
	Max	0.654	1.160	1.060	0.649	1.012			1.160
	F value	131.015	59.194	93.136	136.446	133.328			461.650
	P value[2]	0.000	0.000	0.000	0.000	0.000			0.000

[1] *indicates significant difference between purebred within raw*

[2] *indicates significant difference between liver and kidney tissue within column*

The order of the purebred pigs according to average cadmium content in the liver samples in mg/kg was: H (0.057–0.261, on average 0.146) > LW (0.052–0.268, on average 0.138) > D (0.031–0.252, on average 0.133) > L and P (0.029–0.270 and 0.039–0.227, on average 0.124). Cadmium levels found in the present study did not differ significantly (F = 1.191; *P* = 0.315) among liver tissue for the different purebred pigs (Table 2). Individual cadmium concentrations (maximum/minimum quotient) in liver tissues differed between animals with an average of 9.3. Average wet weight level for cadmium in liver from pigs in Vojvodina was 0.133 mg/kg. The maximum cadmium concentration found (0.270 mg/kg) in the present study was below maximum level (0.5 mg/kg) set by EU and Serbian legislation (Commission Regulation (EC) No 1881/2006; Serbian Regulations 1992a, 1992b, 2002). Overall, 94.2% of liver samples had cadmium levels below half of the maximum level.

The order of the purebred pigs according to average cadmium content in the kidney samples in mg/kg was: L (0.173–1.160, on average 0.412) > D (0.178–1.060, on average 0.398) > P (0.180–1.012, on average 0.367) > H (0.203–0.649, on average 0.366) > LW (0.168–0.654, on average 0.361). Cadmium levels found in the present study did not differ significantly (F = 0.867; *P* = 0.484) among kidney tissue for the different purebred pigs (Table 2). Individual cadmium concentrations (maximum/minimum quotient) in kidney tissues differed between animals with an average of 6.9. Average wet weight level for cadmium in kidney from pigs in

Vojvodina was 0.381 mg/kg. The maximum cadmium concentration found in kidney (1.160 mg/kg) in the present study was above the maximum level (1 mg/kg) set by EU and Serbian legislation (Commission Regulation (EC) No 1881/2006; Serbian Regulations 1992a, 1992b, 2002). However, only 5 kidney samples (2.1%) slightly exceeded the tolerance level. Even 86.3% of kidney samples had cadmium levels below half of maximum level. Average cadmium concentrations in kidney were significantly higher ($F = 461.650$; $P = 0.000$) than those in liver.

The average cadmium concentrations in the pig liver and kidney from Vojvodina were in the higher range than those reported for pig liver and kidney in Spain (López-Alonso et al., 2007), Sweden (Lindén et al., 2003; Lindén et al., 2001; Lindén et al., 1999; Grawé et al., 1997; Jorhem et al., 1991), Czech Republic (Ulrich et al., 2001), Finland (Tahvonen and Kumpulainen, 1994; Niemi et al, 1991), Poland (Falandysz, 1993) and The Netherlands (Vos et al.,1986). On the contrary, the cadmium levels of liver and kidney from pigs in Croatia (Sapunar-Postružnik et al., 2001), a neighbour country of Serbia, were far above the levels found in this study, i.e. several times higher than the maximum set level. According to many authors (Andrée et al., 2010; Oskarsson et al., 2004; Lindén et al. 2003; Lindén et al., 2001; Sapunar-Postružnik et al., 2001; Lindén et al., 1999; Grawé et al., 1997; Sharma et al., 1982) the cadmium concentrations in animal tissues, especially liver and kidney, are strongly related with the cadmium levels in feedstuffs.

CONCLUSION

The results of the present study show that the levels of cadmium in the liver and kidney were not influenced by purebred. However, the variations in cadmium levels in analysed liver and kidney tissues indicate cadmium availability in the local agricultural environment in Vojvodina.

ABSTRACT: In sugar industry, there is a problem of the presence of undesirable macromolecules compounds such as pectins and proteins in sugar beet juice. Separation of these compounds is done mostly by compounds with calcium ion. Affinity of calcium binding with undesirable macromolecules from sugar beet juice is not significant. The aim of this study is application of alternative coagulants with divalent and trivalent cations, $CuSO_4$ and $Al_2(SO_4)_3$ with or without the addition of polyelectrolyte which cause the process of charge neutralization macromolecules followed by polymeric bridging effect. Mechanism of discharge of macromolecules compounds using a model of double electric layer are suggested. Volume 50 cm^3 model solution of pectin (0.1 % w/w) was treated with seven volumes of $CuSO_4$ solution, ranging of 0.47 - 3.29 cm^3 and seven volumes of $Al_2(SO_4)_3$ solution, ranging of 0.59 - 4.15 cm^3. Optimal quantities of the applied coagulants, determined by measuring the Zeta potential values, where estimated as follows: 0.24 % (w/w) $CuSO_4$ and 0.45 % (w/w) $Al_2(SO_4)_3$ & Na_2CO_3 on sugar beet. This is much lower than 1 – 3 % (w/w) CaO commonly used in sugar production. Adding different concentrations of cationic polyelectrolytes in these solutions, the highest efficiency of clarification was noticed by applying cationic polyelectrolytes of concentration 3 mg/dm^3. It was shown that this type of polyelectrolyte further reduced the value of Zeta potential. Zeta potential of sugar beet pectin macromolecules was determined by electrophoretic method.
Key words: *Zeta potential, pectin, sugar beet, metal salts, polyelectrolyte*

INTRODUCTION

Charge neutralization plays a major role in undesirable macromolecules removal in water treatment. These substances are easily coagulated using metal salts. The addition of cationic polyelectrolyte in metal salts increased undesirable substances removal due to the combined charge neutralization of the metals and polyelectrolytes (Hilal et al., 2008, Duan and Gregory, 2003, Karlovič, 2002). Charge neutralization mainly takes place through the reaction of net charge opposite ions with free functional groups on the colloid surface reducing the overall net surface charge.

In sugar industry, separation of nonsaccharose compounds in the sugar beet juice, is done mostly by compounds with calcium ion. Double electric layer which surrounds all colloidal particles in solution, such as sugar beet juice, is consisted of two layers, the adsorbed and diffuse layer. The difference in potential between these layers is called electrokinetic or Zeta potential. Zeta potential is the main parameter in electrokinetic measurements, since this is a measurable value (Delgado et al., 2007, Kuljanin et al., 2008). Pectins in sugar beet juice are anionic charged colloids. Zeta potential of pectin is negative and it is strong enough to impair the coagulation and agglomeration. Addition the oppositely charged polyvalent cations can decrease the Zeta potential to near zero, causing the pectin macromolecules to discharge. In this case system's stability is lost, which leads to the coagulation and precipitation of agglomerated pectin substances (Lević et al., 2007, Kartel et al., 1999, Schneider et al., 2011). The binding affinity of divalent cations with pectins of botanical origin follows the selectivity order (Garnier et al., 1994 and Dronnet et al., 1996):

$$Cu^{2+} \sim Pb^{2+} >> Zn^{2+} > Cd^{2+} \sim Ni^{2+} > Ca^{2+} > Mg^{2+}$$

Such a diversity in the binding affinity of metal ions could be explained by two types of bindings: electrostatic binding of Ca^{2+}, Mg^{2+}, Zn^{2+} ions and formation of surface complexes by Cu^{2+} and Pb^{2+} ions. In accordance with this selectivity order, it is clearly that applying of Cu^{2+} ions will be much efficient in sugar beet juice clarification in relation to classical process by compounds with Ca^{2+} ions (Garnier et al., 1994, Wiedemer et al., 2000, Kuljanin et al., 2010).
Affinity of binding of threevalent cations with pectin macromolecules was not investigate. However, there are many studies of applying of Al^{3+} ions, especially in form of $Al_2(SO_4)_3$ in water treatment (Duan and Gregory 2003, Pattabi et al., 2000). The overall ability of pectin macromolecules to form complexes with polyvalent cations depends primarily on the degree of esterification and degree of polymerization of pectin (Pellerin et al., 1998, Dronnet et al., 1996).
Another mechanism that causes the coagulation and precipitation of the undesirable macromolecules are interparticle bridging. Interparticle bridging occur using high molecular weight polyelectrolytes where colloids are adsorbed into the polymers branches or share ions directly to form ionic bridges. (Hilal et al., 2008, Pattabi et al., 2000, Fellows et al., 2000).
The aim of the study presented in this paper was to investigate the effects of hydrolyzing metal salts ($CuSO_4$ and $Al_2(SO_4)_3$) and polyelectrolyte concentration on pectin macromolecules removal from sugar beet juice. The efficiency of ion binding, with and without addition of cationic polyelectrolyte, was determined according to electrophoretic method by measuring Zeta potential.

MATERIAL AND METHODS

Pectin preparate was extracted from cossettes obtained in the industrial processing of sugar beet (factory Žabalj). The metal salts, $CuSO_4$ and $Al_2(SO_4)_3$ in crystal hydrate form, were used for preparation the studied solutions with de-ionized water. The pH of solutions with $Al_2(SO_4)_3$ was regulated at value 7 before each experiment, using equivalent amount Na_2CO_3. High purity cationic polyelectrolyte with ammonium group (MAGNAFLOC LT-24) was purchased from Low Moor, Bradford. It has an average molecular weight ~ 100 000 kg/kmol and 100 % cationic charge density.
Extraction of pectin was conducted at pH 3.5 and 85°C during 2.5 h. The pectin preparation was precipitated from the extract with 70% ethanol solution. Basic parameters of the pectin preparation were determined according to standard methods of AOAC (Methods of Analysis of Official Analytical Chemists, 2000). Mean molar mass of pectin preparation was determined according to refractrometric and spectrophotometric method (Kar and Arslan, 1999). Degree of esterification (DE) was calculated using equivalents of free (X) and esterified carboxy groups (Y) (Fares, et al., 2003; Kuljanin et al., 2010).
In the first stage of the experiment, a series of coagulant concentrations in the range of 30, 60, 90, 120, 150, 180 and 210 mg/dm^3 was prepared by adding the necessary volumes of the solution to 50 cm^3 of 0.1 % (w/w) pectin solution. To accomplish the desired solution alkalinity (pH 7), Na_2CO_3 was added to $Al_2(SO_4)_3$ (mass ratio of Na_2CO_3 to $Al_2(SO_4)_3$ was 1 : 1.07, calculated on pure $Al_2(SO_4)_3$). After the coagulant was added to the tested preparations, pH was adjusted and the solution was stirred for 30 min on a high-speed magnetic stirrer (500 rpm). Then, the solution was stirred for another 5 min at low speed and left to rest another 5 min. In the second stage of the experiment, basic solution of flocculants was prepared by dissolving 0.5 g of flocculants in 100 cm^3 of distilled water and left overnight to swell at room temperature. In experiment was used operating solution of 0.05 % (w/w). From this solution, flocculants concentrations in the range of 1, 3 and 5 mg/dm^3 was prepared. Pectin solutions with coagulants and flocculants before Zeta potential measurements, was manually and slowly stirred for 5 min and left to rest another 5 min.
Zeta potential was determined by electrophoretic method using a commercial apparatus ZETA-METER ZM 77 (Riddick, 1975). An average value of 3 readings was used to derive the Zeta potential of colloidal particles in the tested solutions using a diagram based on the *Helmoltz-Smoluchowski* equation for electrophoretic mobility of colloidal particles. Experiments were conducted at 6-fold magnitude and voltage adjusted at 200 V.

Immediately before Zeta potential measurements, solution temperatures were measured. Zeta potential was read from the diagram and multiplied by a correction factor for a given temperature.

RESULTS AND DISCUSSION

Results related to the composition of pectin preparation are given in Table 1. The content of galacturonic acid (degree of purity) in the tested preparation is in agreement with the mean content of pectin found in raw sugar beet juices from diffuser reported in literature. The obtained preparation was low esterified pectin (DE < 50) and the molar mass was determined by measuring 5 different concentrations of pectin (Kar and Arslan, 1999).

Table 1. Basic physico-chemical composition of pectin preparation

Solid content, SC (g/100g)	Equivalent of free COOH groups, $X \cdot 10^5$	Equivalent of ester. COOH groups $Y \cdot 10^5$	Content of galacturonic acid (%)	Degree of esterific. DE	Mean molar mass, M_{Wsr} (kg/kmol)
80.35	24.58	16.05	72.24	39.50	87 720

Changes of mean values of Zeta potential (mV) of the tested preparation after adding various quantities of coagulants $CuSO_4$ and $Al_2(SO_4)_3$ in the form of pure salts (mg/dm^3) are shown in Figure 1. Changes of mean values of Zeta potential after the addition of coagulants and cationic flocculants are shown in Figures 2 and 3.

In all experiments, charge inversion of Zeta potential from negative to positive was observed within the whole series of tested coagulants concentrations. Total net charge of Cu^{2+} and Al^{3+} ions (including H^+ ions in the solution) increased in magnitude in comparison to the magnitude of negative charge on the surface of pectin macromolecule. This proves that, besides ionic exchange and lowering of surface potential by charge neutralization, surface complexation of Cu^{2+} and Al^{3+} ions with COO^- groups of pectin macromolecules was occurred. The results indicate that heavy metal ions Cu^{2+} link stronger to polygalacturonic chains of pectin macromolecules than lighter cations Al^{3+}. According to the *Schulze-Hardy* rule, ions with high valence like Al^{3+} should be able to decrease Zeta potential to zero point at much lower concentration. However, from the results presented on Figure 1, it is obvious that in the tested preparation, less amount of $CuSO_4$ (82.0 mg/dm^3) compared to $Al_2(SO_4)_3$ (105 mg/dm^3) was required for lowering Zeta potential to zero point. This can be explained by higher binding ability of these ions considering that Cu^{2+} ions are first-ranged in the previously given selectivity order. It is possible that other mechanisms also take part:

- since Cu^{2+} ions have higher density than Al^{3+} ions, their kinetic energy is higher enabling their easier location in the adsorbed part of double electric layer, neutralising the surface charge of pectin macromolecules.
- Cu^{2+} ions are less hydrated due to larger ionic diameter in comparison to Al^{3+} ions. Less hydrated Cu^{2+} ions affects the velocity of their distribution into the diffuse layer of the double electric layer and consequently, into the adsorbed layer on the macromolecule surface.

If the quantity of $CuSO_4$ is recalculated at the industrial level, 0.24 % (w/w) on sugar beet will be obtained. The combination of $Al_2(SO_4)_3$ & Na_2CO_3 is less efficient. If the quantity of $Al_2(SO_4)_3$ & Na_2CO_3 is recalculated at the industrial level, 0.45 % (w/w) on sugar beet will be obtained. This is much lower than 1 – 3 % (w/w) CaO commonly used in sugar production.

Results of experiments carried out with the cationic polyelectrolytes, show a slight deviation change in Zeta potential using concentrations of 3 and 5 mg/dm^3 (Figure 2 and 3). The addition of cationic flocculants concentration of 3 mg/dm^3, the required amount of coagulant $Al_2(SO_4)_3$ to decrease the Zeta potential to zero point is less and amounts to 95 mg/dm^3 (Figure 3) while the amount of coagulant $CuSO_4$ even lower, at around 70 mg/dm^3 (Figure 2). Though not extensively reported in literatures, it is highly possible that cationic polyelectrolyte provides additional charge neutralization associated with mechanism of interparticle bridging.

Interparticle bridging includes that the pectic macromolecules are adsorbed into the high molecular weight polyelectrolytes branches.

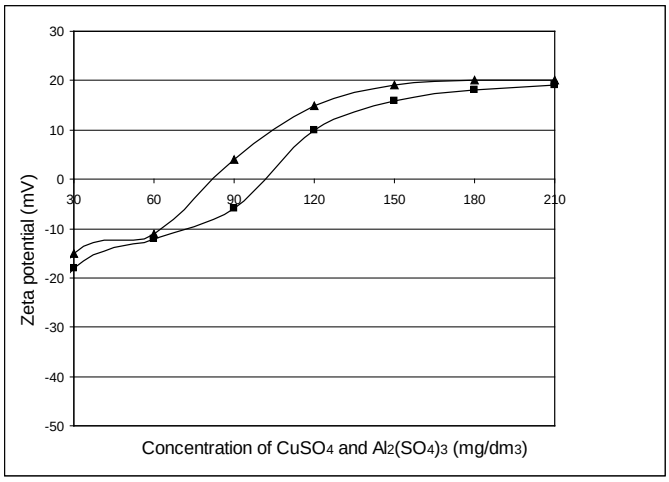

Figure 1. Dependence of the Zeta potential of pectin solution on the $CuSO_4$ and $Al_2(SO_4)_3$ concentration: ▲- $CuSO_4$ ■ - $Al_2(SO_4)_3$

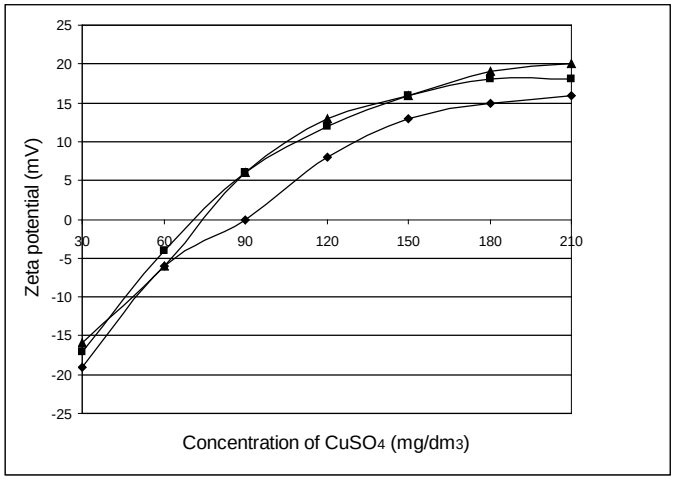

Figure 2. Dependence of the Zeta potential of pectin solution on the $CuSO_4$ concentration using three concentration of cationic flocculants: ♦ - 1 mg/dm^3; ■ - 3 mg/dm^3; ▲– 5 mg/dm^3

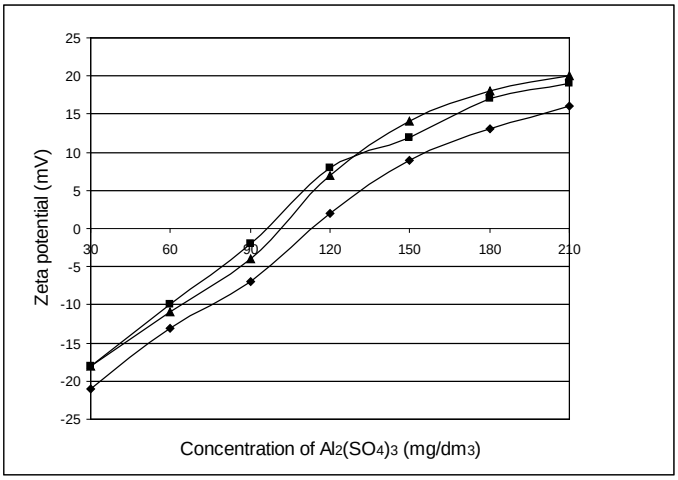

Figure 3. Dependence of the Zeta potential of pectin solution on the $Al_2(SO_4)_3$ concentration using three concentration of cationic flocculants: ♦ - 1 mg/dm^3; ■ - 3 mg/dm^3; ▲– 5 mg/dm^3

CONCLUSIONS

The influence of metal ions and cationic polyelectrolyte on Zeta potential of sugar beet pectin solution has been investigated. Hydrolyzable metal salts, $CuSO_4$, $Al_2(SO_4)_3$ and cationic polyelectrolyte all had a pronounced effect on the magnitude of the particle Zeta potential, which reflected in coagulation and flocculation performance. Cu^{2+} ions have larger influence on surface charge of pectin macromolecules and consequently higher destabilizing effect in comparison with Al^{3+} ions.
Cationic polyelectrolyte (MAGNAFLOC LT-24, concentration of 3 mg/dm^3) in combination with these metal salts, produced better charge neutralization and inter-particle bridging of pectin macromolecules in comparison with metal salts without polyelectrolytes.
Besides the tested ions and polyelectrolyte, for successful coagulation of pectin macromolecules, numerous other factors must be investigated such as kind of ions and polyelectrolytes, mixing effect and effect of mixture of different ions.

ABSTRACT: Since ancient times, aromatic herbs and spices have been added to different types of foods to improve the flavour and sensory properties.Rosemary (*Rosmarinus officinalis* L.) is a perennial herb that belongs to Lamiaceae family. It is used as a food flavouring agent and is also well known medicinally for its powerful antimutagenic, antibacterial and chemopreventive properties. Additionally, it has been demonstrated that the plant exhibits antioxidant activity. The leaves of rosemary as well as other wild edible plants used for culinary purposes give low yields of oil, but this oil is a rich source of essential fatty acids, such as α-linolenic acid (18:3n-3) and linoleic acid (18:2n-6). Linolenic acid and fatty acids of n-3 and n-6 series play an important role in the modulation of human metabolism. In this study, the qualitative and quantitative composition of leaf lipids of rosemary (*Rosmarinus officinalis* L.) grown in Serbia has been investigated. Gas chromatography – mass spectrometric analyses showed major fatty acids to be α-linolenic, linoleic and palmitic acids of which contents were within the ranges of 32.4-42.0; 21.3-27.9 and 12.5-17.1% of the total fatty acids, respectively. Results showed that rosemary is rich source of essential fatty acids (18:3n-3 and 18:2n-6), with favourable n-6/n-3 ratio.
Key words: *fatty acid, rosemary, gas chromatography, mass spectrometry*

INTRODUCTION

Rosemary (*Rosmarinus officinalis* L.) is a very important medicinal and aromatic plant, which belongs to the Lamiaceae family and has been cultivated for a long time. Anthropologists and archaeologists have found evidence that rosemary branchs with their leaves were used as medicinal, culinary and cosmetic virtues in the ancient Egypt, Mesopotamia, China and India (Stefanovits-Bányai et al., 2003). Nowadays, rosemary is one of the most appreciated sources of natural bioactive compounds which are of special interest in the functional food industry (Borrás Linares et al., 2011). In fact, this plant exerts a great number of pharmacological activities, such as antimicrobial (Santoyo et al., 2005; Bozin et al., 2007), antiviral (Auroma et al., 1996), antitumor (Huang et al., 2005), anti-inflammatory (Altinier et al., 2007) and antioxidant (Pérez-Fons et al., 2010; Bozin et al., 2007) activities.
Rosemary is an evergreen branched bushy shrub, attaining a height of about one meter with upright stems and dark green leaves which are small and with edges turned over backward. Underneath these rolled edges are little glands containing aromatic oils. The leaves of rosemary as well as other wild edible plants used for culinary purposes give low yields of oil, but are rich sources of essential fatty acids, such as α-linolenic acid (ALA, 18:3n-3) and linoleic acid (LA,18:2n-6). Both LA and ALA acid are metabolized to longer chain polyunsaturated fatty acids with 20 and 22 carbon atoms. Omega 6- and omega 3-polyunsaturated fatty acids (PUFA) have specific physiological functions, they are necessary for proper growth and development and are therefore of nutritional importance (Trautwein, 2001). Omega-3 fatty acids play an important role in modulating human metabolism and have beneficial effects against cardiovascular disease and cancer, two of the major diseases of the 21st century. Hence omega-3 PUFA has been widely accepted as one of the cornerstones of healthy lifestyle and nutrition.

MATERIAL AND METHODS

Samples of rosemary (*Rosmarinus officinalis* L.) were collected in October 2010 from three different locations in Vojvodina (Northern part of Serbia). For lipid extraction and FA analysis, only the leaves were used, which were removed from the stems. The moisture content was determined drying to the constant mass by the oven method (105°C for 3 h). Total lipids from leaves were extracted according to the method of Soxhlet using petroleum ether as solvent and further analysis were done by gas chromatograph equipped with mass spectrometer detector (GC-MS).

Preparation of fatty acids methyl esters

Fatty acid methyl esters were prepared using a fast method (Kravić et al. 2006), as follows: approximately 60 mg of extracted fat was put into a test tube and dissolved in 2.4 ml of hexane. An aliquot (0.6 ml) of 2 mol/dm^3 methanolic KOH solution was added. The tube was capped and vigorously shaken for 20 s and allowed to boil one minute in water bath at 70°C. After 20 s of shaking 1.2 ml of 1 mol/dm^3 HCl was added and gently stirred. After phase separation 3 ml of hexane was added, and the upper phase containing the fatty acid methyl esters were decanted and dissolved in hexane to 5 ml. Aliquot of 1 µl was taken for GC-MS analysis.

Gas chromatography-mass spectrometry analysis

The analysis of fatty acid methyl esters were performed on a Hewlett-Packard (HP) 5890 gas chromatograph coupled with a HP 5971A mass spectrometer detector. A fused silica capillary column SP-2560 (100 m × 0.25 mm i.d., 0.20 µm film thickness) was used. The inlet temperature was 230°C with a split ratio 1:20. Carrier gas was helium with constant flow rate of 0.58 cm^3 min^{-1}. The initial temperature of 100°C was held for 5 min and increased by 6°C/min to an end temperature of 240°C. The mass spectrometer was operated in the electron ionization mode with quadruple temperature of 180°C. Data acquisition was carried out in the scan mode (range 50 - 400 m/z). A multistandard from Supelco (Cat. No. 47885-U, Bellefonte, PA, USA) containing the methyl esters of 37 fatty acids was used to confirm the retention times and mass spectra for peak identification, as well as to confirm that the peak areas reflected the actual composition of these mixtures.

RESULTS AND DISCUSSION

Samples locality and moisture content are given in Table 1. Table 2 shows the fatty acid composition of rosemary leaves. Fatty acid contents are expressed as weight percentages of total fatty acid methyl esters. Values are presented as the mean ± standard deviation (SD) of three replicates.

To the best of our knowledge, no earlier studies were reported in literature regarding the fatty acids composition of rosemary leaves. Thus, we reported that α-linolenic was the major fatty acid, followed by linoleic and palmitic acids, with mean values of 38.5, 24.8 and 15.0%, respectively. These three fatty acids represent 78% of rosemary total fatty acids. Stearic and oleic acid were presented at moderate level, presenting together 15%. Linoleic and α-linolenic acids are two essential fatty acids that humans and other mammals must ingest for good health because their body requires them for various biological processes but cannot biosynthesize them from other food components (Bettaieb et al., 2011). The contents of fatty acids are in agreement with another report for other edible plant species (Guil-Guerrero and Rodríguez-García, 1999) in respect to the predominant fatty acids.

Table 1. Sample (*Rosmarinus officinalis* L.) locality and moisture content of rosemary leaves

	Sample locality	**Moisture content** (g/100 g)
Sample 1	Novi Sad	55.42
Sample 2	Rumenka	52.21
Sample 3	Irig	54.34

Table 2. Fatty acid centesimal composition of total lipids from rosemary leaves

fatty acid	**Sample 1**	**Sample 2**	**Sample 3**
12:0	0.2 ± 0.01	ND	ND
14:0	1.1 ± 0.03	ND	ND
16:0	12.5 ± 0.12	15.4 ± 0.23	17.1 ± 0.41
16:1	0.5 ± 0.04	ND	ND
17:0	0.3 ± 0.02	ND	ND
17:1	1.2 ± 0.07	ND	ND
18:0	5.2 ± 0.03	5.7 ± 0.31	5.8 ± 0.31
18:1	10.1 ± 0.01	9.8 ± 0.13	9.1 ± 0.13
18:2n-6	21.3 ±0.21	27.9 ± 0.69	25.2 ± 0.15
20:0	2.3 ± 0.06	ND	5.4 ± 0.15
20:1	0.9 ± 0.07	ND	ND
18:3n-3	42.0 ± 0.08	41.1 ± 0.17	32.4 ± 0.92
22:0	1.7 ± 0.12	ND	2.7 ± 0.11
24:0	0.8 ± 0.06	ND	2.3 ± 0.13
SFA	24.1	21.1	33.3
MUFA	12.6	9.8	9.1
PUFA	63.3	69.1	57.6
∑ n-6	21.3	27.9	25.2
∑ n-3	42.0	41.1	32.4
n-6/n-3	0.5	0.7	0.8

Results are given as mean ± standard deviation (n = 3); ND – not detected; SFA - saturated fatty acid; MUFA - monounsaturated fatty acids; PUFA – polyunsaturated fatty acids

In the last decades, it is widely accepted that an excessive intake of saturated fatty acids and/or a low intake of omega-3 polyunsaturated fatty acids may lead to series of severe metabolic disorders. As can be seen from the obtained results rosemary leaves were characterised by a high proportion of polyunsaturated fatty acids (mean value 63.3%) versus 26.2% of saturated and 10.5% of monounsaturated ones. Moreover, examined rosemary samples have had favourable n-6/n-3 ratio, which were between 0.5 and 0.8. An n-6/n-3 fatty acid ratio of 5:1 or less is desired, as suggested by nutrition experts (Rubio-Rodríguez et al., 2010). Reducing the ratio of n-6 to n-3 polyunsaturated fatty acids to 4:1 has been found to reduce total mortality by 70% in secondary prevention of cardiovascular disease; a ratio of 5:1 is beneficial for asthma; 2–3:1 reduces rheumatoid arthritis inflammation and a ratio of 2.5:1 reduces colorectal cancer cell proliferation (McManus et al., 2011). The plant cell membranes are dynamic in behaviour, with a lipid composition depending on the age of the plants and environmental factors such as temperature, drought, salinity levels and the other. No negligible difference in palmitic, linoleic, linolenic and arahidic acid contents, among rosemary samples probably were results of different cultural conditions.

CONCLUSIONS

The fatty acid composition of rosemary (*Rosmarinus officinalis* L.) leaf lipids were determined by gas chromatography-mass spectrometry. Obtained results showed that the rosemary is rich source of polyunsaturated essential fatty acids (linoleic and α-linolenic), with favourable n-6/n-3 ratio. These indicated that fatty acid composition improved other well known nutritional values of rosemary.

ABSTRACT: There is a growing interest in spelt wheat (*Triticum aestivum* ssp. *spelta* L.) due to its low input requirements and valuable nutritional properties. Compared to common wheat, spelt might be more resistant to fungal diseases and perform better in ecologically friendly farming systems. Genus *Alternaria* includes pathogenic and saprophytic species causing economic losses in food production. Many *Alternaria* spp. are allergens and mycotoxin producers harmful for human and animal health. The aim of this work was to investigate the effect of hulls in protection of spelt kernel against penetration of *Alternaria* spp. Additionally, impact of *Alternaria* spp. infestation on length and weight of spike was assessed. Field experiment was carried out in the 2010/2011 season in the region of Vojvodina on three spelt wheat genotypes. Inoculation was performed with an aqueous suspension of *A.alternata* conidia and two isolates of *A.tenuissima* obtained from 14-day old cultures grown on a PDA medium. Spikes treated with fungicide and distilled water treatments were used as two control objects. It was found a significant difference of infection level between hulled (92.3-96.6%) and dehulled (23.3-88.0%) spelt samples, with exception of *A.alternata* treatment. Yield components, length of spike and weight of spike have shown significant difference between fungicide treatment (16.2 cm; 1.82g) and infected kernels by *Alternaria* spp. (10.7cm; 1.03g) respectively. According to obtained results it could be concluded that hulls protect spelt kernels against fungal colonization and therefore increase the eligibility of spelt wheat under unfavorable conditions.
Key words: *Alternaria spp., spelt, hulls, length and weight of spike*

INTRODUCTION

Spelt wheat (*Triticum aestivum* ssp. *spelta*.) is a neglected subspecies of common wheat, which has been prompted recently by the development of organic farming (Konvalina et al., 2010). It had been grown in Europe (mainly in Germany, Switzerland and Austria) for hundreds of years when it was largely replaced by bread wheat (Dark and Gent, 2001). There is a growing interest on the world market for such alternative crop due to its high nutritive and dietetic values (Gomez-Becerra et al., 2010). Stable yielding ability under low input conditions and high tolerance to environmental stresses, consider spelt economically important culture suitable to organic farming system (Rüegger and Winzelerund, 1993; Lacko-Bartošová et al., 2011).

Compared with common wheat, spelt carries high levels of resistance to several fungal pathogens (Kema, 1992), which is probably associated with its morphological properties. Hulled grain cereals are generally more resistant to fungal diseases (Konvalina et al., 2010; Mouldry et al., 2011; Khatibi et al., 2012). Previous studies on spelt wheat indicate that the hulls provided an advantage to the seed germination (Ruegger et al., 1990) and act as barriers against soil borne pathogens (Riesen et al., 1986). Protective effect of hulls on fungal colonization and their metabolites has been reported mostly for *Fusarium* spp. (Moludry et al. 2009; Suchowilska et al., 2010; Wiwart et al., 2009; Bodroža et al., 2010),

Penicillium spp. (Elmholt, 2004) and *Puccinia* spp. (Kema, 1992; Konvalina et al., 2010) etc. There is, however, extremely limiting information on *Alternaria* species concerning hulled grain varieties.

The genus *Alternaria* is widely spread and includes plant pathogenic and saprophytic species that may affect crops in the field or can cause harvest and postharvest decay. Due to their growth even at low temperature, *Alternaria* spp. are also responsible for spoilage of food during refrigerated transport and storage (Ostry, 2008). Beside losses in production and processing, many species of this mycobiota are able to produce toxicological metabolites, which are harmful for human and animal health, (Logrieco et al., 2009). Some *Alternaria* toxins might have even the cancerogenic effect (Liu et al., 1992). *Alternaria* spores, disseminated mainly by air currents, can influence allergen reactions and respiratory problems as well (Corden et al., 2003; Kilic et al., 2010; Pavon et al., 2010). Recent studies reported that fungi of the genus *Alternaria* dominates on wheat kernels (EFSA, 2011) and are frequently found on spelt wheat (Kurowski and Wysocka, 2009). The aim of this work was to investigate the protection effect of hulls of spelt kernels to *Alternaria* spp. disease with addition to evaluation of influence of fungal infection to yield components such as length and weight of spike.

MATERIAL AND METHODS

Field experiment was carried out in the 2010/2011 season in the region of Vojvodina, north Serbia on three spelt wheat genotypes.

Fungus culture and inoculation

The isolates of *A.alternata* and two isolates of different species *A.tenuissima* were multiplied on petri-plates containing potato dextrose agar (PDA) at room temperature for 14 days. For the purpose of inoculation a conidial suspension was made in water and sprayed on the plants with a hand atomizer. Before spraying, flasks were shaken vigorously and 1 mL suspension was poured in to a haemocytometer and the number of spores counted. Concentration of *A.alternata* conidia was $0{,}2475 \times 10^6$ infective particles/mL and two isolates of *A.tenuissima* had concentrations of $0{,}605 \times 10^6$ and $0{,}497 \times 10^6$ infective particles/mL. At the full flowering stage inoculation was performed with 600 mL aqueous suspension of fungal isolates. Inoculated spikes were immediately covered with polyethylene bags for 24 h. Spikes treated with fungicide and water treatments were used as two control objects. In the full ripeness stage spikes from each plot were cut by hands and used for next analysis.

Yield characteristics

These have been based on the methodology of the evaluation of length and weight of spelt wheat spikes. Data on length and weight of spike were recorded in ten repetition on randomly selected samples.

Preparation of plant material

Spelt kernels, from each treatment, were dehulled using laboratory thresher (model MDF1, RePietro, Gaggiano, Italy). Dehulled and hulled kernels were kept separately in dark and dry place before assessing the level of contamination.

Percent of kernel infection

According to the method proposed by Pitt and Hocking (1985) 100 dehulled and hulled spelt kernels were randomly selected from each treatment. The samples were desinfected with 0,4% NaClO, rinsed with water for 2 minutes and placed on petri plates in four repetitions (25 kernels per plate). Incubation was conducted at room temperature and after six days intensity of infection was assessed.

Statistical analysis
Statistica 8.0 Software was used for statistical data processing using one-way ANOVA. The comparison of mean values were performed by the Fisher- test. A value of $P < 0.05$ was considered to be significant.

RESULTS AND DISCUSSION

The obtained results showed a high amount of *Alternaria* isolates in inoculated samples, which is in agreement with Kurowski and Wysocka (2009), where in natural occurrence survey in different farming systems, predominant fungal species was *A.alternata*. In evaluation of level of infection, genomic diversity of spelt wheat did not take in consideration, inasmuch values obtained from different genotypes implied as replication values. It was found a significant difference of infection level between hulled (92.3-96.6%) and dehulled (23.3-88.0%) spelt kernels, with exception of *A.alternata* treatment (Figure 1). That could be explained with higher aggressiveness of *A.alternata* species. These results confirm previous researches where dehulled kernels were 50% less contaminated with *Alternaria* spp. compared to hulled samples (Vučković et al., 2011). The highest level of infection was determined on hulled kernels inoculated with *A.tenuissima* (1) (96.6%), while the lowest was on dehulled kernels treated with fungicide (23.3%).

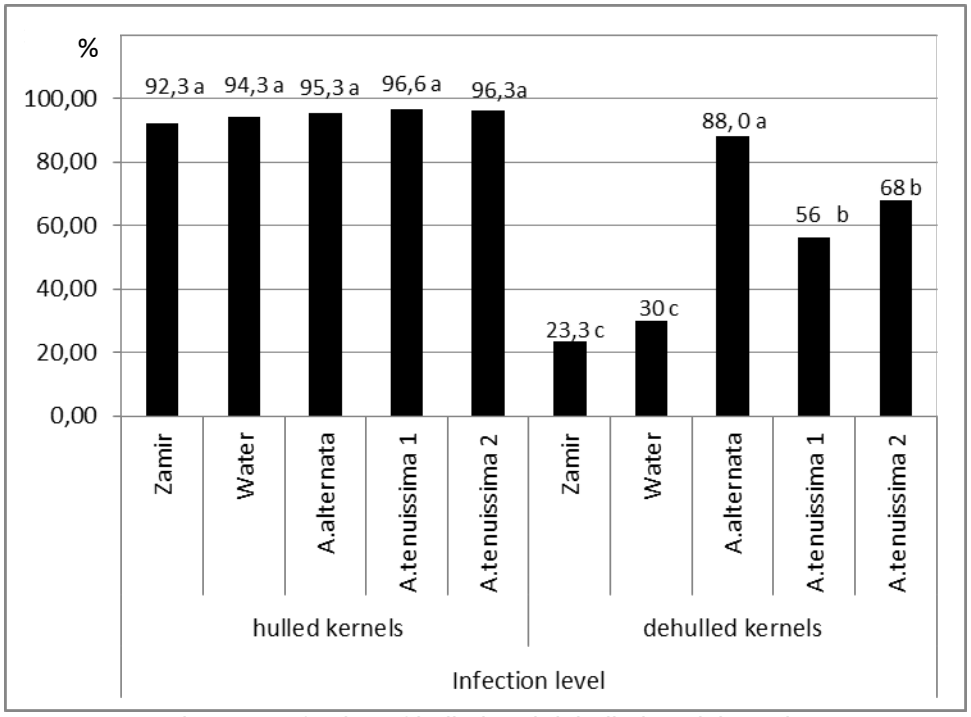

Figure 1. Infection of hulled and dehulled spelt kernels
Means followed by the same letter are not significantly different at P=0.05 (Fisher- test);

Yield components, length and weight of spike, have shown a significant difference between fungicide treatment and infected kernels by *Alternaria* spp. in general, which is presented in Tables 1 and 2. The longest spike was detected in fungicide treatment at genotype 3 (16.15 cm), while the lowest length was at inoculation with *A. tenuissima* (1) at genotype 2 (10.7cm). Maximum weight of spike was in fungicide treatment at genotype 3 (1.82 g), while minimum weight has the same genotype but in *A. tenuissima* (1) treatment (1.03g). The fungal inoculation of spikes led to considerable reduction of the main yield parameters of all the tested spelt genotypes which is in line with results obtained by Suchowilska et al. (2007) in experiment with *Fusarium culmorum*. In organic farming systems, whereas synthetic fungicides are forbidden, spikes of the spelt plants were very long (11.3 cm) according to Konvalina et al. (2010), which point that spelt could have stable yield in organic production.

Table 1. Mean values of length of spikes obtained from inoculation treatments

Spelt genotype	Treatment	Length of spike (mean)
2	At(1)	10.70^{g}
1	At(2)	10.90^{fg}
1	At(1)	11.70^{efg}

2	Aa	1.44^{bc}
2	W	1.45^{bc}
1	W	1.47^{bc}
3	W	1.49^{b}
1	F	1.50^{b}
2	F	1.58^{ab}
3	F	1.82^{a}

Abbreviations used in table: F-fungicide treatment, W-control with water, Aa- A.alternata, At (1)-A.tenuissima (1), At (2)-A.tenuissima (2); Within column values followed by the same letter are not significantly different at P < 0.05 (Fisher- test).

CONCLUSION

The results of our research indicate that fungicide and inoculation treatments have significant impact on length and weight of spikes which were in the range of 10.7-16.5 cm and 1.03-1.82g respectively. The hulls have protective effect of spelt kernels inside from *Alternaria* spp. It should be stressed, however, that protection is partially and additional protective measures are recommended. Additionally, this pathogen deserves more attention considering its toxicological properties and further investigations of *Alternaria* toxins are expected. It could be concluded that hulling will contribute in reduction of mycobiota on spelt kernels.

ABSTRACT: Fresh fruit is susceptible to contamination with filamentous fungi during growing, harvesting, transport, storage and sales. For these reasons it is important to identify and take appropriate measures not only about microbiological contamination but also concerning possible presence of mycotoxins. Due to soft tissue structures berries are very susceptible to mold contamination of different mold genera including toxigenic ones (*Penicillium, Aspergillus and Byssochlamys*). The aim of this research was to investigate the presence of mycotoxin patulin in frozen raspberries harvested under rainy and wet conditions convenient for production of this secondary metabolite of molds in fresh raspberries. Frozen raspberry samples which were visually rated as products with intensive mold attack were taken from the most important cooling warehouses in raspberry growing region in Serbia. The method developed by Arranz et al (2005) widely represented in the EU for the determination of patulin using high-performance liquid chromatography (HPLC) with UV detection (λ = 276 nm) was used for determination of patulin in the raspberry samples. Determined contents of patulin in the samples were ranged from 1.07 to 15.33 µg/kg. Patulin content in fresh fruits as raw material for further processing is not regulated by laws in Serbia or in the European Union, but the Joint Food and Agriculture Organization-World Health Organization (WHO) Expert Committee on Food Additives has established a provisional maximum tolerable daily intake for patulin of 0.4 µg/kg of body weight per day (WHO, 1995).
Key words: *raspberry, patulin, HPLC-UV*

INTRODUCTION

Patulin is mycotoxin produced by a number of fungi (*Penicillium, Aspergillus* and *Byssochlamys*) common to fruit- and vegetable-based products. *Penicillium expansum,* the blue mold that causes soft rot of apples, pears, cherries, berries and other fruits, is one of the most common sources of patulin contamination (Dursch and Ragab, 2003; Watanabe, 2008). Patulin-producing strains have been isolated from a variety of fruits and vegetables including apples, grapes, cherries, crabapples, pears, apricots, persimmons, strawberries, nectarines, raspberries, black mulberries, white mulberries, lingon berries, peaches, plums, tomatoes, greengages, bananas, blueberries, black curants, almonds, pecans, peanuts, and hazelnuts (Moake et al., 2005).

Assessment of the health risks posed by patulin to humans is based upon a wide number of studies during the past 50-plus years that implicate a number of acute, chronic, and cellular level health effects. Results of many studies suggest that acute symptoms of patulin consumption can include agitation, convulsions, dysponea, pulmonary congestion, edema, ulceration, hyperemia, GI tract distension, intestinal hemorrhage, epithelial cell degeneration, intestinal inflammation, vomiting, and other gastrointestinal and kidney damage. Chronic health risks of patulin consumption can include neurotoxic, immunotoxic, immunosuppressive, genotoxic, teratogenic, and carcinogenic effects (Moake et al., 2005). Therefore, patulin contamination is a worldwide problem with regard to food and feed safety, and several countries have instituted patulin restrictions in food products (Doores 1983; Spott and others 1993).

In 1995, a provisional maximum tolerable daily patulin intake of 0.4 µg/kg body weight was established by the Joint FAO/WHO Expert Committee on Food Additives (JECFA, 1995).The

permissible limit for patulin content in apples and their products in the European Union and Serbia has been set at 50 µg/kg, in apple juice, and as juice ingredients in other beverages, has been set at 50 µg/kg, in solid apple products at 25 µg/kg, and in baby food of 10 µg/kg (Commission Regulation (EC) 1881/2006; Sl. glasnik R. Srbije 28/2011). In view of the recognized adverse effects of patulin and the need for regulatory control, monitoring of its level in food products is important to evaluate the risk associated with human consumption of these products. Therefore, a sensitive, selective, and simple method to determine the presence and contents of patulin in raspberry samples is required. Due to soft tissue structures berries are very susceptible to mold contamination of different mold genera including toxigenic ones (*Penicillium, Aspergillus and Byssochlamys*).

For Serbia raspberry is one of the most important agricultural export commodities due to significant and stable export demand for frozen raspberry. Out of total raspberries production more than 90% is dedicated for export markets. During the last years average production of raspberry in Serbia ranged around 80.000 tons, representing share of 5.5% in total fruit production. About 25% of global raspberry production originates from Serbia Serbia exports mainly frozen and only in rare cases cooled fresh raspberry *(Dimitrijević, 2009)*.

Raspberries are grown for the fresh fruit market and for commercial processing into individually quick frozen (IQF) fruit, purée, juice, or as dried fruit used in a variety of grocery products. Traditionally, raspberries were a mid-summer crop, but with new technology, cultivars, and transportation, they can now be obtained year-round. Raspberries need ample sun and water for optimal development. Raspberries thrive in well-drained soil with a pH of between 6 and 7 with ample organic matter to assist in retaining water.

As a cultivated plant in moist temperate regions, it is easy to grow and has a tendency to spread unless pruned. Based on years of statistical data we can conclude that the Serbian raspberries scale production is the leader on the world stage (from 1987 to 2009 was the second place behind Russia) (http://faostat.fao.org/site/339/default.aspx).

In Serbia the raspberry harvesting season (early and mid summer) is usually characterized with hot and dry weather but in exceptional years like 2010 in late June and early July during fruiting of raspberries abundant precipitation were recorded dailyin the areas where the crops are grown. From mid June to mid-July rainfall sum of 40% to 100% above the perennial average for the same period was recorded. Although raspberry is a plant that for successful growing and high yield requires a lot of water especially during ripening, such weather conditions result in increased health safety risks especially from the aspect of fungi development (www.hidmet.gov.rs)

The aim of this research was to investigate the presence of patulin in frozen raspberries harvested under rainy and wet conditions convenient for production of this secondary metabolite of molds in fresh raspberries.

MATERIAL AND METHODS

Samples

Five random samples of frozen raspberries harvested in 2010 were taken from cooling warehouses in raspberry growing region in Serbia around Arilje. Selection of samples was performed on the basis of their visual rating as products with intensive mold attack. Raspberries were frozen immediately after harvest and kept in frozen condition for 6 months.

Reagents

Acetonitrile, ethyl acetate and n-Hexane (HPLC grade), ethanol, acetic acid (extra pure grade), anhydrous sodium sulfate, anhydrous sodium hydrogen carbonate, perchloric acid 60% and sand (p.a.) were purchased from Merck (Darmstad, Germany). The patulin standards were obtained from Sigma-Aldrich. Water was ultra pure (Mili-Q, from Milipore, USA).

Sample preparation
The basic principle of the method developed by Arranz et al. (2005) is based on the extraction of surfactants from the sample with a mixture of ethyl acetate-hexane (60:40, v / v) in the sand, Na_2SO_4 and $NaHCO_3$, and then the extract passed through a C18 SPE column (SPE, Supelco, Bellefonte, PA). The purified extract was evaporated to dryness under stream of nitrogen and redissolved in aqueous acetic acid solution (pH 4). The redissolved samples were filtered through a membrane filter (0.45 µm) and the filtrate was transferred to an HPLC vial and analyzed on HPLC-UV.

Patulin stock solution (200 µg/ml in ethyl acetate)
Stock solution was prepared by dissolving 5 mg of patulin standard in 25 ml of ethyl acetate. This solution was stored in the freezer at -20°C.

Patulin working standard solution for calibration graph
Patulin working standard solutions were prepared from patulin calibrant solution. A series of nine standard working solutions between 0.93 and 89.16 µg/ml were used for calibration graph (R^2=0.9995).

Determination of patulin by HPLC-UV
Numerous chromatographic methods have been developed for the determination of patulin in various food products. One of the most used methods for the quantitative determination of patulin in apple-based products is method published by Arranz et al. (2005).
The aim of this work was to apply procedure for sample preparation described in Arranz method for analysis of raspberry samples and also to use different chromatographic conditions. Determination of patulin was carried out by HPLC Agilent 1200 model equipped with Agilent ultra violet detector (UV), Chemstation Software, a binary pump, a vacuum degasser and an auto sampler. The column was an Agilent RP-HPLC column Zorbax eclipse XDB-C18 (100 x 2.1 mm, particle size 1.8 µm). The mobile phase consisted of an isocratic mixture of with water/acetonitrile/perchloric acid 60% (990+10+1, v/v/v), with a flow rate of 0.3 ml/min. Ten microliters of standards and samples were injected onto the HPLC column. All determinations were performed in duplicate. The spectra were recorded at 276 nm. Identification of patulin was performed by comparing of the retention times and spectra of patulin from samples with those of the standards.

Spike recovery solution
In order to calculate the recovery spiking was performed with sample containers identified as samples with the lowest contents of patulin (sample 2). One milliliter of patulin standard (59.4 µg/kg) was added in 19.0 g defrosted raspberry puree (spiked sample 1), and it was prepared according to the instructions by Arranz et al (2005). This procedure was replayed with 1 ml patulin standard with 86.3 µg/kg patulin contents (spiked sample 2).

RESULTS AND DISCUSSION

The presence of patulin was determined in all of the examined raspberry samples. Determined contents of patulin in the samples were ranged from 1.07 to 15.33 µg/kg. The average values of patulin content in the examined raspberry samples are shown in Table 1.

Table 1. Average values of patulin content, interval (CI) and mean (CM±SD) of raspberry samples

No. samples	patulin contents (µg/kg)
1	1.30
2	1.07
3	2.42
4	15.33
5	3.33
CI	1.07 – 15.33
CM±SD	4.76 – 6.00

SD: standard deviation

Regardless of climatic conditions that prevailed during 2010, which were suitable for the development of pathogenic species of fungi on raspberries, the resulting patulin contents in the analyzed raspberry samples were significantly below the contents of patulin obtained by Demirci et al (2003) for mold contaminated raspberries from other raspberry growing region (48 to 746 µg/kg, with an average content 325.73 µg/kg). This fact can probably be explained either as a consequence of the resistance of the varieties and protection measures applied during growing of raspberries or on the basis of possibility of presence of nontoxigenic mold species in respect to patulin.
Determined precision characteristics of the modified method applied on the raspberry samples are presented in table 2).

Table 2. Method performance characteristics obtained for raspberry puree

Spiked sample	**Results**		2006/401/EC
	1	2	
RSD_r %	17.96	11.00	≤ 30
RSD_R %	9.30	10.28	≤ 40
Recovery %	75.1	92.8	50 to 120

RSD_r – relative standard deviation, calculated from results generated under repeatability conditions
RSD_R - relative standard deviation, calculated from results generated under reproducibility conditions

Based on the obtained results for RSD_r, RSD_R and Recovery it can be concluded that modified method of Arranz (2005) can be used for determination of patulin in raspberry samples.
The method showed acceptable within-laboratory precision for examined matrix, according to Commission Regulation (EC) 2006/401/EC (table 3).

Table 3. Performance criteria for patulin according to Directive 2006/401/EC for analytical methods for the determination of patulin

Level µg/kg	**Patulin**		
	RSD_r %	RSD_R %	Recovery %
< 20	≤ 30	≤ 40	50 to 120
20-50	≤ 20	≤ 30	70 to 105
>50	≤ 15	≤ 25	75 to 105

CONCLUSIONS

Tested method for the determination of patulin in raspberry samples is rapid and simple, involving a single extraction step. No enzymatic removal of pectin is required for purees. Obtained results were significantly below the contents of patulin for mold contaminated raspberries reported by other authors, indicating lower patulin production by molds which contaminated raspberries from Serbia in 2010. This method is suitable for the analysis of patulin in frozen raspberries as the finished product and as a feedstock for further processing. Further studies should include monitoring of the patulin presence in fractions of frozen raspberries, which are included in the composition of various food products (fruit yogurt, marmalade, juice, etc.)

ACKNOWLEDGEMENTS

This paper presents the part of research conducted under the project III 46001 Development and utilization of novel and traditional technologies in production of competitive food products with added value for national and global market CREATING WEALTH FROM THE WEALTH OF SERBIA funded by Ministry of science and technological development of Republic of Serbia

ABSTRACT: A number of somatic cells in milk indicates the presence of an inflammable process in mammary glands and serves as an indicator of milk hygienic suitability and milk quality. Somatic cells are mostly leukocytes which reflect the condition of the body in the view of physiological and pathological changes and a possible incidence of mastitis. Apart from mastitis, a somatic cell count in milk is also affected by the following factors: physiological-pharmacological (the phase of lactation, race, veterinarian drugs) and stress-related ones (method of feeding, transport, keeping conditions, way of milking, technical validity of milking machines). An elevated somatic cell count has a negative effect on the activity of starter cultures and thermal stability of milk. Determination of the somatic cell count in milk is a key factor in evaluation of milk quality and therefore it is necessary to conduct an adequate milk control for presence of somatic cells. The aim of this work is a statistical evaluation of the results obtained by comparing the reference ISO 13366-1 method for determination of the somatic cell count and the DeLaval equipment.
Key words: *cow milk, somatic cells, direct microscopy, DeLaval counter*

INTRODUCTION

Milk is a white coloured biological liquid of complex composition, and specific taste and smell, which is secreted by the mammary glands of female mammals after calving, and which serves for nutrition of infant mammals. Several hundreds of different substances can be isolated from milk and its basic components include water, proteins, fats, carbohydrates, enzymes and mineral substances. Contents of these components and their proportions in milk are different in different kinds of animals. In cow milk, an average content of water is 87.5%, dry substances 12.5%, milk fat 3.8%, proteins 3.15%.

Apart from chemical substances contained in milk, there are a small number of leukocytes in the healthy udder quarter milk, which originate from blood and serve for defence against infection. Together with the smaller number of epithelial cells (originating from the mammary gland mucosa) the leukocytes constitute somatic cells in milk (Harmon, 1994). Concentration of somatic cells in milk is commonly denoted as a somatic cell count (SCC) and it has long been used as an indicator of the inflammable process in the mammary gland (Katić, 2007). Also, the SCC is an important indicator of the hygiene suitability and quality of milk and thus it is necessary and purposeful to conduct an adequate control for the presence of somatic cells (Hanuš et al., 2011).

An average SCC in the healthy udder milk is 70000-90000 cells per ml and in most cases it is lower than 150000 cells per ml. A somatic cell count in milk and proportions of certain types of leukocytes depend on numerous factors including the season, parity and the phase of lactation, environmental factors and technological procedures applied on the farm, the health status of a mammary gland and secreting activities of the udder cells (Barkema et al., 1998, 1999; Hristov, 2002; Hristov et al., 2006). Also, the intensity of increasing the SCC in milk in individual quarters depends on the type of pathogen. With the somatic cell count ≤ 400.000/ml, the requirements for the hygienic suitability and quality of milk are satisfied.

However, this somatic cell count is not such a good indicator of the prevalence of mastitis in dairy cows. Even with the somatic cell count of 400.000/ml in the bulk milk, clinical and subclinical mastitis may be present in the herd of dairy cows (Katić, 2007).
There are several analytic methods used to determine somatic cells. In addition to the reference method of direct microscopy (ISO 13366-1) and the method which enables fluoro-opto-electronic counting (ISO 13366-2), there are numerous instrumental methods which working principle is based on cell staining and electronic counting. The methods in use are Fossomatic, Chemometec, NucleoCounter SCC–100 and DeLaval counter of somatic cells (DCC). DCC is a portable instrument used for fast and operative monitoring (Gonzalo et al., 2006). A DCC working principle is based on optical and automatic counting of somatic cells. A digital camera takes a picture of somatic cells' nuclei which were previously stained in the cassette with a DNA specific fluorescent reagent. Each cassette has a volume of 60 µl and the measuring range of the DeLaval counter is 10 000–4 000 000 somatic cells/ml (www. DeLaval. com).
The aim of this work is a statistical evaluation of the results obtained by comparing the reference ISO 13366-1 method for determination of the SCC and the DeLaval counter.

MATERIALS AND METHODS

Checking the number of somatic cells in cow milk is a well-established method for timely detection of subclinical mastitis in cows. Because of high frequency of subclinical mastitis and enormous material losses in dairy herds caused by it, it is a common practice to conduct routine scanning of cow milk for the somatic cell counts.
Testing was done on the Holstein-Friesian cow farm (PKB Corporation), which uses a tying system and where milking is performed in split shifts in the cowshed, on the bedding. The experiment was carried on 2.5–3.5-year-aged cows, in the first and second lactation phases, which average milk yield for 305 days of lactation amounted about 7500 liters of milk.
Milk samples were taken immediately before morning milking (20 samples) and after noon milking (20 samples). Forty samples were analysed in total. Samples were checked using a method of direct microscopy BS EN ISO 1366-1 (DMC) and by means of a DeLaval (DCC) counter, in three repeats.

RESULTS AND DISCUSSION

The Duncan's multiple range post hoc test as well as the paired t tests were used in this study in order to find out statistically relevant differences in the somatic cell counts measured by two methods. Test results are shown in Tables 1, 2, 3, 4, 5 and 6. and Charts 1 and 2.
Based on the test results (Table 1), out of 20 samples in total, seven samples (35%) showed concentration ≥ 400 000 cell/ml. The SCC (somatic cell count) ranged from 400 000 to 2 600 300 cell/ml. An elevated somatic cell count indicates poor quality milk, and the samples are hygienically unsuitable. An elevated somatic cell count above 400 000 was determined with the DMC and DCC methods in all three repeats.
Test results of samples after the noon milking (Table 2) indicate a lower presence of somatic cells. Only 2 samples (10%) showed somatic cell concentrations higher than the allowed ones. The SCC ranged from 430 000 (sample 9) to 1054 200 (sample 17). Somatic cells were determined by the DMC and DCC methods. Other samples showed contamination below 400 000 cell/ml.

DMC - Direct Microscopic Count; DCC - DeLaval Cell Counter

The SCC depends on many factors. Vuković (2008) claims that the SCC depends on the time of milking, because there are deviations in the morning or evening milking as well as during the same milking process. Dohoo and Meek (1982) established normal diurnal variations of SCC in milk samples taken at different times during the milking and between the milking processes. Generally speaking, the SCC is the highest at the end of a milking process and the lowest immediately before milking. Also, the SCC is significantly higher in colostrum than in milk. In the first few days after calving, in the first lactation, the SCC was higher than one million per ml of milk, and after two weeks it was about 500000 per ml (Boboš and Vidić, 2005). At the end of lactation, the SCC increases again.

Table 3. Testing the significance of differences in somatic cell counts obtained by DMC and DCC methods regardless the time of milking

Method	Average number of somatic cells	Number of samples (3 repeats)	SD	SE
Direct Microscopic Count	280394,17	120	442021,77	40350,88
DeLaval Cell Counter	299027,92	120	474610,85	43325,84

SD – standard deviation, SE – standard measuring error

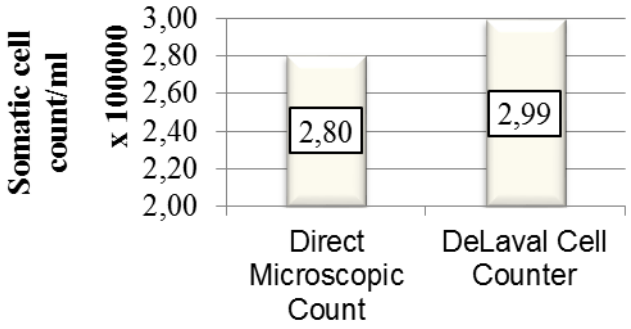

Figure 1. Average somatic cell count by DMC and DCC methods regardless the time of milking (cell/ml)

Table 4. Determination of statistically relevant differences between DMC and DCC methods (t-test) regardless the time of milking (cell/ml)

Pair	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference		t	df	Sig.
				Lower	Upper			
DMC - DCC	-18633,75	48490,13	4426,52	-27398,71	-9868,79	-4,210	119	0,000

Based on the results of testing (Tables 3 and 4, Chart 1), it was found out that an average somatic cell count per ml of milk, measured by the DMC method, was 280394.17, and when measured by the DCC method it was higher and amounted 299027.92. A paired t-test showed that there was a statistically significant difference in somatic cell counts obtained by using the two methods (t(119)=-4,210, p=0,000), whereby an elevated somatic cell count was determined by DCC method. Hanuš et al. (2010) claimed that the SCC, determined by the DCC, DMC and CMT (California mastitis test), was approximately of the same value and that there were not any statistically significant differences (> 0.92, P < 0.001). Using the DCC and DMC methods for milk analysis, Chaiyotwittayakun et al. (2008) got the similar results, which showed a statistically significant difference. Results of comparing SCCs with regard to the time of milking are given in Tables 5 and 6 and Chart 2 **.**

Table 5. Testing the significance of differences in somatic cell counts obtained by DMC and DCC methods with regard to the time of milking

Milking	Method	Average number of somatic cells	Number of samples	SD	SE
Morning	Direct Microscopic Count	391858,33	60	562073,15	72563,33
	DeLaval Cell Counter	418160,00	60	608821,31	78598,49
Noon	Direct Microscopic Count	168930,00	60	229961,22	29687,87
	DeLaval Cell Counter	179895,83	60	234092,74	30221,24

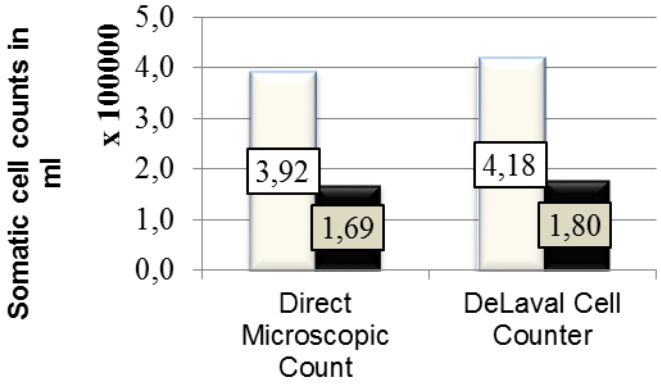

Figure 2. Average somatic cell counts before the morning and after the noon milking (cell/ml)

Table 6. Determination of statistically relevant differences between DMC and DCC methods (t-test) before morning milking and after noon milking (cell/ml)

Pair DMC - DCC	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference		t	df	Sig.
				Lower	Upper			
morning	-26301,67	66138,16	8538,40	-43386,96	-9216,37	-3,080	59	0,003
noon	-10965,83	15766,92	2035,50	-15038,86	-6892,81	-5,387	59	0,000

A paired t-test showed that there was a statistically significant difference (t(59)=-3,080, p=0,003) in somatic cell counts in milk measured by the two methods in the morning milking since the DCC method showed an elevated somatic cell count, which amounted 418160.00, while the cell count measured by the DMC method amounted 391858.33. Also, for the noon milking, it was determined a statistically significant difference (t(59)=-5.387, p=0.000). Using the DCC method a higher SCC (179895.83) was determined than by the DMC method (168930.00). The SCC is a crucial indicator of milk quality and hygienic suitability. Standardization of methods for determination of the SCC is important for laboratories as well as for veterinarians, manufacturers and milk industry. Statistically significant differences determined between the DCC and DMC methods may result from a human factor (sample preparation, counting errors), calibration procedure on the DeLaval counter, way of sample transfer and sample preservation system, type of milk (cow milk, sheep milk, goat milk, human milk, etc.) (Berry and Broughan, 2007; Hering et al., 2008; Hanuš et al., 2010). Hillerton et al. (2004) analysed the possibilities for an error elimination during the SCC determination by establishing a geometrical mean at the level of 13 values (measuring). Test results definitely support the elimination, but the procedure itself is quite impractical for the fast and operative monitoring.

CONCLUSION

Test results, based on 40 samples of cow milk before the morning and after the noon milking, indicate an elevated somatic cell count in 9 samples (22.5%). The elevated SCC was determined by the method of direct microscopy ISO 13366-1 and by means of the DeLaval counter in all three repeats. Statistical analysis showed that there was a statistically significant difference in somatic cell counts in milk measured by these two methods. Namely, the SCC detected was higher when using the DCC method than when using a reference method of direct microscopy. A method of direct microscopy enables an accurate detection of SCC but only if the protocols concerning transfer, preservation, preparation and analyst's skills are fully observed during the sample analysis. A DeLaval counter is portable, requires a small-sized sample, and makes an excellent alternative to expensive counters when fast and operative monitoring is required.

ABSTRACT: A large number of dietary products contains high content of vitamins A, E and D. Depending on usage, the amount of consumed vitamins can significantly surpass the recommended daily intake. Also, if the content does not match the declared, this can lead to consumers misleading. In our market, there is a large offer of dietary products in pharmaceutical forms, as well as enriched foods with these vitamins content declared. By proper use of these foods, it is possible to largely meet the daily requirements for vitaminsOur goal was to determine liposoluble vitamin content in products where their content is declared by using HPLC and UPLC methods with spectral and fluorescent detector. For successful determination of the content of vitamins A, E and D in the complex composition of foods multiple purification of samples is necessary, while for the determination of the synthetic products it is enough to apply the extraction. We applied the extraction with n-hexane, extract steaming and reconstitution in methanol, with membrane filtration. Separation was performed with RP-HPLC method with fluorescent detector with variable wavelengths, and UPLC method with the spectral detector. The dietary products of different backgrounds, forms and methods of production (total 148) were analyzed, of which 8.3% had lower, and 2.1% higher content than declared.
Key words: *vitamin A, vitamin E, vitamin D, HPLC, UPLC, dietary products*

INTRODUCTION

Dietary supplements are foods that supplement the normal diet and which are concentrated sources of nutrients (vitamins, minerals and other substances with a nutritional or physiological effect). They are marketed in dose forms (capsules, tablets, drops, etc.). The oldest and most complete regulation on dietary supplements is a U.S. regulation. The basic law regulating the manufacture, sale, labelling and marketing of dietary supplements is the Dietary Supplement Health and Education Act (DSHEA) from 1994.

The EU regulation on food supplements is only partially harmonized. Directive 2002/46/EC on the approximation of legislation of the Member States relating to food supplements is determined list of permitted vitamins and minerals, substances that are used as their sources, marking units and permitted forms of dietary supplements. Maximum allowable amounts for vitamins and minerals, herbal supplements and health statements are not yet harmonized and apply national regulations that differ as a barrier to trade dietary supplements in the EU. (Orientation paper on the setting of maximum and minimum amounts for vitamins and minerals in foodstuffs, 2007). In Serbia, there is a regulative about dietary supplements.

Required amounts for people of different age and lifestyle are constantly adjusted, as well as the opinion about the preffered way of intake: by food, or by precisely dosed dietary supplements. It is certainly rational to decide is it justified to add supplements to everyday diet before actually applying them. (Ball GFM, 2004).

The most common method for analyzing vitamins A, E and D and its analogs in pharmaceutical preparations, feedstuffs, and tissues is ultra-performance liquid chromatography combined with a UV or high-performance liquid chromatography combined with fluorescence detectors.

A large number of dietary products have a high content of vitamins and minerals. Depending on usage, the amount of nutrients entered can significantly exceed recommended daily

intake. Also, if the content does not match the declared quantity, consumers can be misled. In our market, there is a more diverse supply of dietary products in pharmaceutical forms, as well as foods fortified with declared content of vitamins and minerals. by the proper use of these foods, it is possible to substantially meet the daily needs. Dietary supplements sometimes change contents, under the same generally accepted name.
In food, vitamines A, D and E are found along with other substances, that interfere in process of determination vitamin contents. These substances can be removed in different ways. Saponification removes glycerides, peroxydes and partially pigments, but cannot remove steroles and carotenoides. For dividing tocopheroles from other substances, as well as for dividing different tocopheroles, different methods can be used, but liguid and gas chromatography are the most common (Delgado-Zamerreno MM et al. 2001; Sanchez-Perez et al. 2000; Blake CJ 2007).
Our goal was to determine liposoluble vitamin content in products where their content is declared by using HPLC and UPLC methods with spectral and fluorescent detector.

MATERIAL AND METHODS

In analysis, analytical vitamin standards (manufacturer: Sigma Co, St Louis, MO, USA) were used to prepare solutions for determination of detection limits and quantification limits (series of solutions from 0,01 to 0,5 μg/mL), and solutions for calibration curve (1,0, 2,5, 5,0, 10,0 and 20,0 μg/mL). Methanol and acetonitrile were used (HPLC purity, manufectured by Merck, Germany), hexane (HPLC purity, manufectured by Merck, Germany), water of HPLC purity (water demineralized and purified using commercial „Millipore Milli-Q“ system). Other chemicals were of analysis purity (p.a.).
In our laboratory, HPLC method with fluorescence detecor was used for determination of vitamin A and E. UPLC method with PDA detector was used for determination of vitamin D_3. Operational conditions were given in table (Table 1).

Table 1. Operational conditions

HPLC conditions:	
Pump:	Waters M600 E,
Injector:	Rheodyne 7125, loop 20μl
Column:	RP-HPLC C8, 5 μm,
Detector:	RF-535 Shimadzu, Fluorescence HPLC
Mobile phase:	95% CH_3OH isocratic elution
Flow rate	1,0 mL/min
Column temp	~20 ^{0}C
Wavelengths:	λ_{ex} = 295 nm, λ_{em} = 330 nm for vitamin E λ_{ex} = 325 nm, λ_{em} = 475 nm for vitamin A
Acquisition:	Clarity chromatography station for Windows

UPLC conditions	
LC system:	Waters ACQUITY UPLC System with PDA detector
Mobile phase:	Solvent A: water: acetonitrile (90:10) Solvent B: acetonitrile : methanol (50:50)
Injection volume:	5 μl
Flow rate:	0,7 mL/min
Column temp:	35 ºC
Column:	ACQUITY BEH C18, 2,1 mm x 100 mm 1,7 μm
UVmax: 265 nm	

RESULTS AND DISCUSSION

Using modern instrumentation technique (HPLC, UPLC) with different detection systems, 148 dietetic products were analyzed during the past year. Presence of low vitamin D3 content could be determined using UPLC-PDA method (Figure 1) while for determination of vitamin A and E content HPLC with fluorescent detector was chosen which is enough specific and sensitive for their determination (Figure 2 and Figure 3). Applied methods were validated. Quantification limits were determined: 0,1 µg/mL for vitamins A and E and 0,01 µg/mL for vitamin D_3. Linearity for solutions from 0,1 to 20 µg/mL and from 0,01 to 10 µg/mL was determined, as well as the surface of appropriate peaks. Calibration curves were constructed as a result of four injections for each concentration level. Correlation coeficients are: r=0,9995 for vitamin A, r=0,9992 for vitamin E and r=0,9991 for vitamin D_3. Accuracy of the method was examined by determining recovery for standard solutions of 10 µg/mL (RSD = 98,2% for vitamin A, 97,5% for vitamin E and 97,3% for vitamin D_3). The dietary products of different backgrounds, forms and methods of production (total 148) were analyzed, of which 8.3% had lower, and 2.1% higher content than declared (Table 2). All differences were less than 50% of declared values, which confirms the problem lies in bad technological process or bad material, and not an incident.

Table 2. Accordance of dietetic products to the declared values of vitamins A, E and D

examined parameters	examined samples		
	correct	not correct	
		higher	lower
Vitamin E	127	1	2
Vitamin A	55	2	7
Vitamin D	24	--	3

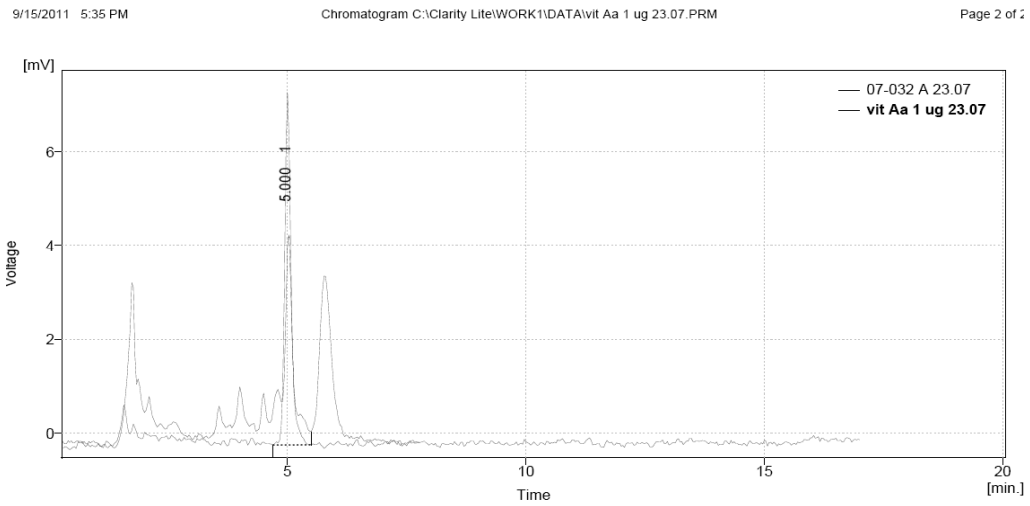

Figure 3. Vitamin A in infant formula

CONCLUSIONS

Adoption of regulations on food supplements based on the new Law on Food and harmonized with EU regulations and international standards is the basis for introduction of making order in the production and distribution of this specific group of foods and for health protection and other consumers' interests. Analyzed samples of dietary supplements mainly respected declared limitations for vitamins A, E and D_3. Those that didn't cannot endanger health, if used as proposed, but they significantly change total daily intake of these vitamins.

ABSTRACT: The experiment was designed to monitor durability of certain diary products stored at proper temperatures (8^{o}C) and elevated temperatures (14^{o}C) within their shelf-life. Samples of fermented milk products were tested during 25 days, samples of cheese spread products over 80 days, while soft white cheese samples were analyzed during a storage period of 100 days. In the defined study periods, depending on the type of product, pH and a_w value of the product, as well as sensory analysis (odor, taste, color and consistency), and microbiological safety were investigated. The above investigations were performed in accordance with National legislation. Research results indicate that products stored at 14°C showed significant acidity (lower pH value), changed sensory properties, as well as an increased number of aerobic bacteria.
Key words: *milk products, shelf life, storage temperature, quality.*

INTRODUCTION

It is well known that, depending on numerous internal and external factors, microorganism growth occurs during diary products storage resulting in sensory changes, i.e. spoilage. This is due to the fact that if storage conditions are inadequate, nutrients in milk products are a good medium for growth and development of individual groups of microorganisms.
The diverse range of dairy products found on the market today is a result of knowledge and experience acquired over the years. However, the contemporary consumer sets high requirements for the producer, expecting him to stay abreast of modern trends, related to both high quality and product safety.
In other words, the consumer's primary requirement is that during the estimated time of storage the food is safe, as well as not subject to adverse changes (Gregory et al, 2006). The length of shelf life of milk products is primarily influenced by: the number and type of microorganisms present in raw milk as the primary raw material, state of packaging material, hygienic and sanitary conditions during the production cycle (washing and disinfection of equipment, pasteurization temperature regimes), as well as by the storage temperature of the final product.
In most cases, microorganisms that cause the spoiling of milk and dairy products (Mostert and Jooste, 2002; Delacroix-Buchnet, 2004), to some extent reduce their quality which results in significant economic loss (Randolph, 2006). Reduced quality is a result of different chemical and biochemical bonds which cause the change in the appearance, odour, texture, taste and aroma of products (Robertson, 2009). The appearance of those bonds is conditioned by metabolic degradation of some components of the product either by microorganisms causing the spoilage or by their enzymes (Randolph, 2006).
Yogurt is known as a good nutritive medium, with a relatively low pH, favorable for the development of acidophilic microorganisms, as opposed to cheese which is less acid and contains less water, as well as added salts, resulting in low a_w value, thus partially limiting growth and multiplication of certain microorganisms. In addition, with its firm consistency, cheese in a manner limits mobility of the microorganisms that cause spoilage (ICMSF, 2005).

MATERIAL AND METHODS

The experiment was designed to monitor durability of certain diary products (fermented milk products, cheese spreads, and soft white cheese), that were stored at proper temperatures (8^{o}C) and elevated temperatures (14^{o}C), within their shelf-life.
Samples were taken from each group of products, in original packaging units, immediately after production, and kept at predefined temperatures (8 and 14^{o}C)
Microbiological, physicochemical and sensory investigations were performed according to a plan, which included testing of the finished product immediately after manufacture, testing in the middle of the declared shelf-life, and at the end of shelf life.
Microbiological examination of diary products was performed in accordance with the Regulations of General and Special Conditions of Food Hygiene at any Stage of Production, Processing and Trade ("Official Gazette RoS", No. 72/2010), as well as with the elements of self-control prescribed in HACCP plans.
Concretely, 25 g of each sample were transferred to a sterile stomacher bag and 225 mL of saline-peptone water was added and mixed for 30 seconds in the stomacher. Further decimal dilutions with the same diluents were made, and the following analysis were carried out on duplicate agar plates: (a) total viable count on Peptone Caunt Agar - ISO 4833:2003; (b) lactic acid bacteria (LAB) on MRS agar incubated with a double layer for 48 h at 30^{o}C; (c) *Escherichia coli* on VRB agar – ISO 16649-1, 2; (f) *Staphylococcus aureus* on Baird Parker medium with added egg yolk tellurite emulsion - ISO 6888-1:1999; (g) yeast and moulds on Sabouraud-4% Maltose agar – ISO 21527-1, 2. Determination of the presence of *Listeria monocytogenes* was carried out following the procedure of ISO 11290−1, 2:2004, and *Salmonella spp.* – ISO 6579:2002.
The physicochemical investigation performed determined pH values (pH meter, MA-5730, No 35 398 PAT, Iskra) and water activity (a_w), using a hygrometer (Wert-Messer, Durotherm), at a constant temperature of 25ºC.
Sensory analysis of products encompassed odor, taste, color and consistency.

RESULTS AND DISCUSSION

Results of physicochemical investigation of milk products during storage are presented in Table 1.
Change of pH in fermented milk products stored at 8^{o}C was statistically significant $p<0.05$ (Day 1, pH=4, 425±0.014, at the end of storage pH=4, 26±0.093). However, for products stored at 14^{o}C, midway through their storage life, pH reduction (3.96±0.040) was established with statistically significant $p<0.01$, at the end of the cycle reaching 4.01±0.017. These products had altered sensory properties with a tendency toward higher acidity.
Change of pH-value in samples of cheese spreads, in both groups was statistically highly significant, $p <0.01$, where was not statistically significant differences in the samples stored in a 14^{o}C, from the 40 to 80 days. At the end of shelf life, these products also had altered sensory properties (rancid taste).
The established pH-values, at soft white cheeses stored at 8 ° C, from 1 to 50 days was not statistically significant ($p < 0.05$), but at the end of of the cycle reaching (100.day) was statistically significant, $p <0.01$ (Day 1, pH=4.82, Day 100, pH=4.65), as opposed to cheese samples stored at 14°C, where, already in mid shelf life, there was a reduction of pH, (statistically significant $p<0,001$) accompanied by a change of sensory properties (bitterness, altered structure, unpleasant odor).

Table 1. Results of the physicochemical testing of products (a_w and pH-value) during storage

Type of product	**Storage temperature**	**Days of testing**		
Fermented milk products		Day 1	Day 13	Day 25
		pH value (Ā±SD)		
	8°C	4.425±0.014	4.20±0.013	4.26±0.093
	14°C	4.43±0.035	3.96±0.040	4.01±0.017
Cheese spreads		**Days of testing**		
		Day 1	Day 40	Day 80
		pH value (Ā±SD)		
	8°C	4.68±0.023	4.61±0.010	4.52±0.014
	14°C	4.71±0.021	4.65±0.013	4.66±0.007
		a_w value		
	8°C	0.962	0.968	0.966
	14°C	0.964	0.966	0.973
Soft white cheese, 45% milk fat in dry matter		**Days of testing**		
		Day 1	Day 50	Day 100
		pH value (Ā±SD)		
	8°C	4.82±0.015	4.73±0.014	4.65±0.018
	14°C	4.83±0.012	4.15±0.010	3.64±0.007
		a_w value		
	8°C	0.958	0.966	0.968
	14°C	0.959	0.977	-

Legend: Ā – average value; SD − standard deviation

For cheese and cheese spreads stored at 8°C, during the investigation period the a_w value was uniform (approximately 0.96), while for samples stored at a higher temperature, this value was somewhat elevated (0.977) in mid shelf life. At the end of shelf life, the a_w value was not measured because samples shower pronounced signs of spoilage.

Table 2. Results of microbiological testing of products during storage

Type of product	**Storage temperature**	**Days of testing**		
Fermented milk products		Day 1	Day 13	Day 25
	Total number of LAB, CFU/ml			
	8°C	$3.4x10^8$	$1.7x10^8$	$2.8x10^7$
	14°C	$3.4x10^8$	$1.4x10^8$	$2.3x10^7$
Cheese spreads		**Days of testing**		
		Day 1	Day 40	Day 80
	Total number of aerobic bacteria, CFU/g			
	8°C	θ	θ	Θ
	14°C	θ	60	200
Soft white cheese, 45% milk fat in dry matter		**Days of testing**		
		Day 1	Day 50	Day 100
	Total number of aerobic bacteria, CFU/g			
	8°C	θ	θ	θ
	14°C	θ	150	6000

Legend: CFU – colony forming units; LAB − lactic acid bacteria; θ - not detected

Microbiology test results showed that tested samples of dairy products did not contain *L. monocytogenes*, *E. coli*, *Salmonella* spp, *Staphylococcus aureus*, or yeasts and molds. Finished products, as well as products during the storage period were safe for use.

The lactic acid bacteria count in fermented milk products was characteristic for this type of product, but also consistent during the storage period, at both investigated temperatures. During the storage period, at a storage temperature of 8°C, no aerobic bacteria were found in samples of cheese spreads and soft white cheese, while at 14°C their number grew until Day 40 i.e. Day 50 of storage.
Investigation results of Huskar et al., (2003), showed that during the storage process of probiotic yogurt at temperatures of 4 and 20^{o}C there is a change of quality of stored products, and that changes are more pronounced at higher storage temperatures. The decrease in product quality is linked to increased content of lactic and citric acid.
For investigations of microbiological processes in butter during the storage period and cooling temperatures, Simonovic (1986) indicates that the increase of the total microorganism and lipolytic bacteria count is intensive after Day 15, and that on Day 30 at 4^{o}C this count was increased by up to 10 times. The same author states that the change in the lipolytic bacteria count is directly proportionate to the increase in the total microorganism count.
By testing the effect of various storage temperatures (-12, 2, 8 and 12^{o}C), as well as the presence of salt on microbiological changes in five different types of thermo processed products, Jensen et al., (1983), state that lower storage temperatures and the presence of salt have a significant effect on reducing the total number of microorganisms, *Coli* bacteria and yeasts, compared to their counts established in products stored at higher temperatures.
The effect of various storage temperatures is directly linked to lipolytic and proteolytic processes taking place in the product itself, with an intensity directly dependent on external temperature. This is corroborated by results of Sheehan et al., (2004), stating that the intensity of proteolyses is more pronounced in samples of Mozzarella cheese stored at higher temperatures (the experiment was done at 4 and 12°C).
Demarigny et al., (2006), showed that “mini cheeses” stored at 18^{o}C for 12 weeks have altered sensory properties compared to cheeses stored at 7^{o}C for 24 weeks. UHT milk samples, taken in the spring and fall from five different dairies distributed in different regions of France (north, north-west, south-west and central France), were stored at various temperatures (4, 20 and 40^{o}C), and analyzed after 21, 42, 62, 90, 110 and 180 days, and it was established that higher temperatures (40^{o}C) have a pronounced effect on pH decrease and the increase in non-casein (Gaucher et al., (2008). In other words, the sustainability of dairy products, as well as their shelf life directly depend on storage temperature.

CONCLUSION

Results of this research enable following conclusions:

- Investigated dairy products stored at 8^{o}C showed no significant pH decrease, as opposed to products stored at higher temperatures (14^{o}C). On the other hand, established a_w values for cheese spreads and UF cheeses showed no variation during shelf life.
- Test results for sensory properties of fermented milk products stored at 14^{o}C demonstrated a tendency toward acidity increase during the investigation period, and for cheese spread samples a rancid taste was also established.
- For cheese samples stored at 14^{o}C, in mid storage period (Day 50), a bitter taste, altered structure, as well as a certain unpleasant odor, were established, with a significantly reduced pH.
- Results of microbiological testing showed that during shelf life investigated products were microbiologically acceptible. No presence of pathogenic microorganisms was established. On the other hand, elevated storage temperatures influence an increase of the total bacteria count, mainly accompanying a change of sensory properties, as well as a decrease of pH value.

ACKNOWLEDGEMENTS

ABSTRACT: Raw beef can be contaminated by microorganisms and support the growth of pathogens, and may lead to serious food-borne diseases. In many cases, plant extracts exibit antimicrobial and antioxidant activity. We investigated the inhibitory activity of 2.5% ethanol extract of Serbian herb *Kitaibelia vitifolia* against ATCC strains: *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Escherichia coli*, *Proteus hauseri*, *Proteus mirabilis*, *Bacillus subtilis* and fungi *Candida albicans* and *Aspergillus niger*, in a lean beef meat. We prepared samples (48 pieces per 25 g), according the sterility demands, from one piece of beef (2 kg). We organized 3 experimental group: samples from first (I - control) group are non-treated; II - samples immersed in sterile water and III - samples immersed in above mentioned herb extract. Analysis was carried out during storage at 4 ^{0}C and 25 ^{0}C (0. d, after 2, 4 and 7 d). Longest sustainability shows samples from experimental group III, on both temperature of storage, determined by method for proving spoilage (Nessler). Antimicrobial activity evaluated by their minimum inhibitory concentrations (MIC). The above mentioned extract showed strong inhibitory activity against *E.coli* (7.820 mg/mL), *S. aureus*, *P. mirabilis and K. pneumoniae* (15.625 mg/mL). Moderate sensibility on applyed herb extract shown *P. hauseri* (31.250 mg/mL) and minimum of inhibitory activity against *B. subtilis* (62.500 mg/mL). Among fungi, *A.niger* is very susceptible (7.820 mg/mL), unlike the *C. albicans* (62.500 mg/mL). This extract may be further investigated as a natural preservative to the food industry.
Key words: *beef, spoilage, antimicrobial activity, herb extract, Kitaibelia vitifolia*

INTRODUCTION

Diseases caused by eating food contaminated with pathogens around the world have strong economic, as well as the impact on public health (Gandhi and Chikindas, 2007). Microorganisms can adapt to survive and grow in a wide level of ambient conditions and the variety of raw and processed foods, including milk and dairy products, various kinds of meat and meat products and fresh products. Failure of food includes physical and chemical changes, oxidation, discoloration, or the occurrence of unpleasant taste and odor, as a result of the growth of microorganisms and their metabolic products (Gram et al., 2002). Spoilage of chilled meat is mainly caused by *Pseudomonas species*, which cause taste and odor, discoloration, production of gas and mucus (Oussalah et al., 2006a). Many pathogenic microorganisms including *Escherichia coli, Staphylococcus aureus, Listeria monocytogenes, Campylobacter jejuni, Candida spp., Zygosaccharomyces spp., Fusarium spp., Aspergillus spp., Rhizopus spp., Penicillium spp.,* and *Salmonella spp.* have been identified as causes of "food-borne" disease or spoilage of foods (Betts et al., 1999; Solomakos et al., 2008).
Davidson et al. (2000) reported that the natural herb extracts are known to have huge antimicrobial activities and listed as Generally Recognized As Safe (GRAS). Many natural herbal extracts contain mainly phenolic compounds, which are potent antioxidants (Wong et al., 1995), and occur only in materials of plant origin. Resistance to antibiotics has become a subject of global concern and interest. In recent years there is a growing number of cases of multiple resistance in terms of pathogenic microorganisms in the human population, mainly

due to reckless commercial use of antibacterial drugs widely used in the treatment of infectious diseases (Westh et al., 2004).
This fact reinforces scientists that are exploring new antimicrobial substances originating from various sources, such as medicinal plants. This investigation is continuing by screening a large number of plant families (Parekh and Sumitra, 2007). Ghasemi et al. (2010) determined the antimicrobial activity of the extracts of eight plant species which are endemic in Iran, by agar disc diffusion and serial dilution assays. Most of the extracts showed a relatively high antimicrobial activity against all the tested bacteria and fungi. Some studies show that plant extracts useful for reducing pathogen contamination in meat (Mytle et al., 2006; Ahn et al. 2007), while others report that the very low or no antimicrobial activity against *L. monocytogenes* or *Salmonella* when they are essential plant oils applied to the beef or chicken (Uhart et al., 2006; Firouzi et al., 2007).The aim of our study is to determine antimicrobial influence of ethanol extract of Serbian herb *Kitaibellia vitifolia* on delaying of the lean beef meat spoilage, at usual temperatures of storage (4 ^{0}C and 25 ^{0}C).

MATERIAL AND METHODS

Plant material

Kitaibelia vitifolia is an imposing & undemanding Mallow from ex-Yugoslavia. Above-ground part of the test plant was collected in Central Serbia, in May 2009, at the flowering stage. Taxonomy of plant was identified and the voucher specimen was deposited at the Department of Botany, Faculty of Biology, University of Belgrade (16350 BEOU, Lakušić Dmitar).

Preparation of extract

Herb samples (10.0 g) were extracted by 96 % ethanol as a solvent. The extraction process was carried out using an ultrasonic bath (Brason and Smith-Kline Company, B-220) at room temperature for 1 hour. After filtration, 5 mL of the liquid extract was used for extraction yield determination. The solvent was removed by a rotary evaporator (Devarot, Elektromedicina, Ljubljana) under vacuum, and was dried at 60 ^{0}C to constant weight. The dried extracts were stored in glass bottles at 4 ^{0}C to prevent oxidative damage until analysis.

Spectrophotometric measurements

Spectrophotometric measurements were performed using a UV-VIS spectrophotometer MA9523-SPEKOL 211 (ISKRA, Horjul, Slovenia).

Samples

Samples of lean beef meat (48 pieces per 25 g) prepared from one piece of beef (2 kg). To simulate the usual way of meat preparing, samples split up and macerated using a knife (scalpel), according the sterility demands, in laminar flow biological safety cabinet Iskra IBK 1H2. Samples were measured on a technical scale (KERN EW 150-3M, Kern/Sohn GmbH, D-72 336 Balingen, Germany, M-2-60, CE 07, ISO 9001). We organized 2 experimental group (EG): twenty four samples from control (C) group are immersed in sterile buffered peptone water (8.5 g NaCl, M = 58.44 g/mol, JUS H. G2. 081, 9431, pro analysi, „ZORKA Pharma“ a.d. Šabac and 1 g of Pepton - Pepton-1, Lot 404001, Institute for virology, vaccines and serums, Vojvode Stepe 458, 11221 Belgrade, Serbia) in 1000 mL distilled water) and prepared solution sterilised by autoclaving, at 121 ^{0}C during 20 minutes; EG I - twenty four samples immersed in above mentioned 2.5 % herb extract (pH = 4.60). Duration of immersing the samples in the study groups was 5 minutes. Excess solution from samples of both (C and EG I) group was removed by placing the dipped pieces onto a sterilized paper towel before transferring them to sterile flask for incubation. Qualitative physic-chemical analysis was carried out during storage at 4 ^{0}C and 25 ^{0}C (0 d to 7 d) and micro dilution method performed with watery meat extract on the 7 d of the experiment.

Antimicrobial activity

Minimum inhibitory concentrations (MIC) of the sausage extract and against the test bacteria were determined using a micro dilution method in 96 multi-well micro-titer plates (Satyajit et al., 2007). All tests were performed in Muller-Hinton broth (MHB) with the exception of yeast, in which case Sabouraud dextrose broth was used. A total of 100 µL stock solution of sausage extract (in ethanol, 200 µL/mL) was pipetted into the first row of the plate. Fifty µL of Mueller-Hinton or Sabouraud dextrose broth (supplemented with Tween 80 at a final concentration of 0.5% (v/v) for analysis of sausage extract) was added to the other wells. Fifty µL from the first test wells was pipetted into the second well of each microtiter line, and then 50 µL of scalar dilution was transferred from the second to the twelfth well. Ten µL of resazurin indicator solution (prepared by dissolution of a 270-mg tablet in 40 mL of sterile distilled water) and 30 µL of nutrient broth were added to each well. Finally, 10 µL of bacterial suspension (10^6 CFU/mL) and yeast spore suspension (3×10^4 CFU/mL) was added to each well. For each strain, the growth conditions and the sterility of the medium were checked. The standard antibiotic Amracin was used to control the sensitivity of the tested bacteria, whereas Ketoconazole was used as the control against the tested yeast. Plates were wrapped loosely with cling film to ensure that bacteria did not become dehydrated and prepared in triplicate, and then they were placed in an incubator at 37 ^{0}C for 24^h for the bacteria and at 28 ^{0}C for 48^h for the yeast. Color change was then assessed visually. Any color change from purple to pink or colorless was recorded as positive. The lowest concentration at which color change occurred was taken as the MIC value.

Test microorganisms

The antimicrobial activity of the herb extract was tested against the following bacteria: *Staphylococcus aureus* ATCC 25923, *Klebsiella pneumoniae* ATCC 13883, *Escherichia coli* ATCC 25922, *Proteus vulgaris* ATCC 13315, *Proteus mirabilis* ATCC 14153, *Bacillus subtilis* ATCC 6633, and fungi: *Candida albicans* ATCC 10231 and *Aspergillus niger* ATCC 16404, in meat extracts prepared from examined lean beef meat pieces, after 8 d of storage. The fungi were cultured on potato-glucose agar for 7 d at room temperature of 20 ^{0}C under alternating light/dark conditions. Then they were cultured on a new potato-glucose substrate for another 7 d. The culturing procedure was performed four times, after which pure cultures required for determination were obtained. The identification of the test microorganisms was confirmed by the Laboratory of Mycology, Department of Microbiology, Institute Torlak, Belgrade, Serbia.

Determination of microbial spoilage

To assess the freshness and quality of examined meat sample during various ways of storage was determined the bound ammonia (easily hydrolyzable nitrogen) with *Nessler* reagent (tetraiodomercurate bipotasic solution in potassium hydroxide), which prepared with 5 g potassium iodide dissolved in 5 cm^3 of hot water in an Erlenmeyer flask. Hot saturated solution of mercuric chloride added until the precipitate formed is no longer dissolved. After cooling the solution separate, decant a 100 cm^3 volumetric flask. Add 15 g potassium hydroxide dissolved in 30 cm^3 water and bring to volume with water. Add 0.5 cm^3 saturated solution of mercuric chloride, allow to make the solution above the precipitate and separated by decantation, pass in a clean dark bottle and kept from light.

The reaction of the meat extract with Nessler's reagent may lead to the formation of turbidity and change of color and indicate slight decomposition. If a precipitate forms, the decomposition is advanced.

RESULTS AND DISCUSSION

The results on antimicrobial effects of herb extract obtained by the micro dilution method are shown in Table 1. As it can be seen from the results, MICs were determined for 8 indicator strains, and revealed that ethanol herb extract of *K. vitifolia* showed inhibitory effects tithing the concentration range of 7.820 µg/mL to 62.500 µg/mL.

Above mentioned herb extract was exhibited strongest inhibitory activity against *E.coli* (7.820 µg/mL), *S. aureus*, *P. mirabilis and K. pneumoniae* (15.625 µg/mL). Moderate sensibility on applyed herb extract shown *P. vulgaris* (31.250 µg/mL). Lowest inhibitory activity herb extract exhibited against *B. subtilis* (62.500 µg/mL). Among fungi, *A. niger* is very susceptible (7.820 µg/mL), unlike the *C. albicans* (62.500 µg/mL). These results are very similar like results were reported by Kurcubic et al. (2011), obtained in examination of the same influence in fermented dry Sremska sausages, but different of data presented by Mašković et al. (2011) for determination of MIC of the ethanol extract of *K. vitifolia* and standard drugs for same 8 indicator strains, *in vitro*.

Our opinion is that the reasons for this differences arising form interaction between microbes and constituents of meat or some other microorganisms from meat, which alter their ability for defense responses, or protect some examined strains. Generally, the efficiency of most antimicrobial properties of natural supplements can be reduced by the action of certain food components (Glass and Johnson, 2004). Cutter (2000) suggested that the use of herb extracts may afford some reductions of pathogens on beef surfaces, because the antimicrobial activity may be diminished in ground beef by adipose components.

Table 1. Minimum inhibitory concentrations (MIC) of the ethanolic extract of *K. vitifolia* for microbial strains in examined samples of meat extract

	MIC (µg/mL)			
Microbial strains	***ATCC number***	***Meat extract of EG I***	***Amracin***	***Ketoconazole***
		Bacteria		
Staphylococcus aureus	*25923*	15.625	0.970	/
Klebsiella pneumoniae	*13883*	15.625	0.490	/
Escherichia coli	*25922*	7.820	0.970	/
Proteus vulgaris	*13315*	31.250	0.490	/
Proteus mirabilis	*14153*	15.625	0.490	/
Bacillus subtilis	*6633*	62.500	0.240	/
		Funghi		
Candida albicans	*10231*	62.500	/	1.950
Aspergillus niger	*16404*	7.820	/	0.970

Table 2. The dynamic of investigated qualitative physic-chemical changes in stored macerated lean beef meat pieces

Samples (12 per group)	**Nesller reaction**							
	day of storage							
	0 d	**1 d**	**2 d**	**3 d**	**4 d**	**5 d**	**6 d**	**7 d**
C (4 ^{0}C) C_1 to C_{12}	**N**	**N**	$C_{9,10}$: **P** $C_{4,5,6,7,8,11}$: **PP** C_{12}: **U** $C_{1,2,3}$: **N**	$C_{9,10}$: **P** $C_{4,5,6,7,8,11}$: **PP** C_{12}: **U** $C_{1,2,3}$: **N**	$C_{8,10,11,12}$: **P** $C_{1,2,3,4,5,6,7,9}$: **N**	C_1 to C_{12}: **P**	-	-
C (25 ^{0}C) C_{13} to C_{24}	**N**	**PP:**4 **U:** 8	C_{13} to C_{24}: **PP**	C_{13} to C_{24}: **P**	-	-	-	-
EG I (4 ^{0}C) EG_1 to EG_{12}	**N**	**N**	**N**	**N**	**N**	**N**	**N**	**N**

*The qualitative results are presented by four categories of reaction interpretation: Positive (**P**); Poorly Positive (**PP**); Uncertain (**U**), and Negative (**N**).*

As shown in Table 2, only the samples from the EG I stored at 4 ^{0}C remained fresh in the absence of bound ammonia during 7 days of storage. In other experimental groups studied discoloration of meat extract were observed on the first day of storage (4 samples in the control group kept at 25 ^{0}C poorly positive and 8 were expressed uncertain reaction, followed by unspecified unpleasant odor). All 12 samples from the control group, which were stocked

at 4 ^{0}C were strongly altered (P) on the fifth day of storage (followed with discoloration), and when stored at 25 ^{0}C for three days. Changes of the color when performing Nessler reaction in samples EG I kept at 25 ^{0}C began the third day, and on the fifth day only 3 samples (E_{22}, E_{23} and E_{24}) were positive, and sixth day all samples above mention experimental group were positive. Qualitative physic-chemical changes confirmed the strong protective antimicrobial activity of the tested plant extracts.

CONCLUSIONS

The present study confirmed the antimicrobial efficiency of the ethanol extract of the Serbian herb *Kitaibelia vitifolia*, and benefits for the sustainability and safety of beef meat (improving microbiological quality and prolonging the shelf-life of the beef to day seven of examination). Above mentioned extract showed relatively high antimicrobial activity against all the tested bacteria and fungi, and may protect consumers from the hazards of food-borne illness. The present study suggests that the extract of *K. vitifolia* is a potential source for the food industry as a natural antibacterial agent.After this screening, further work should be performed to describe the antimicrobial activities in more detail as well as its activity *in vivo*.

ABSTRACT: In the present study the quality of brown sugar from domestic sugar beet processing were investigated. It is either an unrefined or partially refined sugar consisting of sugar crystal with some residual molasses content, or it is produced by the addition of molasses to refined white sugar. At gobal sugar market various types of brown sugar are present. It can be produced from sugar cane or sugar beet, in principle according to three manufacturing processes. Depending on the region brown sugar have different names. In the dependence of origin and manufacturing processes it differs according to chemical composition, nutritive value, color, taste and grain size. Their popularity is due to the idea of consumers that brown-colored products are more natural, healthier and more valuable. Their employment in the food manufacture is based on aroma, color characteristics and nutritive value.
The aim of this paper was evaluation quality of brown sugar, produced in domestic sugar industry, from the aspect of food safety and nutritive value.
Key words: *brown sugar, quality, nutritive value*

INTRODUCTION

World sugar production is based on sugar cane (70 %) and sugar beet (30 %), while in the European Union 98% of total sugar production derived from sugar beet (Nolte and Grethe, 2011). Sugars have used in food production not only as a sweeteners but also as a valuable ingredients contributing to the taste, flavor, colour, energy, texture, nutritional value, hygroscopity, consistency, antioxidant effect, etc., of food (Clarke, 1995). Sugar always acts in more than one way, which accounts for its wide use in foods and beverages (Poel et al., 1998).
In sugar refining special crystal sugar products as brown sugar can be produced beside white sugar. A syrup layer is left around the crystals giving a special colour and flavor to the brown sugar. In principle, there are three manufacturing processes: a) evaporating crystallization of selected syrups b) mixing fine particle size white sugar with syrups, which are always of cane origin because of the flavour and c) cocrystallization method from special syrups. Depending on the origin: sugar cane or sugar beet and manufacturing processes, different types of brown sugar can be produced. Most producers make two or three types: light, medium and dark. The content of nonsugar substances increases with the intensity of the colour.
The aim of this study was to evaluate quality of brown sugar produced from sugar beet in domestic sugar industry.

MATERIAL AND METHODS

The investigations were conducted with samples of brown sugar produced from sugar beet in domestic sugar factory. Basic quality parameters of brown sugar, content of mineral matters and heavy metals were determined according to methods described in handbooks for the laboratory control of sugar processing (Milić et al., 1992). The methods are harmonised with

the regulations guided by the International Commission for Uniform Methods of Sugar Analysis (ICUMSA, 2003). The obtained data were processed using a statistical software STATSOFT. Basic statistical descriptors were calculated (Hadživuković and Čobanović, 1994).

RESULTS AND DISCUSSION

In Table 1 average values and other statistical parameters of the quality parameters of the tested samples are presented in order to get a more realistic picture about the quality of brown sugar produced in our factories.
The results confirmed variation in the quality parameters of the examined samples which is understandable because sugar beet is a biological material whose quality depends on the growth conditions of sugar beet. The variations in certain parameters were also due to characteristics of processing conditions used in each factory. The largest coefficients of variation were observed in the content of sulphur-dioxide and reducing matters which implied to the fact that these parameters were largely dependent upon the processing conditions. Variations showed that sugar factories applied different processing conditions with different efficacy.

Table 1. Basic quality parameters of brown sugar

Parameter	Minimum	Maximum	Avarge	Standard deviation	Coefficient of variation
Polarisation (%)	98.77	99.58	99.13	0.336	0.339
Reducing matters (%)	0.027	0.150	0.081	0.040	48.971
Ash (%)	0.083	0.389	0.210	0.087	41.618
SO_2 (mg/kg)	2.650	7.969	5.323	2.459	46.202
Moisture (%)	0.106	0.288	0.197	0.065	32.960

Table 2 presents the composition of mineral matters in brown sugar. The values of single mineral matters varied widely, that were related to the different content of mother syrup - molasses in brown sugar crystals. Mineral matters in brown sugar have origin from heterogenous sugar beet material and conditions of technology.

Table 2. Mineral matters in brown sugar

Mineral matters (mg/kg)	Minimum	Maximum	Avarge	Standard deviation	Coefficient of variation
Potassium	102.38	461.59	219.04	128.03	58.45
Sodium	52.70	207.57	92.20	55.95	60.69
Calcium	155.80	967.73	436.78	360.13	82.45
Magnesium	2.21	3.59	2.84	0.55	19.28

The contribution of potassium, sodium, calcium and magnesium in ash are presented in Figure 1.
Table 3 presents Daily Values (DV) of nutrients for brown sugar which are calculated on the basis of using one cup of brown sugar daily, according The World's Healthiest Foods (Mateljan, 2007) and USD Nutritive Value of Foods (Gebhardt and Thomas, 2002).

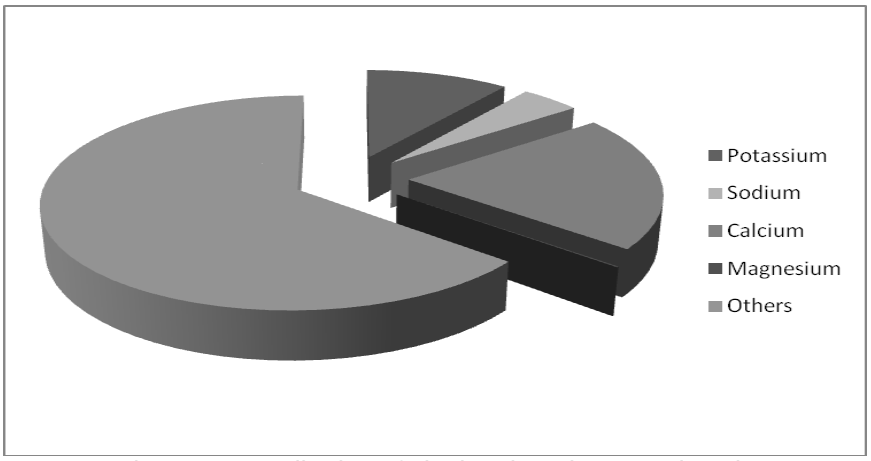

Figure 1. Contribution of single mineral matters in ash

Table 3. Contribution of mineral matters of brown sugar in human daily requirements

	Potassim	Sodium	Calcium	Magnesium
Daily requirements (mg)	3500	2400	1000	400
DV (%)	1.377	0.845	9.610	0.156

In the tested samples of brown sugar, the content of heavy metals (As, Pb, Cd and Hg) was determined and their frequency distribution is presented in Figure 2. The highest frequency distributions for arsenic, lead and coopper were in the concentration range 0.0 - 0.1 mg/kg, whereas 50% of samples had mercury concentration in the range 0.0-0.001 mg/kg.
The contents of heavy metals measured in the samples were all below the regulated limits for brown sugar (Sl.gl. RS br. 25/2010 i 28/2011) that confirming the health safety of brown sugar produced in Serbian sugar factories.

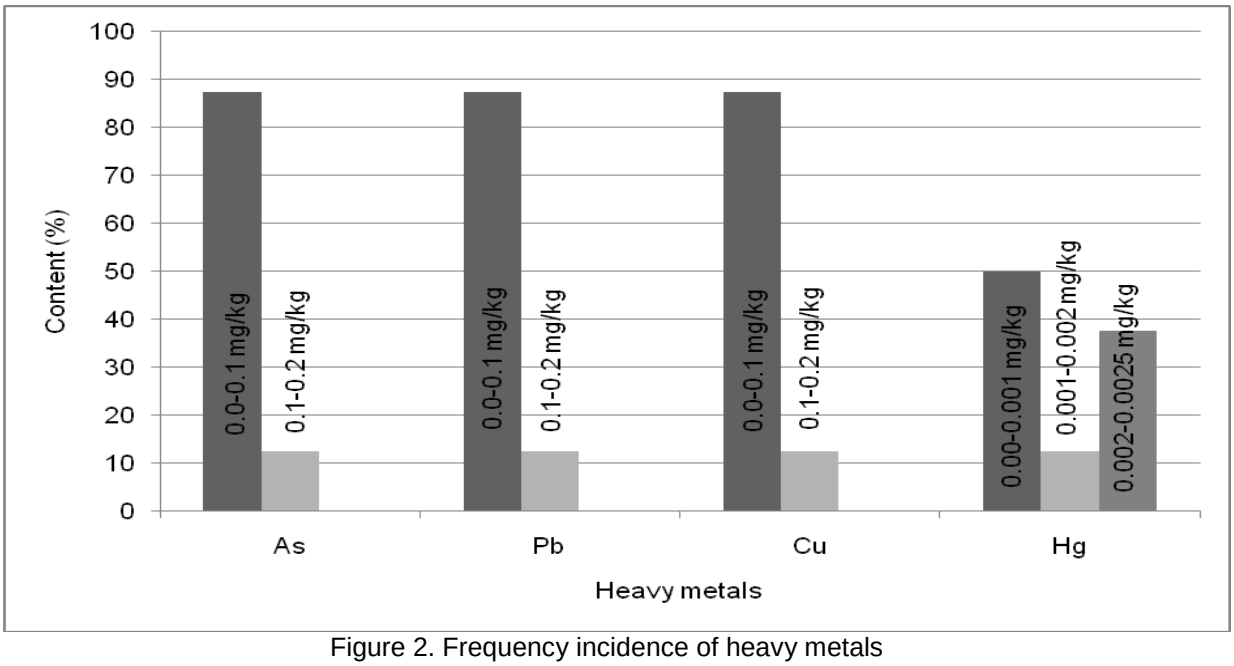

Figure 2. Frequency incidence of heavy metals

CONCLUSIONS

On the basis of the results it can be concluded that the investigated samples show the very different composition of brown sugar. The quality of sugar varies in the dependence of the sugar beet quality as raw material and the conditions of sugar beet processing. The mineral matters: potassium, sodium, calcium and magnesium present about 36 % of ash deterninated conductometrically. The content of nonsucrose compounds varies widely, that is related to the different content of mother syrup - molasses in brown sugar crystals. The content of heavy metals (As, Pb, Cu, Hg) confirm that brown sugar is health safety.

ABSTRACT: This study was carried out 18 villages and towns fronting to a cement factory in Mahmudiye village of Çanakkale district. Four poultry houses from each location was selected and 4 chickens, 4 eggs and the samples of seed wheat from each poultry houses were taken in winter, spring, summer and autumn seasons (January, April, July, October) of 2009 and 2010 years. One of the main aims of the study is to determine the level of selected heavy metals (Pb, Cd, Cu, Cr, Co, Mo and Ni) in the liver, legs and chests of the chickens fed near the places of cement factory. In the experimental period, from 2304 chickens, the samples of chicken liver, legs and chests, 2304 eggs and 576 seeds of wheat were collected. Heavy metal levels analyzed in the livers of the samples were found higher than the ones in the legs and chest samples (P≤0.01) and the heavy metal levels of the seed wheat collected in the poultry houses were found higher than the egg samples in the same poultry houses (P≤0.01). It has found that none of the heavy metals exceeded the limits determined by Turkish Food Codex and European Union.
Key Words: *Heavy metals, cement, poultry, wheat*.

INTRODUCTION

Today, the environmental problems are the most trouble some situations that threaten the natural balance and vibrant health. Environmental pollution which is the result of the developed industries, big powers ambition to earn more, people's and animal's food requirement, increase of population and efforts to get a civilized interviewee are becoming more important. Today, among the factors that cause environmental pollution the cement sector is usually the first thought. Research high lights the importance of cement sector as air pollutants. Indeed, the cement industry is one of the oldest branches of industry that process rather large amounts of solid material by a wide variety of equipments. The modern concrete roads, buildings, structures such as damns indicate that this industry has grown and developed in the past and in the present century. Environmental pollution also increased with the enlargement. The problems that caused by the sector are only limited by the effects of dust and the dust forms. However, in the last 30 years, noise, vibration and emissions of some gases such as sulfur dioxide and nitrogen oxides, an even discussions of possibility of heavy metals that could be in gases changed the size of the problems (Pekin, 2011). Cement factories damage residential areas and productive agricultural lands by the dust particles they emit and cause yield losses of products in those areas and change the natural chemistry of soil (Uysal et all., 2006). The pollution which is cause by cement factories also affect animal production at the same time. Toxic substances which are derived from the cement industry wastes are found in areas where the animals are pastured and particularly in water supplies. Heavy metals, toxic polluters, are durable for the enviromental situations, can effect the biological systems readily and give severe damages to the living organisms through food chains (Baş and Demet, 1992).
Second category of wastes, scrap tires, plastics, contaminated wastes, insecticides, bilge and composite materials are used as an alterntive fuel in the cement factory. Creation of heavy metals are taken place by using alternativ fuels in addtion to carbon-based primary fuels. In this research, the effects of pollutants (heavy metals), which are caused and released into the environment by the cement factory that is located 40 km south of Çanakkale, on feed sources (wheat) and poultries which are breeding in the area.

MATERIAL AND METHODS

The research was conducted in 18 separate locations which are located in the northern and southern directions of cement factory operating in Çanakkale's Mahmudiye town. 4 flocks are selected from each village. Four eggs, 4 chickens and wheat grains, which were used in feeding, were samples which were taken from each flock in 2009's and 2010's winter, spring, summer, autumn (January, April, July, October). 2304 chickens and eggs, 576 grain wheat samples are collected in testing period. The collected samples (leg, breast, liver, egg, wheat) are homogenized by the mixer and grinder. Subsequently, 5 g. each sample, was treated 25 mL of concentrated HNO3 (nitric acid) and 10mL of H_2O_2 (hydrogen peroxide) to in Erlenmayer flask, and burnt in the open area by the method of wet decomposition. Completely burnt samples were, with 10mL of distilled water. A control sample was prepared for each 10 samples. The temperature for wet decomposition in the open area was, set to 100^{o}C, the sample was held at this temperature for 1 hour, then after standing at 130^{o}C for 1 hour, and at 150^{o}C until the sample gets clarified. Each sample (breast, hindquarter, liver, egg and wheat) was measured for lead (Pb), cadmium (Cd), copper (Cu), chromium (Cr), molybdenum (Mo), cobalt (Co) and nickel (Ni) content. Statistical analysis has been done for, investigated years (2009 and 2010), seasons (spring, summer, autumn, winter), regions (nothern, southern and control settlements), Repeated measurement-ANOVA was used to investigate the effects of the amounts of heavy metal accumulated in chicken's hindquarter , liver and breast. Tukey's multiple comparison test was used for determination of different groups. (Winer et all., 1991; Zar, 1999). The statistical analysis was performed using Minitab and SPSS statistical package programme.

Findings

The evaluation of all obtained data has shawn, that the effects of organ x location interaction is very important for all heavy metals. (P=0.00). The amount of heavy metals which are accumulated in chickens' liver, chest and hindquarter, changes by location from where the test samples were received. (Figure 1).

** In the same area, differences between the different organs shown in capital letters are important. (P≤0,01).*

*** Same organ, differences between the different regions shown in small letters are important. (P≤0,01).*

Among the samples gained from the North and South settlements, the most density of heavy metals has been found in liver tissues, the lowest amount has been observed in chest samples. Similar findings were also detected in samples obtained from control areas, the most intense accumulation observed was in liver, and the lowest accumulation was observed in leg and breast. Of all investigated heavy metals, Cu was determined at the highest level in the liver (Figure 1).

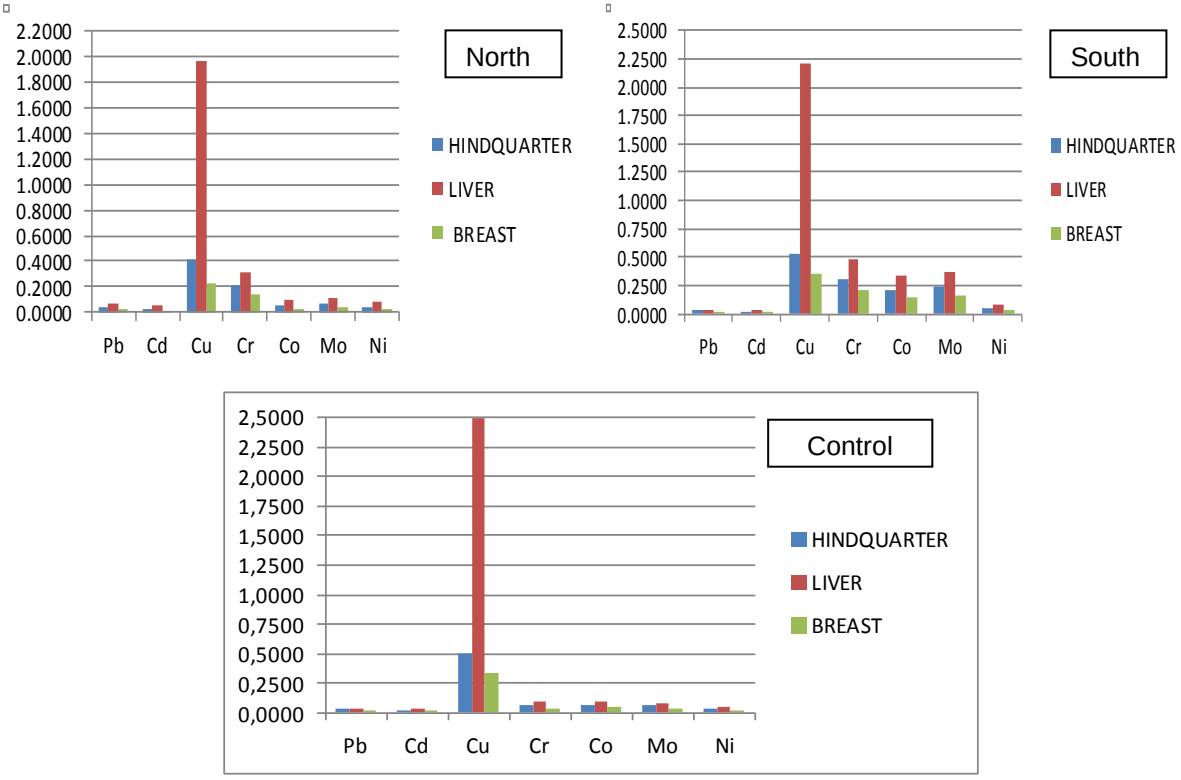

Figure 1: Averages of heavy metal accumulation (ppm) in organs fromin north, south and control groups.

Pb is significantly higher in northern settlements than in southern and control settlements in all analyzed tissue samples. It was determined that there is a significant difference between south and control settlements. Analyses of egg and wheat samples show that some heavy metal contaminations decreases by increasing the distance from the factory. However, when Pb, Cu and Cr are analyzed it is determined that although in some areas accumulation was under the legal limits, it is still high. Level of heavy metals in wheat used as feed for poultry is determined as higher than the level in eggs from same poultry ($P \leq 0.01$). The determined were below the tolerance limits set by Turkish Food Codex (TGK) and EU regulations. In TGK, tolerance limit has been specified for Pb in poultry meat at 0.1 ppm, edible poultry offals (liver, hearth, gizzard) at 0.5 ppm, wheat at 0.2 ppm and for Cd in poultry meat at 0.05 ppm, poultry liver of poultries at 0.5 ppm, wheat grain at 0.1 ppm. This condition indicates that the situation is not harmful for human and animal health in the light of our datas that are identified from accumulation of heavy metals. Provided research findings indicates that analyzed accumulation of heavy metals decrease in the following order: liver > leg > breast. This finding is consistent with similar literature datas. Literature datas report that Pb is a toxic metal that affects bone linearly. Accumulation of heavy metal in bone tissue has not been studied, because the research was focused on edible, tissues, organs and grain used as feed. However, it is known that %90-95 % of lead present in that held in the body is accumulated in bones. (Finley, 1978; Ozan, 1996). This is followed by liver and kidneys (Humphereys, 1991; Roberts et. all , 1978).

DISCUSSION AND CONCLUSION

Animals exposure to metals usually take place through water and feed. However, it is very difficult to identify the environmental problems caused by metals even under today's technology. Confidence limits for heavy metal concentrations in these sources must be known. Especiallly Cu, Pb, Cd, Ni metals causes animals to have acute and chronic toxicity. (WHO, 1987). During the research, it has not been seen any intoxication that can lead to acute poisoning. While acute poisoning can easily be recognized, chronic poisoning is usually hiddesn. Chronic poisoning causes deterioration in terms of quality and quantity of production, thus causes economic losses. Chronic poisoning can be diagnosed in animal by analysis of milk, blood, hair, wool, liver, kidneys and carcasses. (WHO,1987). Although some heavy metals and trace elements are anatomical components for live biological systems taken from the environment; when they are taken in overdose or chronic levels, it may poison animals or people. Irwin et all. (1989), reported that lead accumulated in descending order bone, kidney, liver and muscle in ducks fed for 14 weeks in an artifical pond that has different amounts of lead particles. In samples obtained from the northern areas studied in this research, detection of accumiulation of Pb at relatively high level from examined tissues are similar to the findings of the other studies. Although our findings indicate that accumulation of Cd, especially in liver, is much higher in the nothern region samples, they are not present at toxic levels.

The findings of our study show that Pb levels are higher in the northern areas, but lower in the southern areas. ($P \leq 0.01$). In a similar study, Kurnaz (2008) determined that heavy metal accumulation in the liver is higher than in the hindquarter and it is appropriate for TGK and the European Union notification. This result supports our findings. Exhaust fumes that are carryied by prevailing winds are concentrated in the northern areas more than in the areas where the cement plants are located. This situation can be explained by atmospheric transport of Pb and closeness of İzmir-Çanakkale highway. It is known that living organisms can continue to grow in an environment where heavy metals can be found, but they do not have a mechanism to permanently eliminate the toxic effects. From this point of the research findings, liver, leg, breast, egg and, wheat grain do not affect consumers health in a negative way.

ABSTRACT Grain hardness is a basic differentiating element of wheat standard classifications. The hardness of the wheat endosperm is genetically determined. That is considered as a stable variety's index. The attention that is paid to the hardness as an indicator of the quality is due to the different technological relation of the wheat. Twenty four Bulgarian varieties of common winter wheat, developed over a very long period of time (60 years) at Institute of IRGP-Sadovo were studied. Using Inframat 8600-H, grain hardness, vitreousness and content of crude protein, were determined during 3 crop years. Statistically it has been proven that old varieties like Jubileina 3 and No. 301, as well as Katiya, Lada, Murgavets and Guinness, are wheat with hard endosperm and high vitreousness, but the old variety Okerman and varieties like Sadovo super, Mustang, Prelom and Diamond have soft endosperm and therefore are low vitreous. The rest of the studied varieties have medium hard to hard endosperm.Using analysis of variance it has been proven that under certain agro-climatic conditions the index varies during 3 years of study: F exp.=7.76 > F crit.=3.12
Key words: *wheat variety, grain hardness, vitreousness, crude protein*

INTRODUCTION

The utmost attention paid to hardness as a grain quality trait is due to the different technological handling of wheat having different structural-mechanical properties. It is considered that endosperm hardness is genetically determined and appears a sustainable variety feature.

The better knowledge of the physico-chemical mechanism and the endosperm genetic control helps towards breeding, marketing and utilization of the end-use product. According to Symes (1965) the conversation of hard wheat to soft wheat or vice versa can be achieved by backcrossing. The grain hardness of new wheat will be influence both by the hardness of the donor parent and by the degree to which modifying genes are carried over. This demonstration of the simple inheritance of grain hardness measured by particle size index is significant to wheat improvement programs.

It has been established through a scanning microscope that hardness reflects total cell structure, the protein matrix type, and mostly the protein-starch relation, in this way characterizing the endosperm type (Belcheva, 1993).

Friabiline is a specific endosperm protein associated with starch granules of wheat grain. Chemically these are various polypeptides, primarily puroindolines. Hardness (Ha) locus of chromosome 5DS makes the distinction between hard and soft classes of wheat. (Pasha et al., 2010).

Hard grain wheat and soft grain wheat have different behaviour when ground and sieved, and also take different energy consumption. The difference in the flour microstructure determines their rheological properties. Hard grain flour is sharp and easily sieved. Soft grain flour, on the other hand, is fine, easily adheres, hard to sieve and glide. This is due to relatively smaller particle size, relatively larger surface of the flour, and the greater particle cohesion (Zwingelberg, 1983).

Based on the hardness-protein relation, Moss (1973) suggested the following wheat grading: common soft with 10-11% protein content; common hard with 12-14.5% protein content.

However, the studies of some American and Australian authors on the protein-hardness relation do not establish a relation between these two features.
The studies of Shikrenov at al., (1967) refer to the varieties spread in Bulgaria in the 60s. Stoeva at al., (1988) using Brabender instrument have characterized only some wheat varieties created at Dobrudja Agricultural Institute, near Gen. Toshevo in the 80 s, that were referred to the wheat having hard to medium hard endosperm. The group of varieties studied by Belcheva et al., (1990) includes a few varieties created at the IPGR, Sadovo. Mangova et al., (2004, 2006) were evaluated chiefly hybrid - mutant wheat lines.
The present study comprises a large number of wheat varieties created at IPGR, Sadovo over the long period of 60 years.

MATERIAL AND METHODS

The objects of the present study were 24 common winter wheat varieties (T. Aestivum), created over a 60-year-long period of time at Institute of Plant Genetic Resources, Sadovo.
The following grain quality parameters have been determined over a period of three consecutive crop years: endosperm hardness and crude protein content by Inframat 8600-H and total grain vitreousness by farinotom.

RESULTS AND DISCUSSION

The grain hardness for the three crop years was within the range of 48.0-57.67, and the mean was 54.42 (Table 1). It was statistically proven that the varieties with the hardest grain endosperm were: Katiya, Pobeda, Jubileina 3, Lada, Guinness, and Murgavets. It was also statistically proven that the following varieties have the softest endosperm in descending order: Sadovo super, Diamand, Okerman, Prelom, Mustang and Zdravko. The rest of the studied varieties have medium hard to hard endosperm.

Table 1.Estimation of wheat varieties according to grain hardness

Variety	Range	Average value	Deviation	Significance
№ 301	8	56.33	1.92	*

Boriyana	14	55.0	0.58	*
Petiya	7	56.33	1.92	*

The average grain protein content over a three-year period was 12.5% (Table 2).The highest in protein content were the hard grain varieties Jubileina 3-13.37%, № 301- 13,17%, Pobeda 13% and Sadovo 5.52 -13.3%. The soft grain varieties: Sadovo super, Prelom, Okerman and Diamand were in close range in protein content of 12.2 %-12.8%. However, according to Moss H.J. (1973) and Bushuk W.'s (1986) classification, this is the range of protein content in hard grain varieties. Therefore Bulgarian soft endosperm varieties were characterized by higher protein content, which is not typical of this group. Mc Ritchie (1980) referred to these wheat as exceptions. This resulted from the Bulgarian breeding programs, whose priority has been the protein content without controlling the endosperm hardness, because the requirements for technological qualities parameters to recognizing a new varieties, is 12% minimum protein content.

Table 2. Estimation of wheat varieties according to crude protein content

Dependency of grain hardness - protein content varied within varieties and years. The correlation coefficients were low and statistically not significant, so this cannot serve as a basis to grade the wheat varieties.

According to Mc Ritchie (1980) the common wheat varieties with hard endosperm were characterized as vitreous, whereas the common wheat varieties with soft endosperm as non vitreous. However, some Russian authors' studies present data also on high vitreous varieties with soft endosperm.

The total virtuousness of grain for the three years was within the range of 42.33%-69%, and the mean was 57.78% (Table 3). The old hard grain variety No 301 showed maximum value of 69%, quality standard Pobeda 67% and Murgavets 64%. Sadovo 552 variety is an exception, being high vitreousness wheat 63.3%, but in hardness it ranks 17th (54.33) among the 24 varieties studied.

The soft endosperm wheat, like the old variety Okerman 42.33%, Zdravko 46.67%, Sadovo super 49.67% and Diamant 48% have a well established non vitreous endosperm. It should be noted, that also in the two groups of varieties with hard and soft endosperm, the total vitreousness varies within relatively broad range.

Table 3. Estimation of wheat varieties according to grain vitreousness

Variety	Range	Average value%	Deviation	Significance

Petiya	5	62.67	4.89	*

The dependence between the two parameters- total vitreousness and grain hardness in years, expressed by correlation coefficients, was low to medium high: for 1st year r = 0.51, for the year 2nd r = 0.83, for the 3rd year r = 0.59.

The evaluation of the Bulgarian common winter wheat varieties indicates that the endosperm hardness varies, which requires testing whether or not agro-climatic conditions have affected over the parameter values. Tthrough analysis of variance it was found that abiotic factors statistically significant have affected the grain hardness F exper. = 7.76 > F crit. = 3.12.

CONCLUSIONS

The studied Bulgarian winter wheat varieties were referred to two classification groups according to grain hardness: varieties with hard and medium hard endosperm, and varieties with soft endosperm.

The varieties with the hardest grain endosperm were: Katiya, Pobeda, Jubileina 3, Lada, Guinness and Murgavets. The varieties with the softest endosperm in descending order were: Sadovo super, Diamand, Okerman, Prelom, Mustang and Zdravko.

The correlation coefficients of the dependence grain hardness – crude protein content were low and statistically not significant.

It was found that environmental abiotic factors statistically significant have affected the grain hardness.

ABSTRACT: Phosphate and polyphosphate additives are added to meat and other food products because they serve as an emulsifier of fat, water and protein, and stimulate water binding. Phosphates affect the texture of the product, prevent discoloration, improve emulgation of fat and improve flavor, prevent oxidation of unsaturated fatty acids and affect the pH value. Existing legislation defines the maximum amount of phosphorus (expressed as P_2O_5), that can be added to meat products and which is 5 g/kg. In the Sanitary Chemistry department of Public Health Institute, the content of phosphorus in these products in the samples presented for analysis is determined on a daily basis. In the period from May 2010 to November 2011 there were 85 samples of meat products of ungulates and poultry analised for content of total phosphorus. The content of total phosphorus, g/kg, expressed as P_2O_5 was determined using the standard method "Meat and meat products – Determination of total phosphorus content – spectrophotometric method," JUS ISO 13730, 1999. The principle of the method is based on dry ashing and acid ash hydrolysis using nitric acid, followed by addition of ammonium monovanadate and ammonium heptamolybdate causing the creation of yellow colored compound, whose intensity is measured spectrophotometrically at 430 nm. Providing assurance in the results of testing laboratory secures through internal quality control (using the control map; Nordtest method) and frequent participation in inter-laboratory comparative tests. Of the total number of samples tested 24 samples or 28.2% had a phosphorus content (expressed as P_2O_5) greater than 5 g /kg, while in 47 samples or 55.3% phosphorus content ranged from 4 g/kg to 5 g/kg.
Key words: *phosphorus, meat products*

INTRODUCTION

Phosphorus is an essential element indispensible for normal functioning of both human and animal organism. Most of the phosphorus in an organism is in the form of phosphate and 85 percent of it out of total phosphorus content is found in the bones. Phosphorus is an important component of phospholipids that build cell membranes, then the energy-rich compounds such as adenosine triphosphate and creatine phosphate and plays an important role in maintaining acid-base balance (Stamenković, 2006).

Apart from natural phosphorus which originates from meat, in the meat products there is also phosphorus originating from additives, among which phosphates, as well as some soy-based products are specifically represented. Among water binding agents in meat, phosphates are of greater practical significance in meat processing. When added to chilled meat, in which natural phosphates (ATP) have been spent, phosphates renew their good water binding capacity which prerigoral meat had. Apart from its effect on water binding capacity, the phosphates have an impact on the texture of the product, prevent discoloration, improve emulgation of fat, improve taste, prevent oxidation of unsaturated fatty acids and affect pH values. The dose of phosphates is commonly determined according to the quantity of meat and fatty tissue in the product. It is believed that the technologically optimal quantity of phosphate added is approximately 3 g/kg, and that it should not be greater than 5 g/kg. Phosphates added in larger quantities are not contributing to product's quality, but reduce the water binding capacity, have prooxidative effect and give those products astringent, soapy or bitter taste (Saičić et al., 2008). Certain phosphates create complexes with ions of iron (Fe) and copper (Cu), which are known catalysts for oxidative process, and in this way prevent fat and meat rancidity. Thus the phosphate products are also considered as having the

properties of preventing oxidative changes, so as delaying the prooxidative effect of table salt (Stamenković, 2006).
Apart from colors and sweeteners in food, the use of food additives as the food additive category in various types of food has been regulated by the Regulation on use of food additives, which prescribes specific criteria of purity, as well as other requirements which must be met in production and trade. According to the mentioned Regulation, the maximum quantity of phosphates expressed as P_2O_5 that can be added to meat products singly or in combination is 5 g/kg (Pravilnik o upotrebi prehrambenih aditiva, osim boja i zaslađivača u hrani, 2008).
The Regulations on the quality of meat products and the Regulations on the quality of poultry meat products still have not been in compliance with the Regulations on use of food additives, except for colors and sweeteners in food, as it is done in neighboring countries. By regulations mentioned, the total phosphates content in final product expressed as P_2O_5 should be indicated as larger than the content that can be added i.e. over 5 g/kg (Pravilnik o kvalitetu proizvoda od mesa, 1974 i Pravilnik o kvalitetu proizvoda od mesa pernate živine, 1991).

MATERIALS AND METHODS

In the period from May 2010 until November 2011 were examined 85 samples of meat products of ungulates and poultry meat for content of total phosphorus. The analyzed products, originally from domestic and foreign manufacturers, were from domestic market, delivered to the laboratory.
Total phosphorus content, g/kg, expressed as P_2O_5 was determined by standard method of “Meat and meat products – Determination of total phosphorus content – Spectrophotometric method” JUS ISO 13 730 from 1999.
This method is based on a dry ashing and an acid ash hydrolysis using nitric acid, followed by the addition of ammonium monovanadate and ammonium heptamolydate which results in a formation of a yellow color compound, intensity of which is measured spectrophotometrically at a wavelength of 430 nm (JUS ISO 13730, 1999). Measurments were performed on UV-VIS spectrophometer Cary 1, Varian.
Measurement uncertainty was performed using Nordtest method which consists of two components. The first component is the reproducibility of the method as a result of laboratory performing a minimum of 20 "in house" double tests of reference sample by the same technician and the same chemical analyst on different days. The second component represents the accuracy or bias, which was taken from the reports from interlaboratory competition in which our laboratory participated. The obtained uncertainty (with coverage factor k = 2) was 10%.
As a confirmation of achieving good results, our laboratory successfully participated in interlaboratory competitions, with good results. Within the project "Strengthening BiH Accreditation System" in 2010 by The Institute for Accreditation of Bosnia and Herzegovina, an analysis of autoclaved freshly chopped fish was performed in organization LIVSMEDELS VERKET The National Food Agency of Sweden, and the analysis of pate within the "Interlaboratory comparative foodstuffs testing" in organization of Pharmaceutical Society of Serbia, Division of Sanitary Chemistry, Belgrade.

RESULTS AND DISCUSSION

Content, measured by spectrophotometry, total phosphorus (as P_2O_5) in 85 meat products is shown in Table 1.

Table 1. The content of phosphate (as P_2O_5) in the analyzed samples

Phosphate content as P_2O_5 (g/kg)	Number of samples	Percent
1-2	3	3,5
2-3	4	4,7
3-4	7	8,2
4-5	47	55,3
5-6	12	14,1
6-7	12	14,1
IN TOTAL	85	100

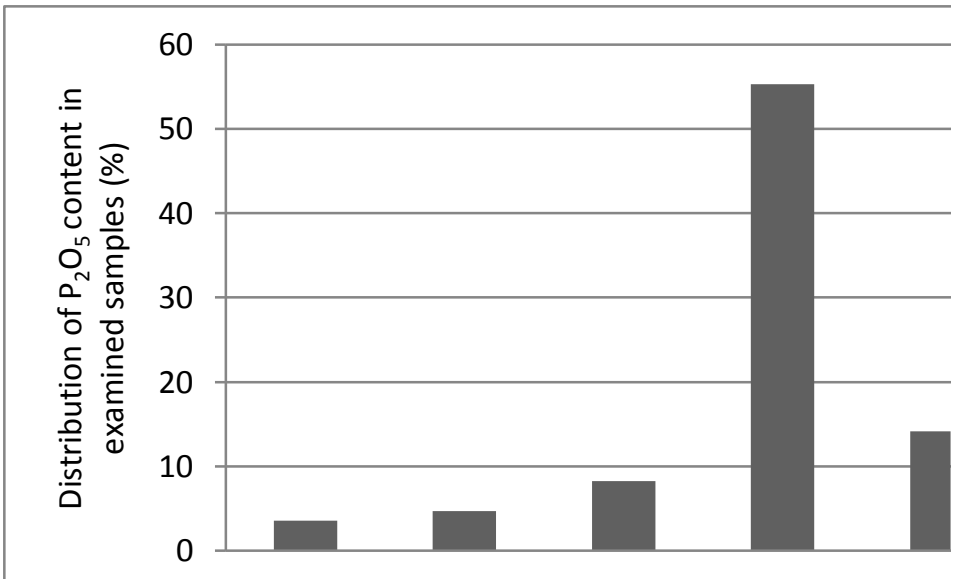

Figure 1. Distribution of P_2O_5, content in examined samples (g/kg)

Higher content of phosphate in meat products does not necessarily have to be the consequence of adding more phosphates, i.e. exceeding the maximum of permitted amounts added. To higher content of phosphorus can contribute not only basic constituents (high quality meat), but also other components which constitute the meat product of either vegetarian or animal origin. High quality meat is rich in proteins, and thus in phosphorus, which has an impact on higher phosphorus content in the product.

To determine the content of "added phosphates" by the standard method (ISO 13730/99), one should determine the total phosphorus content first, and then subtract from it the content of natural phosphorus, obtained by multiplying the protein content of the product by the number 0.0106, which represents the content of phosphorus in 1% meat proteins. Using this method we get reliable results with "clean" meat products, such as "cooked ham", "cooked shank" and "cooked chops", in proteins of which we find a relatively constant amount of phosphorus. However, in products which in addition to meat contain fat and connective tissues, liver, blood, mechanically separated meat from bone, protein products, cheese and other foods, by applying this method it is not always possible to get accurate values for "added phosphate" content (Vuković and Milanović-Stevanović, 2005).

This paper presents the results of a content of total phosphate, i.e., without subtraction of natural phosphorus content. Also, the meat products are not sorted into groups, because of shortcomings of existing legislation. What should be particularly emphasized is that, currently, quality control of these products is estimated on the basis of SFRJ regulations which are still in force (Pravilnik o kvalitetu proizvoda od mesa, 1974 i Pravilnik o kvalitetu proizvoda od mesa pernate živine, 1991) which are still in force and not in compliance with the new regulations on the use of additives (Pravilnik o upotrebi prehrambenih aditiva, osim boja i zaslađivača u hrani, 2008).

CONCLUSION

At the highest percentage of tested samples, the content of total phosphorus ranged from 4-5 g/kg or 55.3% of samples. Over 5 g/kg was measured in 24 samples, and only in 14 samples the total phosphate content was below 5 g / kg.
There were no samples containing over 7g /kg phosphates, which means that all the samples were in accordance with the maximum permissible amount from future Regulations on quality control of these products (which will limit the phosphate content in these products to 7 g / kg) and that they were manufactured in accordance with good manufacturing practice (GMP).

ABSTRACT: The use of pesticides in agriculture has brought many obvious benefits, but their inappropriate use can result in unacceptably high levels of these compounds in cereals. Pesticide residues can be found even when they are applied in accordance with good agricultural practices. A solid phase extraction (SPE) method has been developed for determination of methidathion in barley malt samples. The method involves a rapid extraction procedure with acetonitrile using salting out step. Non-polar coextractives are removed by passing a portion of the acetonitrile extract through an octadecyl (C_{18}) solid phase extraction clean-up cartridge. An aliquot is taken and concentrated for second extract clean-up, which is done with a carbon cartridge coupled to an aminopropyl cartridge using acetonitrile: toluene 3:1 (v/v) as the elution solvent. Analysis is performed by gas chromatography, employing mass selective detection in the selected ion monitoring mode. The method rendered recoveries ranging between 91 and 96%, the associated relative standard deviations ranging between 1 and 3%. Limit of detection methidathion were less than or equal to 0.002 mg/kg. The applicability of the proposed method to detect and quantify pesticide residues has been demonstrated by the analysis of 20 genuine samples. The methidathion content in barley malt samples is not regulated by Serbian legislation (Official Gazette of RS, 28/11) and relevant EU regulation (Council Directive 90/642/EEC, 1990). The methidathion concentration found in barley malt samples were bellow the MAC value permitted by EU regulations and in accordance with the currently valid Serbian regulations for barley.
Key words: *barley malt, methidathion, solid phase extraction, residue analysis*

INTRODUCTION

Barley (*Hordeum vulgare* L.) was originally used as human food but, with the rise in prominence of wheat and rice, its use was altered to animal feed and malting. Presently, about two-thirds of the barley crops are used as feed, one-third for malting and only about 2% for human food (Baik et al., 2004). A high-protein form of malting barley is often an ingredient in blended flours and it is typically used in the preparation of yeast breads and other baked goods (Evers et al., 1994). In view of the present knowledge, barley deserves to be incorporated into various food products on account of its potential heath benefits.
Because of high contents of starch and storage proteins, barley grains are an attractive target for insects and microbial pathogens. The vulnerability of the grain to insect and pathogen attacks is expected to increase during storage when amino acids, fermentable carbohydrates, various nitrogen forms and other degradation products accumulate as reserve polymers in the starchy endosperm (Fincher and Stone, 1993). The increased dependence of successful storage of cereal grains on pesticides has invited concerns about pesticide residues and their effects. It has lead to the development of numerous multiresidue methods as the most advantageous approach to residue analysis. Screening for traces of pesticides in cereals can be an extremely challenging task due to large quantities of co-extracted components (e.g., starch, proteins) which may adversely affect the method and instrument performance. The analytical methods for assessment of pesticide residues in cereal samples require an initial sample preparation step in which the analytes of interest are isolated from the bulk of grain matrix. Some methods may require subsequent steps to further purify the sample extract and to concentrate the analytes for final determination step.

An effective clean-up step is required in order to eliminate interfering compounds from the extract. The trend in the development of methods for sample preparation has been towards reducing solvent volume and the time required for conventional methods such as Soxhlet extraction. Miyake et al. investigated the transformation of agrochemical residues from barley to malt at various stages of the malting process (Miyake et al., 2002). The degree of dissipation of the residue pesticides due to volatilization and formation of breakdown products depends greatly on moisture content, storage temperature and the type of cereal stored (Desmarchelier, 1978; Holland et al., 1994). Studies were conducted on the persistence potential of pesticide residues in grains subject to long-term storage (Hadjidemetriou, 1990; Lalah and Wandiga, 2002). The carryover of pesticide residues to malt was found to depend on the log P_{ow} (partition coefficient between n-octanol and water) values of the active substance.
Methidathion (S-2, 3-dihydro-5-methoxy-2-oxo-1,3,4thiadiazol-3-ylmethyl-O,O-dimethyl-phosphor-odiththioate) is a thioester of the thiophosphoric acid. It belongs to the group of organophosphorus non-systemic insecticides and acaricides (Figure 1) which was commercially available since 1966. It is widely used to control sucking and chewing insects and spider mites on many crops such as corn, fruits, vegetables, tobacco, cotton and sunflowers in the field and stored raw agricultural commodities on account of its low persistence and high effectiveness. Methidathion is declared as highly toxic for humans (Richardson and Gangolli, 1993) as well as birds, bees and aquatic organisms (Hartley and Kidd, 1987). Methidathion is not included among the active substances in Annex I to Directive 91/414/EEC and it is banned from the market in the Republic of Serbia (http://ec.europa.eu/sanco_pesticides).

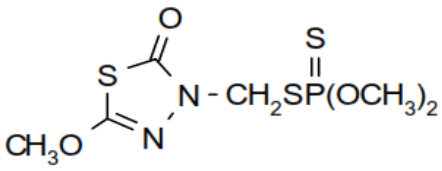

Figure 1. Structure of methidathion

The aim of this work was to determine methidathion residues in barley malt. The monitoring of methidathion residues in barley malt is commonly performed by gas chromatography (GC). Due to fairly common availability of the instrumentation, simplicity of procedures, speed, precision and accuracy, gas chromatography methods enjoy wide popularity. Residues were determined using a gas chromatograph equipped with a mass selective detector (MSD).

MATERIAL AND METHODS

Chemicals and solutions

The analytical standard of methidathion (98.2%) was purchased from Dr. Ehrenstorfer GmbH (Germany). The stock standard solution was prepared in methanol (J.T. Baker, USA) for GC-MS. Calibration standards were prepared by diluting the stock standard solution in methanol. Working standard solutions methidathion were used to calibrate the GC/MS system and spike samples barley malt in recovery experiments. All the solvents were of pesticide residue analysis grade (J.T.Baker, USA). Anhydrous sodium sulfate and sodium chloride (J.T. Baker, USA) were also used.

Sample preparation

Methidathion was extracted from homogenized samples of barley malt (10 g) by mechanical shaking with 20 ml acetonitrile and addition of sodium chloride. The extraction was repeated twice, each time with 20 ml acetonitrile. An advantage of extraction with acetonitrile rather than with other solvents is that it easily separates pesticides when salt is added to the sample.

When combined with salt, acetonitrile provides a well-defined phase separation, it renders unnecessary the use of hazardous non-polar organic solvents, and it achieves high pesticide recoveries (Lazić et al., 2008, Lazić et al., 2009, Ostojić et al., 2009).
Clean-up is necessary in order to reduce the detection limits of the method and/or to avoid interferences from the barley malt matrix. The concentrated sample extracts may contain a high content of co-extractives which can damage the capillary GC column, resulting in a matrix enhancement effect (Hajšlová et. al, 1998). Solid-phase extraction was carried out using C_{18} column packed with 500 mg of highly cross-linked octadecyl sorbent. The extraction columns were conditioned by passing 6 ml of acetonitrile through them. The sorbent was never allowed to dry during the conditioning and sample loading steps. Exactly 4 ml of barley malt extract (equivalent to 2 g sample) was transferred to the column. Anhydrous sodium sulfate was added to the previously collected eluates in order to remove water from them. Afterwards, a 2 ml (equivalent to 1 g sample) aliquot of the eluates was transferred to ENVI Carb column (6 mL, 500 mg) coupled to an aminopropyl column (6 ml, 500 mg). Methidathion residues were eluted from the column by a 20 ml mixture of acetonitrile and toluene (3:1). The eluent was collected in a 50 ml round-bottom flask and concentrated to about 2 ml in an evaporator with a water bath at 35ºC. Ten ml acetone was added to the flask and the flask was re-evaporated to dryness. After that, 10 mL portions of acetone were added two times and evaporated to low volume after each addition. The entire extract was carefully transferred to 2 mL GC vials which were then ready for injection.

GC–MS analysis
Determinations were performed on an Agilent Technology 6890 N gas chromatograph fitted with an HP5975 B mass selective detector and HP-5MS column. The gas chromatograph was equipped with CTC CombiPAL sampler and split/splitless injector with electronic pressure control. The mass spectrometer was used with electron impact ionization (70 eV) in Scan mode (35-500) and selected ion monitoring (SIM) mode for ions 145, 85, 93, 125 (m/z) as presented in Figure 2. The ion source and MS Quad temperatures were 230 and 150ºC, respectively. We used a fused silica capillary column 30 m x 0.25 mm I.D., 0.25 µm (bonded 5% phenyl, 95% dimethylpolysiloxane) supplied by Agilent Technologies.

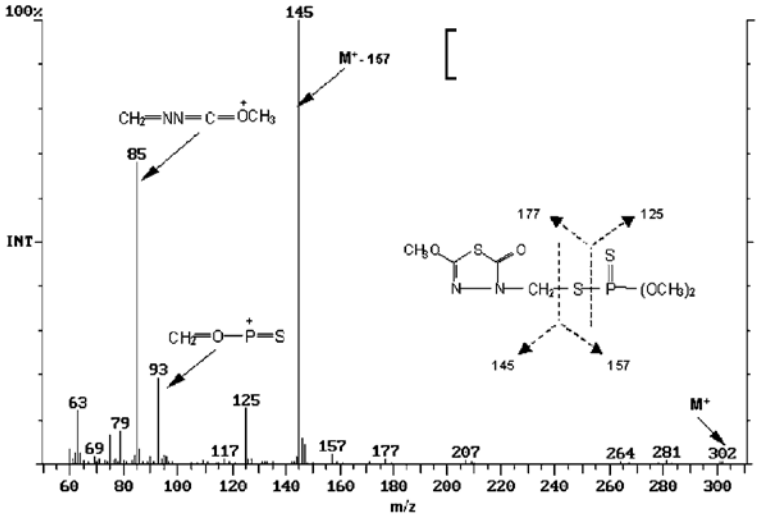

Figure 2. Mass spectar of methidathion

The pulsed splitless injection (pressure pulse 21.80 psi, pulse time 0.5 min, injection volume 1 µl, syringe size 10 µl) was done. The oven temperature program was: initial temperature of 80ºC (hold 2 min), rising at the rate of 25ºC/min to 170ºC, at the rate of 3ºC/min to 200ºC and at the rate of 8ºC/min to 280ºC (hold time 10 min). The total run time was 35.60 minutes. The carrier gas (helium) flow rate was 34.7 ml/min, in constant flow mode. Dwell time was adjusted so that the number of cycles per second was 1.4 throughout the chromatographic

run, providing a sufficient number of chromatographic points. Identification of the studied analyte was done by comparing mass spectra and retention times of the samples barley malt with working standard solutions of methidathion. The identification was confirmed by comparing the relative abundances of the four ions (one quantifier and three qualifiers) of the experimental standards against well-known relative abundances of the US National Institute of Standards and Technology (NIST) library reference spectra. The mass spectrometer was calibrated with perfuorotributylamine (PFTBA). An Agilent Chem Station was used for instrument control, data acquisition and evaluation.

Validation of the analytical method

Fortified samples were prepared by spiking 10 g of barley malt, previously homogenized with appropriate volumes of working standard solutions of methidathion ranging from 0.05 to 1 µg/ml. Limit of detection (LOD) for the analyzed methidathion was estimated from fortified samples. Signal-to-noise (S/N) ratios reported by the instrument software were used to calculate the analyte concentration that yielded a signal-to-noise ratio of 3 for the quantitation of the monitored ion. The limit quantification (LOQ) was calculated from LOD.

RESULTS AND DISCUSSION

Under the selected conditions, the linearity of the calibration curve was evaluated in a concentration range between 0.001 and 0.1 µg/ml using five calibration solutions prepared in methanol. Calculations were based on peak areas. Linear regression was used for quantification and calibration curve did not pass through the origin. The fit of the calibration function was plotted but it was also numerically tested by linearity coefficients, calculated on the basis of curve slope and its deviation ($r = (1-S_b/b) \times 100$). Linearity of methidathion was evidently attained in the whole investigated range. The retention time of the peak and the four ions (145, 85, 93 and 125 m/z) were used for positive identification of methidathion in the samples (Mastovska and Lehotay, 2004). The retention time of methidathion was 22.19 minute. The repeatability of the retention times and peak areas were checked by injecting the standard methidathion solution five times. The relative standard deviations (*RSD)* of the retention times and peak areas were found to be less than 0.1%. The analytical parameters for the developed method of methidathion determination in barley malt samples are presented in Table 1.

Table 1. Analytical parameters for GC-MS detemination of methidathion

Parameter	Concentration interval	Slope[a]	Intercept[a]	Correlation coefficient[a]	LOD	LOQ
	µg/ml				mg/kg	mg/kg
Methidathion	0.001-0.1	9.88×10^3	3.07×10^2	0.9997	0.002	0.004

[a] *Y = a + bc, where c is concentration in µg/ml and Y is response*

The standard addition method was used for methidathion determination in order to eliminate the matrix effect. Barley malt spiked with the concentration levels of 0.02 and 0.04 mg/kg was used to ensure method accuracy (recovery) and data precision. As can be seen in Table 2, the determined amount of methidathion agreed well with the added amount of methidathion. Methidathion recovery in fortified samples was carried out by comparing the detector responses for each independent sample against those measured for calibration standards, which were injected both before and after each fortified sample.

Table 2. Quantitation ion, identification ion, retention time and average recoveries (%) for representative barley malts fortified with 0.02 and 0.04 mg/kg levels

Parameter	Quantitation ion	Identificationion	RT	0.02	0.04
		(m/z)	(minute)	mg/kg	mg/kg
Methidathion	145	85, 93, 125	22.19	93 ± 1.2	95 ± 2.0

The mean recoveries for these two spiking levels ranged from 91 to 96%, with the associated relative standard deviations (RSDs) ranging from 1 to 3%. The small losses in recovery were probably due to matrix effects and suppression of ionization. The final extracts of barley malt samples made by the proposed SPE method were satisfactorily clean for direct GC-MS analysis. A comparison of SIM chromatograms for blank barley malt, malt fortified with 0.02 mg/kg and malt extract is given in Figure 3.

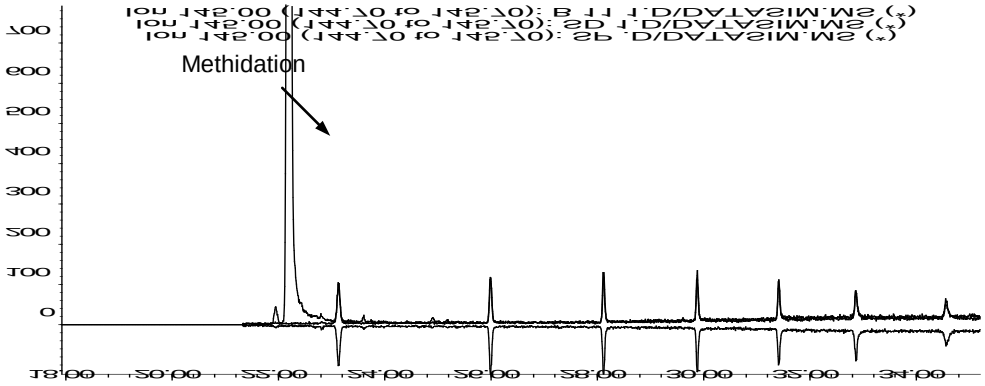

Figure 3. Comparison of SIM chromatograms for blank barley malt extract (lower), fortified barley malt (upper) and barley malt extract (middle)

Besides the regularly shaped and well-defined peaks belonging to the investigated pesticide, the SPE-GC-MS chromatograms (Figure 3) contained a group of peaks which were likely to have originated from the barley malt matrix. There were no significant interfering peaks in the elution region of methidathion. The range of methidathion concentrations in the twenty barley malt samples ranged from 0.004 to 0.018 mg/kg. The obtained positive results could be attributed to the high sensitivity of the developed GC–MS method, as well as to the fact that most cereals grain samples were collected from granaries in which the stored grain had been treated with pesticides in order to control pests.

CONCLUSIONS

This paper describes a SPE-GC–MS method developed for determination of methidathion in difficult matrices such as barley malt. Acetonitrile was used for methidathion extraction from barley malt. Solid-phase extraction in a C_{18} column was used for methidathion isolation and clean-up of the acetonitrile extract. Advantages of this SPE method include simultaneous pre-concentration of methidathion, partial sample clean-up and water removal (the use of drying agents is necessary), applicability to barley malt analysis, and the use of small volumes of solvent per sample (40 ml acetonitrile and 20 ml mixture of acetonitrile and toluene). The additional clean-up on coupled ENVI Carb and aminopropyl columns significantly influences the recovery of methidathion and improves chromatographic performance by minimizing matrix effects. Using MSD, quantification (through selective ion monitoring) and confirmation are achieved simultaneously. The recoveries achieved by the method ranged between 91 and 96% for methidathion, with the associated relative standard deviations (RSDs) ranging between 1 and 3%. Calibration dependences and corresponding regression coefficient values showed that linearity was successfully achieved in the SPE-GC-MS measuring procedure and within the concentration range studied. The corresponding range of methidathion concentrations in the twenty analyzed samples of barley malt was from 0.004 to 0.018 mg/kg. These results were below the permissible levels (MACs) set by Serbian legislation (Official Gazette of RS, 28/11) and the related EU regulations (Council Directive 90/642/EEC, 1990) for methidathion in barley grain (0.02 mg/kg), while these legislations do not regulate methidathion MAC for barley malt.

ABSTRACT: Owing to its several advantages near infrared (NIR) spectroscopy is a widespread analytical method being used in agriculture and food industry as well. It is suitable for identification, qualification and quantitative analysis too. In wheat quality control rheological characteristics of dough made from wheat flour are as important as physical and chemical properties too. Rheological properties like farinograph, alveograph, extensograph parameters are influenced by many factors. For these parameters developing NIR calibration equations with good accuracy is complex problem, prediction of these parameters is more difficult than the chemical composition. In this study we examined wheat samples from different growing area by alveograph and spectral data were collected by FOSS Infratec 1241 instrument. Our first objective was whether it is any effect of the growing area on NIR spectra. Principal Component Analysis (PCA) was developed to examine this effect. We have found that samples from same growing area are close to each other, but there is not any separation in the whole population. According to these PCA results no need to separate the population, we could develop calibration equations on the whole sample set. After qualitative analysis modified partial least squares analyses on NIR spectra were developed for two alveograph parameter (P/L és W) to get calibration equations.
Key words: *wheat flour rheology, NIR, PCA, mPLS*

INTRODUCTION

The study of rheological properties of wheat flour dough plays an important role in the determination of bread-making quality of wheat and has such importance as physical or chemical properties. In last decades, influenced by requirements of the countries and processors a growing use of alveograph and extensograph may be observed. These tests require more sample, time, work and cost, therefore flour quality control needs rapid, reliable tools.

The near infrared spectroscopy such a non-invasive technique, which – owes to its several advantages – widely used in the different industries. The short measuring time of the method makes it possible to get reliable results quickly, in few seconds. This method is applied for not only quantitative analysis than identification or qualification. In agriculture, food industry or other industries there is a higher importance of such techniques which are able to give information with a proper accuracy in short time. If it is identification of raw materials, or prediction of a concrete parameter, near infrared spectroscopy is a good tool for. As this technique is indirect we need a proper sample population for identification, qualification or quantification. This sample group have to be numerous, and representative for the given property (e.g. origin, producer) or parameter (e.g. moisture or protein content). Before developing a calibration model, it is necessary to collect spectra of these samples and to examine the spectra. We can examine the spectra with several chemometric tools, but the Principal Component Analysis is the most common.

Spectra are holders of complex information from chemical and physical aspects too. Composition of the proper sample set for developing calibrations and examination of the spectra is unavoidable. It is necessary even if the laboratory tests show that the sample set

is representative, because there would such variability in the spectra which can cause problem later. Mathematical treatments (e.g. derivation, multiplicative scatter correction, standard normal variate and detrend) are applied to eliminate the differences caused by the physical properties (e.g particle size distribution) of the samples and for example the derivation can solve the problem of separating the overlapping of the peaks (Osborne, 2006). Quality parameters were examined by near-infrared spectroscopy in several studies. In case of moisture and protein content calibration models were made with high accuracy ($0.99<R^2$) (Miralbes, 2003). Miralbes also found that not only these parameters but gluten content is also predictable with almost the same accuracy (R^2=0.95-0.97). Rheological parameters prediction is also in focus. According to Jirsa and co-workers (2008) alveograph P and W value can be predict with $0.8<R^2$. Hruskova and co-workers (2001, 2003) have some studies on wheat rheological properties (alveograph, extensograph) prediction with NIR spectroscopy. They have got different R^2 values for the parameters, but even for extensograph characteristics their accuracy is high ($0.7<R^2$). In the work of Miralbes from 2004 he found that even for the farinograph parameters and for the alveograph parameters the calibrations have high R^2 values, higher than 0.7. Rheological parameters influenced by many factor. The species, the protein content, the gluten composition and other parameters affected the rheological values. Prediction of rheological parameters by near-infrared spectroscopy is a complex problem. The rheological parameters are not linked to concrete bands and wavelengths such as protein or moisture content, because of the affecting factors mentioned above. Therefore the prediction of rheological parameters has lower accuracy than for example for moisture content.
The aim of this study was to examine wheat samples from different origin (grown in different regions of Hungary). We would like to know whether the origin have effects on the spectra, the samples belonging to the different regions show separated groups and the whole sample set could be applied for developing calibration equations on alveograph parameters.

MATERIALS AND METHODS

We examined 207 wheat samples, which were harvested in different regions of Hungary (11 places). Some of these places are arable lands, and one is experimental field.
Infratec 1241 Grain Analyzer (Foss Analytical AB, Sweden) instrument was used for collecting spectra in the range of 850-1050nm from wheat grains. WinISI II v1.50 (Infrasoft International LLC., USA) software was used for the examination of spectra with PCA and for developing calibration equations with mPLS (modified partial least squares regression) on alveograph P/L and W value. For spectra collection we scanned the samples twice.
We used modified partial least squares method with cross validation to examine the relations between the spectra and reference values and develop calibration models. First we did not use any math treatment, but later we applied SNV (standard normal variate) and first derivate (1, 4, 4, 1).
Rheological properties were measured by Chopin alveograph (Tripette & Renaud, Villeneuve La Garevne, France) according to the approved method A.A.C.C. Standard No. 54-30A (A.A.C.C. International, 2000). The recorded alveograph parameters included the biaxial extensibility (L), the maximum overpressure (P), the swelling index (G), the deformation energy (W), and the configuration ratio (P/L).

RESULTS AND DISCUSSION

After collecting spectra we examined them with PCA whether there is any separation between the samples or whether there is any outlier ones. PCA results shows, that the first three principal components are responsible for more than 99% of the total variance in the spectra (Table 1).

Table 1.Individual and cumulative values for the first three principal components

		Individual	Cumulative
PC1	PC1	98.44	98.44
PC2	PC1+PC2	1.48	99.92
PC3	PC1+PC2+PC3	0.05	99.97

Results gave two samples as outliers, and we eliminated them from the sample set.
In graphical interpretation of the results when we signed the samples coming from the same area, we did not see any separation. Samples belonging to the same growing area are close to each other, but these groups are not separated from each other, there are overlaps. This means that we could use the whole sample set for developing calibration models without making different groups and separate models for each growing area.

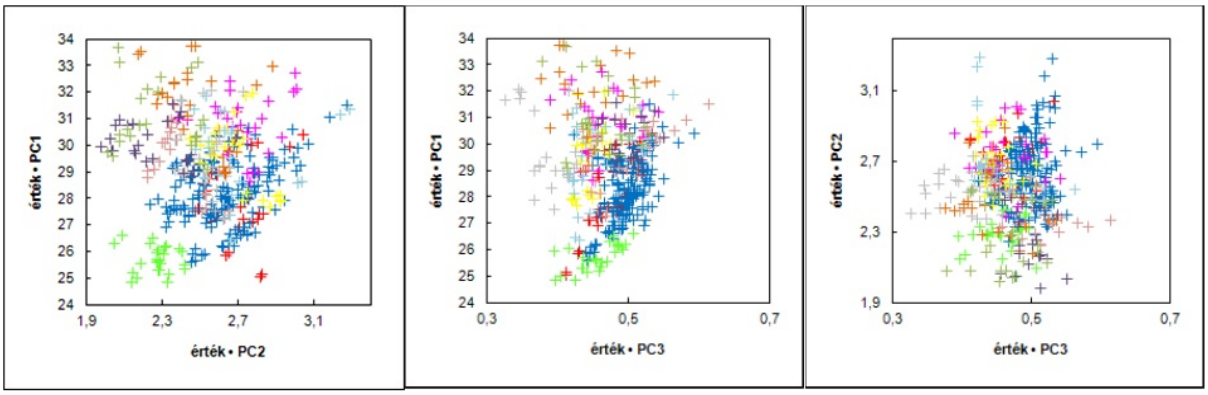

Figure 1. Crop site based coloured presentation of samples for the sample population

The number of the samples was enough high, and according to the laboratory tests we can say that our sample set is representative for the alveograph parameters, these values (P/L, W) are in a wide range (Table 2).

Table 2. Summary of the reference parameters

	P/L	W (10^{-4}J)
Minimum	0,20	43
Maximum	3,31	446
Mean	1,10	244
SD	0,58	84
n	207	207

Table 3. Statistical parameters of NIR calibrations

	n	n_{cal}[1]	Terms	Mean	SD	SECV[2]	R^2	SEP[3]	RPD[4]
P/L	410	394	11	1.07	0.50	0.30	0.64	0.39	1.28
W	410	392	9	246	80.65	39.42	0.75	51.24	1.57

[1] *n_{cal} - number of samples selected for calibration*
[2] *SECV - standard error of cross-validation*
[3] *SEP - standard error of prediction*
[4] *RPD - SD/SEP (Williams, 1993)*

The summary of statistical parameters of the NIR calibrations is showed in Table 3. According to R^2 values alone, both parameters could be predicted with good accuracy, because R^2 values are 0.64 and 0.75 for P/L and W, respectively (Figure 2, Figure 3). For accurate evaluation of the model, we have to see other parameters as well. SEP (standard error of prediction) and RPD (ratio of standard deviation to SEP) must be under consideration. SEP values show bad performance, because in case of P/L value is 36.7% to

mean, and in case of W value is 20.8%. The error for standard method is about 5% and SEP would be close to this value and higher because of the NIR spectroscopy is an indirect method. The SEP values should be minimised for better calibrations. According to Williams (1993) RPD should be as high as possible. If RPD is higher than 10, the calibration is excellent; between 5 and 10 is adequate for quality control; 2.5 and over are satisfactory. We calculated the RPD values for both models, and we have got low RPD values ($RPD_{P/L}$= 1.28, RPD_W=1.57). These RPD values mean that in spite of good R^2 values, the models have not enough accuracy. Other authors gave lower SEP values and higher RPD values, therefore calibrations with good accuracy.

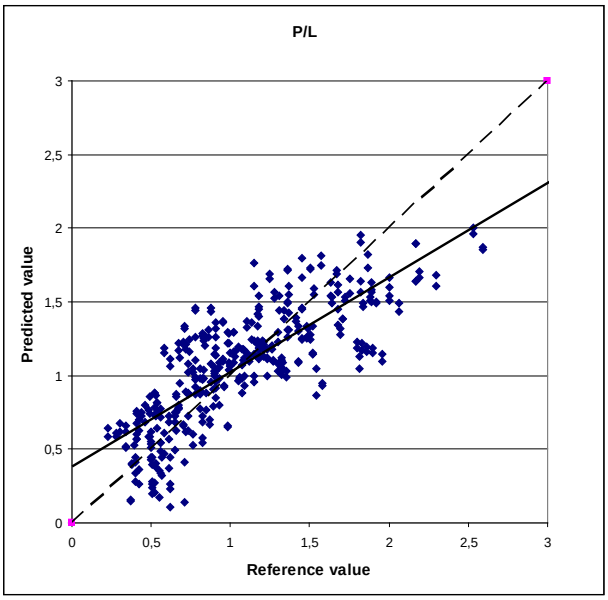

Figure 2. Comparison of P/L determined by prediction model and by reference method

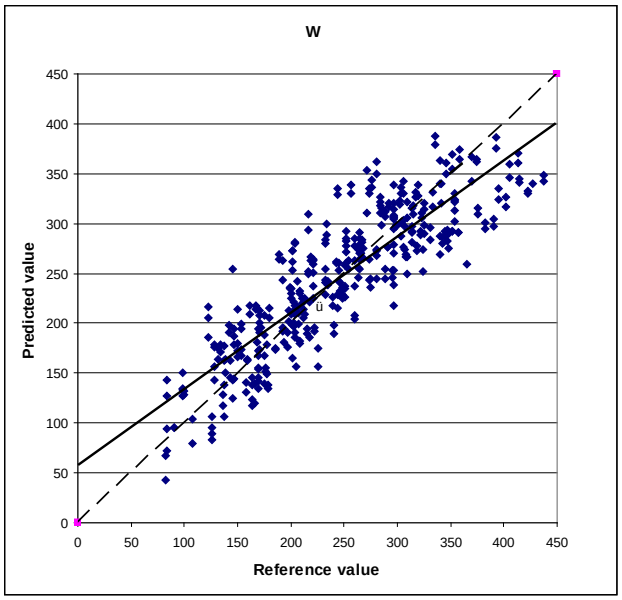

Figure 3. Comparison of W determined by prediction model and by reference method

In case of math treatment of SNV and first derivate the results can be seen in Table 4.

Table 4.Statistical parameters of NIR calibrations with SNV and first derivate

	n	n_{cal}	Terms	Mean	SD	SECV	R^2	SEP	RPD
P/L	410	393	12	1.06	0.51	0.29	0.70	0.38	1.34
W	410	391	9	245	80.33	38.67	0.76	50.27	1.60

[1]*n_{cal} - number of samples selected for calibration*
[2]*SECV - standard error of cross-validation*
[3]*SEP - standard error of prediction*
[4]*RPD - SD/SEP (Williams, 1993)*

Use of SNV and first derivate gave better calibration models. R^2 values are higher: 0.70 and 0.76 for P/L and W, respectively. If we see the SEP and RPD values, these shows better performance than earlier, but the SEP value is still high and RPD is low for good prediction.
Compare to Miralbes (2004) results, he found $SEP_{P/L}$=0.04 and SEP_W=21.5, our results higher, and also for R^2 (0.70 and 0.92, P/L and W, respectively), in case of P/L we have got the same, but for W is lower. RPD values also higher for him (5.7 and 4). Our R^2 value for W (0.76) is higher than for Jirsa and co-workers R^2=0.535 and 0.636 (for two sample sets), but they got lower SEP values.
In our case, the sample set is numerous and representative, but the calibration models would be more accurate. We need more detailed examination of the spectra to get better accuracy.

CONCLUSIONS

In our study we examined wheat samples with NIR spectroscopy and with alveograph rheological test. After collecting spectra PCA was carried out to get information about differences in sample set. PCA showed that there is no difference between the samples from the different growing areas, therefore we can use the whole sample set to develop calibration equations on alveograph rheological parameters (P/L, W). MPLS method was used for calibration, and we have got good R^2 values for both parameters, but evaluation the models by RPD and SEP, these calibrations are not able to predict these two alveograph parameters with good accuracy.

ABSTRACT: The quality of meat depends on the composition and properties of both materials used and conditions of processing. The quality of derived meat can vary under the influence of environmental factors, conditions of cultivation and transportation, ante livestock slaughter conditions and initial processing, refrigeration storage options as well.Therefore a united approach comprising consistent standards robust controls is required to ensure consumers' health and to maintain consumers' confidence and satisfaction. Chemical analysis along the whole food chain downstream (tracking) from primary production to the consumer and upstream (tracing) from the consumer to primary production is an important prerequisite to ensure food safety and quality. In this frame the focus of the following paper is on the "chemical safety of meat and meat products". It should be taken into account inorganic and organic residues and contaminants, the use of nitrite in meat products, the incidence of veterinary drugs, as well as a Failure Mode and Effect Analysis (FMEA) system assessing (prioritizing) vulnerable food chain steps to decrease or eliminate vulnerability.
Key words*: beef, quality of meat, chemical safety of meat, breed, carcass quality*,

INTRODUCTION

The objective of this article is to provide with basic information on different factors that influence meat quality as guidelines for the industry. We have simply defined different areas and factors that influence meat quality. Much of this information is basic knowledge.
This paper is concerned with quality in a broad commercial sense and reviews some of the quality attributes which are important in market place. There are many definitions of quality, but one of them takes into account the need to match products quality to the demands of the market place: "Quality is the composite of those characteristics that differentiate individual units of a product and which have significance in determining the degree of acceptability of that unit to the user". Of course, price is a part of the customer's appraisal of what is offered in the market place and sometimes it is the all important feature. In other market places demand massively exceeds supply and distribution is the main marketing concern. If the product has no genuine appeal, then price will certainly be the key feature.
Meat quality is an essential trait in meat-producing animals, especially pigs. With progress in breed selection and nutritional or non-nutritional manipulations, porcine growth performance has improved significantly and the amount of meat production has correspondingly ncreased. Conversely, however, pig meat quality has decreased. How to improve meat quality while maintaining or increasing the amount of pig meat production is therefore an ongoing challenge.

MATERIAL AND METHODS

Study of animals on the farm were performed during 2010-2011. A number of 2,000 animals were tested and investigated their feeding rations and living conditions. After that such products of slaughter as meat, animal blood, liver, intestine was investigated.

Analyses

Forage quality and balance. Sanitary condition of the animals was determined by organoleptic and visual methods.

RESULTS AND DISCUSSION

The quality of the finished product depends on the composition and properties of materials used, conditions of processing. The quality of derived meat can vary under the influence of environmental factors, conditions of cultivation and transportation, ante livestock slaughter conditions and initial processing, refrigeration storage options (Figure 1).

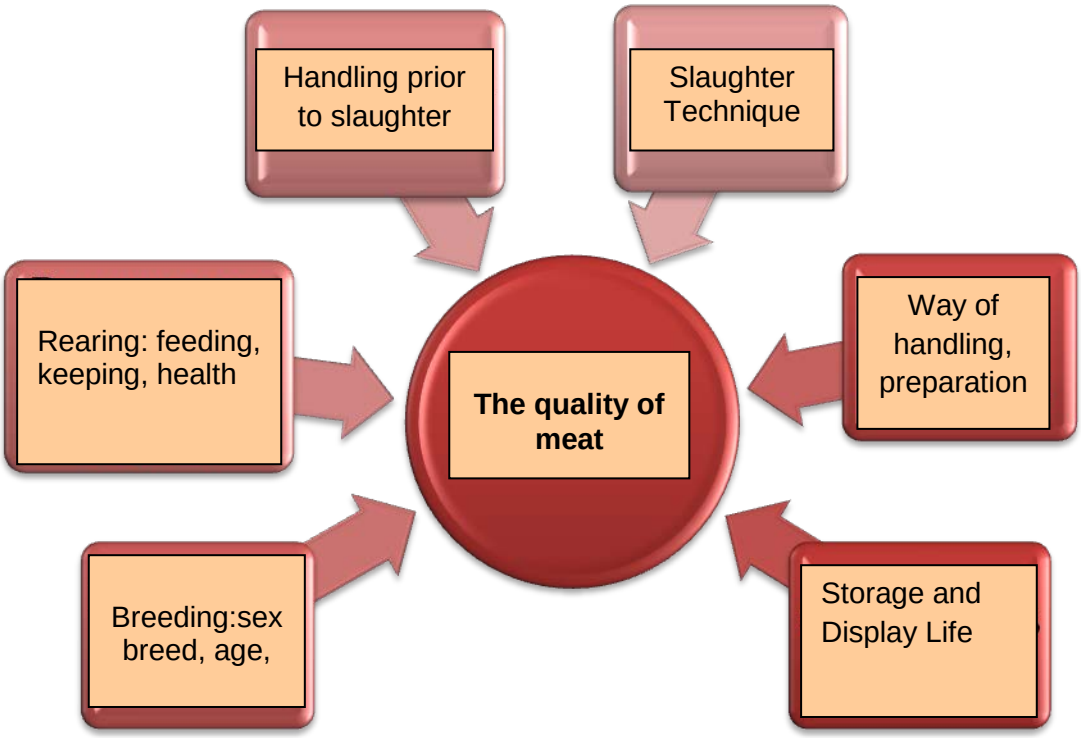

Figure 1. Factors that affect the quality of meat.

Effect of breeding phases on the meat quality

Animals of different species have significant differences in body weight, and quality of meat. Meat breeds of cattle have well-developed muscle and adipose tissue is considered to be juicy, tender and delicious. Meat derived from milk, meat and dairy breeds, characterized with an increased amount of bone and connective tissue have fewer intramuscular fat and inferior organoleptic characteristics.

Animals sex affects the quality and quantity of meat derived. Castration of animals make impact on the growth rate and efficiency of digestion of food animals, and the output of meat. Sex differences in the meat of young animals is less pronounced. With age the meat in males compared with females increases moisture content while reducing the content of protein and fat. At the same time in the flesh of bulls increasing proportion of connective tissue appears dark. Castrated animals are developed more slowly, but meat that is obtained from them has a distinctive picture "marbleness."

With age, the animal meat is coarser due to thickening of the muscle fibers, increasing the proportion of elastin fibers in connective tissue and strengthening of the collagen fibers. The degree of hydrothermal dissolution of collagen from the meat of animals aged 12 months is 40.6% at the age of 8 to 10 years is 21.5%. Changing the chemical composition of meat: fat content increases, the amount of water decreases. At the age of 12 to 18 months, the ratio of the main components of cattle meat is the best value for money. In pigs the best quality characteristics are formed to 8 months.

To ensure the identity of qualitative raw materials used in sausage production, cattle at slaughters are divided into groups: animals older than 3 years (adult cattle meat) and at the age of 3 months to 3 years (young meat animals).The older is an animal the tougher is the

meat. For this reason main stream livestock industries have established grades and/or names to account for the age of the animal. They have also established means for determining the age of the animal. Depending on the specie it may be by teeth development, degree of bone ossification or similar. Provided the animal meets the basic health criteria all meat is fit for human consumption, with different ages having different uses, different markets and therefore different price structures.

The influence of the feeding ration.

The feeding ration influences the quality characteristics of meat. The correlation of the coarse fodder and the concentrates in the ration, the degree of the macro- and micro elements balance, the high energy value define the forming of the high taste qualities of meat and its technological properties. The insufficiency of feeding rations displays the decrease of the category of animal's fatness, the rise water maintenance in meat, the shrinkage of muscle fibers, and the rise of toughness.

The change in the structure of the feeding ration allows getting meat with necessary characteristics. The colour of the muscle tissue of pigs that got the ration with corn and barley is much more intensive than while feeding only with corn.

The influence of the cattle's maintenance conditions.

Conditions of cattle's maintenance that include the way of animal's growing, climatic and weather conditions also affect on the quality of meat. Pork that comes from industrial complexes contains a big amount of muscle tissue and corresponds to meat fatness. In a result of violation of the diet and also because of the increased susceptibility of animals to stress during the mass maintenance, raw materials may have low quality rates that are expressed by specific odour and tastes (fish, oil) by introducing the fish flour and protein additives of microbiological origin into the fodder.

Handling prior to slaughter.

During the time between leaving the farm and slaughter, animals are subjected to removal from their home environment, loading and unloading from vehicles, transport, and holding in unfamiliar surroundings. They may be exposed to stressors such as noise, strange odors, deprivation of food and water, vibration and changes of velocity, extremes of temperature, breakdown of social groupings, close confinement and often overcrowding. These stressors often elicit behavioral and physiological responses, some of which can, if extreme, contribute to a reduction in carcass and meat quality. Herein is the link between welfare and quality.

Table 1.Factors that affect the quality of meat on stage ante animals

№	Factor	Provided that the quality of meat
1.	Diet feeding in the final period of growth and the transport	adherence to diet
2.	Loading and unloading	Reducing the duration of operations, stress effects eliminate
3.	impact the environment	Control of ambient temperature, the relative humidity, air, light
4.	healthy of animals	Do not allow to transport the sick and debilitated animals
5.	Method livestock during transport	Individual livestock by type, sex and age
6.	Handling prior to slaughter	Compliance with conditions, eliminating stress and impacts

Reduction the likelihood of stress in animals allows compliance:

•Support sustainable animal feeding diet in the last 7 to 10 days of their stay at the industrial complex, sometimes recommended to provide livestock feed in excess to increase the supply of glycogen in the muscles, for 10 to 12 hours before the loading animals should be stopped feeding;

•Reducing the period of loading and unloading animals on vehicles, careful treatment of animals during this period to reduce the physical and psychological stress;

•Avoid the impact on animals External factors: abrupt fluctuations in temperature, drop in atmospheric pressure, changes in relative humidity, bright light, ambient temperature during transport must not go beyond -5 to 20 ° C to eliminate drafts, the effect of direct sunlight; monitor the circulation of air in the summer of pigs better transport at night or morning;
•Do not allow the state of physical fatigue in animals during transport;
•Do not allow to transport physically frail and sick animals;
•The duration and speed of transport should be minimal;
•Vehicles must be properly fitted, equipped with ventilation, partitions to separate the animals, feeding troughs;
•Compliance with veterinary and sanitary requirements and zoohihiyenichnyh Pets;

CONCLUSIONS

Main goal of selection and other measures in animal breeding is to increase the quantity of major meat sections in carcass sides but with preserved quality of meat, i.e. that adequate hygiene-toxicological, technological, chemical and sensory traits are maintained. Quality of meat carcasses has effect on competitiveness of production and market demands. Research was carried out in order to investigate the effect of sire breed and sex of progeny on quality of carcass and meat. Based on the research it can be concluded that investigated factors can have significant effect on certain traits of carcass quality, as well as on technological and biological traits of meat For investigated chemical traits of meat no effect of investigated factors was established.

ABSTRACT: Crops are exposed to fungal contamination both on the field before harvest, and especially during storage for longer periods of time in improper conditions. Concerning the origin of fungi contamination the following sources exist: contamination from the warehouse or silo dispersion, the predominant fungi is Aspergilius and Penicillium, contamination remaining from the field before harvest with: *Clamidosporium, Fusarium, Mucor, Rizopus* and advanced alteration, which associates more rare types in remanent contamination.
In this paper, the influence of storage conditions on the fungi growth and mycotoxins production in cereals was studied.
Cereal samples (wheat, maize, barley and oats) collected from warehouse, individual silos and storage cells from the west side of Romania were analysed. The cereals were sampled from private producers, who reported the information regarding storage conditions. The storage period ranged between 6 months and over 1 year. The main measures of conditioning applied to samples before storage were related to: drying, pest removal, aeration and cleaning. Also, the main parameters (temperature, humidity, ventilation) during the storage were monitored in order to preventthe toxins production.
The method used for fungal species with mycotoxigen potential identification was microbiological assay.
The experimental results indicated that the fungus species isolated and identified were *Aspergillus (flavus and terreus, Fusarium roseum, Penicillium sp., Chaetomium sp. and Cladosporium sp*. The most frequent *Fusarium fungal* species in cereal samples were identified F. culmorum, DON mycotoxin producers, *F. subglutinans*, fumonisin producers and *F. acuminatum*, non mycotoxin producer. *Fusarium species* was identified in 45 % maize samples, 25% wheat samples, 100% triticale and barley samples and 0% in oats samples.
In order to avoid the production of mycotoxins after harvest, it is advisable to dry the grain and bring to optimum moisture retention, less than 14%. Also, post-harvest contamination can be avoided by monitoring and keeping optimal grain storage conditions.
Key words: *fungi, storage, cereals, harvest.*

INTRODUCTION

Grain entering store carries a wide range of microorganisms including bacteria, yeasts and filamentous fungi, the population structure being dependent on field climatic conditions and harvesting processes (Lacey and Magan, 1991)
Crops are exposed to fungal contamination both on the field before harvest, and especially during storage for longer periods of time in improper conditions, which have favourable environments for mold development. Concerning the origin of fungi contamination the following sources exist : contamination from the warehouse or silo dispersion, the predominant fungi is *Aspergilius and Penicillium*, contamination remaining from the field before harvest with: *Clamidosporium, Fusarium, Mucor, Rizopus* and advanced alteration, which associates more rare types in remanent contamination with *Sordaria, Papulaspora and Fusarium*, including in this group also unidentified strains and advanced alteration, that associates more rare types in remanent contamination (Alexa, 2008).
The main factors and conditions for fungal development and production of toxins are: *genetic ability of fungi* (it was found that among the many species of fungi only a few grow on certain

agricultural products, and of these only some produce mycotoxins), *substrate* (it was found that the best substrate for the accumulation of toxins is oil seeds and cracked grain), *moisture of the substrate and the environment*. The grain humidity of 13-15% prevail *Aspergillus glaucus*, and to over 15% grow *Aspergillus flavus, A. ochraceus, A. versicolor, temperature* influences both the development of molds and mycotoxin production, *compositions of the atmosphere* influence in a smaller degree the formation of mycotoxins (Magan, 2003; Dumitrache, 1997). Lund and Frisvad (2003) showed that P. Verrucosum contaminated grain during the harvesting process and during drying and storage.
Control of mycotoxins is the need of the day, since their occurrence in foods and feeds is continuously posing threats to both health and economics all over the world (Bazollou, 2009). Prevention of fungal infection during plant growth, harvest, storage and distribution and the measures that must be taken for decontamination is an actuality issue for European Commision [9]. The pre-harvest selection of hybrids, time of planting, plant density and insect control have all be found to have an impact on contamination of maize with mycotoxins pre-harvest and during drying and storage (Magan, Aldred, 2007; Magan et al., 2010).
Storage in adequate conditions (moisture, temperature and insect control) and the addition of antifungal agents may diminish fungal growth but can not detoxify contaminated samples. The previous studies have shown that it is essential that grain is dried to lower moisture contents as quickly as possible regardless of the drying system employed (Cairns Fuller et al., 2005). The most important factors governing the life cycle of micro-organisms are water availability, temperature and their interaction with the nutrient status of the food matrix. The limits for growth and OTA production are approx. 17–18% moisture content (ca. 0.80–0.83aw) (Magan Naresh, Alfred David, 2005*).*
General rules to prevent mycotoxins contamination in the warehouse involve: regular and accurate moisture measurement determinations for cereals, ensuring adequate transport conditions of grain, ensuring appropriate storage conditions at all stages in terms of moisture and temperature control, the general maintenance and effective hygiene of storage facilities for prevention of pests and water ingress, ability to efficiently identify and reject material below specified standards in terms of fungal contamination (Molinié and Pfohl-Leszkowicz, 2003; Alexa et al., 2012).
This paper has studied the influence of deposition conditions on the fungi production of cereals storage in different counties of Romania.

MATERIAL AND METHODS

The method used for fungal species with mycotoxigen potential identification was microbiological assay.
Determining the degree of colonization of seeds with *Fusarium sp.* was achieved by the technique of direct isolation on specific culture media. The medium used was CZID (Czapek iprodione dichloram agar) (Pitt and Hocking Ailsa, 2009). First, the seeds were disinfected with on the surfaces by immersing seeds in chlorine solution 0.4%, for 2 minutes then drain the chlorine. After that the samples were washed thoroughly in sterile water for 2 minutes; driedand plated on surface media in Petri plates. We used an average sample of which 10 seeds were filed on the medium. We worked in three replicates. After seven days, we identified the cultures as genus *Fusarium.* To distinguish species of *Fusarium* we have used the observations about the colour and morphology of colonies, the size and shape of the macroconidia, the presences or absences of the microconidia and the type of phialide on witch microconidia are produced. (Sumalan R., et al., 2011).
The technological conditions during the storage were esthablished on the base of questionnaires that have been completed by farmers in order to determine the causes that lead to fungal contamination of crops in west Romania counties (Timis, Arad, Bihor and Satu Mare).

RESULTS AND DISCUSSION

Cereal samples (wheat, maize, barley and oats) collected from warehouse, individual silos and storage cells from the west side of Romania were analysed. The cereals were sampled from private producers, who reported the information regarding storage conditions. The storage period ranged between 6 months and over 1 year. The main measures of conditioning applied to samples before storage were related to: drying, pest removal, aeration and cleaning.

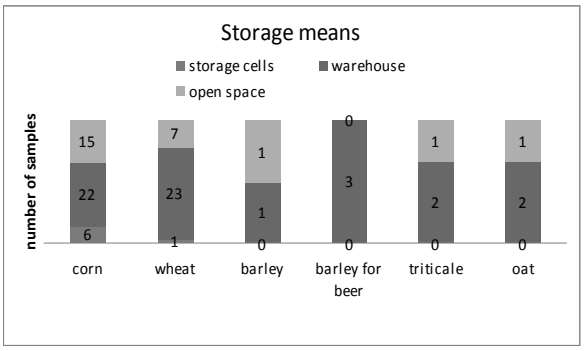

Figure 1.Type of cereals

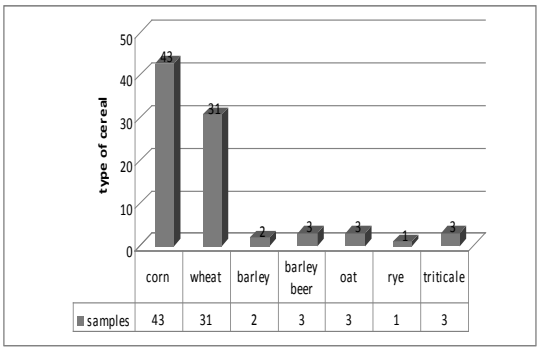

Figure 2. Storage means

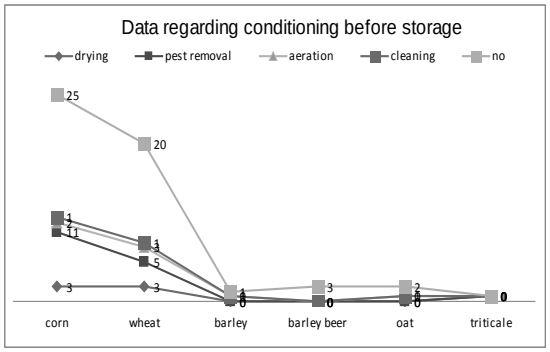

Figure 3. Storage period

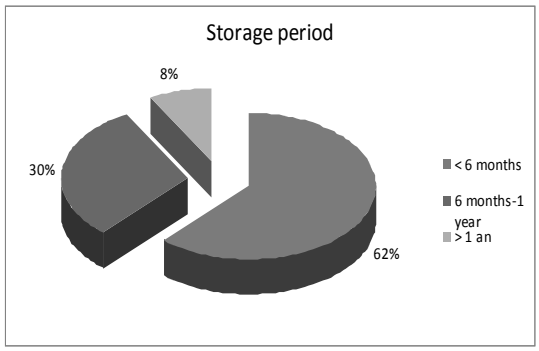

Figure 4. Conditioning measures

From all 86 samples collected from private producers, 43 were corn samples, 31 were wheat samples, 2 barley, 3 oat, 3 barley for beer, 3 triticosecale and 1 rye (figure 1). Regarding storage means, from all 43 corn samples, 22 pursued from warehouses, 15 from open spaces and 6 from cells (figure 2). From all 31 wheat samples, 23 were from warehouses, 7 were from open spaces and 1 from cell. Barley, barley for beer, triticosecale and oat were pursued from open spaces and warehouses (figure 2).
The storage period of sampled cereals ranged between 6 months and over 1 year (figure 3). Regarding conditioning measures, most of the samples were not subjected to any of the conditioning techniques, so from all 43 corn samples, 25 were not subjected to any conditioning measure, 11 samples were subjected to pest removal, 3 samples were subjected to cleaning, 2 aeration and 1 drying (figure 3). Barley, barley for beer, oat and triticosecale were not subjected to any of the conditioning measures (figure 3).
Also, main storage parameters were monitored (temperature, humidity, ventilation) in order to prevent the toxins production.
From all 43 corn samples 8 were subjected to temperature control, 8 to moisture control, 8 to ventilation, 8 to infestation control and 3 to other measures. Regarding wheat samples, out of 31 samples, 6 were subjected to temperature control, 2 to moisture control, 8 to ventilation, 8 to infestation control, 3 to pest control and 4 to other measurements (*figure 5*).

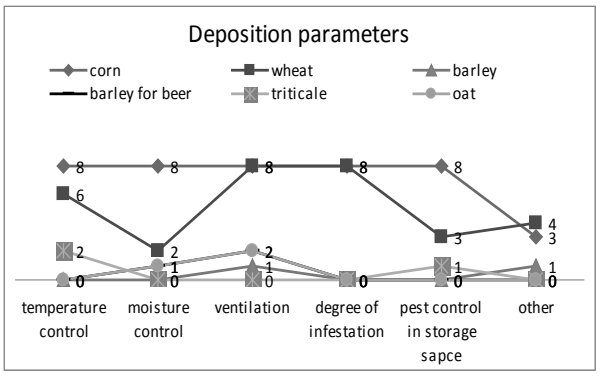

Figure 5. Deposition parameters

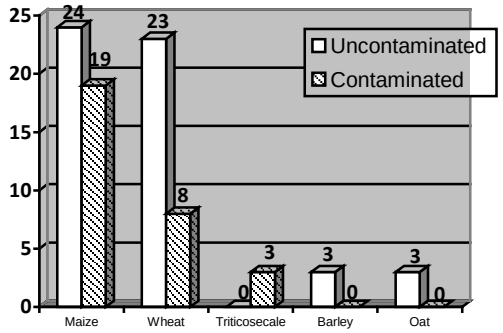

Figure 6.The number of contaminated and uncontaminated samples with Fusarium

The experimental results indicated that the fungus species isolated and identified were *Aspergillus (flavus and terreus, Fusarium roseum, Penicillium sp., Chaetomium sp. and Cladosporium sp.* The most frequent Fusarium fungal species in cereal samples were identified: *F. culmorum*, DON mycotoxin producer, *F subglutinans*, fumonisin producers and *F. acuminatum*, non mycotoxin producer. *Fusarium* species was identified in 45% maize samples, 25% wheat samples, 100% triticale and barley samples and 0% in oats samples (figure 6).

CONCLUSIONS

Storage conditions affect fungal charge of grain. In the grain samples analyzed from counties in western Romania, the predominant fungi were of the species *Fusarium,* especially *F. culmorum*, *F subglutinans* and *F. acuminatum,* fungal charge being due to the absence or failure of optimal storage conditions.An important role in fungal contamination is due to temperature and humidity, ventilation, infestation degree and pest control.

ABSTRACT: Modern consumers demand for fresh and minimally treated food products is dictating a trend of reducing the use of man-made chemical preservatives, although this could increase health risk, caused by foodborne pathogens and spoilage. Therefore the interest in finding new natural antimicrobials and antioxidants is increasing. We investigated antimicrobial activity of hot water and hot alkali extracted polysaccharides from selected medicinal mushrooms, which are known for their broad spectrum of health promoting activities. The most effective against *Staphylococcus aureus* and *Campylobacter jejuni* were crude hot water extracts of *Phellinus linteus* and *Ganoderma lucidum*, composed of a mixture of polysaccharides and phenolic compounds and partially purified extract of *G. lucidum*. MIC (minimal inhibitory concentration) of *P. linteus* and *G. lucidum* crude extracts were 5 mg/ml and >10 mg/ml on *S. aureus*, and 10 mg/ml on *C. jejuni*, respectively. These extracts showed considerable bacteriostatic effect against gram-negative *C. jejuni* already in concentration of 0.25 MIC. Lower antimicrobial effect was observed on *S. aureus*.
Key words: *antimicrobial activity, mushroom polysaccharide extracts, anti-Campylobacter activity*

INTRODUCTION

Many medicinal mushrooms have been proven to contain biologically active components, expressing different medicinal functions including antitumor, anti-inflammatory, immunomodulating, antioxidant, radical scavenging, cardiovascular, antiviral, antibacterial, antiparasitic, antifungal, detoxificative, hepatoprotective, and antidiabetic effects. Medicinal mushrooms have an established history of use in traditional oriental therapies. Modern clinical practice in Japan, China, Korea and other Asian countries continues to rely on mushroom-derived preparations. In searching for new therapeutic alternatives, they have become interesting subject of research (Wasser 2010; Guillamón et al., 2010; Moro et al., 2012; Hsu et al., 2008; Li et al., 2011).
Special attention is paid to mushroom polysaccharides. Polysaccharide extracts from *Ganoderma lucidum, Agaricus bisporus, Agaricus brasiliensis, Phellinus linteus*, *Schizophyllum commune* have been shown to have antioxidant activity and are health beneficial nutritional supplements, which could also be used as natural food additives to prevent oxidative deterioration (Kozarski et al., 2011; Turkoglu et al., 2007; Klaus et al., 2011). Consumers demand for fresh and minimally chemically treated food is namely increasing. As good as this may be from nutritional point of view, it does arise considerable food safety and quality issues. Less conservation treatment not only reduces the shelf life of food products, but also compromises enzymatic and microbiological stability of food products. The extracts of edible and medicinal mushrooms have been proved to have antioxidant and antimicrobial activity against Gram-positive (Hur et al., 2004; Karaman et al., 2010) and Gram-negative bacteria (Moradali et al., 2005; Li et al., 2012) as well as antifungal activity (Turkoglu et al., 2007). Therefore, they could potentially be used as bacteriostatic

agents in food. To our knowledge, their antimicrobial activity against *Campylobacter* has not yet been tested.
The aim of this study was to investigate the antimicrobial effect of mushroom extracts. Most of the tested extracts were water-soluble. More lipid-soluble extracts were excluded from further testing. Extracts were obtained by hot water extraction from *Ganoderma lucidum*, *Ganoderma applanatum*, *Trametes versicolor*, *Lentinus edodes*, *Schizophyllum commune*, *Laetiporus sulphureus*, *Agaricus blazei, Agaricus bisporus* and *Phelinus linteus*. For further testing, polysaccharide extracts from *Ganoderma lucidum, Laetiporus sulphureus, Phelinus linteus and Agaricus blazei* were chosen. To evaluate the impact of potential impurities on antimicrobial activity of polysaccharide extracts, we further tested water-soluble extracts of *G. lucidum* and *L. sulphureus*, partially purified with dialysis. Antimicrobial effect was tested against Gram-positive *Staphylococcus aureus,* most often used model for testing antimicrobial activity, and Gram-negative *Campylobacter jejuni.* This microorganism is the cause of human campylobacteriosis, which has recently become the world's leading bacterial food-borne illness and the most frequently reported zoonosis in humans (EFSA, 2012; Smole Možina et al., 2011).

MATERIALS AND METHODS

Bacterial strains, culture media and growth conditions

Bacterial strains of *S. aureus* ŽMJ 72 and *C. jejuni* ATCC 33560 were stored at -80 °C and revitalized on Müeller-Hinton agar (MHA) and Columbia blood agar (CBA), respectively. Both cultures were incubated for 24 hours; *S. aureus* at 37 °C and *C. jejuni* at 42 °C in microaerobical conditions. A loop of each culture was transferred in Müeller-Hinton broth (MHB) and 5 % horse lysed blood was added in case of *Campylobacter*. Incubation took place for 24 hours in previously mentioned conditions. Working concentrations in range of 10^4-5x10^5 CFU/ml were prepared by proper dilution of culture in MHB.

Reagents and media

INT (2-p-iodophenyl-3-p-nitrophenyl-5-phenyl tetrazolium chloride) (Sigma-Aldrich, USA), Cell-TiterGlo™ (Promega, Madison, USA), MHB, CBA and MHA (Oxoid, Hampshire, UK). Milli-Q water obtained from a Milli-Q water purification system (MQ) was used for preparing all of the extracts.

Instruments

Microplate reader (Tecan, Mannedorf, Zurich, Switzerland).

Preparation of polysaccharide extracts

Hot water extract, partially purified polysaccharides and hot alkali extracted polysaccharides were prepared as described before (Klaus et al., 2011). Partially purified extract was obtained by dialysis from the crude hot water extract, while hot alkali extracted polysaccharides were obtained from the filter cake originated from the first step of making hot water extract. To remove residual small molecules as polyphenols, peptides and polysaccharides < 8-10 kD, i.e. to partly purify hot water extract, dialysis was done with ZelluTrans/Roth® 6.0 regenerated cellulose tubular membrane (MWCO: 8.000-10.000) against a large volume of MQ for 24 h at room temperature.

Determination of the MICs by broth microdilution method

Broth microdilutions were carried out as previously described (Klančnik et al., 2010). Viability of *S. aureus* and *C. jejuni* was determined with INT and Cell-TiterGlo™, respectively. Minimal inhibitory concentrations were defined as minimal concentrations at which no viability was detected, based on color change or absence of bioluminescence. In case of detection with Cell-TiterGlo™ there was possible to determine also the minimal concentration at which viability started to decrease.

Determination of kinetics of microbial inhibition

Kinetics of microbial inhibition was determined by macrodilution method in MHB. Bacterial cultures were prepared in concentration of 10^4-$5x10^5$ CFU/ml. Each extract was diluted in 1 ml of bacterial culture to reach the concentration of 2.5 mg/ml. This concentration represented 0.25 MIC in most cases and was selected to see potential bacteriostatic effect of subinhibitory concentrations. Sampling was carried out at start and after 3, 6, 9 and 24 hours.

RESULTS AND DISCUSSION

Majority of the tested extracts had better antimicrobial effect against *C. jejuni* than *S. aureus* (data shown in Table 1). All, except hot alkali extract from *L. sulphureus* had MIC of 10 mg/ml against *C. jejuni*, while all, except crude *P. linteus* and partially purified *G. lucidum* extracts had MIC higher than 10 mg/ml against *S. aureus* (Table 1).

Table 1. Minimal inhibitory concentrations of tested mushroom extracts

Mushroom	**Extract type**	***S. aureus* ŽMJ 72**	***C. jejuni* 33560**	***C. jejuni* 33560**
		MIC (mg/ml) at 37 ºC	Start of viability reduction (mg/ml) at 42 ºC	MIC (mg/ml) at 42 ºC
Agaricus blazei	Crude	>10	2,5	10
Phellinus linteus	Crude	5	2,5	10
Laetiporus sulphureus	Crude	>10	2,5	10
Laetiporus sulphureus	Hot alcali	>10	2,5	>10
Laetiporus sulphureus	Partially purified	>10	2,5	10
Ganoderma lucidum	Crude	>10	2,5	10
Ganoderma lucidum	Hot alcali	>10	2,5	10
Ganoderma lucidum	Partially purified	5	2,5	10

Crude *P. linteus* and partially purified *G. lucidum* extracts showed the best antimicrobial activity in microdilution assay, with MICs of 5 mg/ml. Interestingly, the viability reduction in microdilution assay on *C. jejuni* were observed already at 2.5 mg/ml for all tested extracts. Thus we investigated the effect of this, in most cases 0.25 MIC concentration, on kinetic of growth inhibition. Tests were carried out at optimal growth temperature; 37 ºC for *S. aureus* and 42 ºC for *C. jejuni*. We used the same concentration, 2.5 mg/ml, of all extracts on both bacteria. The focus of our interest was to examine whether the extracts show any bacteriostatic activity also in this subinhibitory concentration and to see the differences in antimicrobial activity among extracts with different composition (e.g. crude extracts, hot alcali and partially purified extracts).

Crude extracts from *P. linteus* and *G. lucidum* showed overall best inhibitory effect against both, *S. aureus* and *C. jejuni*, with slight growth reduction of 0.7 and 0.4 $\log_{10}$CFU/ml on *S. aureus* and 3.3 and 2.0 $\log_{10}$CFU/ml on *C. jejuni*, respectively (results showed in Figure 1 and 2). Hot alkali extract showed the best inhibitory effect in case of *S. aureus*, with growth reduction of 1 $\log_{10}$CFU/ml. The extract from *P. linteus* worked bacteriostatically on *S. aureus* in first three hours after starting the experiment, while other extracts did not display a typical bacteriostatic activity. In case of *C. jejuni*, crude extracts from *P. linteus* and *G. lucidum* as well as partially purified extract from *G. lucidum* showed bacteriostatic effect in first nine hours of experiment. These extracts were able to prolong the lag phase of *C. jejuni* already in concentration of 0.25 MIC.

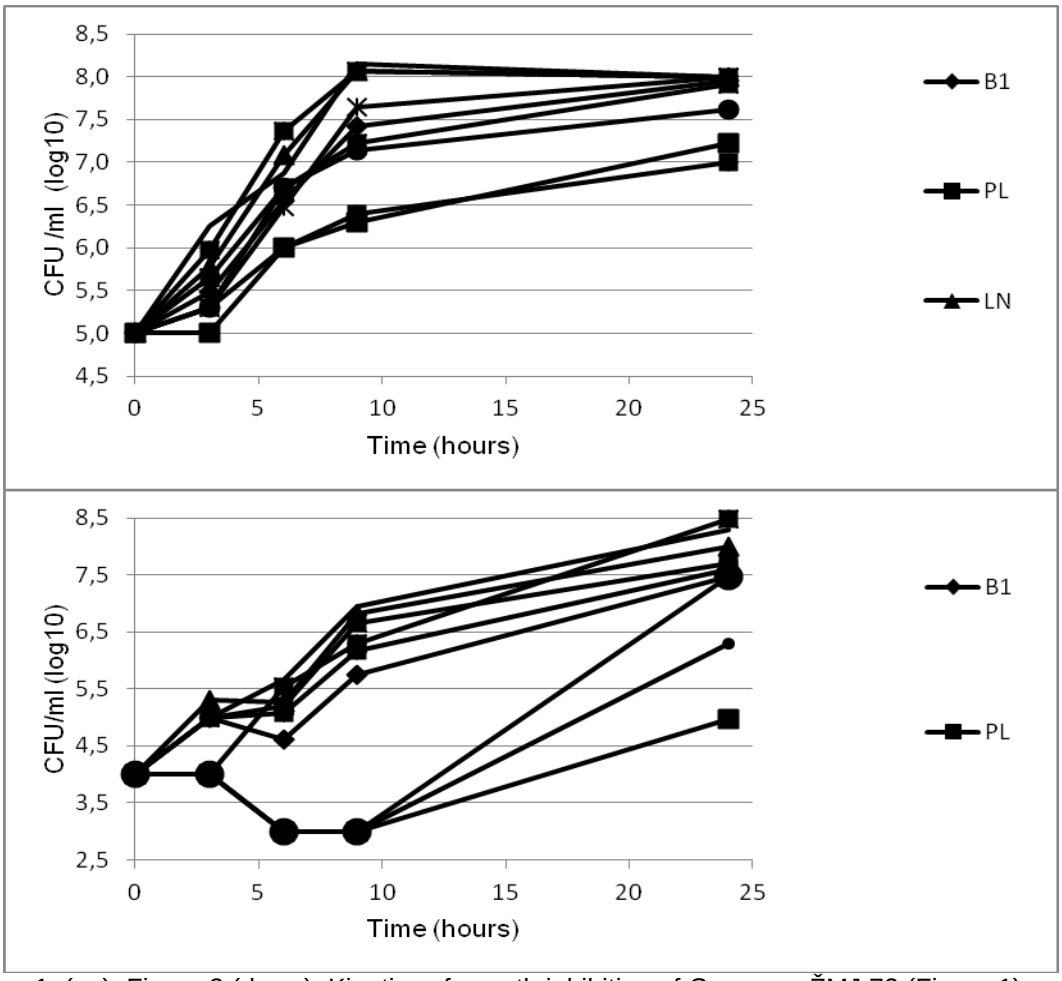

Figure 1. (up), Figure 2 (down). Kinetics of growth inhibition of *S. aureus* ŽMJ 72 (Figure 1) and *C. jejuni* ATCC 33560 (Figure 2) at the extracts concentrations of 2.5 mg/ml and incubation temperature 37 ºC and 42 ºC, respectively.

B1= A. blazei, PL= P. linteus, LN= L. sulphureus (crude), Lna= L. sulphureus (hot alcali), LP= L. sulphureus (partially purified), KN= G. lucidum (crude), Kna= G. lucidum (hot alcali), KP= G. lucidum (partially purified).

To confirm total inhibition of bacterial growth after prolonged incubation, we carried out growth kinetics test with *P. linteus* crude extract, which showed the best antimicrobial activity in subinhibitory concentrations. *P. linteus* crude extract was added to the growth media in minimal inhibitory concentration determined in broth microdilution test (Table 1). At this concentration it was able to inhibit growth of both, *C. jejuni* and *S. aureus.* However, the extract had better antimicrobial activity against *C. jejuni,* where it displayed bactericidal activity, being able to decrease the number of bacteria below 100 CFU/ml (Figure 4). MIC of *P. linteus* extract showed only bacteriostatic effect on *S. aureus* by keeping its concentration on the starting level (Figure 3).

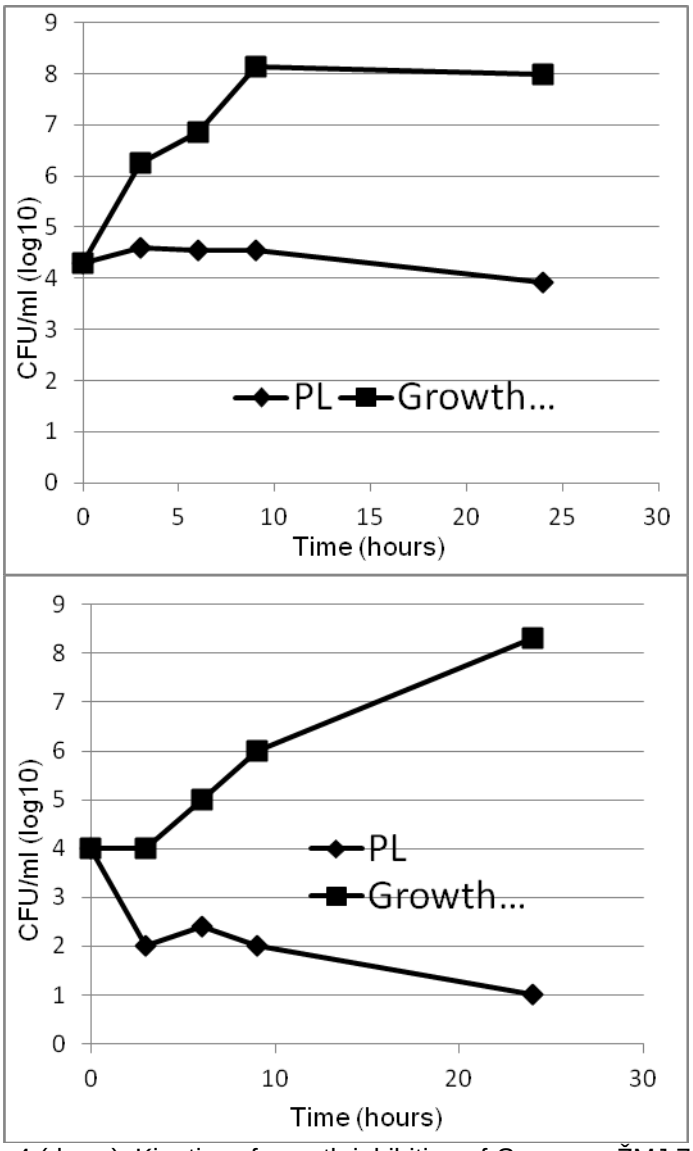

Figure 3 (up), figure 4 (down). Kinetics of growth inhibition of *S. aureus* ŽMJ 72 (Figure 3) and *C. jejuni* ATCC 33560 (Figure 4) at MIC of *P. linteus* crude extract and incubation temperature 37 ºC and 42 ºC, respectively.

In our previous investigations the hot water extract, partially purified polysaccharides and hot alkali extracted polysaccharides showed very high antioxidant properties that have been tested by four antioxidant assays. For *P. linteus* median effective concentrations (EC_{50} values) of the DPPH scavenging activity were low, i.e. < 0.1 mg/ml, while in reducing power and chelating ability of ferrous ions were found to be 0.47 and 0.91 mg/ml. EC_{50} value for inhibition of lipid peroxidation was 7.11 mg/ml (Kozarski et al., 2011). The other tested extracts showed significant antioxidant activity, too, and can therefore be used as a highly effective and valuable food additive, which not only works potentially bacteriostatically, but could also increase the functionality of food product (Kozarski et al., 2011).

This research revealed that crude extracts obtained from *P. linteus* and *G. lucidum,* as well as partially purified extract from *G. lucidum* were effective against *Staphylococcus aureus* and *Campylobacter jejuni*. These data indicate that the tested extracts contain both, antimicrobial and antioxidant components. There was no major difference between antimicrobial activity of tested crude and partially purified extracts, therefore we can conclude that polysaccharides as the main component of the extracts, play the essential role in antimicrobial action against *C. jejuni* and *S. aureus*.

CONCLUSIONS

Crude hot water polysaccharide extracts of *P. linteus* and *G.lucidum* are potential effective bacteriostatical agents against *C. jejuni* in subinhibitory concentrations and at the same time the most effective anti-*Campylobacter* types of mushrooms extracts tested in this study. Further testing in higher subinhibitory concentrations and in food model at lower temperature, as well as sensorial evaluation should be conducted to provide solid evidence for its potential use as a bacteriostatic and functional agent in food.

ACKNOWLEDGEMENTS

ABSTRACT: The purpose of the work was to answer some questions important for a qualitative risk assessment in Serbia. The qualitative risk assessment attempts to understand how the incidence of human campylobacteriosis is influenced by various factors during poultry breeding in our country. In the estimation of risks, foour steps are usually involved. 1. Hazard identification: termophilic *Campylobacter spp* are the leading cause of zoonotic enteric illness. 2. Hazard characterization: it is assumed to be dose-independent based on some studies on healthy human volunteers. 3.Exposure assessment: The incidence of *Campylobacter* at poultry farms in Serbia varies from 20 to 80%. Artificial infection of chickens with 6.77 log cfu *C. jejuni* ATCC 29428 per chicken in 21st day of life leads to 5.26 log cfu/g feces after only 5 days. This number has a trend to decrease in next two weeks when 3.02 log cfu/g feces was found. The prevalence of campylobacter-contaminated chickens from positive flock appears to drop from 100% live birds to 50% of chicken carcasses according to our experimental results. The incidence of human campylobacteriosis in Serbia was 4.88 in 2010. 4. Risk characterization: even there is high exposure of human population to *Campylobacter* in Serbia, the incidence of human campilobacteriosis from raw meat is low, mainly because there is a lack of evidence and confirmation of human campylobacteriosis.
Key words: *risk assessment, Campylobacter, poultry*

INTRODUCTION

Risk analysis comprises of three functions: risk assessment, risk management and risk communication. Risk assessment forms the scientific basis for control actions and it is the determination of quantitative or qualitative value of risk related to a concrete situation and a recognized hazard.The food safety risk analysis usually is used as a tool for the control of biological, chemical and physical hazards associated with foods. It is not possible to completely eliminate microbiological hazards but producers are required to protect consumers as far as it is reasonably practicable.

Risk assessment can be quantitative and qulatitative. Despite a number of large and well-publicized quantitative microbiological food safety risk assessment projects, it is probable that the majority of risk assessments in the fields of food safety, health and microbiology are not fully quantitative. There may be a variety of reasons for this. Quantitative microbiological risk assessment is a new and specialized field, methods are still being developed, the expertise and resources to complete them are not widely available, there is a lack of data for quantitative assessment and a lack of mathematical or computational skills and facilities for quantitative risk assessment. A qualitative risk assessment is much quicker and more accessible. Data are required for any type of risk assessment, irrespective of whether qualitative; semi quantitative or quantitative approaches are used. Numerical data are preferred (*Report, 2002*).

Although various foods can serve as a source of food borne illness, meat and meat products are important sources of *Campylobacter*. The *Campylobacter* is most frequently reported cause of zoonotic diseases in EU in 2007, incidence was 45.2 cases per 100 000 population (*EFSA, 2010*). This bacteria is widespread within the poultry production in Europe. *C. jejuni* is frequent commensal in poultry and cattle, and *C. coli* in swine and poultry. The most common way people become infected with zoonotic enteric pathogens is through the

ingestion of food contaminated with animal feces (contamination usually occurs during processing).
An understanding of thermophilic *Campylobacter* and specifically *C. jejuni* in broiler chickens is important from public health.The aim of this paper was to answer some questions important for a qualitative risk assessment in Serbia. The qualitative risk assessment attempts to understand how the incidence of human campylobacteriosis in Serbia is influenced by various factors during poultry breeding and broiler meat production “from farm to table”. In the estimation of risks, the following steps are usually involved: hazard identification, hazard characterization, exposure assessment and risk characterization. The spread of *Campylobacter* in broiler flock was examined in experimental designe: chickens were artificially infected with *Campylobacter* in life period when usually campylobacter infection occurs in poultry; number of *Campylobacter* were examined during next three weeks; chickens were slaughtered on day 42 of life and prevalence of *Campylobacter* on carcasses were examined

MATHERIAL AND METHODS

Experimental design: The control group (group A) consisted of 30 chickens which were not artificially infected with *Campylobacter.* The group B consisted of 32 chickens which were artificially infected with 6.77 log cfu *C. jejuni* ATCC 29428 per chicken on day 21 of life. Total count of *Campylobacter* was examined in chicken feces five times in the following twenty days. The chickens were slaughtered in the poultry abattoir on day 42 of life (10 chickens from the control group and 10 from the infected group). The prevalence of *Campylobacter* on carcasses and livers were determined immediately after processing.
The total number of *Campylobacter* was determined according to procedures of Chen et al. (2003) and ISO 4833. Isolation and identification of *Campylobacter* were performed according to the standard ISO 10272 procedure.

RESULTS AND DISCUSSION

Hazard identification

The genus *Campylobacter* now comprises 17 member species most of which are microaerophils, i.e. grow preferentially in low oxygen concentrations. The majority of cases of campylobacteriosis are caused by two species: *C. jejuni* and the closely-related *C. coli*. These two species are often referred to as the “thermophilic” or “thermotolerant” *Campylobacter* as they grow preferentially at 42°C (EFSA, 2010). Termophilic *Campylobacter spp* are leading causes of zoonotic enteric disease in most developed countries.They are usually indirectly transmitted to humans through the consumption of contaminated food. The principal reservoir of these organisms are the digestive tract of food producing animals. In the vast majority of cases, the organisms are constantly shed in faeces by asymptomatic animals. Handling raw poultry and eating poultry products are important risk factors for sporadic campylobacteriosis.

Hazard characterization

Hazard characterization provides a description of the public health outcomes following infection, including sequelae, pathogen characteristics influencing the ability of organism to elicit infection and illness, host characteristics that influence the acquisition of infection, and food-related factors that may affect the survival of *C. jejuni* in the human gastrointestinal tract (WHO, 2002).
Hazard characterisation includes analysis of data on food pisoning (WHO, 2002):

- consequences
- pathogen characteristics influencing an organism’s ability to cause infection and illness
- host characteristics that influence the acquisition of infection

- food related factors that aneble the survival of pathogens in human gastrointestinal tract.

Food poisoning data usually are obtained after an outbreak but in the case of campylobacteriosis there is no dose-response data from outbreak, because this disease occurs in sporadic cases. Dose-response analysis - the probability of illness following infection is influenced by the immune response of a host and it is assumed to be dose-independent based on some studies on healthy human volunteers (WHO, 2002).

Exposure assessment at farm level

Initial introduction of *Campylobacter* into poultry flock still remains poorly understood and the phenomenon may be multi-factoral. *Campylobacter* usually colonise chickens in the third week of life. The level of colonisation and the spread of *Campylobacter* between animals depend on different factors: breeding conditions, hygiene measures, immune response of animals etc. In food producing animals campylobacteriosis usualy don't have clinical signs. The occurrence of these bacteria varies depending on the range of factors including the organism, geographical factors, farming and meat production practice. Some animal production conditions facilitate the spread of bacteria, such as high density and/or poor infection control *(Stojanov* et al., 2006; *Stojanov* et al., 2009). EU data reported for 2007 indicates that *C. jejuni* was identified in 42.5%, 86.8% and 2.1% of the isolates from broilers, cattle and pigs respectively, while *C. coli* was identified in 13.1%, 9.5% and 87.1% of the isolates from the same animal species (EFSA, 2009).

According to our experimental results artificial infection of chickens with 6.77 log cfu *C. jejuni* per chicken on day 21 of life leads to 5.26 log cfu/g feces after only 5 days, with a tendency to decrease 4.97 log cfu/g (31st day of life), 4.49 log cfu/g (35th day of life) and 3.02 log cfu/g (39th day of life). After this day the increase in *C. jejuni* count was noticed 4.95 log cfu/g (49 th day of life). Tendency of decrease in *Campylobacter* count was found also in the work of Van Boven et all. (2003). The results are shown in Graph 1. In the control group which was not infected, a total of 40 fecal samples were tested and *Campylobacter* was not found.

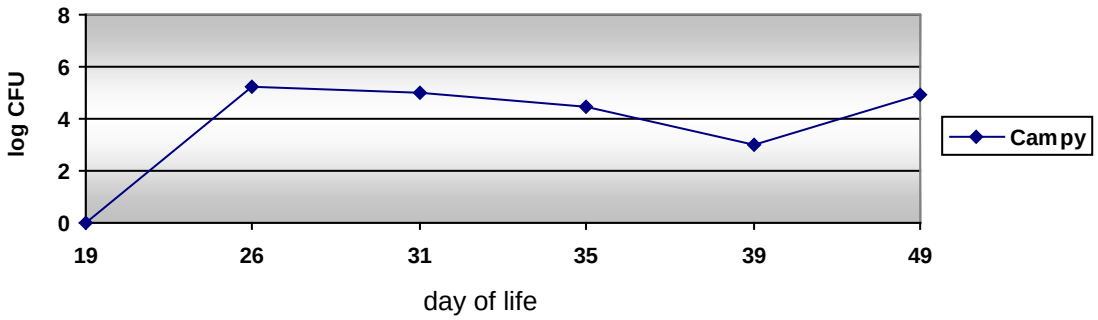

Figure 1. Average number of *C. jejuni* n chicken by days of life (log cfu/g feces)

Exposure assessment at processing

Cooling, freezing, adding of chlorine during water chilling, lactic acid, irradiation may significantly reduce *Campylobacter* contamination of carcasses. According to our experimental results the prevalence of *Campylobacter* -contaminated chickens from positive flock appears to drop from 100% live birds (with 3.02 log cfu/g feces) to 50% of chicken carcasses.These results are shown in Table 1.

Table 1. Prevalence of *Campylobacter* on broiler carcasses

Sample	No samples	Group A control C. jejuni positive (%)	Group B infected C. jejuni positive (%)
Liver	10	0 (0.00%)	5 (50.00%)
Carcase	10	0 (0.00%)	5 (50.00%)
Total	20	0 (0.00%)	10 (50.00%)

These organisms can be transmitted to the production facility and can contaminate the processing environment and the final product. According to our results (Petrović et al., 2007a, b, c) the occurrence of *Campylobacter* is very frequent in poultry carcasses in abbatoirs in Vojvodina region (Table 2). The influence of production management is great, since in poultry abattoirs the prevalence ***varies from*** 11.43 to 90.00% carcasses (Petrović et al., 2008 a, b, c). The prevalence of *Campilobacter* positive carcasses increased during evisceration and decreased uppon the method of chilling.

Table 2: Occurrence of *Campylobacter* in poultry samples (Petrović et al., 2007a)

Occurrence of pathogen (%)		Abattoir mark						
		A	B	C	D	E	F	G
Campylobacter	liver	40.00	5.00	8.56	6.00	34.28	2.86	5.71
	carcasse	90.00	14.28	51.43	20.01	68.57	11.43	31.43

Exposure assessment at disstribution

Cooling is the most important factor that prevents the increase in *Campylobacter* numbers at retail. Frozen chicken posed a lower risk via concumption than fresh meat. In a restaurant and at home cross contamination occcurs rom undercooked and raw meat to other food that is eaten without further cooking. Undercooking is a higher risk than cross contamination. Meat contaminated by *Campylobacter* can either infect humans directly (if not properly cooked or otherwise treated) or indirectly. For indirect contact the contaminated meat acts as a vehicle of *Campylobacter*, especially those in meat juices, which can easily contaminate kitchen equipment such as cutting boards, plates, knives etc. and thereby other foods (salads etc.), which might be eaten without further bacteriocidal treatment (EFSA; 2010).

Exposure assessment-human campylobacteriosis in Serbia

In immunologically-naive humans, the symptoms of *Campylobacter* infection can range from mild, watery diarrhoea to severe bloody diarrhoea with fever, abdominal cramps and an influx of polymorphonuclear leucocytes (dysentery-like disease) (van Vliet and Ketley, 2001). Acute infections may also rarely involve intestinal complications such as appendicitis and colitis, and extra-intestinal infections, such as bacteraemia, hepatitis, abortion/peri natal infection and haemolytic-uremic syndrome (Skirrow and Blaser, 2000). According to the Report of Institute of public health of Serbia »dr Milan Jovanović Batut« In Serbia in 2010 there were 357 cases of *Enteritis Campylobacterialis* diagnosed with the incidence of 4.88, while in the EU in 2005 the incidence rate of 38.2-51.6 cases per 100 000 population was noticed.

Risk characterization

This step links the probability and magnitude of exposure to *Campylobacter* associated with consumption of meat to adverse outcomes that might occur. *Campylobacter* is frequently found in feces of live animals in Serbian farms. Overall *Campylobacter* contamination on carcasses decreased through processing with temporary increases occurring during transport and evisceration. But despite high exposure of population to *Campylobacter* in Serbia, the incidence of human campylobacteriosis from raw meat is low, mainly because there is a lack of evidence and confirmation of human campylobacteriosis. In order to significantly reduce the bacterial load on processed carcasses, interventions would require addressing the bacterial load, both internally and externally. *Enteritis Campylobacterialis* is a sporadic disease; symptoms usually do not require hospitalisation and many sick people do not go to the doctor and only small number of ill people has laboratory confirmation of campylobacteriosis. Also significant factor of exposure to the decrease are cooking habits in Serbia: meat is usually well cooked.

CONCLUSION

In order to significantly reduce the bacterial load on processed carcasses, interventions would require addressing the bacterial load, both internally and externally, since efforts directed at only one of these contamination reservoirs can be readily undermined by high levels of contamination from the other.

ABSTRACT: Milling is the physical process of converting the endosperm of wheat kernel into flour. The first stage of the modern flour milling process is the break system, in which the wheat kernel is opened up and the contents released so that the endosperm may be separated from the bran. The aim of the study presented in this paper was to investigate effect of various structures of the head break system on the yield and ash content of the streams from the three break systems at the laboratory mill. The conventional milling break system (A), the break system with double high roller mills at B1 and B2 (B), the break system with debranning pre-treatment (C) and the break system with pre-break as a pre-treatment (D), at the similar break release on B1 and B2 were compared. The lower coarse fraction (through 1000-µ and over 630-µ) yield, higher yield of other streams, higher ash content of common streams from three break systems and higher energy requirements for grinding has been obtained using double high roller mill. In the opposite of that grinding with debranning pre-treatment led to increase in coarse fraction yield, decrease in small fractions yield (including break flour yield) and decrease in energy requirements for grinding but ash content of common streams was close to the ones using double rollermill and was higher compared to conventional break system. The most effective break system structure was grinding with pre-break system pre-treatment (3-5% break release through 1000-µ) in which yield of all fractions was close to conventional break system, but with insignificantly lower ash content of all fractions and energy requirements for grinding.
Key words: *grinding, wheat, break system, debranning, eight-roller, break release, pre-break, streams, pre-treatment, yield, ash, energy requirements*

INTRODUCTION

Wheat is one of the most important cereal crops in the world with annual world production of about 650 million tons. According to statistical data from WOH/FAO wheat constitutes about 27% of the total world production of cereals by weight, with maize and rice 35% and 28%. Approximately 70% of wheat is used for food production. Milling is very important in wheat processing. Wheat is milled into flour which is then made into products such as bread, cakes, cookies, cereal, pasta, and noodles. Other uses include the manufacture of alcohol, gluten, and livestock feed.

Flour milling is the process by which wheat is grounded into fine particles and through which the wheat grain is separated into its constituent parts: bran, germ and endosperm. The germ and bran are largely discarded while the endosperm is then further reduced into the fine powder that we call flour.

In principle the milling process is established in three stages, which are break system, purification system and reduction system. The break system is used to break open the wheat kernel and continued to scrape endosperm from the bran, step by step, by sequential passages. The purification system is to separate the outer branny material from inner white endosperm. The aim of this purification system is to purify the milling material that almost no flour is produced. The reduction system is used to deliberately mill the center particles of the wheat grain into flour (Siti Mazlina et al., 2006).

The break system is the beginning of the actual milling process. The break system has two parts: (1) the primary or head break, which releases relatively pure particles of endosperm; and (2) the secondary or tail break, which cleans up the bran and releases smaller pieces of endosperm along with finer pieces of bran and germ (Posner and Hibbs, 1997).

The head break process at most of commercial mill plants consists from three break systems. The objective of grinding on the head break is, at first, to open the whole grain on the first break (B1), and, at second, to obtain as much yield of intermediate-sized particles such as either semolina, middlings and dunst with the lowest of ash content and the lowest energy requirements for grinding.
In recent years, as energy has become increasingly expensive, power costs have assumed much greater importance in the economics of flour mill operations. It is known that as much as 75% of the energy used in a modern flour mill was associated with the actual milling process. The remaining 25% was for processes such as grain cleaning, storage, flour blending, shipping and packaging, and preparation of mill feed (Zwingelberg, 1980).
Emerging trends in recent years are looking for new opportunities and technologies for processing wheat which could decrease energy requirements for wheat milling by improving the grinding process itself by shortening and simplifying. In our recent investigations it was established that at the 20,8 t/h mill the most energy requirements are consumed at the head break stage. About 34% of the total energy is directly used for grinding and 49% for pneumatic lift, respectively (Zhygunov, 2011). This means that the potential for further cost reductions in this stage is high.
As a result, twin grinding stages without any intermediate sifting were applied. It was called a new roller mill design featuring two grinding stages in one machine, known today by the name of eight-roller mill (Baltensperger, 1993, Fišteš, 2009). Another solution is the process of debranning of wheat prior milling. It's a pre-milling treatment that allows a controlled and progressive removal of the grain's layers (Alymkulov, 1979, Satake, 1990). The other solution is the pre-treatment of wheat known as pre-break which is often used in rye milling and widely used in wheat milling at 70-80 (Sukharev, 1983, Dexter, 1986). In recent times, with the trend to shorter mill flows, the prebreak has largely been eliminated.
In the present investigation we report the effect of various structures of the head break system on the milling performance: yields of different fractions of intermediate products, their ash content and energy requirements for grinding.

MATERIAL AND METHODS

Wheat

A hard red winter wheat from the crop of 2009 from south of Ukraine was used. The physicochemical properties of this material were: 12.8% moisture content, 50% glassiness, 1.75% ash content, 12.3% protein content, 38.2 g 1000-kernel weight, 0.74 g/sm^3 bulk density.

Milling procedure

One-kilogram samples of cleaned wheat were tempered to 16,0% moisture content in two stages. At first, the wheat was held in tempering bin for 16 h to reach 15,5% moisture. Then wheat was tempered to 16,0% during 15 min before milling. The mill room was controlled for both temperature (22 □C) and relative humidity (60%).
Conventional milling procedure (model A) was carried out with grinding on B1, B2 and B3 break systems on the laboratory roll stand Nagema which has 220-mm diameter rolls with a fast roll speed of 520 rpm and a slow roll speed of 208 rpm. The effective grinding length is 150 mm. The corrugation of the rolls was 16 cuts per 2,54 cm and they were operated in dull to dull disposition.
For the simulation of the eight-roller milling system on B1 and B2 (model B) the milled stock after the first break was fed to second break without sifting. In a case of debranning procedure (model C) treatment of wheat was carried out using the laboratory pearling mill with an abrasive stone which rotates inside a slotted screen. The wheat sample (500 g) after the first stage of tempering was placed in the hopper of the pearler, with the outlet blocked, and abraded 90 s for the bran ratio of approximately 3%. Polishings removed during the debranning process were determinated by sifting the stock on a 1400 μm screen in a Ro-Tap

sifter for 2 mins. For the pre-break treatment (model D) corrugated rolls with 3-5% break release through 1000-µm screen were used.
The roll gaps were set at 0.54, 0.27 and 0.1 mm for the B1, B2 and B3 breaks, respectively. This way it was possible to obtain 43% break releases (through 1000-µ) both on the first and second break and 33% break release (through 630-µ) on the third break, for the conventional and pre-break models of head break. For the debranning model the roll gaps on the first and second break were adjusted to 0.56 and 0.35 mm in order to obtain the similar break releases on the B1 and B2 according to the ones in conventional model. For the model B only the roll gap on the second break was changed (0.28 mm). Roll gap on the B3 was constant for all models.
After grinding the milled products were sieved for 10 min on a laboratory sifter oscillated at 150 rpm with a throw of 8 cm, using mesh sieves of 1000, 630, 438, 294, and 160 µm along with a bottom pan. Six streams were obtained: overtails (OT, over 1000 µm); coarse fraction (CF, through 1000 µm and over 630 µm); medium fraction (MF, through 630 µm and over 438 µm); fine fraction (FF, through 438 µm and over 294 µm); dunst (DU, through 294 µm and over 160 µm); break flour (FL, through 160 µm). Overtails from the first and second break were milled step-by-step on the next break passages. The same fractions from three breaks were collected (except coarse fraction from third break which with overtails forms a branny product) and the ash content was determined according to the standard method (ICC Standard No.104/1). The total ash content of all milled fractions was calculated from their mass balance.
Watt-hour meter was used to measure the electric energy of the motor. Two different power readings were recorded corresponding to operation with and without the material flow. The no-load energy values were substracted from the values measured during grinding.

RESULTS AND DISCUSSION

The results of intermediate products and flour yield are shown in Table 1. As it can be seen from the results, the highest yield of coarse fraction (1.3 times higher related to conventional milling model) was given using model C. This is because the outer layers serve as external carcass of wheat kernel, and when they were removed debranned wheat kernel becomes more fragile (Kupritz, 1946). In opposite of this fact, the lower yield of coarse fraction and higher yield of other milled fractions has been obtained using double stage grinding on B1 and B2 (model B) compared to conventional break grinding. These results are expected and in consistence with other literature data (Pankratov, 2000). The yield of milled fractions for the grinding with pre-break conditions was similar to conventional grinding.

Table 1. Yield (% w/w) of intermediate products and flour for different structures of head break process

Processing model	CF [a]	MF	FF	DU	BF	Total
Model A	20.40 ± 0.82	15.47 ± 0.05	13.10 ± 0.22	11.83 ± 0.24	18.07 ± 0.37	78.87 ± 0.62
Model B	11.97 ± 0.21	17.90 ± 0.14	16.10 ± 0.62	12.97 ± 0.33	19.07 ± 0.34	78.00 ± 0.92
Model C	26.50 ± 0.78	13.47[a] ± 0.50	11.67 ± 0.45	11.73 ± 0.75	15.17 ± 0.17	78.53 ± 0.37
Model D	20.77 ± 0.29	15.03 ± 0.56	13.63 ± 0.66	11.60 ± 0.14	17.40 ± 0.37	78.43 ± 0.62

Results are given as mean ± standard deviation (n = 3); [a] – collected only from B1 and B2

The results of the ash content, as they are illustrated in Table 2, show the difference in the ash content between the milled fractions from different structures of head break. The ash content decreased from coarse fraction to flour for all samples. The highest ash content of all milled fractions was obtained using model B, the lowest using model D and similar data to conventional model was obtained for the model C. It is possible to assume that the similar dependence may be distributed for the ash content of common flour under industrial conditions (Merko, 1971).

As for the ash content of break flour which was obtained in this investigation it was found to deviate slightly between the flour samples. The ash content of the unpearled flour was only slightly higher (0.02% absolute difference) compared to pearled and such difference could be considered negligible. This is in agreement with other findings that suggest the ash content of pearled flour is approximately similar to that from the unpearled flour, if not slightly higher (Evers et al., 2002; Moss et al., 1998). The findings from this investigation showed that the ash content for the unpearled flour was only slightly higher compared to pearled. The ash content of flour obtained with pre-break on corrugated rolls was the same compared to pearled. The highest ash content was found for break flour obtained with double stage grinding.

Table 2. Ash content (% d/w) of intermediate products and flour for different structures of head break process

Processing model	CF [a]	MF	FF	DU	BF	Total
Model A	1.49 ± 0.04	1.27 ± 0.02	0.85 ± 0.02	0.70 ± 0.03	0.63 ± 0.00	1.03 ± 0.02
Model B	1.62 ± 0.04	1.45 ± 0.04	0.95 ± 0.02	0.83 ± 0.02	0.64 ± 0.00	1.07 ± 0.01
Model C	1.52 ± 0.05	1.30[a] ± 0.05	0.86 ± 0.01	0.65 ± 0.04	0.61 ± 0.02	1.08 ± 0 .02
Model D	1.44 ± 0.04	1.22 ± 0.03	0.82 ± 0.06	0.66 ± 0.03	0.61 ± 0.02	0.99 ± 0.01

Results are given as mean ± standard deviation (n = 3); [a] – collected only from B1 and B2

Table 3 shows the result of the energy requirements for grinding using different head break structures. The highest energy consumption directly for grinding was observed for the model B. It was higher more than 1.07 times compared to the conventional grinding. The energy consumption directly for grinding for both C and D models was almost the same and it was 1.28-1.29 times lower compared to the conventional grinding. However, it was found that the total energy consumption including energy for pre-treatment was only slightly less for the model D whereas the energy consumption for the model C was more than 1.19 times higher compared to the conventional grinding.

Table 3. Energy consumption (KJ/kg) during break grinding for different structures of head break process

		Break system			
Processing model	**Pre-treatment**	**B1**	**B2**	**B3**	**Total**
Model A	—	16.80 ± 0.17	5.76 ± 0.29	5.76 ± 0.29	28.32 ± 0.45
Model B	—	16.44 ± 0.61	7.80 ± 0.61	6.12 ± 0.29	30.36 ± 0.90
Model C	11.64 ± 0.45	12.72 ± 0.17	4.44 ± 0.74	5.04 ± 0.59	33.84 ± 0.59
Model D	6.12 ± 0.29	10.56 ± 0.45	5.52 ± 0.17	5.88 ± 0.34	28.08 ± 0.59

CONCLUSIONS

Five milled fractions were investigated to determine any difference in their weight yield and quality (ash content) due to the structure of head break milling process (conventional, double stage grinding, pre-treatment with debranning and pre-break system). It was found that the different structures of head break process exhibited differences in yield and ash content of milled fractions with the best results for the pre-break grinding. The lowest energy requirements were obtained for this structure of head break, too. The worst results of ash content of milled fractions were found for grinding without sifting after B1 system. The highest energy requirements for grinding were obtained for the double stage grinding as well as for the grinding with debranning prior to milling. However, improvement considering the energy requirements should be expected under industrial conditions because of decreased energy consumption for the pneumatic lift in case of eight-roll grinding, and shortening and simplifying the flow diagram, especially on the tail break stage using debranning process.

ACKNOWLEDGEMENTS

ABSTRACT: Potatoes baking at different types of ovens were studied with respect to some physical and chemical quality criteria of baked sample as a function of baking time. As well as convectional baking, steam assisted baking was utilized in the study. Steam assisted baking is a hybrid method combining the advantages of steam-baking and convectional baking. The shorter baking times provided with steam results in healthier products, with the constitution of harmful compounds at a minimal level. The potatoes by steam assisted baking were produced in a hybrid oven having an inner steam generator. The steam generated from ~350 ml water was injected into the oven cavity totally five times, at five minutes intervals during the baking process. Potatoes baked in steam assisted (steam+forced convection/turbo) and convectional ovens for different baking times (20-70 minutes) was analyzed in the scope of this study. Moisture content, color (CIE a* value, ΔE), texture (hardness, N), sensory evaluation and acrylamide content were investigated. The results of natural and forced convection/turbo baking of potatoes were compared with steam assisted baking, statistically. Acrylamide content of potatoes was found to be related to the oven type; where, the steam assisted oven baking resulted in minimum formation of this compound ($p<0.05$). The sensory points of the potatoes baked at different times was significantly different ($p<0.05$), for all baking ovens.
Key words*: potatoes, steam assisted baking, acrylamide*

INTRODUCTION

Steam assisted cooking of foods is a hybrid cooking method which produces sharing advantages of steam-cooking with natural and/or forced convection baking. It is a healthy cooking method, which provides shorter cooking times with constitution of harmful compounds such as acrylamide, at a minimal level. The increase in society's health standards perspective has resulted in an increase of interest on steam and/or steam assisted cooking of foods.

Desirable quality of thermally-treated potatoes includes proper color, taste and texture. Abnormal colour and excessive softening or firming cause rejection of the product by a consumer (Nourian et al., 2003). During the process of thermal treatment, the composition of the potato changes. The kind and extent of those changes connected with the starch affect the quality of thermal treatment and the quality of potatoes especially textural quality after that process. Texture of cooked potato was investigated by many researchers (Thybo et all., 1998; Truong et all., 1998; Binner et all., 2000; Kaur et all., 2002; Van Dijk et all., 2002; Abu-Ghannam ve Crowley, 2006; Chiavaro et all., 2006; Garcia-Segovia et all., 2008).

Recent studies have reported significant levels of acrylamide in heated foods, most especially, carbohydrate-rich foods (Rosen and Hellenas, 2002; Tareke et all., 2002). The researchers reported moderate levels of acrylamide (5–50 ppb) in protein-rich heated foods and higher content (150–4000 ppb) in carbohydrate-rich foods such as potato. Simple cooking experiments showed that different cooking practices can dramatically affect the acrylamide content of foods. Acrylamide content can be correlated to food browning, although this may or may not be a causal relationship. The method of cooking significantly affects the acrylamide content of foods. For instance, grilling of potatoes produced higher levels of acrylamide than either frying or oven baking (Ahn et al., 2002).

In this study, in order to obtain healthy cooking with low acrylamide content and at the same time to protect the quality features of potatoes, steam assisted (steam+forced convection) hybrid oven was used to cook potatoes as a comparison to conventional cooking. Potatoes were cooked at 210°C for different baking times (10, 20, 30, 40, 50 and 60 minutes) and moisture content, colour (CIE a* value, ΔE), texture (hardness, N), sensory evaluation and acrylamide content of potatoes were investigated for natural convection, forced convection and steam assisted hybrid ovens.

MATERIAL AND METHODS

Potatoes (*Granola*) were stored at 10ºC for maximum 5 days in a dark room after harvesting. The skin of the potatoes was removed before the oven cooking. Cooking experiments were carried out in a steam assisted oven (Blomberg) and also in a domestic use electrical convectional oven (Blomberg, BKO 9566). Steam assisted oven used in the study is a hybrid oven with 48×43×25 cm dimensions having an inner steam generator mounted at the back panel of the oven. The steam generated from ~350 g water was injected into the oven cavity in five times, at five minutes intervals during the cooking process. For the potatoes cooked at different times at 210°C, the physical quality; (moisture content (w/w, wb), color (a* and ΔE value), hardness (N)) as well as acrylamide content (ppb) and sensory quality were determined. The comparison has been made with the results of natural and forced convection/turbo cooking of potatoes, statistically.

Moisture content and colour measurement

The moisture content of potato samples was determined by gravimetric method under vacuum at 70ºC for 24 h as two parallel (AOAC, 1990). The surface colour of the potato samples (a*, b*, L*) was measured by CIE-Lab and ΔE values of cooked samples were calculated from the following equation (CIE, 1978);

$$\Delta E = \sqrt{\Delta L^2 + \Delta a^2 + \Delta b^2} \qquad (1)$$

Texture analysis

Texture analyses were achieved in texture analyser (TA-XTPlus, Stable Microsystems, Surrey, England) using 2 mm needle probe with 5 kg load cell. The test parameters are pre-test speed of 1.0 mm/s, test speed of 1.5 mm/s, post-test speed of 5.0 mm/s, distance of 6 mm and trigger force of 5 g. The hardness was determined from the maximum peak force (N).

Acrylamide content determination

Determination method of acrylamide content of potatoes includes extraction with water, addition of D_3 acrylamide as an internal standard, bromination and GC-MS analysis in the selected ion monitoring (SIM) mode. Bromination of acrylamide to 2,3-dibromopropionamide (2,3-DBPA) was achieved using potassium bromide and potassium bromate under an acidic condition. The operating parameters for GC-MS analysis were as follows: oven temperature was 65℃ (for 1 min), then increased to 240℃ by ch anging temperature by 15℃/min, the temperature was maintained at 240℃ for 10 min, inj ection block temperature was 250℃ and transfer line temperature 240℃. In the SIM mode, m /z 149 for 2,3-DBPA and m/z 153 for internal standard were used for quantification (Tareke et all., 2002).

Sensory evaluation

All sensory tests were performed by a semi-trained panel using uni-polar and bi-polar scale with 8 anchor to determine following attributes: crust redness (1=absent, 8=extreme), brightness (1=pale, 8=bright), hardness (1=extreme soft, 8=extreme hard). Also overall

acceptance were determined using 1-5 scale (1=unacceptable, 2=poor, 3=acceptable, 4=good, 5=excellent).

RESULTS AND DISCUSSION

It was resulted that moisture content of potatoes cooked in steam assisted oven was higher than that of cooked in natural and forced convection, statistically ($p<0.05$). The moisture content of the potatoes decreased with increasing cooking time (Fig 1).

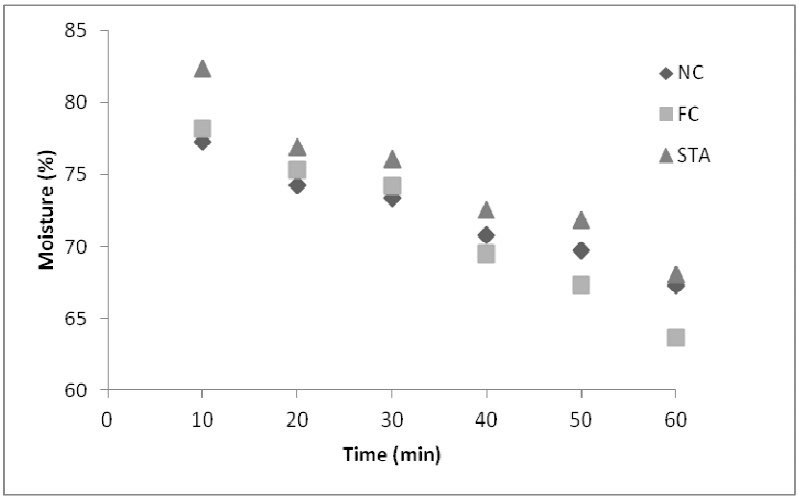

Fig 1. Moisture content of potatoes (wet basis) cooked at natural convection (NC), forced convection (FC) and steam assisted hybrid oven (STA)

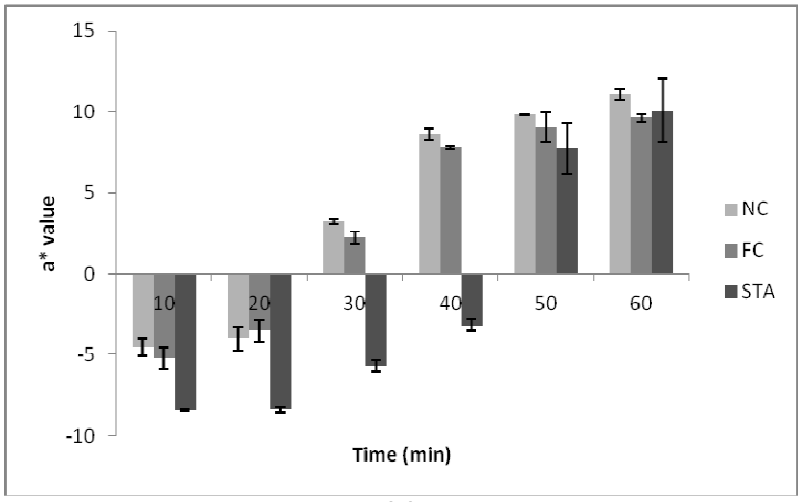
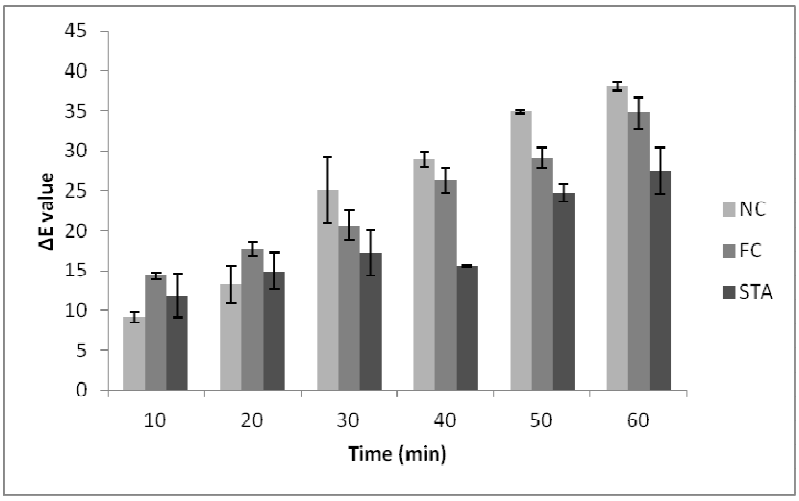
Colour change of samples (ΔE) baked in natural and forced convection ovens was higher than that of baked in the steam assisted oven. This result indicated that radiation mechanism was more responsible for colour change in convection baking. This result was supported by a* values of potatoes cooked in natural, forced convections and steam assisted ovens which are illustrated in Figure 2. ΔE values were lower for steam assisted cooked potatoes ($p<0.05$).



(a)



(b)

Fig 2. Color values of potatoes cooked at natural convection (NC), forced convection (FC) and steam assisted hybrid oven (STA), (a): a* values, (b): ΔE values

The steam assisted cooking resulted softer potatoes than those of cooked in the convectional ovens (Fig 3). Softening increased with increasing cooking time for all oven types. However, in steam assisted hybrid oven heating rate increased due to steam in the oven chamber and this phenomenon caused an increase of softening of potatoes cooked in this type of oven.

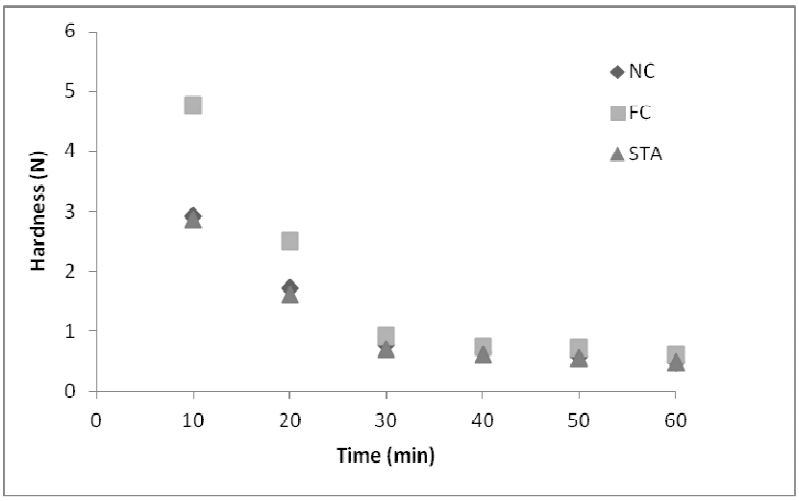


Fig 3. Hardness (N) values of potatoes cooked at natural convection (NC), forced convection (FC) and steam assisted hybrid oven (STA)

Acrylamide content of the potatoes was found to be related to the oven type ($p<0.05$), the forced convection oven baking resulting in the maximum formation. Steam assisted baking caused a reduction in the acrylamide formation compared to the natural convection and forced convection oven baking (Fig 4).

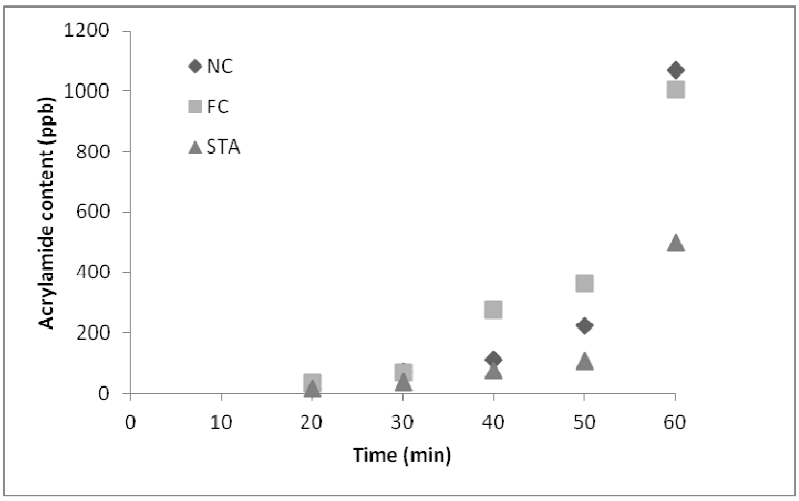

Fig 4. Acrylamide content of potatoes cooked at natural convection (NC), forced convection (FC) and steam assisted hybrid oven (STA)

Sensory evaluation results of cooked potatoes are illustrated in Table 1. Crust redness of samples was determined higher in convectional ovens whereas crust brightness was higher in steam assisted hybrid oven. It was observed that hardness values of potatoes cooked in steam assisted hybrid oven were lower, those were in line with instrumental hardness values. Overall acceptance of steam assisted cooked potatoes was also high.

CONCLUSIONS

Steam assisted oven cooking can be concluded as a good choice over natural convection or forced convection cooking in that it was resulted in lower acrylamide content, lower ΔE value and high overall acceptance as result of sensory evaluation. In addition steam assisted oven may offer shorter cooking time because of yielding fast softening of potatoes.

ABSTRACT: Vacuum dehydration technique (VDT) is known as a rapid evaporative technique for moist and porous solid products. Known advantages of VDT is short processing time, extension of products shelf life and improvement of product properties related to quality and safety issues. In this study, animal feed wheat-based diets with different particle size distributions, ground by hammermill, through 1, 3 and 5mm screen size was manufactured through different pellet-die hole diameters (2, 3.5 and 5mm). Moisture was removed by traditional air dehydration technique (ADT) or VDT. Measuring the dry matter was done immediately after the dehydration of feed pellets. Pellet durability index (PDI %) and hardness analysis were done 30 days after the dehydration. Successive dynamics of water loss was performed better while using the VDT compared to ADT where VDT appeared to reach the industrial moisture equilibrium much faster. It was not observed a clear pattern of influence on dehydration efficiency of different feed structure represented by particle size distribution. The volume increase of the product confirmed to have negative influence on moisture removal from feed pellets when conventional ADT was subjected whereas no clear outline was confirmed for VDT. This explains that increase of feed pellets diameter can limit the moisture removal for both, VDT and ADT. The VDT has demonstrated positive influence on PDI when compared to traditional ADT. Pellet hardness analysis didn't show clear influence of the different dehydration techniques on manufactured feed solids.
Key words: *vacuum, air drying, feed moisture, dehydration, animal feed, durability*

INTRODUCTION

At a given temperature and pressures, molecules of the moist solids vibrate in a random and chaotic way and the water molecules are getting easily released from solids in the gaseous state. At a rate that depends on temperature and the state of binding at the surface, water molecules may break their bonds, leave the solid surface and enter the gaseous phase (Chambers et al., 1998). In porous feed solids, an internal mass transfer may occur through the solid part or within the void spaces (Karel, 1975). Dehydration technique (DT) used on feed solids differs by the heat transfer properties. Moisture-containing solids can be dehydrated by subjecting them to reduced pressures, better known as the vacuum. Vacuum treatment can be defined as an act to reduce the density of a gas in a vessel to a value adequate for its planned purpose. First known commercial vacuum product dehydration was performed in 1948 for reducing field heat of lettuce (Thompson and Rumsey, 1984). All recent research advances have confirmed that vacuum technique is a method to shorten processing time and improve product quality (Zheng and Sun, 2004). Many factors affect the speed and efficiency of the product being dehydrated by vacuum technique. These factors are: the surface area exposed to the atmosphere (Do et al., 1999), specific heat of the product prior the dehydration (Haas and Gur, 1987), density (Cheyney et al., 1979; Krokida et al., 2000) as well as porosity (McDonald and Sun, 2001a,b; Tsami and Katsioti, 2000) and particle size of the product (Krokida et al., 2000).

Different moisture removal rate between conventional ADT and VDT is caused by differences in dehydration mechanisms (Sun and Wang, 2000). Air dehydration is principally achieved through heat transfer (conduction and convection), while vacuum dehydration is managed by mass transfer, or water evaporation in the micro pores and at the surface of the product. Vacuum dehydration is caused by pressure difference between the saturation pressure on the walls of the micro pore and diffusion of water vapor through the pore spaces to the surface of the moist-solids and surrounding atmosphere (Wang and Sun, 2002b). In VDT the porous structure plays important role in determination of water evaporation (Zheng and Sun, 2004). Important factor in VDT is that a manufactured solids are being dehydrated in controlled atmosphere which gives advantages as prolonging the shelf life (McDonald and Sun, 2000). The steam is the important ingredient for manufacturing the animal feed, among the other reasons because of the given hydrogen bonds which are connecting various particles of mixed ingredients with the help of adhesion process (Kinlock, 1987). Moisture content and its type play an important role in these processes (Behnke, 2001). Close contact between the wetting adhesive molecules (water) and the solid surface of the feed mash particles give rise to attractive forces known as physical intermolecular interactions (Van der Waals forces). In this way different size of macromolecules in the feed solids inter-diffuses and creates an interpenetration layer in the capillary microstructure capable to bear mechanical load (Possart, 2005). In such microstructure there are some driving forces for the mass transfer of water molecules defined as pressure gradients and capillary forces. The exchange of a gas or liquid in vacuum environment is driven by a pressure difference (Fito and Chiralt, 2000).

Moisture removal by VDT presumably can decrease the time for such requiring operation in the feed production. Moisture removal from feed pellets in vacuum environment can influence positively on intermolecular bonding, thus assumable better physical properties of the feed pellets might occur. The exhaust air from cooler and dryer used in the feed industry is usually highly contaminated with fine powder carry-over which must be run through a cyclone separator to recover the carry-over and also an exhaust air filter in order to reduce the air pollution to an acceptable level. This can potentially create an unstable product quality. With the VDT these problems can be avoided. Advantages of the animal feed dehydration by VDT might meet the quality control requirements much easier than ADT. So far, no detailed experimental study has yet been done for determining the influence of VDT on the quality of feed solids and its final moisture. The current experiment was undertaken to test the assumption that different texture, volume and surface area of the animal feed products have an influence on the moisture removal and the physical quality by VDT and ADT.

MATERIAL AND METHODS

Nine feed experimental diets were produced by pelleting technique at the Center for Feed Technology (Fôrtek) at the Norwegian University of Life Sciences (UMB), Ås, Norway. Major feed ingredient in the experimental feed formulation was wheat and the formulation was typical broiler feed diet. Wheat was milled in Bliss hammer mill (Bliss Industries, Inc. Oklahoma U.S.A. Model E-22115-TF) fitted with 1, 3 and 5-mm screens with the constant energy consumption of 15 amps. The hammermill chamber was equipped with two screens and was driven by 18.5kW electric motor with a rotational speed of 3000 rpm. Air was sucked through the hammermill screens by the speed of 7.2 m/s with the use of a Jesma Co (Sprout Matador A/S, Esbjerg, Denmark) fitted with a type DFC filter. Mixing of all experimental diets was done in a twin-shaft paddle mixer Dinnissen (Pegasus Menger 400 l, Sevenum, Holland) for 180 seconds. Prior to production, apparent bulk density of a mash was measured by filling up the mash in 1000 ml beaker by the free fall, in order to ensure the same production output (table 1). The production output for all the diets was 1100 kg/h. The temperature of the feed mash prior production for all diets was 20 ℃. The feed-mash was conditioned for 30 seconds prior pelleting. Conditioning temperature was 75℃ (± 1 ℃) in a continuous conditioner with the steam produced at 5.4 bars and 153.23℃ by fire-tube boiler (Peder

Halvorsen A/S, Norway, No. 18388, 1997, Model: PH Kvikk-600 kg/hr, max.10 bar) and steam pressure regulated down to 2.5 bar by steam regulating valve (Gestra 1,1 – 10 bar, AG type 5801, F-340, Bremen, Germany) prior pelleting process. The ring-die pellet press (Munch Wuppertal, Germany, 1.2 t/h, 2×17.5kW, RMP350.100) was used. The die hole diameter of the pellet dies used for the experiment was 2, 3.5 and 5 mm. Rolls distance from the die inner-surface was set on 1mm for all the dies used for this experiment. Pellet length and diameter was set proportionally to pellet diameter (table 1).

Table 1, Feed pellet length, diameter, sieve size used before and after holmen durability analysis and the feed mash densities

Pellet diameter (mm)	Pellet length (mm)	Sieve size used before & after Holmen durability analysis[1] (mm)	Feed mash milling particle size and densities (HM- hammermill) (kg / liter)
2	8	1,6	**HM 1mm** - 0,59; **HM 3mm** - 0,61; **HM 5mm** - 0,68
3,5	14	2,8	**HM 1mm** - 0,59; **HM 3mm** - 0,61; **HM 5mm** - 0,68
5	20	4	**HM 1mm** - 0,59; **HM 3mm** - 0,61; **HM 5mm** - 0,68

[1] *Pre-sieving of all the experimental pellet samples was done to give us precise weight of pellets without any dust, thus more precise results for holmen durability analysis. Sieving was run for 30 seconds with vortexing amplitude of 1.5 mm prior and after the holmen durability tests. The size of the sieves for pre and post holmen durability analysis sieving was chosen upon the pellet diameter.*

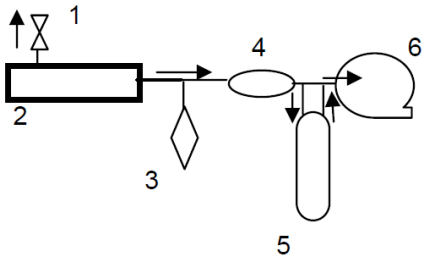

Figure 1, The schematic diagram of the research vacuum moisture removal apparatus:

(1) Pressure release valve (2) Vacuum chamber (3) Pressure control valve and barometer, (4) Steam condenser, (5) Air filter, (6) Vacuum pump

Two different DTs, VDT and ADT, were used immediately after the production of feed pellets. Conventional air flow (ADT) was used for all the diets with the same volume of feed pellets in the batch coolers (UMB - Center for Feed Technology, Ås, Norway). The average air speed in the batch coolers was 1,5 m/s created by the fan (W2E 300-DA 01, W-160) with the air volume capacity of 2550 m³/h. For moisture removal by VDT the research vacuum moisture removal apparatus (figure 1) was used. In the vacuum chamber a residual pressure of 200 mbar was used. A preset heated vacuum chambers wall had a temperature of 75 ºC for all the diets in order to avoid condensation of water on the vacuum-chambers inner-walls. Temperature was measured by digital thermometer (Arnitsu-M, HA-250k; Arnitsu meter co.ltd., Japan).The dwell time for dehydration of the feed was five minutes for all the diets and both DTs. After the moisture removal by VDT the vacuum pump was switched off and the air was re-admitted into the chamber very fast in order to avoid the back-return of any potential remaining condensate from chamber into the pellets. For ADT the air flow was stopped by switching off the fan. All experimental representative feed pellet samples were placed into the sealed plastic bags and stored immediately on the constant temperature of -18℃ for 30 days prior the analysis. Dry-matter analysis was performed in the oven (Termaks) with the standardized procedure (EU 71/393). Thereafter, duplicate samples were weighed, and the differences between the wet and the dry weights were given as calculated mean for moisture level. Durability of pellets was measured using the holmen durability tester (Holmen Chemical Ltd., Borregaard Group, Norsolk, UK), where 100 g of pre-sieved feed pellets, without any dust, were conveyed pneumatically in a closed circuit for 60 s, followed by sieving through a sieve size chosen proportionally to feed pellet diameter (table 1). PDI

(%) was recorded as the proportion of feed not passing through the given sieve size after the stress applied by holmen tester. Durability test was run as duplicate. Hardness analyses defined as the maximum force needed to crush a pellet were performed by Kahl cylinder tester. Methods have been described in detail by Thomas and Van der Poel (1996). The uniformity of feed pellets ready for the analysis (30 per sample) was recorded with an electronic digital caliper (Würth 0-150mm) before the hardness analysis. The experimental data were partially subjected to t-test analysis to examine possible effects of the dehydration methods on the responses, feed moisture and the physical pellet properties. Software used for descriptive and inferential statistics was SAS (SAS Institute Inc., 1999). Significant differences between treatments were determined by using the GLM procedure, LSD t-test. The Unscrambler (CAMO Software AS, Norway) was used as a tool for complete multi-factorial data analysis to examine possible effects and interactions between the production factors on the responses as well as an interactions between the responses.

RESULTS AND DISCUSION

Comparison of the results obtained from usage of different DTs and its influence on physical properties of feed pellets with the results from the literature was difficult due to differences in product composition, production technology, treatment and the structure of the product.

Influence of the feed structure, DT and volume of the feed pellets on dehydration rate and physical quality of feed pellets

No notable changes were seen in process parameters during the feed production to rationalize the differences in moisture content and PDI for all the diets. That should be addressed to experimental production parameters as pellet diameter, length, particle size distribution and DTs.

The dehydration rate during the ADT is initially dependent on the evaporation rate of unbound water at the surface of the feed solids where water needs to diffuse between the feed particles to its dry surface in order to be removed. Yet, during the VDT critical moisture content was easily reached in the vacuum conditions where the moisture loss was balanced within the entire volume of the product. This has shown that dehydration in vacuum conditions is faster while at the atmospheric pressure and air flow slower. Results presented in table 2 and figure 2 shows that the DT has major influence on moisture removal.

Milling with the hammer-mill and the screen size-set of 1, 3 and 5 mm showed to have different particle size distribution with the major particle size mean between 0.2 and 0.5 mm. The mobility of water in feed pellets is shown to be dependent of the pore structure and that is in agreement with Van Brakel and Heertjes (1974) (table 2). The mechanism of DT during VDT showed to be influenced by the difference in particle size distribution and larger pellet volume. However, a clear pattern for ADT was not observed. For more dense feed pellets, with small void space between the particles (HM 1mm) the quantity of water, existed as the vapor which takes part in diffusion, showed better results than in less dense feed pellets (HM 3 and 5mm). That is not in correspondence with findings from Waananen and Okos (1996). In 5 mm pellet diameter no clear difference was observed between particle size distribution obtained by grinding through 5 mm and 1 mm hammer mill screen. Possible reason for this might be an unstable steam quality while feed mash was conditioned hence different adsorption between the particles.

[1] HM 1, 3 & 5 indicates hammer mill grinding with the screen hole size of 1, 3 & 5 mm
[2] PDI (%) indicates Pellet Durability Index % (a predictor of pellet fines produced during mechanical handling)

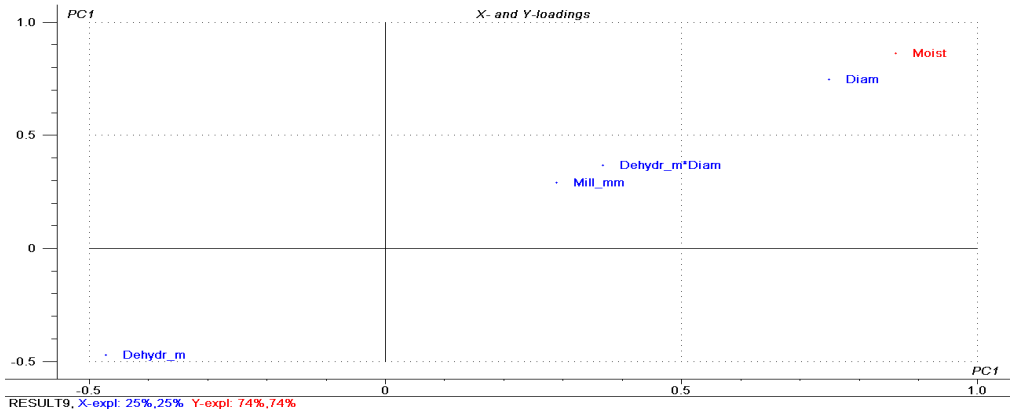

Figure 2, Unscrambles Partial Least Square (PLS) I regression. The DT (Dehydr_m) shows the greatest influence on diagonally positioned moisture (Moist) when compared to other factors.

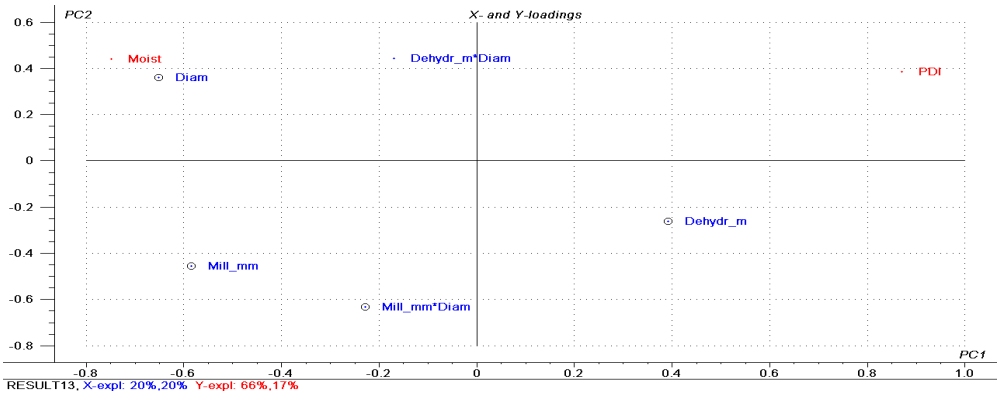

Figure 3, Unscrambles Partial Least Square (PLS) II regression test with jack knifing. The black rings not positioned in the same squared field in the figure assign what factors are influencing moisture and PDI. No influence of products moisture content on PDI %.

As Xiong et al. (1991) have postulated, the binding energy at high moisture levels is small and increases as the moisture content decreases. Since moisture was removed faster with VDT this can partially explain the enhanced physical properties of feed pellets dehydrated by vacuum. In order to acknowledge that moisture did not have any influence on PDI, partial least square regression II test with jack knifing was performed (figure 3). The Unscramblers model for X-variable (dehydration technique, milling, pellet diameter, interaction between particle size distribution and pellets diameter as well as dehydration method and diameter) was used against both outputs, PDI (%) and moisture (figure 3). Durability of feed pellets showed to be positively influenced by DT or precisely, when VDT was applied (table 2, figure 3). This can be explained by allowance of rapid transfer of moisture in the gaseous state to vacuum environment where structural collapse is prevented as suggested by Lin et al. (1998). During the ADT the increase of porosity was supposedly influencing on weakening the inter-particle links inside the feed pellets. Considerably better durability of feed pellets after using the VDT presumably can be explained by rapid decreasing of the moisture content where vapor is no longer in equilibrium with the liquid and the rate of vapor desorption becomes rate-controlling which is a consequence of high binding energy at low moistures. Second assumption is that polymerized network among the feed nutrients and its complexes were set by VDT from chaotic into the organized network. Therefore the greater durability of feed pellets was observed. This phenomenon was explained by Bistac and Galliano (2005), when the arranged network increases, macro-friction decreases due to chain orientation phenomena. Therefore, the effects of elastic contact and bulk dissipation are minimized and the interfacial adhesive behavior of feed components is magnified. Molecular orientation during the adhesive interactions at the surface must be mentioned, where the cracks on pellets might be recovered by VDT and hence better physical properties achieved through formation of attractive properties within the cracks in the polymerized feed structure. Also, better physical properties occurrence by usage of VDT might be explained on the molecular level where the adhesion on polymer fiber interface can be improved by static generation of the low-stress matrix, which will all potentially lead to high-bond strength. Considering that the durability of pelleted feed was increased by VDT, it can be concluded that vacuum has assisted mechanical and chemical adhesion of feed components after the pelleting process with dispersive (van der Waals) forces and diffusive adhesion where the surface pressure of the liquid vapor was decreased and surface energy increased. On the other side, the physical properties defined by hardness analysis didn't seem to be influenced by DTs when statistically analyzed by LSD t-test derived from the GLM procedure.

CONCLUSIONS AND SUGGESTION

Shown results indicate that a VDT can be used for the moisture removal from the animal feed pellets. The advantages of VDT are several. Most important is that a feed product can be dehydrated in shorter time. VDT has already demonstrated to provide many benefits to the food processing industry as shortening product hold up time, increasing production throughput, reducing energy consumption and minimizing microbial growth. Furthermore, unlike conventional air flow dehydration, by using the VDT it is easier to remove large proportions of water molecules in the short time span, which makes itself a much more advantageous method for products of high water content, especially in the extruded fish feed and pet food. After the extrusion the fish feed is subjected to the high air temperatures for a short time where the thermo-labile components with the excess water content, as astaxanthin, and vitamin E would be damaged. VDT might be used here as a hybrid DT composed of complementary drying which donate advantages of dehydration of extruded fish pellets on lower temperatures where anti-oxidative components can be preserved. In addition to the above, the VDT is a more hygienic process since the air goes only into the chamber at the end of the cooling process when the chamber is open to release vacuum, thus the hazardous material level can be diminished. As VDT is carried out in a static state, there is no mechanical load thus damage as in some other DTs. Regarding the apparatus for VDT, the vacuum chamber should include some mixing equipment for rearranging the position of product in order to prevent uneven product dehydration. The chamber must not allow condensation of water on its interior and that's why should be heated. In case of feed pellets, such condensation can cause the product to be unevenly dehydrated. High share mixing can damage the product being dehydrated, therefore slow speed twin-shaft mixing elements should be set in the vacuum chamber with the evaporator. However, modeling of VDT for the feed pellets is still largely unexplored and requires further research. Optimal method should be selected according to a few factors, such as: the economy, convenience, utilization of equipment, operating conditions, personal preference and product requirement. The cost of VDT is comparable with the cost of other DTs even though the initial capital investment might be high. The VDT might make a significant contribution to better quality and easier feed manufacturing.

ABSTRACT: Technology briquetting is the process by which the crushed material under high pressure is converting into a compact form of high density.
Because of the variability of biomass consisting of: wheat, barley, oat, rye straw, maize, oilseed straw, sunflower stalks and remnants of shells, fruit and pruning of vineyards, forest biomass, waste wood in wood processing machine consists of a complex technological process of production of briquettes.
